Results: Deep learning models, particularly convolutional neural networks, consistently achieved high diagnostic performance in imaging-based liver disease classification (AUC commonly >0.90). Ensemble learning methods such as XGBoost demonstrated superior predictive stability compared to traditional statistical models. NLP-based systems improved automated

information extraction from electronic health records. However, variability in datasets and limited model interpretability remain significant challenges.

Conclusions:

AI technologies show strong potential in liver disease analytics and knowledge synthesis. Future development should emphasize explainable AI, standardized datasets, and cross-institutional validation to ensure reproducibility and clinical integration.

Keyword(s) : Artificial Intelligence; Machine Learning; Deep Learning; Hepatology; Natural Language Processing

2871 - Genetic Variants in Bile Transporter Genes in Prolonged Cholestatic Jaundice Associated with HAV and Drug Induced Liver Injury

Krishnakanth Sarda¹, Rajesh Gupta², Anand Kulkarni³
Asian Institute Of Gastroenterology, Medical Gastroenterology, Hyderabad-India¹ Asian Institute Of Gastroenterology, Hepatology, Hyderabad-India² Aig Hospitals, Hepatology, Hyderabad-India³

Background / Hypothesis:

Cholestatic jaundice results from impaired bile formation or secretion, leading to retention of bile acids and bilirubin. While many cases are attributable to identifiable causes such as Hepatitis A virus (HAV) infection and drug-induced liver injury (DILI), particularly due to complementary and alternative medicine (CAM) use, only a subset of patients develop prolonged cholestasis. This variability suggests an underlying genetic susceptibility. Genes involved in bile acid transport, including ABCB11, ABCB4, and ATP8B1, play a critical role in maintaining bile acid homeostasis. Variants in these genes may impair bile salt export pump function and phospholipid transport, predisposing individuals to persistent cholestasis following hepatic insults. We hypothesized that patients with prolonged cholestatic jaundice secondary to HAV infection or DILI may harbor polymorphisms in bile transporter genes that contribute to disease persistence.

Materials and Methods:

This observational study was conducted at the Asian Institute of Gastroenterology, Hyderabad. Adults (>18 years) with cholestatic jaundice persisting for more than 12 weeks were included. Patients with mechanical biliary

ORAL ABSTRACTS

obstruction were excluded. Peripheral blood samples were collected after informed consent. Genomic DNA was extracted and analyzed using next-generation sequencing targeting a PFIC gene panel comprising ABCB11, ABCB4, and ATP8B1. Clinical data including demographics, biochemical parameters, virological status, and history of drug or CAM intake were recorded and correlated with genetic findings.

Results:

Thirty-four patients were included. The mean age was 26.9 years, with a male predominance (82%). HAV-related hepatitis was identified in 60% of patients (20/34), among whom 7 patients (20% of total cohort) had concurrent CAM exposure. Drug-induced liver injury accounted for 40% (14/34), and 70% of these DILI cases (10/14) were attributed to CAM use. Genetic analysis revealed that 79.4% of patients (27/34) harbored at least one primary gene variant. The most frequent variant was p.Val444Ala (rs2287622) in the ABCB11 gene, detected in both homozygous and heterozygous states. Variants in ATP8B1 and ABCB4 were less common.

Conclusions: A substantial proportion of patients with prolonged cholestatic jaundice secondary to HAV infection and drug-induced liver injury, particularly CAM-related hepatitis, carried variants in bile transporter genes. Screening for these genetic variants may help identify individuals at risk of developing prolonged cholestasis following viral or drug-related hepatic injury.

2874 - Dynamic evolution of the gut microbiome predicts therapeutic response in liver cancer A large scale longitudinal study with a cross cohort meta analysis

Jie Han ¹, Zhenwei Qian ², Aizier Ainiwaer ², Yinying Lu ¹
The Fifth Medical Centre Of PLA General Hospital, Liver Cancer Centre, Beijing-China ¹ Peking University 302 Clinical Medical School, Peking University, Liver Cancer Centre, Beijing-China ²

Background / Hypothesis: The gut microbiota modulations influence therapeutic efficacy in liver cancer, yet high-resolution longitudinal evidence remains limited. We hypothesized that specific, dynamically evolving microbial signatures could serve as

robust predictors of treatment response across different clinical settings.

Materials and Methods: A total of 315 consecutive patients with liver cancer (HCC 88%, ICC 12%; HBV-dominant, 64%) receiving systemic therapies (targeted therapy and immunotherapy) were prospectively enrolled. Patients were categorized into Responders (n=175) and Non-responders (n=140). Fecal metagenomes and clinical data were analyzed at baseline (T0) and multiple treatment timepoints (T1, T2). Differential taxa at each timepoint were identified using LEfSe analysis ($P < 0.05$, absolute LDA score > 1.5). To ensure robustness, a timepoint trend meta-analysis was performed by integrating our data with multiple public HCC microbiome databases to identify consensus response-associated taxa.

Results: Our cross-cohort meta-analysis independently validated that specific butyrate-producers, including *Anaerobutyricum hallii* (Beta: 1.45), *Eubacterium rectale* (Beta: 1.25), and *Faecalibacterium SGB15346* (Beta: 1.08), were universally enriched in responders across different cohorts and timepoints. Longitudinally, non-responders demonstrated a rapid and progressive loss of these beneficial taxa, accompanied by the expansion of opportunistic species such as *Escherichia coli* and *Enterococcus faecium*. Spearman correlation analysis revealed that the abundance of these validated beneficial species was significantly positively associated with liver function markers, specifically albumin, prealbumin, and choline esterase, while exhibiting strong negative correlations with alpha-fetoprotein, C-reactive protein, and Child-Pugh Score. Notably, the dynamic decline of meta-analysis-validated taxa provided an early warning signal of resistance that preceded clinical and radiological progression.

Conclusions: By integrating a large-scale longitudinal HCC cohort with a multi-database meta-analysis, we identified a robust microbial signature centered on butyrate-producers that predicts therapeutic response. These findings highlight the potential of using cross-cohort validated microbial markers for early clinical monitoring and personalized therapeutic intervention in liver cancer.

Keyword(s) : Liver cancer, Gut microbiome, Meta-analysis, Longitudinal cohort, Therapeutic resistance, Butyrate-producing bacteria

2876 - Immune Checkpoint Inhibitor-Induced Hepatitis in HCC Poor Response to Immunosuppression.

ORAL ABSTRACTS

Deepak Jha¹, Anand Kulkarni¹
Aig, Hepatology, Hyderabad-India¹

Background / Hypothesis: Immune checkpoint inhibitors (ICIs) are increasingly used in India for the treatment of advanced hepatocellular carcinoma (HCC). Immune Checkpoint Inhibitor-Induced Hepatitis is a recognized, though uncommon, immune-related adverse event and can result in significant morbidity and in severe cases mortality.

Materials and Methods: We report four patients who developed ICI-induced hepatitis at our center.

Results: Three were males (75%) and one female (25%), with a mean age of 62 years (range 60–66). Etiologies included NASH in three patients (75%) and HBV in one (25%). Most patients had advanced HCC (BCLC stage C in 75%). ANA was positive in three patients (75%), with one showing markedly elevated IgG (4650 mg/dL). Mean total bilirubin was 6.7 mg/dL, direct bilirubin 3.8 mg/dL, SGOT 394 U/L, SGPT 294 U/L, total protein 7.5 g/dL, and albumin 3.2 g/dL. All patients received immunosuppression with steroids $\pm$ mycophenolate; however, two patients (50%) were non-responders, one patient (25%) responded, and one patient (25%) died due to complications.

Conclusions: ICI-induced hepatitis in HCC can lead to poor outcomes, with a significant proportion showing inadequate response to immunosuppressive therapy. Further studies are needed to identify predictors of Immune Checkpoint Inhibitor-Induced hepatitis and optimize monitoring strategies during immunotherapy.

Keyword(s): ICI-induced hepatitis

2877 - The Effect of Portal Vein Tumor Trombosis on Survival in Patients with Hepatocellular Carcinoma Treated with Different Therapies

Background / Hypothesis: Portal vein tumor thrombosis (PVTT) is common among patients with advanced hepatocellular carcinoma (HCC) and its presence is associated with dismal prognosis with median overall survival ranging between 2 and 6 months, and 3-years survival of around 5% in untreated patients. Although international guidelines recommend systemic treatments as the standard of care, a tremendous differences exist between East and West in the management of these patients. In clinical practice many patients receive various treatments, including hepatic resection, locoregional treatments, and even liver transplantation. Here we investigated the impacts of PVTT scope and the treatment modalities on patient survival.

Materials and Methods: This study included 954 patients with HCC and PVTT between October 2015 and January 2024. PVTT was classified according to Cheng's classification as follows: Type I, tumor thrombus in the segmental branches of the PV or above; type II, thrombus extending to the right or the left PV; type III, thrombus extending to main PV; type IV, thrombus involving the superior mesenteric vein. Median overall survival was analyzed according to both Cheng's classification and treatment modalities using Kaplan-Meier survival test.

Results:

The mean age was $62,54 \pm 11,95$ years, and the median follow-up period was $10,05 \pm 17,22$ months. The median

ORAL ABSTRACTS

OS according to treatment approaches was as follows: resection $12,10 \pm 12,10$ months, transplantation $38,90 \pm 41,51$ months, RF ablation $31,53 \pm 25,02$ months, sorafenib $6,78 \pm 6,84$ months, TACE $11,79 \pm 10,60$ months, TARE $8,09 \pm 5,16$ months, immunotherapy $11,75 \pm 8,44$ months, others $5,03 \pm 5,88$ months. Median OS was significantly longer in transplantation, and ablation groups compared to other treatment groups in patients with segmental PVTT ($p < 0.001$).

Conclusions:

Treatment modalities for HCC with PVTT should not be limited to systemic therapy. The extend of PVTT should be considered when deciding on treatment alternatives. In patients with segmental PVTT, surgical techniques should be evaluated.

Keyword(s) : Hepatocellular carcinoma; Portal vein tumor thrombosis; Cheng's classification; Median overall survival, Locoregional therapies

2878 - From Stool to Personalized Screening Approach A Comprehensive Meta analysis of Metagenomic Gut Microbiota Assessment in Patient with MAFLD and Control Cohort

Krisanto Tanjaya¹, Vincenzo Jocelino², Dionisius Seraf Saputra³, Aulia Rahmi Pawestri¹
Faculty Of Medicine - Universitas Brawijaya, Department Of Biomedicine, Malang-Indonesia¹ Faculty Of Food Technology - Universitas Brawijaya, Department Of Biotechnology, Malang-Indonesia² Faculty Of Computer Science, Universitas Brawijaya, Department Of Information Technology, Malang-Indonesia³

Background / **Hypothesis:**
The global prevalence of metabolic dysfunction-associated fatty liver disease (MAFLD) is increasing, yet no effective personalized screening approach exists to prevent its progression. Emerging evidence regarding the gut-liver axis indicates a correlation between gut dysbiosis and MAFLD, highlighting the potential for microbiome-based screening. This study evaluates genus-specific gut microbiome abundance in individuals with MAFLD compared to controls to assess their potential utilization for MAFLD screening and diagnosis.

Materials and **Methods:**
Metagenomic projects were identified from the NCBI SRA database using the keywords ("MAFLD" OR "Fatty Liver" OR "NAFLD") AND ("Gut Microbiome" OR "stool" OR "microbiota"). Inclusion criteria comprised human cohort studies, MAFLD-diagnosed samples, and 16S

rRNA analysis targeting the V3 or V4 region. Selected projects underwent preprocessing with the QIIME2 pipeline, followed by taxonomic identification using the SILVA database. Outcomes included community-level differences assessed by alpha- and beta-diversity analyses, study-level genus performance evaluated by random forest area under the receiver operating characteristic curve (AUROC), and genus-level meta-analysis. Metadata of interest included disease status and sample geographic region (Asia or Europe).

Results:

Six metagenomic projects, comprising 297 MAFLD patients and 133 control samples, were included in the analysis. The MAFLD group exhibited lower Shannon diversity compared to controls (SMD: -0.29; 95% CI: -0.6 to 0.17, $p = 0.03$). Bray-Curtis PERMANOVA showed that MAFLD accounted for at most 11% of the variation in gut community composition within a single cohort ($R^2 = 0.11$, $p < 0.05$). Further PCoA analysis showed stronger clustering by geographic region than by disease status. Genus-level microbiome profiles effectively discriminated MAFLD from controls (AUROC 0.85–1) in five cohorts. Genus-level meta-analysis identified several genera as more abundant in the MAFLD population, including *Hartmannibacter* sp., *Streptomyces* sp. and *Sphingosinithalassobacter* sp. in Asia region, while *Oribacterium* sp. is found in Europe region. On the other hand, *Papilibacter* sp., *Merdibacter* sp., and *Peptococcus* sp. were depleted in both Asia and Europe.

Conclusions:

This meta-analysis supports the potential use of gut microbiota analysis for personalized MAFLD screening. However, due to the absence of a large, consistent global change in diversity and the microbiome's genus profile, further studies are required. Future investigations that consider MAFLD severity, sex, country, age, and comorbidities are recommended to enable a more personalized approach.

2879 - AARC score predicts survival in patients with Acute on Chronic Liver Failure due to Severe Alcoholic Hepatitis undergoing Plasma Exchange

Jaifrin Daniel¹, Ankur Jindal¹, Vinod Arora¹, Ashok Choudhury¹, Jitendra Kumar Singh¹, Guresh Kumar², Shiv Kumar¹, Sarin¹
Institute Of Liver And Biliary Sciences, Hepatology, New Delhi-India¹ Institute Of Liver And Biliary Sciences,

ORAL ABSTRACTS

Biostatistics, New Delhi-India ²

Background / Hypothesis: Plasma exchange has emerged as a therapeutic treatment modality in individuals with acute-on-chronic liver failure (ACLF) due to severe alcoholic hepatitis (SAH) who are ineligible for corticosteroid therapy and are not candidates for liver transplantation. The aim of this study was to identify predictors of non-survival in these individuals.

Materials and Methods: It a retrospective study in which the electronic medical records of the patients admitted with acute on chronic liver failure due to severe alcoholic hepatitis and had undergone plasma exchange was analysed. Individuals receiving steroids or eligible for liver transplantation were excluded. The study period was between January 2015 to April 2025.

Results: There was total 126 patients. The mean age was 40.77 ± 6.9 years and 38.7 ± 6.9 years in the non-survivor and survivor group. The mDF (Maddrey's Discriminant Function) was higher in the non-survivor group 92.2 (73-113.2) as compared to the survivors 90.5 (72-112.5), $p:0.83$, and was not statistically significant. The number of Plasma Exchange was similar between both the groups, 3 ± 1.8 and 3.2 ± 1.5 , $p:0.45$ respectively. Mortality was seen in 31 (24.6%) individuals. Baseline Platelet count 122.7 ± 70.7 and 158.01 ± 93.6 , $p:0.03$ and AARC score was 10.7 ± 1.6 and 9.2 ± 1.4 , $p:0.01$ respectively in the non-survivor and survivor group and were the statistically significant predictor of mortality. Serum bile acid was statistically not significant between the two groups. On multivariate analysis AARC score with HR of 2.241, CI:1.316-3.816, $p:0.003$ was predictor of mortality.

Conclusions: Plasma exchange is a therapeutic treatment modality in patients with ACLF due to severe alcoholic hepatitis. A higher baseline AARC score independently predicts mortality in these patients and may guide in risk stratification and management decisions.

Keyword(s) : ACLF - Acute on chronic liver failure, PLEX - Plasma exchange, SAH - Severe alcoholic hepatitis.

2881 - Impact of an AI Supported Triage System on the Diagnostic Workflow of Focal Pancreatic Lesions A Real World Clinical Utility Analysis

Qinmei Wang ¹, Yiyang Wang ², Bo Wang ¹

Tongji Hospital, Gastroenterology, Wuhan-China ¹
University Of Sydney, Brain And Mind Centre, Sydney-Australia ²

Background / Hypothesis: Accurate and early differentiation of focal pancreatic solid lesions (FPSLs) in the outpatient setting remains a significant clinical challenge. Benign inflammatory conditions, such as focal autoimmune pancreatitis (fAIP) and mass-forming chronic pancreatitis (MFCP), often present similarly to pancreatic ductal adenocarcinoma (PDAC) in terms of clinical features and conventional imaging findings, leading to diagnostic uncertainty and potential unnecessary pancreaticoduodenectomy. Current serum biomarkers lack accuracy, and invasive diagnostic procedures are limited by sampling variability, highlighting the need for a reliable, non-invasive triage tool suitable for outpatient care. Venous phase contrast enhanced computed tomography (CECT) effectively captures pancreatic parenchymal and lesional enhancement patterns, and radiomics derived from this phase can quantify subtle, visually imperceptible differences in enhancement homogeneity, tissue heterogeneity, and periductal parenchymal remodelling.

Materials and Methods: we first summarized the current evidence, including serological markers, imaging findings, histopathology, novel biomarkers, and liquid biopsy techniques, for differentiating benign lesions (particularly fAIP) from PDAC. We then designed a retrospective study, involving 307 FPSLs outpatients (51 MFCP, 67 fAIP, and 189 PDAC cases) who underwent venous-phase CECT. The cohort was split into a training set and a validation set at a 7:3 ratio. Whole-pancreas segmentation was performed automatically, and radiomics features were extracted from CECT images. Clinical variables, including demographics and laboratory indices, were also collected. After multi-step feature selection, six machine learning classifiers, including logistic regression, support vector machine, random forest, XGBoost, k-nearest neighbors, and Extra Trees, were developed and evaluated in both training and validation sets. Calibration curves and decision curve analysis were applied to assess potential clinical utility. The SHAP method was applied to the best-performing model to assess feature importance and enhance interpretability. Furthermore, we proposed a practical three-stage diagnostic algorithm based on our data as well as the present guidelines.

Results:

ORAL ABSTRACTS

The final model included five clinical variables and six wavelet texture features. In the validation cohort, the Extra Trees model achieved the best performance, with an AUC of 0.840. The sensitivity was 0.825 and the specificity was 0.694. SHAP analyses revealed that CA19-9 was the most significant contributor to differentiation, while wavelet texture features and age were also important variables.

Conclusion:

A multimodal machine learning model combining radiomics with clinical variables exhibited robust diagnostic performance in distinguishing between benign and malignant FPSLs. Based on our stepwise workflow, the model, with its high sensitivity and moderate specificity, is well-suited for risk stratification in equivocal FPSL cases, offering valuable insights prior to further invasive evaluations.

Keyword(s) : focal autoimmune pancreatitis; pancreatic ductal adenocarcinoma; Artificial intelligence ; machine learning models; Focal Pancreatic Lesions

2886 - Comparative Analysis of Epidemiological Research Output Metabolic Dysfunction Associated Steatotic Liver Disease vs. Alcohol Associated Liver Disease

Pavithra Senadheera ¹, Bhagya De Silva ¹, Renisha Karunanayake ¹, Shashini Hathurusinghe ¹, Tiloka De Silva ², Madunil Niriella ¹, Janaka De Silva ¹
Faculty Of Medicine, Univerity Of Kelaniya, Medicine, Ragama-Sri Lanka ¹ Faculty Of Business, University Of Moratuwa, Decision Sciences, Moratuwa-Sri Lanka ²

Background / Hypothesis: Metabolic dysfunction-associated steatotic liver disease (MASLD) and alcohol-associated liver disease (ALD) are leading causes of chronic liver disease. Comparative analysis of their epidemiological research can reveal knowledge gaps and guide resource allocation. We conducted a comprehensive bibliometric comparison of epidemiological research on MASLD and ALD, published between 2005-2026.

Materials and Methods: Epidemiological studies on MASLD and ALD were systematically identified and reviewed in PubMed/MEDLINE and Google Scholar to identify relevant studies. Search strategies employed combinations of Medical Subject Headings (MeSH) terms and keywords related to MASLD, ALD, and study design terms. Studies were included if they were original epidemiological research, human studies, focused on

prevalence, incidence, risk factors, mortality, or disease burden, published in peer-reviewed journals, and published in English language. Extracted variables included publication year, geographical origin, study design, study population, World Bank income classification, WHO region, journal quality (SCImago quartile), data source type, citation metrics, and declared funding. Statistical analyses included chi-square tests, independent samples t-tests, and compound annual growth rate (CAGR) calculations.

Results:

A total of 324 studies were included: 292-MASLD, 32-ALD, and 9-classified under both. MASLD research volume substantially exceeded ALD (292 vs. 32); however, growth rates were not significantly different between fields ($p=0.35$), reflecting high variance in both series. Significant geographical disparities were observed: MASLD research was predominantly region-specific, whereas ALD studies more frequently spanned multiple regions (58% of multi-region studies were ALD; $\chi^2=35.93$, $p<0.001$). ALD research was more concentrated in high-income countries (72% vs. 59%), with no ALD studies from low-income countries; the USA contributed disproportionately to ALD output (31% vs. 17% for MASLD), while China dominated MASLD (16% vs. 3%). ALD papers were more likely to have declared funding (31% vs. 16%; $p=0.04$) and to be published in Q1 journals ($\chi^2=6.67$, $p=0.083$). ALD studies also made greater use of secondary data and the Global Burden of Disease database, whereas MASLD studies more commonly used primary data ($\chi^2=29.98$, $p<0.001$). Raw citation counts were higher for MASLD (mean 27.73 vs. 11.27; $p=0.006$), but this difference was not significant after adjustment for publication year ($p=0.28$).

Conclusions:

Despite greater overall volume, MASLD research exhibits significant geographical and methodological gaps, particularly in low- and middle-income countries. ALD research, while more limited in quantity, demonstrates broader international scope, stronger funding support, and higher publication in top-tier journals. Both conditions are markedly underrepresented in low-income settings. These findings underscore the need for targeted research investment in under-resourced regions where disease burden may be highest.

2888 - Evaluation of selected Plasma Long Non Coding RNAs as predictive Biomarkers in HBV Related Hepatocellular Carcinoma

Najifa Yeasmin Yeasmin ¹, Umme Shahera Shahera ¹,
Munira Jahan Jahan ²

Bangladesh Medical University, Department Of Virology, Dhaka-Bangladesh ¹ Bangladesh Medical University, Department Of Hepatology, Dhaka-Bangladesh ²

Background:

Long non-coding RNAs (lncRNAs) have come to light as promising biomarkers for the early detection of hepatocellular carcinoma (HCC). This study focused on estimating the plasma levels of selected lncRNAs—highly upregulated in liver cancer (HULC), metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), long intergenic non-coding RNA 152 (LINC00152), and urothelial carcinoma-associated 1 (UCA1)—in patients with hepatitis B virus (HBV)-related chronic liver diseases and HCC in Bangladesh.

Materials and Methods:

In this cross sectional study, diagnosed cases of HBV-infected patients with chronic hepatitis, cirrhosis, and hepatocellular carcinoma were included. Total 160 participants were enrolled: 40 with chronic hepatitis, 40 with cirrhosis, 40 with HCC, and 40 healthy controls. Plasma RNA was isolated, reverse-transcribed into complementary DNA (cDNA), and expression of four lncRNAs—HULC, MALAT1, LINC00152, and UCA1—were quantified using GoTaq qPCR Master Mix (Promega, USA) on a QuantStudio 5 Real-Time PCR System (Applied Biosystems, USA). Results of alanine aminotransferase (ALT), aspartate aminotransferase (AST), alpha-fetoprotein (AFP), HBV DNA, HBsAg, viral load, and other biochemical parameters were obtained from prior laboratory reports conducted within one month of enrollment.

Results

In this study, in patients with HCC, serum ALT and AST levels were significantly higher ($p < 0.001$). HBV DNA viral load ($\log_{10}$ copies/mL) was highest in chronic hepatitis patients, followed by HCC and cirrhosis ($p < 0.001$). Alpha-fetoprotein (AFP) levels were markedly elevated in HCC patients compared with the other groups ($p < 0.001$). The expression of HULC, MALAT1, LINC00152, and UCA1 was markedly elevated in patients with HCC compared to those with cirrhosis, chronic hepatitis, and healthy controls. Although increased expression of these lncRNAs was also observed in cirrhosis and chronic hepatitis groups, but the differences were not statistically significant. Receiver

operating characteristic (ROC) analysis indicated that all four lncRNAs achieved area-under-the-curve (AUC) values above 0.8 in discriminating HCC from healthy individuals. HULC exhibited the highest diagnostic accuracy (AUC = 0.910, sensitivity = 92.5%, specificity = 85.0%). The other lncRNAs (MALAT1, LINC00152, and UCA1) also showed sensitivity of 95.0%, 92.5%, and 90.0% and specificity of 80.0%, 85.0%, 77.5% respectively. Compared with alpha-fetoprotein (AFP), HULC and MALAT1 demonstrated superior diagnostic accuracy in distinguishing HCC from cirrhosis.

Conclusions:

Plasma HULC, MALAT1, LINC00152, and UCA1 are potential noninvasive biomarkers for HBV-related detection of HCC. The inclusion of lncRNA profiling within established diagnostic frameworks, combined with AFP and other biomarkers, has the potential to strengthen early diagnosis and monitoring strategies.

2894 - Splenic probe (100 KPa) is superior to liver probe (75 KPa) in assessment of liver stiffness and predicting outcomes in Acute on chronic liver failure patients

Sudhir Verma ¹, Chitranshu Vashistha ², Manoj Kumar Sharma ³, Ashok Choudhary ⁴, Shiv Kumar Sarin ⁴
King George's Medical University, Hepatobiliary Unit, Medicine, Lucknow-India ¹ Institute Of Liver And Biliary Sciences, Hepatology, New Delhi-India ² Nstitute Of Liver And Bikiary Scirnces, Hepatology, New Delhi-India ³ Institute Of Liver And Biliary Sciences, Hepatology, New Delhi-India ⁴

Background

Early identification of acute on chronic liver failure (ACLF) patients with a high risk of mortality is important to prioritize the need for ICU monitoring and liver transplantation (LT). In ACLF, inflammation and an acute rise in portal pressure drive the outcome and can raise liver (LSM) and spleen stiffness (SSM). Liver stiffness measurement (LSM) using the liver probe of transient elastography is increasingly explored for prognostication in ACLF. However, the conventional liver probe(LP) has a ceiling effect with an upper limit of 75 kPa only. The splenic probe(SP) with an upper limit

/

Hypothesis:

ORAL ABSTRACTS

of 100 kPa may overcome this limitation. We prospectively evaluated the prognostic performance of liver stiffness measured using the splenic probe versus the conventional liver probe using the Fibro-scan 630 expert model at baseline and during early follow-up in ACLF patients

Materials and Methods: Patients of ACLF between 18 to 70 years of age were included. The study aimed to compare the prognostic utility of the acute change in LSM measured using SP versus LP on days 7 and 14 for predicting transplant-free survival at day 90 in patients with ACLF.

Results: Study included 56 patients (mean age 40.9 ± 8.6 yrs, males 88.9%, alcohol associated 83.76 %) with ACLF. At day-90, 38 (68.4%) patients had LT free survival, with 15 (26.78%) deaths and 3 (1.68%) LT. Mean baseline AARC score among survivors and non-survivors was 7.68 ± 1.37 and 10.14 ± 1.25 , respectively ($p < 0.001$). Baseline LSM measured through SP (82.67 ± 17.7 kPa) was significantly higher than LP (70.95 ± 9.13 kPa) among survivors ($p = 0.005$) and non-survivors (SP = 90.96 ± 12.79 vs LP = 73.56 ± 9.13 kPa, $p < 0.001$). On day 7, mean change in LSM by SP (-7.09 ± 3.48) was significantly higher than LP (-0.69 ± 0.63) among survivors ($p < 0.001$) and non-survivors (SP = -2.46 ± 1.29 vs. LP = -0.11 ± 0.3 kPa) ($p < 0.001$). Similarly, on day 14, the mean change in LSM by SP (-13.14 ± 7.21 kPa) was significantly higher than LP (-1.83 ± 0.95) among survivors ($p < 0.001$) and non-survivors (SP = -5.89 ± 1.2 vs. LP = -0.08 ± 0.12 , $p < 0.001$).

Conclusions: LSM measured using a splenic probe provides a larger range of stiffness measurement, required for assessing inflammation inherent in ACLF patients. The splenic probe was found to be superior to the conventional probe in stratifying high-risk ACLF patients. Serial assessment of LSM using the splenic probe during the first two weeks reliably segregates ACLF patients at high risk of short term mortality.

2897 - Integrative Metabolomic and Cytokine Profiling Reveals a "Metabolic Inflammatory" Signature in Chronic Hepatitis B Combined with Metabolic Dysfunction Associated Fatty Liver Disease

Yichen Peng¹, Ju Chen², Liang Huang³, Qiuping Chen⁴, Haiyang Hu⁵, Peijie Wu⁵, Baixue Li⁵, Quansheng Feng⁶

Chengdu University Of Traditional Chinese Medicine, Clinical Medical College, Chengdu-China¹ Chengdu Public Health Clinical Medical Center, Chengdu, School Of Intelligent Medicine, Chengdu-China² Chengdu Public Health Clinical Medical Center, Research Department, Chengdu-China³ Chengdu University Of Traditiona, Clinical Medical College, Chengdu-China⁴ Chengdu University Of Traditiona, School Of Basic Medi, Chengdu-China⁵ Chengdu University Of Traditiona, School Of Basic Medical Sciences, Chengdu-China⁶

Background / Hypothesis: The coexistence of chronic hepatitis B (CHB) and metabolic dysfunction-associated fatty liver disease (MAFLD) is increasingly common and worsens liver outcomes. Noninvasive biomarkers that distinguish CHB-MAFLD from CHB alone are lacking. We aimed to identify integrated cytokine and metabolomic signatures that differentiate CHB-MAFLD from CHB.

Materials and Methods: In this cross-sectional study, 406 participants were enrolled: healthy controls (HC, n=30), CHB alone (CHB, n=149), and CHB with MAFLD (CHB-MAFLD, n=227). CHB was defined by HBsAg positivity >6 months with detectable HBV DNA; MAFLD was diagnosed by imaging proven steatosis plus metabolic dysfunction. Exclusion criteria included other viral hepatitis, malignancy, significant organ dysfunction, systemic disease, and pregnancy. Demographics, clinical labs, serum cytokines (IL-17, TNF- α ; Luminex), and non-targeted serum metabolomics (LC-MS/MS) were compared across groups. Differential metabolites were identified and subjected to KEGG pathway enrichment. **Results:** Compared with CHB alone, CHB-MAFLD patients had higher ALT, AST, GGT, BMI, and uric acid ($P < 0.05$). Serum IL-17 and TNF- α were significantly elevated in CHB-MAFLD versus CHB alone ($P < 0.05$). Metabolomic profiling identified 110 differential metabolites between CHB-MAFLD and CHB groups; the top altered metabolites were Ethyl (S)-3-hydroxybutyrate glucoside, Indole-3-propionic acid, and Hippuric acid. Branched-chain amino acid L-Leucine and L-Tyrosine were decreased in CHB-MAFLD. KEGG enrichment highlighted perturbations in ketone body metabolism, tryptophan metabolism, branched-chain amino acid metabolism, and purine metabolism.

ORAL ABSTRACTS

Conclusions: CHB-MAFLD is characterized by a distinct “metabolic-inflammatory” signature reflecting mitochondrial energy reprogramming, gut microbiota related metabolite shifts, and proinflammatory cytokine activation. Serum IL-17, TNF- α , Ethyl (S)-3-hydroxybutyrate glucoside, Indole-3-propionic acid, and L-Leucine warrant further validation as noninvasive biomarkers to distinguish CHB-MAFLD from CHB alone and to guide precision management.

Keyword(s) : chronic hepatitis B; metabolic dysfunction-associated fatty liver disease; metabolomics; cytokines; biomarkers; metabolic-inflammatory signature

2904 - Clinical Analysis of Liver Transplantation in Patients With Severe Liver Disease

Jinzheng Cai¹, Qingguo Xu¹, Jiahao Liu¹, Yudong Wang², George Lau²

The Affiliated Hospital Of Qingdao University, Organ Transplantation Center, Qingdao-China¹ Humanity & Health Medical Center, Humanity & Health Clinical Trial Center, Hong Kong-Hong Kong SAR, China²

Background / Hypothesis:
To evaluate the clinical efficacy of liver transplantation in patients with severe liver disease, analyze the risk factors for short-term postoperative mortality, and assess the value of modified piggyback liver transplantation and preoperative and intraoperative continuous renal replacement therapy (CRRT) in improving patient outcomes.

Materials and Methods:
A retrospective analysis was conducted on adult patients who underwent liver transplantation at our center between July 2013 and December 2025. A total of 1,534 patients were included, comprising 143 patients with severe liver disease and 1,391 with non-severe liver disease. Clinical characteristics and postoperative outcomes were compared between the two groups. Logistic regression analysis was performed to identify risk factors for death within 90 days after transplantation in patients with severe liver disease.

Results:
Compared with patients with non-severe liver disease, those with severe liver disease were younger and had a higher proportion of alcohol-related chronic liver disease. They experienced greater intraoperative blood loss, required larger volumes of plasma transfusion, had longer ICU stays, higher rates of early postoperative complications, and lower survival rates within 25 days

(93.01%) and 90 days (91.61%) after transplantation ($P < 0.05$). However, there were no significant differences in 1-year and 3-year patient survival rates or graft survival rates between the two groups. Risk factors for death within 90 days after transplantation in patients with severe liver disease included older age (OR 1.097), longer operative time (OR 1.369), greater intraoperative blood loss per 100 mL (OR 1.053), and uncontrolled postoperative infection (OR > 1.965). Compared with the conventional surgical technique, the modified surgical approach significantly reduced postoperative ICU stay ($P < 0.05$). Patients receiving a three-dose basiliximab induction regimen showed a significantly higher rate of effective infection control compared with those who did not receive the three-dose regimen ($P < 0.05$). Patients who received CRRT preoperatively and intraoperatively had a significantly shorter ICU stay compared with those who did not receive CRRT ($P < 0.05$), while infection control rates were not significantly different between the two groups.

Conclusion:

Liver transplantation is an effective treatment for patients with severe liver disease, providing long-term survival benefits comparable to those of non-severe patients. Risk factors for postoperative mortality include advanced age, excessive intraoperative blood loss, prolonged operative time, and uncontrolled postoperative infection. The use of a staged three-dose basiliximab induction regimen, modified piggyback liver transplantation with optimized surgical techniques, and CRRT for patients with preoperative infection can effectively improve postoperative outcomes.

Keyword(s) : Severe liver disease; liver transplantation; clinical efficacy

2905 - A clinical study on the reduction of donor lymphocyte chimerism rate in recipient tissues after liver transplantation by extracorporeal perfusion of anti thymocyte globulin via portal vein

Qingguo Xu¹, Jiahao Liu¹, Jinzheng Cai¹, Yudong Wang², George Lau²

The Affiliated Hospital Of Qingdao University, Organ Transplantation Center, Qingdao-China¹ Humanity & Health Medical Center, Humanity & Health Clinical Trial Center, Hong Kong-Hong Kong SAR, China²

Background / Hypothesis:

This study aimed to determine whether ex vivo perfusion of donor livers with antithymocyte globulin (ATG) could reduce donor lymphocyte chimerism in recipients after liver transplantation, and to evaluate the safety of this approach.

ORAL ABSTRACTS

Materials and Methods:

A retrospective cohort of 35 liver transplant recipients who underwent ex vivo ATG perfusion of the donor liver via the portal vein was included. A matched control group was generated using 1:1 propensity score matching. Postoperative liver and renal function parameters, as well as infectious events, were compared between the two groups. In addition, lymphocyte subsets (CD3⁺, CD4⁺, and CD8⁺) in donor liver tissue were assessed, and donor-derived CD8⁺ T-cell chimerism in recipients' peripheral blood was quantified. Statistical comparisons were performed using the Mann–Whitney U test.

Results:

Postoperative liver and renal function, as well as the incidence of infectious complications, were comparable between the ATG-treated group and the matched control group. In contrast, ex vivo ATG perfusion was

associated with a pronounced reduction in CD3⁺, CD4⁺, and CD8⁺ lymphocyte populations within donor liver tissue. Correspondingly, donor-derived CD8⁺ T-cell chimerism in the peripheral blood of recipients was significantly lower in the ATG-treated group.

Conclusions:

In this study, ex vivo ATG treatment of donor livers was not associated with an increased risk of postoperative complications. At the same time, it effectively suppressed donor lymphocyte activity. These findings indicate that ATG perfusion may serve as a feasible and clinically meaningful strategy for the prevention of graft-versus-host disease (GVHD) following liver transplantation.

Keyword(s) : Ex vivo perfusion; antithymocyte globulin; donor lymphocyte chimerism

E-POSTER ABSTRACTS

1002 - Assessing the Utility of Serum Kallistatin in the Diagnosis of Liver Cirrhosis A Meta analysis

Dr Rukesh Yadav ¹

Maharajgunj Medical Campus, Institute Of Medicine, Tribhuvan University Teaching Hospital, Internal Medicine, Kathmandu-Nepal ¹

Background / Hypothesis: Kallistatin, which protects organs and cells against inflammation, fibrosis and oxidative stress, is mainly synthesized and secreted in liver. As it is a negative acute-phase protein, its blood level decreases with a decline in liver function. Although liver biopsy is the gold standard for the assessment of liver fibrosis in cirrhosis, it has its own limitations. Therefore, noninvasive methods to detect liver fibrosis are widely preferred. However, they also have their own limitations. Thus, there is always a need to extend the battery of serum-based assays. Meta-analysis of clinical data on serum kallistatin level in patients with liver cirrhosis and its potential association with the pathophysiology of is lacking. Thus, this meta-analysis evaluates the levels of serum kallistatin as a diagnostic marker in liver cirrhosis.

Materials and Methods: From the inception to May 2025, the PubMed, Google Scholar, and Embase were searched for studies that assessed serum kallistatin in liver cirrhosis patients and matched healthy controls. Results comprised the standardized mean difference (SMD) in the kallistatin level in the serum of the two groups with a 95% Confidence Interval (CI). According to the heterogeneity, the serum kallistatin values were analyzed using the Revman 5.1 program using either a fixed or random effect.

Results: In this meta-analysis, five studies were included. 370 had cirrhosis and 159 were healthy controls. Participants were adults. The analysis revealed a significantly lower serum kallistatin in liver cirrhosis patients as compared to healthy controls (SMD: -3.30, CI: -5.34 to -1.26, I²=98%, P value 0.002). Furthermore, the serum kallistatin level was even lower in the patients with hepatocellular carcinoma as compared to the liver cirrhosis and healthy controls groups.

Conclusions: The meta-analysis revealed significantly decreased serum kallistatin level in liver cirrhosis

patients. Therefore, further studies to investigate the role of the kallistatin may be valuable for the development of future diagnostics or therapeutics of liver cirrhosis. The low levels of serum kallistatin in cirrhosis can be considered as a diagnostic marker for liver cirrhosis and liver cancer. Incorporating serum kallistatin screening into routine check-ups for patients with hepatitis, non-alcoholic fatty liver, and autoimmune diseases could aid in the early detection and prevention of cirrhosis-associated complications.

Keyword(s) : Kallistatin, Liver cirrhosis

1003 - Is drug induced autoimmune hepatitis being underdiagnosed

Thanh Quynh Ngan Le ¹, Phuong Huynh Hoai ¹

Tam Anh General Hospital, Gastroenterology, HCM-Vietnam ¹

Background: Drug-induced autoimmune hepatitis (DIAIH) is a rare but important clinical entity that mimics idiopathic autoimmune hepatitis (AIH) both clinically and histologically. It is triggered by certain medications in genetically predisposed individuals and poses diagnostic and therapeutic challenges due to its overlapping features with classical AIH and drug-induced liver injury (DILI). At present, there are still few reports on this condition both globally and in Vietnam. **Introduction:**

DIAIH represents a subset of liver injury that shares features with idiopathic AIH but is precipitated by drug exposure. Common causative agents include minocycline, nitrofurantoin, hydralazine, and statins. The exact mechanisms underlying DIAIH remain unclear. It is hypothesized that certain drugs act as haptens or modify self-antigens, triggering a loss of immune tolerance in susceptible individuals

Clinical and Histological Features:

Patients with DIAIH often present with non-specific symptoms. Histologically, DIAIH is indistinguishable from idiopathic AIH, showing interface hepatitis, plasma cell infiltration, and sometimes rosetting of hepatocytes.

Diagnosis:

The diagnosis of DIAIH is based on a combination of clinical history, laboratory findings, and liver biopsy. Key elements include the temporal relationship between drug exposure and onset of hepatitis, presence of autoantibodies (ANA, ASMA), elevated IgG, and histological findings.

Management:

Initial management involves prompt discontinuation of the offending drug. Corticosteroid therapy may be

E-POSTER ABSTRACTS

required in more severe cases or when there is no improvement after drug withdrawal. The long-term need for immunosuppressive therapy is less common than in idiopathic AIH.

Keyword(s) : Keywords: drug - induced autoimmune hepatitis hepatitis, liver disease,

1004 - An acute flare of chronic hepatitis B in a patient with eosinophilic ascites and diabetic ketoacidosis represents a clinical challenge

Ngan Le Thanh Quynh¹

Tam Anh General Hospital, Gastroenterology, HCM-Vietnam¹

Background / Hypothesis: Eosinophilic ascites is an uncommon clinical presentation, most frequently associated with eosinophilic gastroenteritis or parasitic infections. Diagnosis requires careful exclusion of other causes of ascites, especially in patients with underlying chronic liver disease. The treatment of an acute flare of chronic hepatitis B is challenging, particularly in patients with eosinophilic ascites and diabetic ketoacidosis.

Objective: We report a case of eosinophilic ascites in a young man with chronic hepatitis B, newly diagnosed diabetic ketoacidosis, and positive serology for Toxocara exposure, illustrating the diagnostic complexity and successful therapeutic approach.

Materials and Methods: clinical case report and literature review

Results: Corticosteroids remain the cornerstone of treatment for eosinophilic gastroenteritis and associated eosinophilic ascites. In patients with chronic hepatitis B, immunosuppressive therapy poses a risk of HBV reactivation, warranting concurrent antiviral prophylaxis. High-dose corticosteroid therapy in poorly controlled diabetes mellitus cases is also a precipitating factor for recurrent diabetic ketoacidosis. Our patient responded favorably to combined corticosteroid and antiviral therapy, with complete resolution of symptoms and normalization of eosinophil counts.

Conclusion: This case highlights the diagnostic challenges of eosinophilic ascites in a patient with overlapping chronic hepatitis B, diabetic ketoacidosis, and parasitic exposure. Early recognition and appropriate management can lead to favorable outcomes.

1005 - Drug induced autoimmune hepatitis three case reports.

Ngan Le Thanh Quynh¹

Tam Anh General Hospital, Gastroenterology, HCM-Vietnam¹

Background: Drug-induced autoimmune hepatitis (DIAIH) is a rare but important clinical entity that mimics idiopathic autoimmune hepatitis (AIH) both clinically and histologically. It is triggered by certain medications in genetically predisposed individuals and poses diagnostic and therapeutic challenges due to its overlapping features with classical AIH and drug-induced liver injury (DILI). At present, there are still few reports on this condition both globally and in Vietnam.

Objective: We report three cases of drug induced autoimmune hepatitis diagnosed at Tam Anh General Hospital, Ho Chi Minh city.

Materials and Methods: clinical case reports and literature review

Results: Three patients were diagnosed with drug induced autoimmune hepatitis and their conditions are stable during follow up period

Conclusion: DIAIH should be considered in patients with compatible clinical features

and a history of recent drug exposure. Early recognition, withdrawal of the offending agent, and timely immunosuppressive therapy when needed are key to favorable outcomes. Given the limited number of reported cases worldwide and particularly in Vietnam, further research is essential to enhance understanding of its pathogenesis, improve diagnostic criteria, and guide therapeutic strategies

1008 - Efficacy and Safety of Terlipressin versus Octreotide for esophageal variceal bleeding A retrospective study at a tertiary hospital in the UAE

Thaer Swaid¹, Ahmed Sadeq¹, Omar Galal¹, Abdulla Aljanahi¹, Carl Kassab¹, Layth Hamzeh¹, Noha Abou Khater¹, Salma El Shawish¹, Ahmad Al-rifai¹
Ssmc, Gi, Abu Dhabi-United Arab Emirates¹

Background / Hypothesis:

Esophageal variceal bleeding (EVB) is a severe complication of cirrhosis with significant morbidity and mortality. Pharmacologic therapy, including terlipressin and octreotide, is commonly used alongside endoscopic variceal ligation (EVL) to control bleeding. However, the comparative effectiveness of these agents remains uncertain. This study evaluates the efficacy and safety of terlipressin versus octreotide in patients with EVB in a real-world clinical setting

Materials and Methods:

We conducted a retrospective cohort study at a tertiary hospital in the UAE, analyzing patients with EVB who received either terlipressin or octreotide as adjuvant therapy to EVL. Patient data were extracted from electronic health records, and outcomes included in-hospital mortality, 30-day mortality, and the need for repeat endoscopy within five days.

Results:

A total of 275 patients were included (terlipressin: 153, octreotide: 122). There were no significant differences in 30-day mortality (24% vs. 16%, $p=0.144$), in-hospital mortality (24% vs. 20%, $p=0.371$), or the need for repeat endoscopy (11% in both groups, $p=0.941$). Cardiac events occurred at similar rates between

groups (14% vs. 18%, $p=0.808$).

Conclusions:

Terlipressin and octreotide demonstrated comparable efficacy and safety as adjuncts to EVL in EVB management. Given the lack of significant differences in clinical outcomes, treatment selection should consider patient-specific factors, cost, and drug availability. Further prospective studies are needed to confirm these findings.

Keyword(s) : Esophageal variceal bleeding , Terlipressin , Octreotide, Endoscopic variceal ligation

1012 - Thromboangiitis obliterans in a Non Smoker Complicated by Budd Chiari Syndrome A Rare Case of Visceral Thrombosis

Ziad W. Elmezayen¹

Faculty Of Medicine, kafr Elsheikh University, Kafr Elsheikh, Egypt., Faculty Of Medicine, Kafr El Sheikh- Egypt¹

Background / Hypothesis: Thromboangiitis obliterans is a rare inflammatory vascular condition that usually affects young male smokers, with symptoms limited to the limbs. Visceral involvement is extremely rare, especially in non-smokers

Materials and Methods: We present the case of a 20-year-old male with no history of smoking, who was evaluated for symptoms including digital ischemia, ulcers, and dry gangrene. A comprehensive workup ruled out atherosclerosis, autoimmune diseases, and other forms of vasculitis, leading to a diagnosis of thromboangiitis obliterans. The patient received medical therapy and wound care for symptom management.

Results: After nearly a year, the patient was readmitted with signs indicative of hepatic congestion, ascites, and spontaneous bacterial peritonitis. Imaging studies revealed hepatic vein outflow obstruction, leading to a diagnosis of Budd-Chiari syndrome. No thrombophilic disorders were identified, although the patient was found to have glucose-6-phosphate dehydrogenase deficiency.

E-POSTER ABSTRACTS

Conclusions: This case highlights a rare, severe form of thromboangiitis obliterans in a non-smoker, complicated by visceral thrombosis. It underscores the importance of considering systemic involvement even in atypical presentations and maintaining close follow-up in patients at risk of disease progression.

Keyword(s) : Thromboangiitis obliterans, Buerger's disease, non-smoker, Budd-Chiari syndrome, visceral thrombosis, glucose-6-phosphate dehydrogenase deficiency, spontaneous bacterial peritonitis, hypercoagulability, peripheral ischemia, atypical vascular presentation.

1014 - Validation of the CLIF SIG score in patients with HBV related acutely decompensated cirrhosis

Jiyang Chen¹, Xianbin Xu¹, Sisi Yang¹, Xia Yu¹, Ferran Aguilar², Joan Clària³, Jonel Trebicka⁴, Juan-josé Lozano⁴, Julia Sidorova⁴, Paolo Angeli⁵, Alberto Queiroz Farias⁶, Richard Moreau⁷, Wenyi Gu⁸, Zelu Meng¹, Ying Nie¹, Yining Zhang¹, Yu Shi¹, Yida Yang¹
The First Affiliated Hospital, Zhejiang University School Of Medicine, Department Of Infectious Diseases, Hangzhou-China¹ European Foundation For The Study Of Chronic Liver Failure, Department Of Biomedical Sciences, University Of Barcelona, Barcelona-Spain² University Of Barcelona, Department Of Biomedical Sciences, Barcelona-Spain³ University Of Münster, Department Of Internal Medicine B, Munster-Germany⁴ University Of Padova, Department Of Clinical And Experimental Medicine, Padova-Italy⁵ Hospital Das Clinicas, University Of Sao Paulo School Of Medicine, Department Of Gastroenterology, Sao Paulo-Brazil⁶ Université Paris Cité, Centre De Recherche Sur L'inflammation (cri), Inserm, Paris-France⁷ Ren Ji Hospital, School Of Medicine, Shanghai Jiao Tong University, Department Of Gastroenterology, Shanghai-China⁸

Background / Hypothesis:The CLIF-SIG (Chronic Liver Failure-Systemic Inflammation Gene) score has been proposed to quantify systemic inflammation and predict outcomes in acutely decompensated (AD) cirrhosis, primarily validated in alcohol-related cases. However, its applicability to hepatitis B virus (HBV)-related cirrhosis remains uncertain, given the distinct clinical profile of HBV-ACLF (acute-on-chronic liver failure). We hypothesized that CLIF-SIG is a valid prognostic tool for HBV-related AD cirrhosis.

Materials and Methods:Peripheral blood mononuclear cell (PBMC) transcriptomes from 220 HBV-related AD patients and 29 healthy controls were analyzed. CLIF-

SIG scores were calculated based on a 28-gene panel. Patients were stratified into clinical subgroups (stable decompensated cirrhosis [SDC], unstable decompensated cirrhosis [UDC], pre-ACLF, and ACLF). The prognostic performance of CLIF-SIG was compared with MELD and MELD-Na scores for predicting 90-day transplant-free mortality and AD-ACLF progression. **Results:**Expression analysis revealed significant upregulation of 24 inflammatory genes and downregulation of 4 NK cell-related genes in AD/ACLF patients, with a stepwise increase in CLIF-SIG scores across disease stages. The CLIF-SIG score effectively distinguished between SDC, UDC, pre-ACLF, and ACLF groups. Using a cut-off of 0.386, high-score patients exhibited markedly higher 90-day mortality ($p < 0.0001$). The area under the ROC curve (auROC) for CLIF-SIG in predicting 90-day mortality was 0.821 in AD and 0.73 in ACLF, outperforming MELD and MELD-Na. Furthermore, CLIF-SIG surpassed traditional inflammatory markers in assessing disease severity and progression. Combining CLIF-SIG with MELD further enhanced prognostic accuracy.

Conclusions:The CLIF-SIG score reliably quantified systemic inflammation and predicted clinical outcomes in HBV-related AD cirrhosis, demonstrating robust stratification across clinical phenotypes and outperforming conventional models. These findings support its generalizability beyond alcohol-related cirrhosis, underscoring systemic inflammation's pivotal role in HBV-related cirrhosis progression.

Keyword(s) : CIRRHOSIS; LIVER FAILURE; HEPATITIS B; INFLAMMATION

1015 - Gut Microbial Succession and Escalating Antibiotic Resistance from Chronic Hepatitis B to Acute on Chronic Liver Failure A Metagenomic Study

Jiyang Chen¹, Xianbin Xu¹, Sisi Yang¹, Xia Yu¹, Zelu Meng¹, Ying Nie¹, Yani Zhou¹, Siqi Sun¹, Yining Zhang¹, Huilan Tu¹, Yingfeng Lu¹, Jiangshan Lian¹, Hongyu Jia¹, Yu Shi¹, Yida Yang¹

The First Affiliated Hospital, Zhejiang University School Of Medicine, Department Of Infectious Diseases, Hangzhou-China¹

Background / Hypothesis:Disruption of the gut microbiota is increasingly recognized as a pivotal driver of chronic liver disease progression, promoting systemic inflammation, immune dysregulation, and bacterial translocation. We performed a comprehensive metagenomic analysis to characterize the ecological and functional shifts in the gut microbiota across

E-POSTER ABSTRACTS

patients with chronic hepatitis B(CHB), acute decompensation (AD), and acute-on-chronic liver failure (ACLF).

Materials and Methods:Fecal samples (n = 90) collected from patients with CHB, AD, and ACLF were subjected to whole-genome shotgun metagenomic sequencing. Microbial diversity was assessed using alpha and betadiversity metrics, principal coordinate analysis (PCoA), and non-metric multidimensional scaling(NMDS). Differential taxa were identified using linear discriminant analysis effect size (LEfSe).Functional annotation of antibiotic resistance genes (ARGs) and virulence factors (VFs) was performed using the Comprehensive Antibiotic Resistance Database (CARD) and the VirulenceFactors Database (VFDB).

Results:Alpha diversity decreased progressively from CHB to ACLF, while beta diversity demonstrated significant group-wise separation (Kruskal-Wallis test, $p < 1 \times 10^{-100}$). Symbiotic genera, including Blautia, Ruminococcus, and Coprococcus, were enriched in AD, whereas pathobionts such as Escherichia coli and Enterococcus faecium dominated in ACLF. ARG profiling revealed a substantial increase in resistance burden in ACLF, characterized by the enrichment of β -lactamases, efflux pumps, and multidrug resistance elements (e.g., ARO:3005041, ARO:3000833).VFDB analysis showed upregulation of virulence determinants including type III secretion systems, lipopolysaccharides (LPS), and β -hemolysins. Functional analysis indicated a shift from a commensal-driven resistance profile in CHB and AD to a pathogen-dominated profile in ACLF, largely mediated by Enterococcus, Klebsiella, and Streptococcus species.

Conclusions:Progression from CHB to ACLF is associated with a stepwise ecological succession of the gut microbiota, culminating in pathogen-driven dysbiosis and heightened antimicrobial resistance. These findings highlight the gut microbiota as a potential biomarker for disease staging and a target for microbiota-directed therapeutic interventions in advanced liver disease.

Keyword(s) : CIRRHOSIS; LIVER FAILURE; HEPATITIS B; ACUTE-ON-CHRONIC LIVER FAILURE; GUT MICROBIOTA

1016 - Single cell analysis identifies RETN+ monocyte derived resistin as a therapeutic target in hepatitis B virus related acute on chronic liver failure

Xianbin Xu ¹, Jiyang Chen ¹, Xia Yu ¹, Sisi Yang ¹, Yida Yang ¹, Jifang Sheng ¹, Shi Yu ¹

The First Affiliated Hospital, Zhejiang University School Of Medicine, Department Of Infectious Diseases, Hangzhou-China ¹

Background and aims:Acute-on-chronic liver failure (ACLF) is characterized by intense systemic inflammation and high short-term mortality, yet effective targeted therapies are lacking. We aimed to explore monocyte heterogeneity in hepatitis B virus-related ACLF (HBV-ACLF) to identify specific subsets and associated therapeutic targets.

Materials and Methods:Peripheral blood mononuclear cells from healthy controls (n=4), patients with acute decompensation (AD, n=5), and ACLF patients (n=9) underwent single-cell RNA sequencing (scRNA-seq). Findings were integrated with hepatic scRNA-seq, bulk transcriptomics, multiplex immunohistochemistry, and in vitro functional assays. The in vivo roles of candidate targets were validated in two murine ACLF models.

Results:We identified a distinct RETN+ monocyte subset that was expanded in the circulation and liver of HBV-ACLF patients. These RETN+ monocytes displayed a transcriptional program enriched for anti-inflammatory and pro-resolving signatures, including MS1-B-like features. Interleukin-6 (IL-6) promoted the expansion of RETN+ monocyte via the JAK/STAT3/RUNX1 signaling axis. In murine ACLF models, neutralization of Resistin exacerbated liver injury, increased systemic cytokine levels, and augmented hepatocyte apoptosis. Conversely, administration of recombinant Resistin mitigated liver damage and diminished levels of inflammatory cytokines, and improved survival. Mechanistically, Resistin activated PI3K/AKT signaling in hepatocytes, preserved the Bcl-2/Bax balance, and suppressed intrinsic apoptosis. Clinically, plasma Resistin levels in HBV-ACLF patients inversely correlated with systemic inflammatory markers, liver injury, ACLF severity scores (MELD, CLIF-C ACLF), and short-term mortality.

Conclusions:RETN+ monocytes constitute a distinct immunoregulatory subset enriched in HBV-ACLF, and their product, Resistin, exerts significant hepatoprotective and anti-inflammatory effects. These findings highlight RETN+ monocytes and Resistin as promising immunotherapeutic targets for HBV-ACLF.

Keyword(s) : Liver failure; Single-cell analysis; Inflammation; Cirrhosis

E-POSTER ABSTRACTS

1024 - Comparison of effectiveness of mycophenolate mofetil associated with standard dosage or reduced dose tacrolimus for liver transplantation immunosuppression

Ulil Albab Habibah ¹

Islamic University Indonesia, Internal Medicine
Profession Doctor, Yogyakarta-Indonesia ¹

Background / Hypothesis:

Liver transplantation necessitates lifelong immunosuppressive therapy to prevent graft rejection. This systematic review evaluates the effectiveness of mycophenolate mofetil (MMF) in combination with standard-dose (SD) versus reduced-dose (RD) tacrolimus in liver transplant recipients.

Materials and Methods:

A systematic search was conducted across databases including PubMed, Cochrane, and Embase for studies published from 2000 to 2024. Inclusion criteria focused on randomized controlled trials (RCTs) and observational studies involving human subjects aged ≥ 18 . Primary outcomes included graft survival, acute rejection rates, and patient survival, while secondary outcomes encompassed renal function, infection rates, and adverse effects.

Results:

Out of 85 initially identified studies, 81 were excluded based on predetermined criteria. Ultimately, four studies involving a total of 255 patients (standard-dose: $n = 131$; reduced-dose: $n = 124$) were included for analysis. The findings indicated that mycophenolate mofetil (MMF) combined with tacrolimus, whether standard-dose or reduced-dose, allowed for a significant reduction in tacrolimus dosage, effectively minimizing nephrotoxic effects. Graft and patient survival rates were comparable between the MMF-tacrolimus regimen using standard and reduced doses. Additionally, the MMF group exhibited lower rates of acute rejection and showed improvements in renal function, with safety and efficacy profiles being similar across both dosage groups.

Conclusions:

The combination of MMF with either standard-dose or reduced-dose tacrolimus is an effective immunosuppressive strategy for liver transplant recipients. Both approaches facilitate a reduction in tacrolimus dosage while maintaining similar safety and efficacy. The MMF-tacrolimus regimen contributes to lower rates of acute rejection, with comparable graft and patient survival rates. Further research is warranted

to optimize immunosuppressive protocols and enhance patient outcomes.

Keyword(s) : Liver transplantation, Immunosuppression, Tacrolimus, Mycophenolate mofetil (MMF)

1026 - EXPLORING LABORATORY VARIATIONS IN CIRRHOSIS ETIOLOGIES A COMPARATIVE ANALYSIS OF CBC AND LIVER SYNTHETIC FUNCTION BETWEEN PATIENTS WITH ALCOHOLIC LIVER DISEASE AND OTHER ETIOLOGIES

Lilit Harutyunyan ¹, Edmond Baghdasaryan ¹, Sofya Grigoryan ¹, Anush Kharabakhtsyan ¹, Iskuhi Navoyan ², Asya Gabrielyan ², Aleks Israelyan ², Anna Mkrtchyan ², Ofelya Podosyan ², Varduhi Jamkchyan ², Manik Gemilyan ², Gagik Hakobyan ²

Ysmu, Gastroenterology And Hepatology, Yerevan-Armenia ¹ Ysmu, Gastroenterology And Hepatology, Yerevan-Armenia ²

Background / Hypothesis: Cirrhosis remains a major cause of global morbidity and mortality, with varying clinical and laboratory features depending on etiology. Alcoholic liver disease (ALD) is one of the most prevalent causes of cirrhosis, globally. This study aimed to compare laboratory parameters—complete blood count (CBC) markers (hemoglobin [Hb], white blood cell count [WBC], platelet count [PLT]) and liver synthetic function tests (albumin and prothrombin time [PT])—between patients with ALD and those with other cirrhosis etiologies (e.g., MASLD, HCV, PBC) at the time of hospital admission.

Materials and Methods: We retrospectively analyzed the data of 160 cirrhotic patients admitted to Mikayelyan University Hospital, Yerevan, Armenia, between 2021 and 2024, categorized into ALD ($n=70$) and non-ALD ($n=90$) groups. Patients with hepatocellular carcinoma (HCC) were excluded. The patients had nearly the same age distribution, with male predominance in the ALD group. Laboratory data (albumin, PT, WBC, PLT, Hb) and clinical characteristics (including diabetes, hypertension, and substance use history) were recorded. Statistical comparisons between groups were performed using t-tests and Mann-Whitney U tests, as appropriate.

Results: Significant differences were found in multiple laboratory parameters between ALD and other cirrhosis groups. Patients with ALD exhibited significantly lower albumin levels (mean 2.95 g/dL) and higher PT (mean 18.5 seconds) compared to other cirrhosis patients (albumin: 3.35 g/dL, PT: 15.2 seconds) ($p<0.01$). In addition, ALD patients showed more severe thrombocytopenia (mean PLT: $107 \times 10^3/\mu\text{L}$) and a

E-POSTER ABSTRACTS

higher WBC count (mean $8.9 \times 10^3/\mu\text{L}$) compared to those with other cirrhosis etiologies (PLT: $129 \times 10^3/\mu\text{L}$, WBC: $7.3 \times 10^3/\mu\text{L}$) ($p < 0.05$). No significant difference was noted in Hb levels between the two groups (mean Hb for ALD: 12.4 g/dL vs. 12.3 g/dL for other cirrhosis). Additionally, patients with ALD demonstrated a higher prevalence of ascites and splenomegaly (both 70% vs. 55%, $p < 0.05$), reinforcing the severity of liver dysfunction and portal hypertension in this cohort. Conclusions: This study highlights clinically significant differences in laboratory markers between patients with ALD and other etiologies of cirrhosis. ALD was associated with more severe liver synthetic dysfunction (lower albumin, higher PT), thrombocytopenia, and a higher WBC count. These findings suggest that ALD has a unique clinical profile that may have implications for diagnosis and treatment strategies. Specifically, ALD patients may require more aggressive management of a complication such as ascites. Further prospective studies are warranted to validate these findings and investigate how they could inform therapeutic decisions, potentially improving patient outcomes in ALD and cirrhosis.

Keyword(s) :

1027 - Long term follow up of HCV patients who treated with DAA [Direct Acting Antivirals]

Eliza Vashakidze¹, Mariam Kvitashvili¹, Tamar Megrelishvili¹, Marina Djangavadze¹, Tea Bochorishvili¹

Tsmu, Infectious Disease, Tbilisi-Georgia¹

Background: Our country ranks 5th in the world in terms of HCV infection prevalence, after Gambia, Mongolia, Egypt and Uzbekistan [WHO 2017]. 5.4% of the adult population is HCV RNA positive. The highest infection rates [15-24%] occur in men aged 30-49 years [NCDC]. Since 2015, the "Hepatitis C Elimination Program" has been launched in Georgia, within the framework of which antiviral treatment has been provided to more than 65 000 infected people. Five years after the start of the program, the prevalence of HCV infection was already reduced by 2 times in a repeated epidemiological study conducted by NCDC

Material/methods: The aim of the study was longitudinal follow-up of patients who achieved a sustained virological response [SVR] after antiviral therapy with DAA in 2016-17yy. The patients had been treated with ledipasvir/sofosbuvir [Harvoni] or sofosbuvir/velpatavir for 12 weeks. 200 patients with

past-HCV were included in the study. Of these, 100 patients had minimal liver fibrosis - F 1-2 [5-7 kPa] - I group, 100 patients - significant fibrosis - F 3-4 [10-12 kPa] - Group II.

result: After 8 years of antiviral treatment, 15 patients in the first group of patients developed fibrosis to F3, and no ultrasound or laboratory signs of hepatocellular carcinoma [HCC] were detected. 9% had type 2 diabetes mellitus, 45% had hyper- and dyslipidemia. All patients had fat accumulation in the liver parenchyma [S2-S3] - pronounced fatty liver disease [FLD]. 1/3 of patients in group II had progressive liver damage with the development of liver cirrhosis [Child-Pugh score Class A and Class B]. Cofactors for the development of liver cirrhosis were: alcoholic liver disease, type 2 diabetes mellitus, and obesity [BMI 34 and more]. 4 patients were already undergoing treatment for HCC. HCC was detected in 5 more patients during the study. [Total 9 patients]

conclusion: The most important measures to reduce the prevalence of HCV infection are total screening of the population and treatment of infected people with DAA. Treatment is highly effective in the early stages of liver damage. In addition, past-HCV individuals are more likely to develop FLD, which requires medical management. As for patients with significant liver damage, continuous monitoring is necessary to improve the quality of their lives and improve survival rates, for timely detection of damage progression and complications and adequate treatment.

Keyword(s) : HCV, DAA, treatment, FLD, LC

1028 - Chronic viral hepatitis [HCV HBV] course and outcome in patients with severe COVID 19]

Eliza Vashakidze¹, Khatia Khatiaishvili¹, Mariam Kvitashvili¹, Lia Goliadze²

Tsmu, Infectious Disease, Tbilisi-Georgia¹

V.bochorishvili Clinic, Infectious Disease, Tbilisi-Georgia²

Background / Hypothesis: Chronic viral hepatitis [HCV, HBV] is a significant burden on the country's healthcare system. According to a study conducted by WHO [1917], 5.4% of the adult population is infected with HCV, more than half of whom have liver damage at the stage of significant fibrosis and cirrhosis. As for HBV infection, according to a study conducted by NCDC, the prevalence of HBsAg in the country was 2.9% [3.4% in men, 2.5% in women]. The highest prevalence was

E-POSTER ABSTRACTS

observed in the age groups of men: 30-39 and 40-49 years. The global COVID 19 pandemic of 1920-24, which was naturally also noted in our country, significantly affected this cohort of patients.

Material/Methods: The aim of the study was to study the course and outcome of chronic viral hepatitis [HCV, HBV] in patients with severe COVID 19 who were treated in the emergency and intensive care unit of the Bochorishvili Clinic. 112 patients were under observation. A - who had received antiviral treatment within the framework of the State Hepatitis C Elimination Program and achieved SVR, and patients with chronic HBV infection who were treated on an outpatient basis with antiviral treatment [with tenofovir or entecavir], and B - patients with chronic viral hepatitis [HCV, HBV] who had relapsed after infection with SARS CoV2 and hospitalization in a hospital.

Results: It was established that the more severe course of COVID 19, prolonged fever in the viremia phase, high rate of lung parenchymal damage on CT scan, the need for intensive care, including artificial ventilation of the lungs, and the unfavorable outcome of the disease did not depend on the etiological factor of liver damage. Worse prognosis, severe hypoalbuminemia, severe coagulopathy, thrombocytopenia The prevalence of bacterial sepsis, a high incidence of complications and a 2-fold higher mortality rate were observed in patients with liver damage in the stage of decompensated cirrhosis. In patients who had undergone antiviral treatment [past-HCV], or HBV was controlled with antiviral treatment, During the severe course of COVID 19, no high risk of complications and mortality was observed.

Conclusions: Therefore, in order to achieve a positive outcome in the further effective management and treatment of patients with chronic liver disease in the emergency department, it is necessary to immediately determine the stage of liver damage and carefully monitor the clinical and laboratory parameters of patients and correct impaired liver functions using appropriate medications.

Keyword(s) : HCV, HBV ,LC, COVID 19 ,complications.

1030 - A case of drug induced liver injury caused by salt fleshed psoralea corylifolia

Chaojian He¹, Qingqiang Yi²

Rocky Vista University, Utah Msbs 2026, Ivins-United States¹ Tai'an 88 Hospital, Department Of Hepatology, Tai'an-China²

Background / Hypothesis:

Drug-induced liver injury (DILI) is one of the most frequent and serious adverse drug reactions and may progress to liver failure. Although traditional Chinese medicines (TCMs), natural medicines (NMs), health products (HPs), and dietary supplements (DSs) are often regarded as safe, their potential to cause DILI has gained increasing global attention. *Psoralea corylifolia* (Bu Gu Zhi) is a commonly prescribed TCM. Here, we describe a case of DILI associated with salt-processed *Psoralea corylifolia*.

Case Report:

A 61-year-old woman was admitted with abnormal liver function persisting for more than 20 days. Following lung cancer surgery, she had been taking herbal decoctions.

Prescription 1 contained Pinellia, Pericarpium Citri Reticulatae, Glycyrrhiza, Ostrea, Panax notoginseng powder, Scutellaria, Houlttuynia, and others.

Prescription 2 included Curcuma, Corydalis, Astragalus, Codonopsis, Atractylodes, Lycium, and Poria. Both prescriptions were taken twice daily. Liver function remained normal after one month.

Subsequently, Prescription 2 was modified by removing Corydalis and adding 15 g of salt-processed *Psoralea corylifolia*. One month later, liver tests showed ALT 135 U/L and ALP 122 U/L; after two months, ALT further increased to 541 U/L and ALP to 131 U/L. The patient reported no fatigue, anorexia, jaundice, pruritus, abdominal pain, or weight loss, and had no history of viral hepatitis, chronic liver disease, or drug/food allergies.

On examination, there was no jaundice, palmar erythema, or spider angiomas; the liver and spleen were not palpable. Viral hepatitis serology, autoimmune antibodies, HIV, CMV, EBV, and ceruloplasmin tests were negative. Renal function was normal, INR was 0.95, and abdominal ultrasonography was unremarkable.

DILI was strongly suspected. The herbal therapy was discontinued, and hepatoprotective agents (tiopronin and polyene phosphatidylcholine) were administered. After 15 days, ALT decreased to 77 U/L and ALP to 105 U/L.

Final diagnosis: drug-induced liver injury, hepatocellular type (ALT 10.8 × ULN, R = 10), acute; Roussel Uclaf Causality Assessment Method (RUCAM) score 10 (highly probable, salt-processed *Psoralea corylifolia*), severity grade 1.

Conclusions:

Salt-processed *Psoralea corylifolia* is frequently

E-POSTER ABSTRACTS

combined with other herbs to manage lumbar strain, osteoarthritis, and disorders attributed to liver–kidney deficiency or blood stasis. Clinical use of prescriptions containing *Psoralea* requires close monitoring of liver function, ideally at monthly intervals. Once abnormalities are detected, the agent should be discontinued promptly, and hepatoprotective therapy considered.

Keyword(s) : Drug-induced liver injury; Salt-fleshed *psoralea corylifolia*

1031 - Idiopathic Inflammatory Myopathy Presenting as Hepatic Injury A Case Report

Chaojian He¹, Qingqiang Yi²

Rocky Vista University, Utah Msbs 2026, Ivins-United States¹ Tai'an 88 Hospital, Department Of Hepatology, Tai'an-China²

Background / Hypothesis:

Idiopathic inflammatory myopathies (IIM) are heterogeneous disorders characterized by proximal muscle involvement, with polymyositis (PM) and dermatomyositis (DM) as the most common subtypes. They are rare, frequently misdiagnosed in the early stage, and often associated with elevated serum enzymes; liver enzyme abnormalities occur in over 70% of patients. We describe a case of DM initially misattributed to hepatic injury.

Case Report:

A 65-year-old woman presented with 2 weeks of proximal muscle pain and weakness, unrelieved by rest or medication, followed by progressive left shoulder pain. Laboratory evaluation revealed ALT 348 U/L, AST 518 U/L, negative hepatitis B/C serology, WBC $8.95 \times 10^9/L$, neutrophils 82.5%, and ESR 35 mm/h. Hip MRI demonstrated diffuse inflammatory changes, vascular ultrasound revealed bilateral atherosclerosis with venous thrombosis, and shoulder MRI indicated rotator cuff injury. Because liver enzymes exceeded $10 \times ULN$, she was admitted with a presumptive diagnosis of hepatic injury.

On admission, she appeared fatigued with forehead and periorbital erythema, a V-sign rash, neck weakness, proximal muscle tenderness, impaired leg elevation (MRC grade III), and limited arm lifting. Cardiac enzyme showed AST 476 U/L, LDH 1600 U/L, CK 9798 U/L, CK-MB 570 U/L, and troponin I 1.01 ng/mL.

Autoantibodies and autoimmune liver markers were

negative.

Dermatomyositis was diagnosed. She was treated with intravenous methylprednisolone, cyclophosphamide, and tacrolimus, alongside hepatoprotective, anticoagulant, and supportive therapy. Her condition improved rapidly: rash resolved, muscle pain subsided, and repeat testing showed ALT 304 U/L, AST 321 U/L, CK 3013 U/L. She was discharged on outpatient follow-up.

Conclusions:

This case highlights that elevated liver enzymes in PM/DM often reflect muscle rather than hepatic injury. Given the heterogeneous and frequently atypical presentation, particularly in elderly patients, early misdiagnosis is common. Recognition of characteristic rashes and muscle weakness, combined with serum muscle enzyme testing, is essential for timely diagnosis and management.

Keyword(s) :

1032 - Drug Induced Liver Injury from Shenbao Tablets in an Elderly Patient A Case Report

Chaojian He¹, Qingqiang Yi²

Rocky Vista University, Utah Msbs 2026, Ivins-United States¹ Tai'an 88 Hospital, Department Of Hepatology, Tai'an-China²

Background

Drug-induced liver injury (DILI) related to traditional Chinese medicines (TCMs), natural medicines (NMs), health products (HPs), and dietary supplements (DSs) has become a growing global concern. In China, elderly patients frequently use such products in an unregulated manner. Shenbao Tablets, a kidney-yang-tonifying preparation, are commonly prescribed in this population but carry a potential risk of hepatotoxicity. We report a severe case of Shenbao Tablet-induced DILI in an elderly man.

Case Report

A 65-year-old man presented with fatigue and dark urine for 10 days. He had been self-medicating with Shenbao Tablets for 20 days. Past history included hypertension treated with nimodipine and benazepril.

Examination revealed marked jaundice of skin and sclera without stigmata of chronic liver disease. Abdomen was soft with no hepatosplenomegaly or

E-POSTER ABSTRACTS

ascites. No peripheral edema was noted. Laboratory tests: TBil 199 $\mu\text{mol/L}$, DBil 118 $\mu\text{mol/L}$, albumin 34 g/L, ALT 1006 U/L, AST 1128 U/L, GGT 270 U/L, ALP 242 U/L; INR 1.13, prothrombin activity 74%. Viral hepatitis serology and autoimmune markers were negative. Ultrasound showed normal liver morphology, dense parenchymal echoes, and gallstones without biliary dilatation.

Shenbao Tablet-related DILI was suspected. The drug was discontinued, and hepatoprotective therapy (compound glycyrrhizin, polyene phosphatidylcholine, Ganshukang, Wuzhi capsules) was initiated. Despite treatment, jaundice progressed: one week later, TBil 294 $\mu\text{mol/L}$, DBil 151 $\mu\text{mol/L}$, ALT 535 U/L, AST 592 U/L, GGT 396 U/L, ALP 391 U/L. After 50 days of therapy, liver function normalized. The patient remained symptom-free during 2 years of follow-up without re-exposure.

Final diagnosis: drug-induced liver injury, hepatocellular type (ALT 20.1 $\times$ ULN, R=10), acute; RUCAM score 9 (highly probable, Shenbao Tablets); severity grade 3 (severe).

Discussion and Conclusions

Shenbao Tablets contain 22 herbal ingredients, including Epimedium, Psoralea, Polygonum multiflorum, and Cnidium, all reported to cause hepatotoxicity. Although marketed as a tonic, its safety is not assured. In conclusion, health supplements are not universally safe, particularly in elderly patients. Their use should be guided by professionals, and unexplained symptoms during administration warrant immediate medical attention.

Keyword(s) :

1033 - A Rare Case of Peptic Ulcer Perforation Associated with Lenvatinib in Hepatocellular Carcinoma

Zyrah Lou Samar¹, Miguel Edgardo Forès¹
Makati Medical Center, Department Of Medicine,
Section Of Gastroenterology, Makati City-Philippines¹

Introduction: Lenvatinib is a type I tyrosine kinase inhibitor with antiangiogenic activity, approved as first-line treatment for patients with advanced, unresectable hepatocellular carcinoma (HCC). Gastrointestinal (GI) adverse effects are most commonly observed within the first six months of treatment initiation. Among these, gastrointestinal perforation is a rare but life-

threatening complication, occurring in approximately 1.3% of patients receiving lenvatinib.

Case Presentation: We report the case of a 54-year-old Asian male with unresectable HCC who presented to the emergency department with acute, severe abdominal pain after two months of lenvatinib therapy (8 mg daily). An esophagogastroduodenoscopy (EGD) performed prior to treatment initiation revealed no abnormalities. Physical examination showed diffuse abdominal tenderness with guarding. Laboratory results were notable for elevated serum creatinine, hyponatremia, and prolonged INR. A non-contrast CT scan of the abdomen revealed massive pneumoperitoneum with extraluminal air surrounding the stomach and diffuse thickening of the gastric fundus wall. Empiric antibiotic therapy with piperacillin-tazobactam was initiated for suspected peritonitis secondary to GI perforation. An emergent exploratory laparotomy revealed a 2 $\times$ 2 cm perforated peptic ulcer on the lesser curvature of the stomach. Modified Graham patch repair was performed, and biopsy specimens were negative for *Helicobacter pylori*. Histopathology showed chronic inflammation, hemorrhage, and ulceration. The patient recovered well postoperatively and was discharged in stable condition.

Conclusion: This case highlights the importance of clinician awareness regarding the potential for serious, albeit uncommon, gastrointestinal complications associated with lenvatinib therapy. Early recognition and timely surgical intervention are critical to improving patient outcomes and reducing the risk of morbidity and mortality.

Keyword(s) : "lenvatinib", "perforated peptic ulcer", "unresectable hepatocellular carcinoma"

1036 - Two cases of drug induced liver damage in the elderly caused by Tusanqi (Gynura japonica)

Chaojian He¹, Qingqiang Yi²
Rocky Vista University, Utah Msbs 2026, Ivins-United States¹ Tai'an 88 Hospital, Department Of Hepatology, Tai-China²

Background:

Herbal medicine-related drug-induced liver injury (DILI) has become increasingly recognized in the elderly, partly due to widespread use of health supplements. Tusanqi (*Gynura japonica*), a traditional herb containing hepatotoxic pyrrolizidine alkaloids, is

E-POSTER ABSTRACTS

easily mistaken for Sanqi (*Panax notoginseng*), which is non-toxic. We report two elderly patients who developed severe chronic liver injury after prolonged ingestion of Tusanqi.

Case Reports:

The first patient, an 80-year-old man, presented with progressive abdominal distension for three months and jaundice for one month. He had ingested self-prepared Tusanqi powder daily for over three years. Laboratory tests revealed marked hyperbilirubinemia, hypoalbuminemia, and coagulopathy, with negative viral and autoimmune markers. CT imaging confirmed cirrhosis with reduced liver volume. He was diagnosed with Tusanqi-induced DILI (RUCAM score 10), decompensated cirrhosis, and hepatic encephalopathy. Despite cessation of the herb and supportive therapy, his condition deteriorated, leading to liver failure and death after 40 days of hospitalization.

The second patient, his 75-year-old wife, had consumed Tusanqi in the same manner. Approximately six months after her husband's diagnosis, she developed confusion, behavioral changes, and hepatic encephalopathy. Laboratory findings showed hypoalbuminemia and mild hyperbilirubinemia, while ultrasonography revealed cirrhotic changes. She was likewise diagnosed with Tusanqi-induced DILI (RUCAM score 10), decompensated cirrhosis, and hepatic encephalopathy. Her encephalopathy responded to branched-chain amino acid therapy, but due to poor adherence she experienced repeated relapses, resulting in 10 hospital admissions over three years. She remains alive with persistent hepatic dysfunction.

Discussion:

Unlike the acute hepatic sinusoidal obstruction syndrome (HSOS) commonly associated with pyrrolizidine alkaloids, both patients developed progressive cirrhosis and chronic liver failure after long-term use. This difference may relate to ingestion method, cumulative exposure, comorbidities, and individual susceptibility. The male patient's rapid deterioration contrasted with his wife's relatively milder course, suggesting variability in host response.

Conclusions:

These cases highlight the hepatotoxic risk of Tusanqi, especially in the elderly. Misidentification with Sanqi contributes to accidental ingestion and delayed recognition of toxicity. Clinicians should maintain vigilance for chronic DILI in patients with unexplained cirrhosis, particularly with a history of herbal use.

1038 - Comparative Analysis of Epidemiological Characteristics of Hepatitis A and Hepatitis E in Beijing from 2015 to 2024

Chao Wang¹, Wei Li¹, Xiao Hu¹

Beijing Center For Disease Prevention And Control, Institute Of Information And Statistics Center, Beijing-China¹

Background: Although both hepatitis A and hepatitis E are primarily transmitted through the ingestion of contaminated food or water, the differences in their epidemiological characteristics in Beijing remain poorly understood.

Materials and Methods: thods were used to characterize the epidemiological fDescriptive epidemiological meeasures of HAV and HEV cases reported in Beijing from 2015 to 2024. Chi-square tests or t-tests were employed to compare differences in time, region, and population distribution between the two diseases.

Results: From 2015 to 2024, a total of 1,123 HAV cases (977 confirmed, 87.00%) and 3,321 HEV cases (2,972 confirmed, 89.49%) were reported in Beijing. The proportion of confirmed cases was lower for HAV than for HEV ($\chi^2 = 5.265$, $P = 0.022$). Temporally, both diseases showed an initial increase (2015–2018), followed by a decline (2019–2022), and then a resurgence (2023–2024). Urban areas accounted for 61.44% of HAV cases and 61.55% of HEV cases. The proportion of HAV cases in suburban areas (35.17%) was higher than that of HEV (30.38%), while the proportion in rural areas was lower for HAV (3.38%) than for HEV (8.07%), with a statistically significant difference ($\chi^2 = 32.863$, $P < 0.001$). Both diseases were more common in males, but HEV had a higher male predominance (65.70% vs. 51.91% for HAV, $\chi^2 = 67.876$, $P < 0.001$). The mean age of onset for HAV patients (51.0 years) was younger than that for HEV patients (54.9 years), with a statistically significant difference ($t = -7.018$, $P < 0.001$). The top five occupations among HAV cases were homemakers or unemployed (297 cases, 26.45%), retirees (293 cases, 26.09%), office workers (193 cases, 17.19%), commercial service workers (80 cases, 7.12%), and farmers (63 cases, 5.61%). For HEV, the top five were retirees (1,193 cases, 35.92%), homemakers or unemployed (827 cases, 24.90%), office workers (475

E-POSTER ABSTRACTS

cases, 14.30%), farmers (233 cases, 7.02%), and workers (172 cases, 5.18%). The occupational distribution differed significantly between the two diseases ($\chi^2 = 69.730$, $P < 0.001$).

Conclusions: The incidence trends of HAV and HEV in Beijing were generally consistent. Both diseases were predominantly reported in urban areas, but their distributions in suburban and rural areas differed. The main affected populations for both diseases were retirees, homemakers or unemployed, and office workers. HEV cases had a higher proportion of males and an older age of onset.

Keyword(s) : Hepatitis A, Hepatitis E, epidemiological characteristics, Beijing

1040 - Small Intestinal Bacterial Overgrowth A Missing Link in Gut–Liver Axis Dysregulation of MASLD

Ziteng Wang¹, Wentao Tan², Lingling He¹, Hongshan Wei¹, Hong Liu³

Beijing Ditan Hospital, Capital Medical University, Department Of Gastroenterology, Beijing-China¹
Beijing Friendship Hospital, Capital Medical University, Department Of Gastroenterology, Beijing-China²
Beijing Shijitan Hospital, Capital Medical University, Department Of Gastroenterology, Beijing-China³

Background / Hypothesis:

Small intestinal bacterial overgrowth (SIBO) may implicate in the progression of metabolic dysfunction-associated steatotic liver disease (MASLD) by disrupting the gut microbiota, compromising intestinal barrier integrity, and elevating levels of endogenous metabolites. Our study aims to explore the relationship between both, specifically focusing on the role of gut microbiota composition and its metabolic byproducts in the pathogenesis and progression of MASLD.

Materials and Methods:

We included patients who underwent abdominal scans and lactulose hydrogen methane breath tests at our hospital. Independent sample t-tests were conducted for basic statistical analyses of the MASLD population. Stratified analyses of MASLD patients were then performed, and the relationship between MASLD and SIBO was assessed using chi-square tests. To identify factors associated with MASLD, a multivariate logistic regression model was applied. Additionally, stool

samples from MASLD patients were collected for 16S rRNA gene sequencing to assess the impact of SIBO status on the distribution of intestinal microbiota and metabolic characteristics in MASLD patients.

Results:

A total of 350 participants were included (97 MASLD [27.7%], 253 non-MASLD [72.3%]). SIBO was highly prevalent (300/350, 85.7%) and differed significantly between MASLD and non-MASLD groups. Multivariate analysis identified SIBO as an independent risk factor for MASLD, with methane-positive SIBO showing a stronger association. The characteristic flora in the MASLD group was primarily distributed within the phylum Firmicutes, with significant enrichment of genera such as Lactobacillales and Bacilli. The SIBO group was predominantly characterized by Proteobacteria, with a notable increase in the Burkholderiaceae family and related genera, such as Dialister, Limnobacter, and Acidovorax. Differential metabolic pathways between the groups were largely concentrated in metabolic processes.

Conclusions:

SIBO contributes to MASLD development, particularly methane-positive SIBO. Distinct microbial signatures were observed, with Firmicutes enrichment in MASLD and Proteobacteria in SIBO patients. Altered gut metabolites mainly involved metabolic pathways, highlighting the potential role of gut microbiota and its metabolites in MASLD pathogenesis.

Keyword(s) : MASLD; Small intestinal bacterial overgrowth; SIBO; Gut–liver axis; Gut microbiota;

1041 - Controlled Attenuation Parameter Factors and Steatosis Grading in Metabolic Dysfunction associated Steatotic Liver Disease

Ningrui Su¹, Da Zhou²

Shanghai Medical College, Fudan University, Shanghai Medical College, Shanghai-China¹ Zhongshan Hospital, Fudan University, Department Of Gastroenterology And Hepatology, Shanghai-China²

Background / Hypothesis:

To identify factors influencing liver-controlled attenuation parameter (CAP) and establish its optimal diagnostic thresholds for hepatic steatosis grading in metabolic dysfunction-associated steatotic liver disease (MASLD).

E-POSTER ABSTRACTS

Materials and Methods:

758 prospectively enrolled MASLD patients (Zhongshan Hospital, Sep 2022-Jun 2023) were randomized into training (n=619) and validation (n=139) cohorts, stratified by BMI (normal-weight: BMI<25 kg/m²; overweight: BMI≥25 kg/m²). Demographics, laboratory parameters, CAP, and MRI proton density fat fraction (PDFF) were recorded. Using MRI-PDFF as the reference, ROC analysis established CAP thresholds for steatosis grades.

Results:

In the training cohort, multivariate analysis showed CAP correlated with uric acid (b=0.11, P=0.073), glucose (b=13.76, P<0.001), and HDL (b=-45.47, P=0.020) in normal-weight patients, and with ALT (β=0.164, P=0.004), total cholesterol (β=8.41, P=0.006), and BMI (β=2.47, P=0.006) in overweight patients. Overall cohort CAP thresholds were: S1 (≥5%) 283.5 dB/m (AUC=0.880), S2 (≥33%) 311.5 dB/m (AUC=0.712), S3 (≥66%) 328.5 dB/m (AUC=0.799). Normal-weight thresholds: S1 259.5 dB/m (AUC=0.922), S2-3 323.5 dB/m (AUC=0.779). Overweight thresholds: S1 304.0 dB/m (AUC=0.829), S2 311.5 dB/m (AUC=0.677), S3 328.5 dB/m (AUC=0.767). Validation confirmed robust diagnostic performance (Youden index 0.82 overall, 0.83 normal-weight, 0.81 overweight).

Conclusions:

CAP correlates significantly with metabolic factors (uric acid, glucose, HDL) in normal-weight MASLD patients and with liver markers/metabolic factors (BMI, ALT, TC) in overweight patients. CAP demonstrates good diagnostic accuracy for grading hepatic steatosis severity in MASLD, particularly for mild to moderate steatosis.

Keyword(s) : control attenuation index; metabolic dysfunction-associated steatotic liver disease; normal weight; overweight; correlation analysis

1043 - Non invasive detection of occult yet significant liver pathology in ALT normal chronic hepatitis B a multicenter study

Xinjie Li ¹, Meijie Shi ², Xiaozhong Wang ³, Feng Guo ³, Yingjie Qi ⁴, Xihong Wang ⁵, Ming Lin ², Xiaoling Liu ⁶, Pengyuan Kang ¹, Yuqi Zhang ¹, Shanshan Ji ⁵, Yizhong Hu ⁵, Jinbao Huang ⁵, Xiaoling Chi ², Tao Shen ¹
School Of Basic Medical Sciences, Peking University, Department Of Microbiology And Infectious Disease

Center, Beijing-China ¹ Guangdong Provincial Hospital Of Traditional Chinese Medicine, Department Of Hepatology, Guangzhou-China ² Traditional Chinese Medicine Hospital Affiliated To Xinjiang Medical University, Department Of Liver Disease, Urumqi-China ³ Infection Hospital Area Of The First Affiliated Hospital Of University Of Science And Technology Of China (hefei Infectious Disease Hospital), Department Of Laboratory Medicine, Hefei-China ⁴ The People's Hospital Of Chizhou, Department Of Laboratory Medicine, Chizhou-China ⁵ The People's Hospital Of Chizhou, Department Of Infectious Diseases, Chizhou-China ⁶

Background / Hypothesis:

Individuals with chronic hepatitis B (CHB) may harbor occult yet significant liver pathology despite normal alanine aminotransferase (ALT) levels, representing a major diagnostic challenge. We aimed to identify and validate non-invasive biomarkers for detecting significant liver pathology among these population.

Materials and Methods:

This multicenter study screened 3,258 CHB cases from 2013-2023, enrolling 137 treatment-naïve HBeAg+ and 253 HBeAg- infection patients with normal ALT (≤40 U/L). All participants underwent liver biopsy (gold standard), liver function and novel biomarker measurement (including CK18-M30, CK18-M65, GP73, IL-10, and IL-2R). Significant liver pathology was defined as inflammation grade (G) and/or fibrosis stage (S) ≥2. Sixteen CK18-M65-centered biomarker combinations were evaluated using eight machine learning algorithms with multicenter stratified validation.

Results:

Significant liver pathology was observed in 45.2% of HBeAg+ infection cases. CK18-M65, CK18-M30, and GP73 strongly correlated with pathology severity (G stage: 0.757, 0.688, and 0.453, respectively; p<0.0001), independent of ALT levels. CK18-M65 demonstrated optimal diagnostic performance (AUC=0.934, 95% CI: 0.896-0.973) with 85.5% sensitivity and 88% specificity, especially in those with low-normal ALT. High CK18-M65 levels conferred >40-fold increased risk of severe liver injury (adjusted OR=40.64). The optimal biomarker combination (CK18-M65+CK18-M30+GP73) achieved AUROC of 0.942, significantly outperforming LSM (0.824), APRI (0.783), and FIB-4 (0.745; all p<0.01), with enhanced clinical utility. HBeAg- infection cases

E-POSTER ABSTRACTS

showed 46% significant pathology but weaker diagnostic performance.

Conclusions:

CK18-M65-centered biomarker models provide promising non-invasive tools for detecting occult liver pathology and risk stratification of ALT-normal HBeAg+ CHB infection, potentially reducing unnecessary biopsies while identifying candidates for early intervention.

Keyword(s) : chronic hepatitis B (CHB); CK18-M65; non-invasive diagnosis; ALT-normal; liver pathology

1044 - Multifactorial Anemia Unveiling Gastric Antral Vascular Ectasia in a Stage IV Breast Cancer Survivor Endoscopic Resolution with Argon Plasma Coagulation

John Derek Clutario¹, Gerardo Pedregosa¹
Makati Medical Center, Gastroenterology, Pasig-Philippines¹

Background / Hypothesis:

Gastric Antral Vascular Ectasia (GAVE), or "watermelon stomach," is an uncommon cause of upper gastrointestinal bleeding and chronic anemia. While typically linked to cirrhosis or autoimmune disorders, GAVE may occur in non-cirrhotic elderly patients, especially those with prior oncologic treatments that compromise mucosal integrity. We report a unique case of GAVE in a non-cirrhotic, elderly Filipino female with metastatic breast cancer, successfully managed with argon plasma coagulation (APC).

Materials and Methods:

An 85-year-old female with a remote history of bilateral mastectomy and recent diagnosis of Stage IV invasive ductal carcinoma presented with transfusion-dependent anemia. Laboratory and imaging findings revealed no overt gastrointestinal bleeding. Endoscopy uncovered classic GAVE with linear vascular streaks in the antrum and associated Forrest III gastric ulcers. APC was performed in two sessions with excellent endoscopic and hematologic response. Argon plasma coagulation (APC) was applied in two sessions targeting ectatic vessels in the antrum. Narrow-band imaging aided lesion demarcation. Treatment settings were 40W, 1.5 L/min.

Results:

Follow-up endoscopy revealed marked resolution of lesions. Hemoglobin stabilized, transfusions ceased, and the patient remained asymptomatic. This underscores the importance of considering GAVE in multifactorial anemia, even in non-cirrhotic oncology patients.

Conclusions:

This case highlights GAVE as a reversible cause of anemia in elderly cancer survivors, particularly those with prior chemotherapy and radiation. It also reinforces the safety and efficacy of APC in frail patients. Serial endoscopy provides a compelling narrative for diagnosis and therapeutic success.

Keyword(s) :

1047 - Comparative Analysis of Epidemiological Characteristics and Co infection of Hepatitis B and Hepatitis C in Beijing from 2010 to 2024

Chao Wang¹, Yunping Shi², Ying Zhou², Gang Li²
Peking University, School Of Public Health, Beijing-China¹ Beijing Center For Disease Prevention And Control, Institute Of Information And Statistics Center, Beijing-China²

Background:

Through continuous prevention and control effect, the incidence rate of viral hepatitis has been significantly reduced in Beijing. There are similarities in transmission routes between hepatitis B and hepatitis C, the difference in epidemic characteristics between them and the status of coinfection remain to be determined.

Materials and Methods:

Descriptive epidemiological methods were used to analyze the characteristics of HBV and HCV cases in Beijing from 2010 to 2024. The prevalence of co-infection in different populations was calculated. Chi-square tests or rank-sum tests were employed to compare case distributions or differences in age of onset between groups.

Results:

From 2010 to 2024, a total of 45,728 HBV cases and 15,769 HCV cases were reported in Beijing. The annual number of cases decreased from 4,724 (HBV) and 1,671 (HCV) in 2010 to 2,556 (HBV) and 945 (HCV) in 2016, rebounded slightly in 2017–2018, and then increased significantly to 2024(3,546 HBVs and 1,137 HCVs). Both HBV and HCV cases were concentrated in urban areas. The proportion of male patients was higher in HBV (64.14%) than in HCV (56.24%, $P < 0.001$). Retirees accounted for a higher proportion of HCV cases

E-POSTER ABSTRACTS

(26.54%) than HBV cases (14.88%). The median age of onset for HBV (47 years) was younger than for HCV (53 years). Among HBV patients, 76.04% were aged 20–59 and 22.81% were ≥60 years old, compared to 64.16% and 34.68% for HCV, respectively ($P < 0.001$). 201 cases of HBV/HCV co-infection were reported. 143 (71.14%) were diagnosed with both infections within one month, 34 (16.92%) were first diagnosed with HBV, and 24 (11.94%) were first diagnosed with HCV. The co-infection rate among HBV cases was 0.44% (201/45,728), with no significant difference between genders. The rate was higher in urban areas (0.58%) than in suburban (0.41%) and rural areas (0.21%) ($P < 0.001$). The median age of co-infected patients (52 years) was higher than that of HBV-only patients. The co-infection rate among HCV cases was 1.27% (201/15,769), with a higher rate in males (1.58%) than females (0.88%) ($P < 0.001$). No significant differences were observed among regions. The median age of co-infected patients (52 years) did not differ significantly from that of HCV-only patients (53 years) ($P = 0.112$). Conclusion: The reported cases of HBV and HCV in Beijing exhibited similar temporal trends, with both diseases showing a higher proportion of male cases and urban clustering. The proportion of co-infection was low, and differences in co-infection rates were observed across genders and regions.

1048 - Analysis of the Epidemiological Characteristics of Hepatitis B in Beijing from 2008 to 2024

Quanyi Wang¹, Yanlin Gao², Yang Liu², Jiaze Li²
Beijing Center For Disease Prevention And Control, Institute For Infectious Diseases, Beijing-China¹ Beijing Center For Disease Prevention And Control, Institute Of Information And Statistics Center, Beijing-China²

Background:

Beijing has made significant achievements in controlling hepatitis B through vaccination programs, but there may be differences in the epidemiological patterns of hepatitis B in specific regions and populations in recent years.

Materials and Methods:

Descriptive epidemiological methods were used to analyze the temporal, spatial, and population distribution characteristics of hepatitis B cases in Beijing from 2008 to 2024.

Results:

A total of 56,694 hepatitis B cases were reported in Beijing from 2008 to 2024, including 4,736 acute cases (8.36%), 48,841 chronic cases (86.22%), and 3,072 unclassified cases (5.42%). The annual number of hepatitis B cases showed a declining trend from 2008 to 2016 and from 2018 to 2022, with minor increases in 2017–2018 and 2023–2024 (primarily chronic cases). In 2024, 3,546 cases were reported (including 66 acute cases), representing a 40.70% decrease compared to 2008 (5,980 cases, including 824 acute cases), with a 91.99% decline in acute cases. No obvious seasonal trend was observed in monthly case reports.

Geographically, urban areas reported more cases (24,743 cases, 43.68%) than suburban (21,190 cases, 34.71%) and rural areas (9,181 cases, 16.21%), with 1,535 cases from unspecified regions (all reported before 2015). Acute cases declined significantly across all regions (all decreased by 90%), while chronic cases decreased markedly in urban and suburban areas (decreased by 44.75% and 33.44% in 2024 compared to 2008, respectively) but only slightly in rural areas (7.05%). Males accounted for 63.85% of all cases.

Among acute cases, males accounted for 69.17%, with the proportion gradually decreasing from 72.33% in 2008 to 59.09% in 2024. The mean age of acute and chronic cases increased from 37.4 and 44.0 years in 2008 to 51.0 and 51.3 years in 2024, respectively (median ages increased from 36 and 43 to 50 and 51 years, respectively). The top five occupations among reported cases were household workers/unemployed (29.40%), farmers (16.09%), retirees (14.31%), office workers (10.93%), and laborers (8.25%). Students and healthcare workers accounted for 1.71% and 0.42% of cases, respectively. Compared to 2008, the number of new cases in 2024 decreased significantly across all occupational groups except household workers/unemployed and retirees.

Conclusions:

The overall number of hepatitis B cases in Beijing has shown a declining trend, with a more pronounced decrease in acute cases. However, the decline in new chronic cases has been slower in rural areas, and the age of new cases has gradually increased. Cases among homemakers/unemployed and retirees have decreased more slowly.

1049 - Rifaximin to reduce the risk of overt hepatic encephalopathy in patients undergoing TIPS real

E-POSTER ABSTRACTS

world experience in a diverse population

Charles Gallaher¹, Emma Cook¹, Mzamo Mbelle¹, Ashley Barnabas¹

King's College Hospital Nhs Foundation Trust,
Hepatology, London-United Kingdom¹

Background / Hypothesis:

Bureau et al. (Ann Intern Med, 2021) demonstrated that rifaximin reduces the risk of overt hepatic encephalopathy (HE) in patients with cirrhosis undergoing TIPS when started prior to and continued after TIPS. Eighty-six per cent of the study population had ALD.

This practice has been incorporated into EASL CPG. We reviewed current practices and real world outcomes of TIPS in our institution, in a more diverse population.

Materials and Methods:

A retrospective analysis of all adults undergoing TIPS at our hospital between 2/2/21 and 7/5/24 was performed. Primary outcome was rifaximin prescription.

Seventy-six patients were identified, of whom three were excluded due to being on broad-spectrum antibiotics at repatriation and six patients were excluded due to incomplete records. Sixty-seven patients were included.

Results:

Fifty-four patients (80.6%) were cirrhotic. Median UKELD score was 50 (IQR = 47-53) and median MELD-Na was 12 (IQR = 9-17).

Primary indication for TIPS was to treat variceal bleeding in 38.8%, diuretic-intractable ascites in 23.9%, hydrothorax +/- ascites in 3%, and for non-cirrhotic indications (e.g., Budd-Chiari syndrome) in 14.9%. 53.7% had alcohol-related cirrhosis.

Fourteen patients (20.9%) had documented HE prior to TIPS (excluding those patients whose HE had occurred historically, prior to liver transplantation), of whom eight (57.1%) were on rifaximin prior to TIPS. All eight patients continued on rifaximin post-TIPS, of whom four (50%) developed HE; two patients (25%) did not develop HE, and data was unavailable for two patients. Of the remaining six patients, three (50%) were commenced on rifaximin prior to hospital discharge, of whom one (33.3%) developed HE. Of the three patients not prescribed rifaximin prior to hospital discharge, two (66.7%) developed HE; the one patient who did

not was not cirrhotic.

Overall, 47 patients (70.1%) were prescribed rifaximin prior to hospital discharge. Of these, 22 (46.8%) are known to have developed HE, 18 (38.3%) did not develop HE, and data is unavailable for seven patients (14.9%).

Overall, 20 patients (29.9%) were not prescribed rifaximin prior to hospital discharge. Of these, eight (40%) are known to have developed HE, 10 (50%) did not develop HE, and data is unavailable for two patients (10%).

Conclusions:

Rifaximin prescription is usual post-TIPS.

Despite rifaximin being commonly used, HE incidence remains high.

Excluding unknowns, HE incidence post-TIPS was unrelated to UKELD ($p = 0.9937$), however, it approached significance for MELD-Na ($p = 0.0605$), and the small sample sizes (22 HE post-TIPS, 18 no HE post-TIPS) may explain the lack of statistical significance.

Keyword(s) : hepatic encephalopathy, rifaximin, TIPS

1052 - Pan cancer analysis identifies hemopexin as a tumor suppressor in HCC via TNF alpha mediated mitochondrial apoptosis

Liyang Ren¹, Dongbo Chen¹, Hongsong Chen¹

Peking University People's Hospital, Peking University Hepatology Institute, Beijing-China¹

Background / Hypothesis: Fibrinolysis, a crucial physiological and pathological process responsible for fibrin degradation in the vascular system, serves as a pivotal regulatory mechanism in coagulation homeostasis. Despite its significance, the pan-cancer biological role of fibrinolysis remains largely unexplored. This study investigates the functional characteristics of fibrinolysis across cancers, with particular focus on its pivotal role in hepatocellular carcinoma (HCC). We aimed to establish a novel molecular classification and risk signature for HCC and identify a key gene influencing its occurrence and progression.

Materials and Methods: Firstly, the differential expression of fibrinolysis-related genes was analyzed in pan-cancer. Subsequently, the non-negative matrix factorization method was employed to identify the fibrinolysis-related molecular subtypes in HCC, and a risk signature was developed. The key gene was

E-POSTER ABSTRACTS

determined by this risk signature. Further in vivo and in vitro experiments were performed to elucidate the role and underlying mechanism of this gene in the occurrence and progression of HCC.

Results: Fibrinolysis is highly expressed in liver tissues and serves as a protective factor for HCC across pancreatic cancers. Three different molecular subtypes of HCC were successfully distinguished based on the characteristics of fibrinolysis, which were correlated to the prognosis, ImmuneScore, StromaScore, and ESTIMATEScore of HCC patients. A prognostic signature including ACAT1, GRHPR, HPX, PCK2, IYD, and PON1 was developed based on the weighted gene co-expression network analysis (WGCNA) and least absolute shrinkage and selection operator (LASSO) analysis. With the largest absolute value of log2foldchange, hemopexin (HPX) was determined as key gene and for further in vivo and in vitro validation. HPX showed an anti-tumor phenotype via clone formation, EdU assay, wound healing, transwell and xenograft tumor model. Furthermore, RNA-seq results suggest that HPX is associated with apoptosis and TNF- α signaling pathways, flow cytometry apoptosis assay, mitochondrial membrane potential assay and TUNEL staining and were performed to validate these findings above. Western blot and immunohistochemistry showed HPX could upregulate Bax/Bcl-2 expression by activating of TNF- α signaling pathway.

Conclusions: This study identified novel molecular subtypes of HCC. A risk signature with clinical application value was constructed, and the key gene HPX in HCC was further identified. It provides a new direction for the precise treatment of HCC patients.

1053 - Development and validation of the FAAP model for prognostic stratification in HCC patients treated with TACE sintilimab plus bevacizumab a multicenter study

Liying Ren¹, Dongbo Chen², Hongsong Chen²
Peking University People's Hospital, Peking University Hepatology Institute, Beijing-China¹ Peking University Hepatology Institute, Peking University Hepatology Institute, Beijing-China²

Background / Hypothesis: Although the transcatheter arterial chemoembolization (TACE) combined with sintilimab and bevacizumab improves outcomes in

unresectable HCC (uHCC), predictive tools are lacking. This study developed and validated a prognostic model for triple therapy efficacy.

Materials and Methods: A multicenter study enrolled uHCC patients receiving TACE-sintilimab-bevacizumab. Overall survival (OS) was the primary endpoint; a Cox model was developed and validated.

Results: This study enrolled 147 patients (training cohort: n = 92; validation cohort: n = 55). The optimal cutoff value for the fibrin degradation product-to-cholinesterase ratio*1000 (FCR) was determined as 0.8. Univariate and multivariate Cox regression analyses identified FCR, AST, AFP, and PVTT as independent OS predictors. These variables were integrated to establish the FAAP scoring system, which demonstrated robust discriminative performance with AUC of 0.804 (95% CI: 0.703-0.893) and 0.799 (95% CI: 0.67-0.911) in the training and validation cohorts, respectively. Patients were stratified into three risk groups based on FAAP scores: low (FAAP < 0.7), intermediate (0.7 $\leq$ FAAP < 2.2), and high (FAAP $\geq$ 2.2). Kaplan-Meier analyses revealed significant prognostic stratification for both OS and progression-free survival (PFS) across groups. Subgroup analyses confirmed the prognostic relevance of FAAP scores in key clinical subsets, including age, gender, extrahepatic metastasis status, viral hepatitis etiology, PVTT presence, and Child-Pugh stage.

Conclusions: The FAAP scoring system effectively predicted survival outcomes in HCC patients receiving TACE-sintilimab-bevacizumab therapy, which suggests its clinical utility for treatment benefit evaluation. Further large prospective studies are required for external validation.

1057 - Serum N glycomics for non invasive detection of significant liver pathology across clinical phases of treatment naïve chronic hepatitis B

Xinjie Li¹, Meijie Shi², Hao Yu³, Jinbao Huang⁴, Shanshan Ji⁴, Bo Han⁴, Yan Zhong⁵, Pengyuan Kang¹, Yuqi Zhang¹, Cuiying Chen⁶, Chao Zhang⁶, Lei Xu⁶, Xiaoling Chi², Tao Shen¹
School Of Basic Medical Sciences, Peking University, Department Of Microbiology And Infectious Disease Center, Beijing-China¹ Guangdong Provincial Hospital Of Traditional Chinese Medicine, Department Of

E-POSTER ABSTRACTS

Hepatology, Guangzhou-China ² The First People's Hospital Of Shuangliu District (west China Airport Hospital Of Sichuan University), Department Of Clinical Laboratory, Chengdu-China ³ The People's Hospital Of Chizhou, Department Of Laboratory Medicine, Chizhou-China ⁴ National Center For Aids/std Control And Prevention, State Key Laboratory Of Infectious Disease Prevention And Control (sklid), Beijing-China ⁵ Sysdiagno (nanjing) Biotech Co. Ltd, Department Of Research And Development, Nanjing-China ⁶

Background / Hypothesis:

Early identification of significant liver pathology is crucial for timely antiviral intervention in individuals with chronic hepatitis B (CHB) infection. Current non-invasive methods show limited accuracy in detecting occult liver damage, particularly in those with normal ALT. This study evaluated serum N-glycan profiles for diagnosing significant liver pathology in treatment-naïve CHB patients across clinical phases.

Materials and Methods:

This cross-sectional study analyzed 626 treatment-naïve CHB patients confirmed by liver biopsy, classified according to 2025 EASL guidelines. Serum N-glycan profiles were determined using DNA sequencer-assisted fluorophore-assisted carbohydrate electrophoresis. Significant liver pathology was defined as inflammation grade $\geq$ G2 and/or fibrosis stage $\geq$ S2. Multivariate logistic regression models were developed and compared with traditional non-invasive markers.

Results:

Among 626 CHB patients, 66.0% had significant inflammation and 58.9% had significant fibrosis. Patients with significant pathology showed characteristic alterations, with elevated P1, P3, P6, P7, P11 peaks and decreased P0, P5, P8, P10 peaks (all $p < 0.0001$). Compared to infection phases, hepatitis phases showed P1 increases of 19.6%/36% and P11 increases of 82.4%/73.4% in HBeAg(+)/HBeAg(-) patients, while P0 decreased by 20.3%/27.6% and P10 decreased by 21.6%/20.3%. In patients with significant pathology (G and/or S $\geq$ 2), P1 increased by 27% on average, reaching 58.7%/48.7% in G4/S4 stages. In ALT-normal patients, particularly HBeAg(+) infection phase, P1 increased by 80.2%/65.8% in G4/S4 stages, with P2 also increasing by 54.1%/45.2%. Multivariate analysis identified P11 as strongest risk factor (OR=3.84, 95%CI: 1.74-8.45, $p=0.0008$), followed by P1 (OR=2.04, 95%CI: 1.57-2.64, $p < 0.0001$) and P7

(OR=1.75, 95%CI: 1.31-2.34, $p=0.0002$), while P2 (OR=0.07, 95%CI: 0.02-0.26, $p < 0.0001$) and P0 (OR=0.30, 95%CI: 0.12-0.79, $p=0.0140$) served as protective factors. The glycomics combined model (AUC=0.876) achieved superior performance outperformed the clinical model (0.818), LSM (0.817), APRI (0.830), and FIB-4 (0.672), with 78.7% sensitivity and 83.2% specificity. The optimized model reached AUC=0.917 with accuracy 84.2%, with 78.7% sensitivity and 94.6% specificity. Both glycol-based models maintained diagnostic capability in ALT-normal patients particularly in HBeAg(+) infection.

Conclusions:

Serum N-glycomics demonstrates promising potential for non-invasive identification of significant liver pathology in treatment-naïve CHB patients, providing an alternative approach for early treatment decisions, especially in ALT-normal patients with occult liver damage.

1059 - The predictive value of different frailty assessment tools for the prognosis of hospitalized patients with liver cirrhosis

Huiling Zhu ¹

The Second Affiliated Hospital, Kunming Medical University, Kunming-China ¹

Background / Hypothesis:

Patients with cirrhosis are often accompanied by frailty. The lack of consensus on the clear definition and assessment tool limits the clinical practice of frailty. This study attempts to analyze the predictive value of six frailty tools for mortality in patients with cirrhosis.

Materials and Methods:

200 patients with cirrhosis were enrolled in this prospective cohort study, which the median age was 55 years (IQR 49-64), and the prevalence of frailty ranged from 16.0% to 52.0%. The ROC curve was used to compare the predictive value of six frailty tools. All six frailty tools could predict the mortality of patients with cirrhosis at 1, 3, 6, and 12 months. The predictive efficacy of LFI, FFP, SPPB, and FRAIL was similar, while CFS and EFS was slightly worse in predicting 1- and 3-month mortality. The predictive efficacy of LFI, FFP, and SPPB was similar, followed by FRAIL, while CFS and EFS were poor in predicting 6-month mortality. LFI and FFP had the best predictive efficacy, followed by FRAIL and SPPB, which CFS and EFS were poor in predicting 12-month mortality. The survival analysis revealed that the 12-month survival rate of the frailty group was significantly lower ($P < 0.05$).

Results:

The predictive efficacy of LFI, FFP, and SPPB was similar, followed by FRAIL, while CFS and EFS were poor in predicting 6-month mortality. LFI and FFP had the best predictive efficacy, followed by FRAIL and SPPB, which CFS and EFS were poor in predicting 12-month mortality. The survival analysis revealed that the 12-month survival rate of the frailty group was significantly lower ($P < 0.05$).

Conclusions: LFI and FFP are superior to other frailty assessment tools in identifying the risk of poor prognosis. The applicability of FRAIL and EFS to mortality prediction was first demonstrated in cirrhosis. All six frailty assessment tools can effectively stratify

E-POSTER ABSTRACTS

the death risk of liver cirrhosis.

1060 - Transitional Hepatocytes and Mortality Associated Gene Programs Drive NASH Associated Liver Cancer Revealed by Single Cell Transcriptomics

Firdian Makrufardi¹

Universitas Negeri Yogyakarta, Faculty Of Medicine, Yogyakarta-Indonesia¹

Background / Hypothesis: Non-alcoholic fatty liver disease (NAFLD), particularly its progressive form non-alcoholic steatohepatitis (NASH), has become a leading cause of hepatocellular carcinoma (HCC). Mortality from NASH-associated liver cancer (NALC) is disproportionately higher in older adults and in populations from low- and middle-income countries (LMICs), but the molecular basis of this poor prognosis remains unclear. This study aimed to identify transitional hepatocyte states and mortality-associated gene programs that underpin progression from NASH to HCC.

Materials and Methods: Publicly available single-cell RNA sequencing datasets of liver tissue from healthy, NASH, and HCC samples were integrated using the Harmony algorithm to correct for batch effects and preserve rare cell populations. Dimensionality reduction, clustering, and marker-based cell annotation were conducted with Seurat, supported by classical markers and differential expression profiles. Pathway activation was quantified with Vision using curated MSigDB gene sets. CopyKAT was employed to distinguish malignant from non-malignant hepatocytes via inferred copy number variation. Cell-cell communication networks were reconstructed with NicheNet to identify ligand-receptor interactions between hepatocytes, macrophages, and stromal cells.

Results: We identified a population of transitional hepatocytes bridging normal and malignant states. These cells expressed mortality-associated genes including MKI67, PCNA, STMN1, TOP2A, MALAT1, FABP5, CDK1, and HSP90AA1, which have been linked to poor survival and aggressive HCC phenotypes. Metabolic variants such as PNPLA3 and TM6SF2, as well as immune regulators like TREM2 and GDF15,

were also enriched, providing a mechanistic link between metabolic injury, immune suppression, and high mortality risk. Progressive activation of HIF1A signaling suggested hypoxia as a key driver of malignant transformation. Concurrently, macrophages polarized into immunosuppressive TREM2⁺ states, recruited by hepatocyte-derived signals via the CCL15-CCR1 axis, reinforcing a suppressive microenvironment.

Conclusions: Transitional hepatocytes and their mortality-associated gene programs, together with immunosuppressive macrophages, drive the progression of NASH to liver cancer. These findings highlight high-risk molecular targets (MALAT1, TOP2A, PNPLA3, TREM2, GDF15) that may explain the elevated mortality observed in older adults and LMIC populations, and provide potential avenues for early intervention in NASH-associated liver cancer.

1061 - Integrative AI Based Multi Omics Approach to Uncover Endothelial Diversity and Predict Cholestatic Liver Disease Across Vulnerable Populations

Firdian Makrufardi¹

Universitas Negeri Yogyakarta, Faculty Of Medicine, Yogyakarta-Indonesia¹

Background / Hypothesis: Cholestatic liver diseases disproportionately affect vulnerable populations, including neonates with congenital disorders, women with primary biliary cholangitis or intrahepatic cholestasis of pregnancy, men with primary sclerosing cholangitis, and critically ill patients with sepsis- or drug-induced cholestasis. Despite its clinical importance, the molecular mechanisms underlying cholesterol accumulation and its predictive potential in these populations remain poorly characterized. This study aimed to leverage multi-omics data and AI-driven analytics to uncover key regulators of cholesterol saturation and develop predictive models of cholestatic liver disease, with an emphasis on vulnerable patient groups.

Materials and Methods: We integrated transcriptomic, epigenomic, and proteomic data from human liver tissues and in vitro hepatic models. Unsupervised deep

E-POSTER ABSTRACTS

learning algorithms were applied to identify molecular profiles associated with cholesterol homeostasis. SHAP and LASSO regression were used for feature selection. A machine learning classifier was trained and validated using clinical datasets stratified by age, sex, and disease subtype, incorporating serum cholesterol, bile acid profiles, and histology.

Results: Distinct molecular signatures were identified across vulnerable groups. Elevated hepatic cholesterol saturation correlated with upregulation of SREBF2 and HMGCR, and downregulation of ABCG5/8. Epigenetic modifications near NR1H3 and CYP7A1 were linked to disrupted bile acid synthesis and cholesterol export. The predictive model demonstrated high diagnostic performance (AUC = 0.93; 95% CI: 0.89–0.96). Stratified analyses highlighted differential molecular signatures in neonates, women with autoimmune or pregnancy-related cholestasis, and men with IBD-associated PSC. Pathway analysis revealed dysregulation of cholesterol biosynthesis, FXR/RXR signaling, and ER stress responses.

Conclusions: Our integrative AI-based multi-omics approach reveals key molecular drivers of hepatic cholesterol saturation and provides a robust predictive tool for cholestatic liver disease. By highlighting mechanisms across vulnerable populations, this study offers novel opportunities for early diagnosis, risk stratification, and targeted therapeutic strategies.

Keyword(s) : artificial intelligence, multi-omics, endothelial heterogeneity, cholestasis, vulnerable populations

1062 - GALNT7 Mediated Glycosylation of TAZ at Serine 307 Promotes Gallbladder Cancer Progression via Stabilization and Feed Forward Activation

Peng Qiu¹, Ming Zhang¹, Yunxiang Feng¹
Division Of Hepato-pancreato-biliary Surgery, tongji Hospital, Tongji Medical College, Huazhong University Of Science & Technology, Tongji Hospital, Tongji Medical College, Huazhong University Of Science & Technology, Wuhan-China¹

Background / Hypothesis: Gallbladder cancer is a highly aggressive malignancy with limited therapeutic options and poor prognosis. Post-translational modifications,

particularly glycosylation, have emerged as key regulators of tumor progression. We hypothesized that the glycosyltransferase GALNT7 may drive gallbladder cancer progression through modulation of the Hippo pathway effector TAZ.

Materials and Methods: Clinical tissue samples, including gallbladder cancer and adjacent non-tumor tissues, were analyzed using proteomics, immunohistochemistry, and quantitative polymerase chain reaction (qPCR). Functional assays including cell proliferation, migration, and invasion were performed using gallbladder cancer cell lines with genetically modified GALNT7 and TAZ expression. Protein interactions were assessed by co-immunoprecipitation and mass spectrometry. To investigate transcriptional regulation, luciferase reporter assays and chromatin immunoprecipitation followed by qPCR were employed to assess TAZ and TEAD1 binding to the GALNT7 promoter. In vivo tumor growth and metastasis were evaluated using mouse xenograft and lung metastasis models. Peptides targeting glycosylation were synthesized and tested for therapeutic efficacy.

Results: GALNT7 was significantly overexpressed in gallbladder cancer tissues and correlated with advanced tumor stage and poor survival. Silencing GALNT7 reduced cell proliferation, migration, and invasion, while overexpression enhanced these malignant behaviors. Mechanistically, GALNT7 interacted with TAZ and induced its glycosylation at serine 307, which inhibited ubiquitination and prolonged protein stability. This modification facilitated the recruitment of the deubiquitinase USP7, further stabilizing TAZ. Glycosylation-defective TAZ (serine 307 to alanine) failed to restore oncogenic properties even in the presence of GALNT7. Additionally, TAZ and its partner transcription factor TEAD1 transcriptionally upregulated GALNT7, forming a self-amplifying loop. Targeting this glycosylation site with a cell-penetrating peptide effectively suppressed tumor growth and metastasis in preclinical models.

Conclusions: Our findings reveal a novel glycosylation-dependent mechanism that stabilizes TAZ and drives gallbladder cancer progression. The GALNT7-TAZ feed-forward loop represents a promising therapeutic target, and inhibition of TAZ glycosylation may offer a new strategy for treating this aggressive cancer.

Keyword(s) : Gallbladder cancer, GALNT7, TAZ, glycosylation, USP7, therapeutic peptide

1063 - Paraspinal Vein Shunt A Potential Key Factor Leading to Hepatic Myelopathy

Yuhong Suo¹, Fuliang He¹, Yu Wang¹, Jidong Jia¹

E-POSTER ABSTRACTS

Beijing Friendship Hospital, Capital Medical University,
Liver Research Center, Beijing-China ¹

Background / Hypothesis:

Hepatic myelopathy (HM) is a rare neurological manifestation in patients with chronic liver diseases. It has been previously reported to be associated with a surgical or spontaneous portosystemic shunt. However, the specific shunt leading to HM occurrence remains unclear. This study tried to identify a key shunt to explore therapeutic approach for HM.

Materials and Methods:

In this retrospective study, 54 patients with portal hypertension (including 19 patients with HM) were enrolled into the analysis of independent risk factors for HM, who had undergone biochemical testing and abdominal enhanced computed tomography (CT) examinations. Three kinds of venous shunt including the splenorenal shunt (SRS), the gastro-renal shunt (GRS), and the paraspinal vein shunt (PVS) were evaluated using CT examinations.

Results:

The PVS, ascites and hepatic encephalopathy were identified as independent risk factors for patients with HM. PVS exists in wide range of patients with HM, which is not an isolated case. The symptoms in patient with HM were substantially reversed by further embolization of the PVS, while only embolizing the GRS or SRS did not improve the symptoms in patients with HM.

Conclusions:

PVS, as one of independent risk factors of HM, is a key shunt among the extensive collateral circulation for HM occurrence. The embolization of PVS is a potentially treatment strategy for HM.

1064 - Analysis of clinical characteristics and risk factors of liver injury in treatment naïve patients with lung cancer

Yaqian Mao ¹, Ziwei Yuan ¹, Yuanbin Zhong ¹

The First Affiliated Hospital Of Nanchang University,
Infectious Diseases Department, Nanchang-China ¹

Background / Hypothesis:

Anti-cancer drug-induced liver injury (DILI) is a

common adverse event in anti-cancer therapy, with rising incidence amid widespread use of novel antineoplastic agents and combination regimens.

Materials and Methods:

A retrospective analysis was conducted on the clinical data of patients diagnosed with primary lung cancer at The First Affiliated Hospital of Nanchang University between January 1, 2023, and December 31, 2023. A total of 709 patients who met the study's inclusion criteria and received standardized anti-cancer therapy were enrolled, and 243 developed anti-cancer DILI. Relevant clinical data was collected, including age, gender, smoking/alcohol consumption history, comorbidities, and a history of pre-existing liver diseases. Statistical analyses were then performed.

Results:

Among the 243 patients with liver injury, the majority (65.02%, 158/243) were elderly (aged ≥ 60 years), with a male predominance (male-to-female ratio: 2.92:1). Liver injury occurred within 8 weeks of initial treatment (71.19%, 173/243). A total of 42 patients met the diagnostic criteria for acute DILI, predominantly presenting with hepatocellular injury (45.24%, 19/42). The remaining 201 cases who did not meet the criteria for acute DILI presented with drug-induced liver biochemical abnormalities, mainly of cholestatic injury (46.77%, 94/201) and mixed injury (46.27%, 93/201), with most showing only mild elevations in liver enzymes. The cure rate of acute DILI was significantly lower than that of drug-induced liver biochemical abnormalities (33.33% vs. 46.77%, $P = 0.036$). 28 patients developed chronic DILI, with cholestatic injury as the main clinical phenotype. Multivariable logistic regression analysis identified pre-existing liver disease as an independent risk factor for anti-cancer DILI (odds ratio [OR] = 1.51, 95% confidence interval [CI]: 1.01-2.26, $P = 0.043$). Compared with immunotherapy alone, chemotherapy combined with immunotherapy (OR = 4.38, 95% CI: 1.28-14.95, $P = 0.018$), chemotherapy combined with targeted therapy (OR = 4.93, 95% CI: 1.40-17.42, $P = 0.013$), and chemotherapy alone (OR = 5.56, 95% CI: 1.53-20.16, $P = 0.009$) were all significantly associated with an increased risk of liver injury.

Conclusions:

A history of pre-existing liver diseases and antineoplastic treatment regimens are independent

E-POSTER ABSTRACTS

risk factors for DILI in treatment-naïve patients with lung cancer. Acute DILI (especially hepatocellular type) carries higher fatal risk, while cholestatic injury tends to chronize. Close monitoring of liver function (within 8 weeks of initial treatment) and early intervention are essential in clinical practice to mitigate adverse outcomes.

Keyword(s) : Drug-induced liver injury, lung cancer, risk factors, anti-cancer therapy, hepatotoxicity.

1066 - Efficacy of laparoscopic assisted Microwave Ablation for treating giant hepatic hemangioma a retrospective controlled study

Changle Wu¹, Haoyu Wu¹, Kai Jiang¹

Senior Department Of Hepato-pancreato-biliary Surgery, The First Medical Center Of PLA General Hospital, Beijing 100853, China, Beijing-China¹

Background / Hypothesis:

Hepatic hemangioma (HH) are usually benign, but surgery is recommended for symptomatic cases or when the tumor diameter is ≥ 10 cm, defined as giant hepatic hemangioma (GHH). Although laparoscopic hepatectomy (LH) is effective, it often involves considerable surgical trauma and high costs. The role of transarterial embolization (TAE) combined with laparoscopic microwave ablation (LMWA) as a minimally invasive alternative has not been well established, and little is known about how tumor location might influence recovery. This study evaluated the safety and effectiveness of TAE+LMWA for GHH, compared its perioperative outcomes with LH, and explored, in patients treated with TAE+LMWA alone, whether tumor location (parenchymal vs. capsular) affects postoperative liver and kidney function.

Materials and Methods:

We retrospectively reviewed 118 patients with GHH treated between November 2014 and October 2024: 60 underwent TAE+LMWA and 58 underwent LH. Perioperative outcomes were compared between the two groups. We also analyzed 42 additional patients with HH who underwent TAE+LMWA alone and were discharged in September 2025, dividing them into parenchymal (n=19) and capsular (n=23) groups to assess postoperative hepatic and renal function.

Results:

Compared with the LH group, patients in the TAE+LMWA group had shorter operative times, less blood loss, lower hospitalization costs, and faster recovery ($p < 0.05$). Cure rates were similar between groups ($p > 0.05$). During follow-up, the ablation zone shrank significantly in the TAE+LMWA group. Among

the 42 patients treated with TAE+LMWA alone, liver and kidney function markers (ALT, AST, Cr) did not differ significantly between the parenchymal and capsular groups ($p > 0.05$). However, in subgroup analysis by tumor size, patients with GHH (n=21) had significantly higher TB and DB levels compared with those with large hepatic hemangioma (LHH, n=21; $p < 0.05$).

Conclusions:

TAE combined with LMWA appears to be a safe, cost-effective, and minimally invasive option for managing GHH. Postoperative recovery is influenced mainly by tumor size rather than tumor location.

Keyword(s) : Hepatic hemangioma, Microwave ablation, Laparoscopy, Transarterial embolization, Outcome comparison, Safety and effectiveness

1068 - Gut Microbiota Derived 3 Methylxanthine Regulating T Cell Immune Response to Inhibit Viral Replication and Liver Injury in Chronic Hepatitis B comorbid with Metabolic Dysfunction associated Fatty Liver Disease

Xin Zhou¹, Shiyu Zhang², Ruihan Gao², Shuting Liu², Jing Zhang², Bin Zhu², Dongliang Yang², Tianshu Zeng¹, Baoju Wang²

Union Hospital, Tongji Medical College, Huazhong University Of Science And Technology, Endocrinology, Wuhan-China¹ Union Hospital, Tongji Medical College, Huazhong University Of Science And Technology, Infection, Wuhan-China²

Objective:

The incidence of chronic hepatitis B (CHB) complicated by metabolic dysfunction-associated steatosis liver disease (MASLD) is increasing, posing a significant threat of progressive liver injury/fibrosis, yet underlying mechanisms remain unclear. Gut microbiota (GM) and metabolites are linked to CHB/MASLD progression, but their role in CHB-MASLD is undefined. This study explored GM's role and mechanisms in CHB-MASLD.

Methods:

CHB-MASLD models were established by hydrodynamic injection of pAAV/HBV1.2 into mice fed a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD). GM and metabolites were analyzed via 16S rRNA sequencing and untargeted metabolomics; intrahepatic T cell responses by flow cytometry.

Results:

Compared with single CHB or MASLD models, CHB-MASLD mice exhibited significantly exacerbated liver

E-POSTER ABSTRACTS

inflammation and fibrosis, evidenced by marked elevations in hepatic enzymes (ALT, AST), proinflammatory cytokines (TNF α , IL-1 β , IL-6), and fibrosis markers (α -SMA, Collagen I). Paradoxically, serum HBsAg, HBeAg, and HBV DNA levels were substantially reduced in CHB-MASLD mice, suggesting suppressed viral replication despite severe liver injury. Further analyses revealed reduced gut microbial α -diversity and altered community structure in CHB-MASLD mice. Notably, the abundance of the opportunistic pathogen Parabacteroides was significantly increased, accompanied by a marked decrease in the microbial metabolite 3-methylxanthine (3-Mx). 3-Mx levels were negatively correlated with both Parabacteroides abundance and ALT/AST elevations. Concomitantly, CHB-MASLD mice showed enhanced intrahepatic CD4⁺ Granzyme B⁺ T cell responses, reflecting heightened cytotoxic activity. Supplementation with 3-Mx in CHB-MASLD mice delayed HBsAg/HBeAg clearance, reduced ALT/AST levels, and promoted intrahepatic CD4⁺ T cell exhaustion (upregulation of CTLA4 and PD1) while suppressing effector phenotypes (Granzyme B). These findings highlight 3-Mx as a key modulator of viral control and liver inflammation in CHB-MASLD.

Conclusion:

Increased Parabacteroides in CHB-MASLD depletes 3-Mx, thereby promoting intrahepatic CD4⁺ Granzyme B⁺ T-cell-mediated viral clearance but exacerbating liver injury. This study provides new insights into the GM-driven pathogenesis of CHB-MASLD and identifies potential therapeutic targets for this emerging comorbidity.

Keyword(s) : Gut Microbiota, 3-Methylxanthine, Chronic Hepatitis B, Metabolic Dysfunction-associated Fatty Liver Disease, T-Cell Immune Response

1070 - Analysis of Epidemiological Characteristics and Risk Factors of Liver Function Impairment Among Middle Aged and Older Community Residents in Beijing

Quanyi Wang¹, Gang Li², Jing Du², Yanlin Gao², Chao Wang²

Beijing Center For Disease Prevention And Control, Beijing Research Center For Respiratory Infectious Diseases, Beijing-China¹ Beijing Center For Disease Prevention And Control, Institute Of Information And Statistics Center, Beijing-China²

Background / Hypothesis:

With socioeconomic development and changes in

lifestyle, non-viral liver diseases have become increasingly prominent and are now common liver conditions in China. Liver function impairment is a critical marker of liver disease progression, and its dynamic changes can reflect the evolution of liver health status. However, there is a lack of dynamic observational data on liver function impairment, particularly regarding its trends and related factors among middle-aged and older community-dwelling adults.

Materials and Methods:

This study utilized data from the Beijing Air Pollution and Population Health Cohort. Participants aged 45-75 years at baseline who provided blood samples during surveys in 2017, 2019, and 2023 were included. Liver function impairment was defined as AST >35 U/L or ALT >40 U/L for females, and AST >40 U/L or ALT >50 U/L for males. The incidence and changes in liver function impairment were analyzed. Logistic regression was employed to identify potential risk factors associated with liver function impairment.

Results:

A total of 1,906 community residents were included, of whom 1,119 (58.71%) were female, with a mean age of 61.85 years. The prevalence rates of liver function impairment in 2017, 2019, and 2023 were 7.66%, 7.08%, and 8.55%, respectively. From 2017 to 2023, the proportions of participants who never experienced, or experienced 1, 2, or 3 episodes of liver function impairment were 82.53%, 13.01%, 3.10%, and 1.36%, respectively. Among the 146 individuals with liver function impairment in 2017, 96 (65.75%) returned to normal levels by 2019. Similarly, among the 135 individuals with impairment in 2019, 91 (67.41%) normalized by 2023. Logistic regression analysis identified that liver function impairment was associated with age (55-64 years: OR=0.64, 95% CI [0.42-0.99]; 65-75 years: OR=0.44, 95% CI [0.27-0.71]), obesity (OR=1.46, 95% CI [1.05-2.02]), diabetes (OR=1.34, 95% CI [1.00-1.79]), and coronary heart disease (OR=1.53, 95% CI [1.05-2.23]). No significant associations were found with gender, educational level, smoking, alcohol consumption, high-intensity exercise or work, sleep duration, sedentary time, hypertension, allergic diseases, stroke, or tumors.

Conclusions:

The overall prevalence of liver function impairment among middle-aged and older adults in Beijing remained stable at approximately 8%, with a low proportion of persistent impairment. At the individual

E-POSTER ABSTRACTS

level, liver function status exhibited considerable variability over time, with about two-thirds of individuals with impairment returning to normal within a follow-up period. Factors potentially associated with liver function impairment include age, obesity, diabetes, and coronary heart disease.

Keyword(s) : Liver Function Impairment; Epidemiological Characteristics; Risk Factors

1074 - Mediating role of BMI in alcohol linked liver enzyme elevation among adults at a tertiary care hospital in South India

Arivarasan Barathi¹, Yuvaraj Krishnamoorthy², Suthanthira Kannan³

Esic Medical College And Hospital, Community Medicine, Chennai-India¹ Propul Evidence, Evidence Synthesis, Chennai-India² Esic Medical College And Hospital, Community Medicine, Chennai-India³

Background / Hypothesis:

Excessive alcohol consumption is a major risk factor for liver disease, with significant variations in its impact across populations. Unlike prior studies that examine alcohol-induced liver dysfunction and obesity-related liver conditions in isolation, our research integrates these aspects to provide a comprehensive understanding of their interaction. Body mass index (BMI) has been identified as a potential mediator in alcohol-related liver damage. This study aims to examine the association between alcohol consumption and liver function and to explore the mediating role of BMI in a population from India, where both are rising public health concerns.

Materials and Methods:

A cross-sectional study was conducted using data from adult participants. The study included all eligible adults aged 30 years and above who attended the Annual Health Checkup Clinic and underwent routine liver function testing as part of their check-up. Liver function was assessed using serum levels of gamma-glutamyl transferase (GGT), alanine aminotransferase (ALT), aspartate aminotransferase (AST), and alkaline phosphatase (ALP). Alcohol consumption was self-reported, and BMI was calculated from height and weight measurements. Multiple linear regression models were used to evaluate the relationship between alcohol consumption and liver enzymes, while adjusting for BMI as a mediator. Statistical significance was set at $p < 0.05$.

Results:

The study included a total of 706 participants, comprising 335 (47.5%) males with a mean age of 47.9 years (SD: 10.7). Alcohol use was noted in 37 (11.4%) participants, predominantly among males (36, 22.4%). In the multivariable analysis, alcohol consumption showed a significant association with elevated liver enzyme levels, including GGT ($\beta = 5.9$), ALT ($\beta = 6.2$), and AST ($\beta = 6.1$). BMI was found to mediate this relationship, with individuals having higher BMI showing a greater increase in liver enzyme levels in response to alcohol consumption. However, no significant association was observed for ALP. BMI also independently correlated with higher levels of GGT, ALT, and AST.

Conclusions:

The study findings suggest that individuals with higher BMI are more susceptible to alcohol-related liver damage, as evidenced by elevated levels of GGT, ALT, and AST. These results underscore the need for integrated public health strategies that address both alcohol consumption and obesity to mitigate the rising burden of liver disease, particularly in South Asia. Clinicians should consider both BMI and alcohol consumption when assessing liver function, and interventions targeting both lifestyle factors may have significant public health benefits.

Keyword(s) : Liver enzymes, Alcohol, Body Mass Index, Mediation Analysis

1077 - Performance of BAVENO VI and BAVENO VII Criteria for Excluding High Risk Esophageal Varices in Compensated Cirrhosis with Hepatocellular Carcinoma

Benjaphol Panyapornsakul¹

Khon Kaen University, Medicine, Bangkok-Thailand¹

Background / Hypothesis:

High-risk esophageal varices (HRV) are commonly found in patients with hepatocellular carcinoma (HCC). The BAVENO VI criteria, which use liver stiffness measurement (LSM) < 20 kPa and platelet count $> 150 \times 10^9/L$, have been applied for risk stratification. Moreover, the BAVENO VII criteria, which include spleen stiffness measurement (SSM) ≤ 40 kPa, further improve the identification of patients at risk for HRV. However, the use of these criteria in patients with HCC remains limited.

E-POSTER ABSTRACTS

Objective:

To evaluate the diagnostic performance of BAVENO VI and BAVENO VII in ruling out HRV in compensated cirrhosis with HCC.

Materials and Methods:

This cross-sectional study included patients with compensated liver cirrhosis and HCC who had not received non-selective beta blockers or endoscopic band ligation. Liver stiffness measurement was performed using a 50 Hz shear wave frequency, and spleen stiffness measurements were performed using a 100 Hz shear wave frequency. Endoscopic findings were used as the reference standard.

Results:

Among the 44 patients included in the study, the mean age was 61 years, and the majority were male (84%). Hepatitis C virus infection was the most common etiology (54%). The distribution of Barcelona Clinic Liver Cancer (BCLC) stages 0, A, B, and C were represented by 2 (4.5%), 16 (36.4%), 18 (40.9%), and 8 (18.2%) patients, respectively. Most patients (84.1%) were treatment-naïve for HCC at the time of enrollment. HRV were identified in 19 patients (43.2%). The BAVENO VI criteria demonstrated the best diagnostic performance, with a sensitivity of 100% (95% CI: 82.4–100%), a negative predictive value of 100% (95% CI: 63.1–100%), an endoscopy-sparing rate of 18.2%, and no cases of HRV were missed (HRV miss rate of 0%). BAVENO VII and SSM ≤ 40 kPa were identical in diagnostic performance, with a sensitivity of 57.9% (95% CI: 33.5–79.7%), a negative predictive value of 70.4% (95% CI: 49.8–86.2%), and associated with a significantly higher endoscopy-sparing rate of 43.2% compared to the BAVENO VI criteria ($p = 0.02$). However, these algorithms resulted in a significantly higher HRV miss rate of 42.1% ($p < 0.01$).

Conclusions:

The BAVENO VI criteria demonstrated excellent performance in ruling out HRV in patients with compensated cirrhosis and HCC. The addition of SSM did not enhance diagnostic performance in this population. Further studies are needed to validate the applicability of these criteria across different etiologies of cirrhosis and various stages of HCC.

1078 - "When Treatment Triggers Disease Hepatic Abscess as a Paradoxical Reaction to Antitubercular Therapy"

Rebeka Sultana Mousumi¹, A B M Shakil Gani¹, Nur Alam Lenin¹

Dhaka Medical College And Hospital, Hepatology, Dhaka-Bangladesh¹

Background / Hypothesis:

Paradoxical reactions during antitubercular therapy (ATT) represent clinical or radiological worsening of existing lesions or the appearance of new ones after initial improvement. Although more often observed in patients with immune dysfunction, such responses can also occur in those without identifiable immunosuppression. Hepatic abscess as a paradoxical manifestation of tuberculosis (TB) is exceedingly rare and poses significant diagnostic and therapeutic challenges.

Materials and Methods:

A 55-year-old male with sputum and GeneXpert-confirmed pulmonary tuberculosis was treated with ATT. After seven weeks of therapy, he developed jaundice, high-grade fever, abdominal pain, and shortness of breath. The diagnostic evaluation included biochemical tests, imaging studies, pleural fluid analysis, and a liver biopsy. ATT was temporarily discontinued due to drug-induced liver injury and replaced with supportive therapy. Once liver function improved, ATT was cautiously reintroduced in conjunction with corticosteroids.

Results:

Investigations revealed elevated liver enzymes, hyperbilirubinemia, and a large hepatic abscess associated with ascites and right-sided pleural effusion. Microbiological studies, including bacterial culture, GeneXpert, and PCR for Mycobacterium tuberculosis from the abscess aspirate, were negative. Liver biopsy demonstrated granulomatous hepatitis consistent with tuberculosis. Following gradual reintroduction of ATT and corticosteroid therapy, the patient became afebrile, regained appetite, and showed radiological resolution of the abscess with normalization of liver function.

Conclusions:

This case demonstrates a rare hepatic manifestation of tuberculosis presenting as a paradoxical reaction during ATT. Recognizing paradoxical responses is crucial to distinguishing them from treatment failure or drug resistance. Careful monitoring, continuation, or cautious reintroduction of ATT, and adjunctive corticosteroid therapy can result in favorable clinical outcomes.

1081 - Risk factors and outcomes of carbapenem resistant enterobacteriaceae infection in liver transplant patients a systematic review and meta analysis

Kapil Khanal¹, Naveen Gautam², Kailash Mani Pokhrel³

Gulmidurbar Basic Hospital, Medical Officer, Gulmi-Nepal¹ Gulmidurbar Basic Hospital, Medical Superintendent, Gulmi-Nepal² Kharanitar Phc, Medical Officer, Nuwakot-Nepal³

Background / Hypothesis:

Infectious complications are the major source of mortality following liver transplantation. Over the past decade like Carbapenem Resistant Enterobacteriaceae (CRE) has-infection have evolved as a serious healthcare problem. The aim of this study was to analyze the risk factors for CRE infection and their outcomes in liver transplant patients following liver transplantation.

Materials and Methods:

Medical databases like PubMed, Embase, and Google Scholar databases were systematically searched until April 2025. Any observational studies reported on risk factors and outcomes of CRE-infection among adult liver transplant patients were included. The risk factors studied were pre-transplant MELD score, pre-transplant CRE colonization, pre-transplant ICU stay, HCC, undergoing re-transplantation, combined transplantation or re-operation, intraoperative bleeding, post-transplant need of prolonged mechanical ventilation (MV), renal replacement therapy (RRT), post-transplant CRE colonization and biliary complications. Likewise, outcomes like 6-months survival, 1-year survival and length of hospital stay were also analyzed.

Results:

Eleven studies (n=3927) were analyzed. Pre-transplant MELD score (OR=2.92, 95% C.I.= 1.81-4.70, p<0.001), pre-transplant CRE colonization (OR=4.86, 95% C.I.=1.68-14.06, p<0.001), undergoing re-transplantation (OR=2.73, 95% C.I.=1.23-6.04, p=0.01), combined transplantation (OR=2.52, 95% C.I.=1.63-3.91, p<0.001) or re-operation (OR=3.68, 95% C.I.=2.09-

6.48, p<0.001), significant intraoperative bleeding (OR=2.06, 95% C.I.=1.11-3.84, p=0.02), post-transplant need of prolonged MV (OR=3.95, 95% C.I.=3.06-5.09, p<0.001), RRT (OR=3.91, 95% C.I.=2.32-6.60, p<0.001) and biliary complications (OR=2.24, 95% C.I.=1.13-4.44, p=0.02) were associated with increased risk of CRE-infection. However, Pre-transplant ICU stay (OR=1.49, 95% C.I.=0.69-3.20, p=0.31), HCC (OR=0.88, 95% C.I.=0.70-1.12, p=0.30) and post-transplant CRE colonization (OR=2.69, 95% C.I.=0.88-8.25, p=0.08) were not significantly associated with CRE-infection. Likewise, patients with CRE-infection had significantly lower 6-months (OR=0.12, 95% C.I.=0.06-0.24, p<0.001) and 1-year survival (OR=0.09, 95% C.I.=0.06-0.14, p<0.001) and were likely to have a longer hospital stay (Hedge's g=2.00, 95% C.I.=0.73-3.28, p<0.001).

Conclusions:

This systemic review and meta-analysis found several risk factors like higher pre transplant MELD score, pre transplant CRE colonization, re-transplant, combined transplant or reoperation, intraoperative bleeding, prolonged MV, RRT and biliary complications for CRE infection after liver's transplantation and CRE infection was associated with poor outcomes when compared to no CRE infection.

1082 - Prediction of Hepatic Functional Reserve Using a Novel "Severity Index" on Hepatobiliary Phase Gadoteric Acid-Enhanced MRI

Fatih Işık¹, Ahmet Yalçın², Sinan Yilmaz³, Muhammed Furkan Barutçigil⁴, Ahmet Tugrul Akkus¹, Adem Karaman², Gürkan Öztürk⁵, Hakan Dursun⁶, Fatih Alper²

Erzurum Regional Training And Research Hospital, Radiology, Erzurum-Türkiye¹ Atatürk University, Radiology, Erzurum-Türkiye² Atatürk University, Department Of Public Health, Erzurum-Türkiye³ Ismail Fehmi Cumalıoğlu City Hospital, Radiology, Tekirdağ-Türkiye⁴ Atatürk University, Department Of Transplantation Center, Erzurum-Türkiye⁵ Atatürk University, Department Of Gastroenterology, Erzurum-Türkiye⁶

Background / Hypothesis:

Accurate evaluation of hepatic functional reserve is crucial for risk stratification in chronic liver disease (CLD). Existing biochemical scores such as Child-Pugh,

E-POSTER ABSTRACTS

MELD-Na, ALBI, and FIB-4 provide systemic information but fail to capture spatial or transporter-level hepatic function. We hypothesized that a novel MRI-derived biomarker—the “Severity Index”—which integrates parenchymal uptake and vascular retention on hepatobiliary phase (HBP) gadoxetic acid-enhanced MRI, could noninvasively predict hepatic functional reserve across disease stages.

Materials and Methods:

This retrospective study included 193 individuals (122 CLD, 71 controls) who underwent 1.5T gadoxetic acid-enhanced liver MRI between 2021 and 2023. The Severity Index was defined as (Aortic SI × Portal Vein SI) / Liver SI, measured on 20-minute HBP images. Group comparisons were performed using the Mann-Whitney U test, correlations with MELD-Na, ALBI, and FIB-4 were analyzed via Spearman’s correlation, and diagnostic accuracy was assessed with ROC analysis. Intra- and inter-reader reproducibility were evaluated using the intraclass correlation coefficient (ICC).

Results:

The Severity Index was significantly higher in CLD patients than in controls (median 162.0 vs. 90.6; $p < 0.001$) and effectively differentiated decompensated from compensated disease (AUC = 0.848). It also identified subclinical dysfunction in clinically compensated patients (AUC = 0.800; sensitivity = 90.1%). The index correlated strongly with MELD-Na ($r = 0.503$, $p < 0.001$) and moderately with ALBI ($r = 0.389$, $p < 0.001$), but not with FIB-4 ($p = 0.224$). Reproducibility was excellent (intra-reader ICC = 0.961; inter-reader ICC = 0.863).

Conclusions:

The Severity Index provides a physiologically grounded, reproducible, and noninvasive marker of hepatic functional reserve. By integrating both hepatocellular uptake and vascular clearance, it complements traditional biochemical scores, enables early detection of subclinical dysfunction, and offers a promising imaging biomarker for precision risk stratification in advanced chronic liver disease.

1083 - Functional Liver Imaging Score on Gadoxetic Acid-Enhanced MRI Correlation with MELD Na ALBI FIB 4 and Clinical Status in Chronic Liver Disease

Fatih Işık¹, Ahmet Yalçın², Sinan Yılmaz³, Muhammed Furkan Barutçigil⁴, Ahmet Tugrul Akkus¹, Adem Karaman², Gürkan Öztürk⁵, Hakan Dursun⁶, Fatih Alper², Said Ali Atalay⁷
Erzurum Regional Training And Research Hospital, Radiology, Erzurum-Türkiye¹ Atatürk University Research Hospital, Radiology, Erzurum-Türkiye² Atatürk University Research Hospital, Department Of Public Health, Erzurum-Türkiye³ Ismail Fehmi Cumalioğlu City Hospital, Radiology, Tekirdağ-Türkiye⁴ Atatürk University Research Hospital, Department Of Transplantation Center, Erzurum-Türkiye⁵ Atatürk University Research Hospital, Department Of Gastroenterology, Erzurum-Türkiye⁶ Bayburt State Hospital, Radiology, Erzurum-Türkiye⁷

Background / Hypothesis:

Accurate, noninvasive assessment of hepatic functional reserve is crucial in CLD. Biochemical scores (MELD-Na, ALBI, FIB-4) may miss spatial and transporter-level dysfunction. We hypothesized that the semi-quantitative Functional Liver Imaging Score (FLIS)—integrating hepatobiliary phase parenchymal enhancement, biliary excretion, and portal-vein signal on gadoxetic acid-enhanced MRI—correlates with liver function indices and clinical decompensation and shows high reproducibility across readers.

Materials and Methods:

This single-center retrospective study included 107 adults with CLD who underwent 1.5T gadoxetic acid-enhanced liver MRI (20-min hepatobiliary phase) between 2021–2024. Three radiologists (25, 8, and 6 years’ experience) independently scored FLIS (0–6) blinded to clinical data; one reader repeated scoring after one month. Correlations between FLIS and MELD-Na, ALBI, and FIB-4 were analyzed using Spearman’s rho. Diagnostic performance was evaluated by ROC analyses for ALBI grade 3, MELD-Na <15, and decompensation status. Reproducibility was assessed via two-way random, absolute-agreement ICCs.

Results:

Mean age was 52.4 ± 10.8 years; 67.3% male. Etiologies

E-POSTER ABSTRACTS

included HBV (59.8%), autoimmune hepatitis (10.3%), HCV (5.6%), cryptogenic (5.6%), PBC (1.9%), and others (16.8%). FLIS demonstrated strong negative correlations with MELD-Na ($r = -0.780, -0.780, -0.816$; all $p < 0.001$) and ALBI ($r = -0.643, -0.644, -0.665$; all $p < 0.001$); correlations with FIB-4 were weaker ($r = -0.235$ to -0.283 ; $p = 0.003-0.015$). For identifying ALBI grade 3, $FLIS \leq 3$ yielded $AUC = 0.939-0.943$, sensitivities 0.75–0.85, specificities 0.931–0.943. For predicting $MELD-Na < 15$, $FLIS \geq 5$ achieved $AUC = 0.903-0.918$, sensitivities 0.875–0.906, specificities 0.800–0.853. For distinguishing decompensated from compensated disease, $FLIS \leq 4$ produced $AUC = 0.829-0.842$. Reproducibility was excellent: intra-observer $ICC = 0.96$ (95%CI 0.94–0.98); inter-observer ICCs 0.96–0.97.

Conclusions:

FLIS on gadoxetic acid-enhanced MRI strongly correlates with MELD-Na and ALBI, shows high diagnostic accuracy for adverse clinical strata, and demonstrates excellent reproducibility. As a fast, cost-efficient, and vendor-agnostic visual score, FLIS can complement biochemical indices for noninvasive functional assessment and risk stratification in CLD and cirrhosis.

1084 - Long Term Virological Response Dynamics and Clinical Outcomes in HBV Related Cirrhosis A Real World Cohort Study

Yuwei Wang¹, Yaxin Li¹, Huiguo Ding¹

Beijing You'an Hospital, Capital Medical University, Department Of Gastroenterology And Hepatology, Beijing-China¹

Background / Hypothesis:

The long-term prognostic value of dynamic virological response in HBV-related cirrhosis receiving nucleos(t)ide analogue (NAs) therapy remains inadequately characterized. This study aimed to evaluate its association with clinical outcomes, with stratification by baseline cirrhosis compensation status.

Materials and Methods:

This was a retrospective-prospective cohort study enrolled HBV related cirrhotic patients receiving NAs

treatment from January 2009 to December 2019.

According to the serum HBV DNA level during 2 years of follow-up, The patients were classified into complete virological response (CVR) or partial virological response (PVR) groups. Patients in the CVR group were stratified into maintained virological response (MVR) or virologic breakthrough (VBT) groups based on their dynamic HBV DNA levels throughout the extended follow-up. The primary endpoint were HCC, liver failure (LF) or liver-related death. Secondary endpoints were recompensation or progression to decompensation.

Results:

Among 1,869 patients followed for a median of 7 years, MVR (65.4%) was associated with the most favorable outcomes. In decompensated cirrhosis, the MVR group demonstrated a slow accumulation of HCC risk, with a 10-year cumulative incidence of 25.7%. In contrast, the PVR and VBT groups showed early and sustained elevations in risk, reaching 32.2% and 53.2% at 10 years, respectively ($P < 0.001$ for overall difference). A similar pattern was observed for liver failure and liver-related mortality, with the MVR group consistently exhibiting the lowest risk profile throughout the follow-up (all $P < 0.001$). Furthermore, the MVR group showed the highest rate of clinical recompensation (34.2% vs 22.6% in the VBT group, $P < 0.001$). Among compensated patients, the MVR group demonstrated a significantly lower 10-year HCC risk (14.2% vs 33.6%; $P < 0.001$) and the lowest rate of disease progression to decompensation (16.1% vs 37.0%; $P < 0.001$) compared to patients with suboptimal response. In addition, Within the MVR cohort, HBsAg levels < 100 IU/mL identified a subgroup with a substantially lower HCC risk.

Conclusions:

MVR is crucial for favorable prognosis in HBV-related cirrhosis, especially in patients with HBsAg level less 100 IU/ml. However, about 26.5% of long-term NAs antiviral therapy patients have VBT and poor outcomes. These findings not only highlight the critical role of long-term viral suppression in optimizing clinical prognosis, but also underscore the necessity of long-term strictly monitoring for VBT after achieving CVR.

E-POSTER ABSTRACTS

1086 - COVID 19 Pandemic's Impact on the Global Disease Burden of HBV related Hepatocellular Carcinoma in the Elderly

Yuwei Wang ¹

Beijing You'an Hospital, Capital Medical University,
Department Of Gastroenterology And Hepatology,
Beijing-China ¹

Background / Hypothesis:

With the advancing aging population, the disease burden in the elderly has become a critical public health issue. This study utilized data from the Global Burden of Disease Study (GBD) 2021 to evaluate the global, regional, and national disease burden of hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC) in the elderly, with particular focus on trend changes before and after the COVID-19 pandemic. The study further analyzed differences across Socio-Demographic Index (SDI) categories and between genders to provide evidence for public health policymaking.

Materials and Methods:

Based on GBD 2021 data, we analyzed age-standardized incidence and mortality rates of HBV-related HCC in the elderly from 1990 to 2021, with emphasis on comparing trends between 2019 and 2021. Joinpoint regression was used to assess trend changes, while age-period-cohort (APC) analysis examined the effects of age, period, and birth cohort. Decomposition analysis quantified contributions of population aging, epidemiological changes, and population growth to disease burden changes. The association between age-standardized rates and estimated annual percentage change was explored using nonlinear regression models.

Results:

From 1990 to 2021, the global age-standardized incidence rate (ASIR) and mortality rate (ASDR) of HBV-related HCC in the elderly showed an overall declining trend, though with significant regional heterogeneity. African regions maintained higher rates, while some American regions had lower rates. After the COVID-19 pandemic, the global decline rate accelerated, though some countries experienced rising trends. Males consistently showed higher ASRs than females across most regions, with a faster post-pandemic decline in male rates. Decomposition analysis indicated epidemiological changes were the primary drivers of incidence and mortality trends, while aging's

contribution to incidence increased after 2019. APC analysis revealed that HCC risk initially increased then decreased with advancing age, with significant differences across birth cohorts.

Conclusions:

Despite recent progress in global HBV-related HCC control in the elderly, evidenced by declining overall incidence and mortality rates, significant regional disparities persist, with elderly males bearing a heavier disease burden. The post-pandemic period has seen accelerated declines in most regions but rising trends in some countries. Future prevention and control strategies should prioritize elderly populations, particularly males, through enhanced health education, screening, and personalized treatment, while optimizing public health measures and establishing comprehensive surveillance systems to effectively reduce the global disease burden.

Keyword(s) : Global Burden of Disease;Hepatitis B virus;Hepatocellular carcinoma;COVID-19

1087 - Bibliometric Analysis and Research Trends of Specialty Theses on Cirrhosis in Turkey

Fatma Zehra Agan ¹, Ahmet Uyanikoglu ²

Harran University, Internal Medicine, Şanlıurfa-Türkiye ¹
Harran University, Gastroenterology, Şanlıurfa-Türkiye ²

Background / Hypothesis:

Liver cirrhosis is a major global health concern, caused by factors such as obesity, non-alcoholic fatty liver disease, alcohol abuse, viral hepatitis B/C, autoimmune and cholestatic diseases, as well as iron or copper overload(1). Clinical management varies by etiology and disease stage. This study aims to analyze cirrhosis-related theses in Turkey to identify research trends.

Materials and Methods:A descriptive retrospective study was conducted by searching the Higher Education Council (YÖK) National Thesis Center database for theses with "Cirrhosis" in the title. Ninety-eight accessible theses published between 2011 and 2025 were evaluated. Parameters included publication year, language, institution, department, advisor academic title, publication status, time to publication, journal index, and citation count.

Results:

E-POSTER ABSTRACTS

Most theses (98.97%, n=97) were written in Turkish; only one was in English. The peak year for theses was 2022 (n=14, 14.28%), followed by 2020 (n=11, 11.22%), 2014 (n=10, 10.20%), and 2024 (n=9, 9.18%) Figure 1. Health Sciences University produced the highest number (n=16, 16.32%), followed by Ege, Atatürk, and Harran Universities Figure 2. The majority of theses were from Gastroenterology (57.14%, n=56) and Internal Medicine (19.38%, n=19) departments Figure 3. Regarding advisors, 58.16% (n=57) were professors, 31.63% (n=31) associate professors, and 10.20% (n=10) assistant professors. Only 23.46% (n=23) of theses were published as articles, with a median time to publication of 2 years (range 1–12). Published articles appeared mostly in SCI/SCI-E (34.78%, n=8), followed by other international (26.08%, n=6), national (21.73%, n=5), and ESCI-indexed journals (17.3%, n=4). Median citation count was 2 (range 0–78). Statistical analysis showed no significant association between thesis year, department, institution, or advisor title and publication status ($p > 0.05$), but a significant link was found between thesis type and publication ($p=0.008$), with all subspecialty theses (n=3) published.

Conclusions:The fact that the highest number of theses were submitted in 2022 indicates that academic interest in the field of cirrhosis has increased in recent years. The fact that the majority of theses were submitted at Health Sciences Universities demonstrates a strong research infrastructure. The fact that most advisors are professors reflects the influence of experienced academics in the studies. The low rate of theses in English limits international visibility. Only 23.46% of theses were published, suggesting the need for support during the publication process.

1088 - The cGAS STING IFITM3 Axis Drives Monocyte Phenotypic Shift and Immune Dysregulation in Acute on Chronic Liver Failure

Junyi Wang¹, Zhouhan Wang¹, Zhiliang Gao¹, Bingliang Lin¹

The Third Affiliated Hospital Of Sun Yat-sen University, Infectious Disease Department, Guangzhou-China¹

Background / Hypothesis:Acute-on-chronic liver failure (ACLF) is a lethal syndrome characterized by intense systemic inflammation. Monocytes are pivotal in ACLF immunopathology, particularly the pro-inflammatory CD16+ subset, but their upstream drivers remain elusive. Our preliminary single-cell RNA sequencing of

ACLF patients identified IFITM3 as a hub gene upregulated during both CD16+ monocyte differentiation and disease progression. We hypothesize that hepatocyte-derived DAMPs activate the cGAS-STING pathway in monocytes, leading to IFITM3 upregulation, which subsequently drives CD16+ phenotypic shift and enhances hepatic chemotaxis, thereby exacerbating immune imbalance in ACLF.

Materials and Methods:In silico, we re-analyzed single-cell data from HBV-ACLF patients to validate IFITM3's central role. In vitro, IFITM3 was knocked down or overexpressed in human monocyte lines (THP-1, Mono Mac 6). Phenotype (CD14/CD16) was assessed by flow cytometry, and chemotaxis towards liver sinusoid endothelial cell (LSEC) or hepatocyte conditioned media was evaluated via Transwell assays. Key chemokine receptors (CCR2, CX3CR1) and ligands (CCL2, CX3CL1) were measured by qPCR, flow cytometry, and ELISA. In vivo, a preventive strategy using Ifitm3-shRNA lentivirus was employed in a CCl₄-induced ACLF mouse model to assess its impact on monocyte subsets, liver injury, and inflammation.

Results:Our single-cell analysis confirmed IFITM3 as a core gene during monocyte transition to CD16+ subset in progressive ACLF. In vitro, IFITM3 knockdown reduced the CD16+ population, while its overexpression promoted it. Furthermore, IFITM3 knockdown significantly impaired monocyte chemotaxis towards LSEC and hepatocyte signals, correlating with reduced surface expression of CCR2 and CX3CR1. Preliminary data successfully demonstrated efficient knockdown and overexpression of IFITM3 in monocytic cells.

Conclusions:The cGAS-STING-IFITM3 axis is a novel signaling pathway driving CD16+ monocyte skewing and enhancing their liver homing in ACLF. IFITM3 represents a potential key node linking initial injury to sustained immune dysregulation, making it a promising therapeutic target for mitigating inflammation in ACLF.

Keyword(s) : Acute-on-Chronic Liver Failure; Monocyte; IFITM3; cGAS-STING; Immune Dysregulation

1089 - CEP290 a primary cilium related gene as the positive feedback regulator of Nrf2 that modulates liver cancer cells ferroptosis

Ruilian Ma¹, Yiru Shan¹, Bin Zhang², Qi Pan²
Jiulongpo People's Hospital Of Chongqing, Department Of Oncology, Chongqing-China¹

E-POSTER ABSTRACTS

Chongqing Hospital Of Traditional Chinese Medicine,
Department Of Dermatology, Chongqing-China ²

Background / Hypothesis:

Though dysfunction of primary cilium is associated with cancers, the molecular basis by which activates signal pathway against ferroptosis are still ambiguous.

Materials and Methods:

Here, in The Cancer Genome Atlas Liver Hepatocellular Carcinoma(TCGA-LIHC) expression data, we utilized weighted gene co-expression analysis (WGCNA) combined with molecular subtype clustering model to prioritize potential novel oncogenes, and validated them in vitro and in vivo.

Results:

We found that the expression of a centrosomal protein 290 (CEP290) increased within liver cancer cells and tissues, and its repression promoted ciliogenesis, iron and malondialdehyde (MDA) accumulation. Mechanically, CEP290 binds nuclear factor erythroid 2-related factor 2 (Nrf2) to displace kelch like ECH associated protein 1 (Keap1), thus inhibiting Nrf2 ubiquitination, stabilizing Nrf2 protein and activating Nrf2 signal transduction. Interestingly, expression of CEP290 was also regulated by recruiting Nrf2 to its promoter. The directly interplay between CEP290 and Nrf2 formed a positive feedback loop. Moreover, inhibition of Nrf2 significantly enhanced ferroptotic effects of CEP290 knockout in vivo.

Conclusions:The above results shed more lights on the important part of CEP290 in connecting ciliogenesis with ferroptosis, and present an important implication for liver cancer treatment.

Keyword(s) : Ciliogenesis, CEP290, Nrf2, ubiquitination, ferroptosis

1090 - Hermansky Pudlak syndrome (HPS)

Vedat Goral ¹

Istanbul Medipol University, Gastroenterology, Istanbul
Medipol Üniversitesi-Türkiye ¹

Background / Hypothesis:

Hermansky-Pudlak syndrome (HPS) is a rare, autosomal recessive disorder characterized by visual impairment, decreased pigmentation with nystagmus

(oculocutaneous albinism), and blood platelet dysfunction accompanied by prolonged bleeding. Hermansky-Pudlak syndrome (HPS) was diagnosed in a patient presenting with nausea and vomiting.

Materials and Methods:

Case: A 23-year-old female patient presented with nausea and vomiting. Endoscopy revealed no gross pathology to explain the nausea and vomiting. The patient's history revealed HPS. Because there were no bowel (colitis) complaints, a colonoscopy was not recommended.

Results:

The patient was referred to a specialized center for hematology, genetics, and neurology follow-up.

Conclusions:HPS is a hereditary disease with autosomal recessive transmission. Numerous genetic tests are available for diagnosis. Some individuals with this disease may also present with lung fibrosis, inflammatory bowel disease, immunodeficiency, or abnormal deposition of a fat-like substance (seroid lipofuscin) in various body tissues. Hermansky-Pudlak syndrome should be considered in cases characterized by inflammatory bowel disease, albinism, and nystagmus.

Keyword(s) :

1092 - Triple A (Allgrove) Syndrome

Vedat Goral ¹

School Of Medicine, Gastroenterology, Istanbul
Medipol Üniversitesi-Türkiye ¹

Background / Hypothesis:

Allgrove syndrome (AS), or 3A syndrome (AAA), is characterized by the triad of adrenocorticotrophic hormone (ACTH)-resistant adrenal insufficiency, alacrimia, and achalasia, accompanied by progressive neurological impairment with or without mild mental retardation. A rare case of Allgrove (3A) Syndrome is presented here.

Keywords: Triple A syndrome, 3A syndrome, Allgrove syndrome

Materials and Methods:

Case: The patient was a 30-year-old female living in Oman. Endoscopy revealed signs of achalasia and adrenal insufficiency during examinations performed for difficulty swallowing. Initially, endoscopy was

E-POSTER ABSTRACTS

performed for achalasia, followed by a bougie dilation and then a Heller myotomy. The difficulty swallowing persisted, albeit mildly.

Results:

Treatment was initiated for adrenocortical insufficiency.

Conclusions: Triple A, or Allgrove syndrome, is a hereditary syndrome characterized primarily by achalasia, alacrima, and adrenocorticotropin (ACTH) resistance-addisonianism. In cases of achalasia, triple A syndrome should not be overlooked, and adrenal insufficiency should be investigated.

1093 - Towards HCV Elimination Time for Clinical and Laboratory Collaboration

Burcu Çalışkan Demirkiran¹, Neşe Inan², Irem Ataöv¹, Gülşen Iskender¹, Duygu Mert¹, Semra Tunçbilek¹, Tuba Dal², Mustafa Ertek¹

Dr Abdurrahman Yurtaslan Ankara Oncology Training And Research Hospital, Infection Diseases And Clinical Microbiology, Ankara-Türkiye¹ Dr Abdurrahman Yurtaslan Ankara Oncology Training And Research Hospital, Medical Microbiology, Ankara-Türkiye²

Background / Hypothesis:

Achieving HCV elimination requires identifying and addressing diagnostic gaps. This study aimed to detect undiagnosed HCV cases, evaluate the level of clinical awareness in the diagnostic process, and explore strategies to reduce the number of undiagnosed patients.

Materials and Methods:

Anti-HCV-positive patients identified at our hospital between January 1, 2022, and December 31, 2023, were retrospectively reviewed. Patients who tested anti-HCV-positive but had no HCV RNA test ordered were contacted and invited to the hospital. Those who attended were subsequently tested for HCV RNA.

Results:

A total of 78,769 anti-HCV tests were performed, with 555 patients (0.7%) testing positive. HCV RNA testing was requested for 307 (55.3%) of anti-HCV-positive patients during follow-up visits (Table 1). The rate of HCV RNA testing requests among anti-HCV-positive patients was significantly lower in surgical clinics compared with other departments ($p < 0.001$) (Table 2). Telephone calls were made to 248 patients without prior HCV RNA testing, of whom 114 (46%) could not

be reached. An anti-HCV S/Co ratio above 10.38 predicted HCV RNA positivity with 100% sensitivity and 89% specificity (AUC: 0.95, $p < 0.001$) (Table 3, Figure 1).

Conclusions:

Increasing awareness of HCV diagnosis among surgical clinics and implementing reflex testing algorithms to ensure diagnosis at the patient's first hospital visit will substantially support HCV elimination efforts. In addition, developing reflex testing algorithms based on the identified anti-HCV S/Co cutoff value of 10.38 may enable a more targeted and cost-effective approach to detecting previously undiagnosed HCV cases.

Keyword(s) : HCV screening, HCV RNA, reflex test

1094 - Oxidative Stress-Immunotherapy Gene Signatures Define Prognosis and Immune Subtypes in Hepatocellular Carcinoma

Yuxin Liang¹, Deyuan Zhong¹, Qinyan Yang¹, Zhengwei Leng¹, Xiaolun Huang¹

Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School Of Medicine, University Of Electronic Science And Technology Of China, Liver Transplantation Center And Hbp Surgery, Chengdu-China¹

Background: Hepatocellular carcinoma (HCC) exhibits complex interactions between oxidative stress and immune regulation that critically influence tumor progression and treatment response. This study aimed to identify oxidative stress- and immunotherapy-related genes (OSIRGs) associated with HCC prognosis, to construct a predictive model, and to explore novel immune subtypes relevant to immunotherapeutic sensitivity.

Methods: Transcriptomic and clinical data for HCC were obtained from TCGA-LIHC and GSE14520 cohorts. Differentially expressed genes (DEGs) were identified using DESeq2, and intersected with curated oxidative stress and immunotherapy gene sets to obtain OSIRDEGs. Functional enrichment (GO, KEGG, GSEA), WGCNA, and Cox-LASSO regression were applied to construct and validate a prognostic risk model. Consensus clustering defined molecular subtypes, which were further analyzed by TIDE, immune checkpoint, ICD, and HLA profiling, as well as immune infiltration (CIBERSORT and ssGSEA). Somatic mutation, copy number variation, and drug susceptibility analyses were performed to elucidate genomic and therapeutic correlations.

Results: Twenty-four OSIRDEGs were identified,

E-POSTER ABSTRACTS

primarily enriched in cell cycle regulation and mitotic pathways. WGCNA and LASSO analyses yielded six key genes (BUB1B, CDKN2A, CENPE, HMMR, PTTG1, SPP1), forming a robust prognostic model validated across independent cohorts ($p < 0.001$). Based on these genes, HCC samples were divided into two distinct subtypes (Cluster 1 and Cluster 2) with significantly different survival outcomes ($p < 0.001$). Cluster 2 exhibited lower TIDE scores and higher expression of immune checkpoint and ICD-related genes, suggesting greater potential responsiveness to immunotherapy. Immune infiltration analyses revealed distinct immune cell compositions and correlations across subtypes. Somatic mutation and CNV analyses indicated recurrent alterations in CDKN2A, CENPE, and HMMR. Drug sensitivity screening linked key model genes to multiple targeted agents. qPCR and western blotting confirmed upregulation of all six genes in HCC cell lines compared with normal hepatocytes. Conclusions: We identified and validated an oxidative stress-immunotherapy-related prognostic model that effectively stratifies HCC patients by survival and immune characteristics. The six-gene signature provides insights into tumor immune heterogeneity and may serve as a biomarker set for predicting immunotherapeutic efficacy and guiding personalized HCC management.

Keyword(s) : Hepatocellular carcinoma; Oxidative stress; Immunotherapy; Prognostic gene signature; Immune subtypes; Biomarkers

1095 - Efficacy and safety of postoperative adjuvant HAIC combining lenvatinib with or without PD 1 inhibitors in solitary large HCC A multicenter retrospective study

Yuxin Liang¹, Yuhao Su¹, Hongtao Yan¹, Zhengwei Leng¹, Xiaolun Huang¹
Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School Of Medicine, University Of Electronic Science And Technology Of China, Liver Transplantation Center And Hbp Surgery, Chengdu-China¹

Background: Solitary large hepatocellular carcinoma (HCC; >5 cm) remains prone to early recurrence despite curative resection. Adjuvant strategies that integrate hepatic arterial infusion chemotherapy (HAIC) with systemic therapy are increasingly explored. HAIC achieves high intrahepatic drug exposure, while lenvatinib and PD-1 inhibitors have shown efficacy in advanced HCC. Whether adding PD-1 inhibitors to postoperative adjuvant HAIC plus lenvatinib can further

reduce postoperative recurrence in solitary large HCC warrants evaluation.

Methods: A total of 183 patients with solitary large HCC who underwent curative resection and subsequent PA-HAIC plus lenvatinib (HAIC-L, $n = 108$) or PA-HAIC combined with lenvatinib and PD-1 inhibitors (HAIC-L-P, $n = 75$) were enrolled from three centers between April 2021 and April 2023. Propensity score matching (PSM) was applied to balance baseline characteristics. Disease-free survival (DFS) and overall survival (OS) were analyzed using the Kaplan-Meier method and Cox proportional hazards models, while treatment-related adverse events (TRAEs) were compared between groups.

Results: The HAIC-L-P group demonstrated significantly improved DFS compared to the HAIC-L group both before (HR: 0.570; $P = 0.007$) and after PSM (HR: 0.518; $P = 0.018$). In contrast, no statistically significant difference was observed in OS between the two groups. Multivariate analysis identified elevated AFP (≥ 400 ng/mL), microvascular invasion, and treatment strategy (HAIC-L vs. and HAIC-L-P) as independent predictors of DFS. Additionally, the overall safety profiles were comparable, with similar incidences of TRAEs and no significant increase in hepatic toxicity with PD-1 inhibitor addition.

Conclusion: In patients with solitary large HCC after curative resection, adding PD-1 inhibitors to adjuvant HAIC plus lenvatinib significantly prolongs DFS with acceptable safety, although an OS benefit was not observed within current follow-up. These findings support tri-modality adjuvant therapy as a promising postoperative option. Further prospective, biomarker-driven trials are warranted to validate these findings and optimize patient selection.

Keyword(s) : Solitary large hepatocellular carcinoma; Postoperative adjuvant therapy; Hepatic arterial infusion chemotherapy; PD-1 inhibitors; Combined therapy

1097 - The Roadtrip PEERS AND MEDICAL STAFF IS THE BEST MATCH TO TEST AND TREAT DRUG USERS FOR HEPATITIS C

Juliette Pont¹, Pascal Melin², Veronique Monot³, Laurence Garbet⁴, Jacky Sainty⁴
Sos Hepatites Bfc, Association, Dijon-France¹ Sos Hepatites Federation, Hospital And Patients Association, Paris-France² Sos Hepatites Bfc, Hospital And Patient Association, Dijon-France³ Sos Hepatites Bfc, Patient Association, Dijon-France⁴

Background / Hypothesis:

E-POSTER ABSTRACTS

To achieve the goal of eliminating hepatitis C by 2030, it is essential to prioritize screening among key populations: people who use drugs, those experiencing homelessness or social precarity, incarcerated individuals, and people attending day shelters, accommodation centers, or asylum seeker centers. The process must be simplified and shortened as much as possible, while building trust with a population that can be difficult to reach. This has been the mission of the "Roadtrip" team since 2019.

Materials and Methods:

The team consists of former drug users cured of their hepatitis C infection, a nurse, and a physician.

Together, they offer hepatitis C screening within various facilities that serve these populations.

Four objectives:

Screening: Perform rapid diagnostic tests (RDTs) for HCV. When an RDT is positive, confirm with a point-of-care RNA test (POCT) and assess liver stiffness using Fibroscan®. If viral load is confirmed and there is no significant fibrosis, treatment is prescribed on the same day by the physician.

Confirmation of cure: Confirm sustained virological response (SVR) in individuals who have not done so for various reasons (lack of health insurance, damaged venous access, etc.).

Detection of reinfection: Verify that no reinfection has occurred and reintegrate patients into care pathways if necessary.

Liver assessment: Perform Fibroscan® for all participants to assess liver health.

Results:

A total of 411 people accepted testing, and 394 HCV (Rapid Diagnostic Tests) were performed. 42 were positive. After POCT confirmation, 30 individuals were RNA positive (7.2%), consistent with published data. All had low Fibroscan® scores, meaning no significant fibrosis, and were therefore eligible for treatment prescribed directly by a general practitioner (in France, any GP can prescribe hepatitis C treatment in the absence of advanced fibrosis). Among these 30 people who use drugs, one case was a reinfection and another was a treatment failure; the latter was referred to a specialized center. The POCT also confirmed cure in 24 individuals.

Beyond hepatitis C, 5 HBsAg-positive cases were detected in asylum seeker centers, and 6 suspected

cirrhotoses were identified in shelters for people in precarious situations. The Roadtrip has just begun activities in prisons; it is too early to present concrete results.

Conclusions:

These Roadtrips, led by peer workers trained in screening tools and supported by a patient association, appear to be an effective way to reach marginalized populations who are often reluctant to seek care. A 7.3% HCV positivity rate and immediate access to treatment demonstrate the effectiveness of this outreach approach.

1100 - MRI differential diagnosis of hepatic metastasis of choroidal melanoma in the patient with hepatitis B cirrhosis

Chenxi Liu¹, Yao Yang¹, Xinya Zhao², Qiang Zhu³

Shandong Provincial Hospital Affiliated To Shandong First Medical University, Gastroenterology, Jinan-China

¹ Shandong Provincial Hospital Affiliated To Shandong First Medical University, Radiology, Jinan-China ²

Shandong Provincial Hospital Affiliated To Shandong First Medical University, Infectious Disease, Jinan-China ³

Choroidal melanoma is a primary intraocular malignant tumor with a propensity for metastasis to the liver. However, it is uncommon in areas with a high incidence of hepatitis B and poses a challenge to clinicians' diagnosis in the absence of complete history information. MRI is an important method for the diagnosis of liver diseases, and there has been no study on the differential diagnosis between choroid melanoma liver metastasis and hepatitis B related hepatocellular carcinoma. Here, we present a case of choroidal melanoma liver metastasis in a patient with HBV cirrhosis and discuss the specificity significance of MRI in differential diagnosis of hepatic metastasis of choroid melanoma and HBV related hepatocellular carcinoma. This suggests that clinicians should consider the possibility of liver tumors other than hepatocellular carcinoma according to their clinical and imaging findings in areas with high incidence of hepatitis B.

1105 - Comparative Efficacy of NSAIDs and Opiates in Alleviating Pain Associated with Mild to Moderate Pancreatitis A Randomized Controlled Trial

Asif Khan¹, Musarrat Hussain², Rafi Ullah¹, Muhammad Jawad Zahid³
Hayatabad Medical Complex, Peshawar, Gastroenterology, Peshawar-Pakistan¹ Hayatabad Medical Complex, Surgery, Peshawar-Pakistan² Hayatabad Medical Complex, Peshawar, Surgery, Peshawar-Pakistan³

Background / Hypothesis:

While both non-steroidal anti-inflammatory drugs (NSAIDs) and opioids are utilized for pain relief in acute pancreatitis, the preferred analgesic for mild to moderate cases remains uncertain. We evaluated Opioid and NSAID for analgesic efficacy and side effect profile, in mild to moderate acute pancreatitis.

Materials and Methods:

In parallel arms single-blind randomized clinical trial, mild to moderate acute pancreatitis patients were randomized into NSAID (ketorolac) and Opioid (tramadol) groups. The primary outcome was effectiveness in a reduction in pain at 2-hours of intervention. The secondary outcomes were a reduction in pain at 4-hours, 6-hours, 8-hours, and 24-hours, reduction in hospital stay, and an improvement in patient satisfaction.

Results:

A total of 60 patients were randomized into NSAID (n = 30) and Opioid group (n = 30) in a 1:1 pattern. Both drugs significantly reduced the pain score over 24-hours (p = 0.02). However, there was no significant difference in reduction in pain at 2-hours (Difference: -0.18, 95% CI: -0.70 – 1.03). In addition, regarding patient satisfaction and length of stay in the hospital, both drugs showed almost similar effectiveness. The opioids were most associated with sedation (p = 0.03) and epigastric pain (p = 0.04) compared to the NSAIDs

Conclusions:

The current study demonstrated that both NSAIDs and opioids are equally effective in managing pain in patients with mild to moderate acute pancreatitis. No significant differences were found between the two drug classes regarding pain relief, patient satisfaction, or length of hospital stay. However, opioids were

associated with a higher incidence of adverse effects, including sedation and epigastric pain, compared to NSAIDs.

Keyword(s) : Acute Pancreatitis, Opioid, NSAID, pain management, RCT

1106 - BEDSIDE NUTRITIONAL ASSESSMENT IN PATIENTS WITH LIVER CIRRHOSIS USING MINI NUTRITIONAL ASSESSEMENT PROFORMA

Asif Khan¹, Sher Rehman², Rafi Ullah¹
Hayatabad Medical Complex, Peshawar, Gastroenterology, Peshawar-Pakistan¹ Hayatabad Medical Complex, Gastroenterology, Peshawar-Pakistan²

Background / Hypothesis:

Patients suffering from advanced liver cirrhosis often exhibit compromised nutritional status as a result of reduced appetite and significant metabolic disruptions. These nutritional deficiencies contribute to further complications and an increased risk of death. Early detection of such deficits is essential for optimizing patient management. In this study, we applied the approved Mini Nutritional Assessment (MNA) tool to assess the nutritional condition of individuals who have received a diagnosis with cirrhosis.

Materials and Methods:

This investigation employed a cross-sectional design conducted within the Department of Gastroenterology at HMC Peshawar, encompassing a sample of 330 adult patients aged 18 years and older, all of whom had an established diagnosis of liver cirrhosis. Patients concurrently diagnosed with cancer or with severe liver encephalopathy (grade 3& 4) were excluded. Anthropometric measurements i.e. Body Mass Index (BMI), Mid-Arm Circumference (MAC), and Triceps Skin-fold thickness (TSF) were recorded. Nutritional status was determined using MNA scores, while liver disease severity was categorized according to Child-Pugh classifications. Statistical methods including logistic regression analysis were used to explore the relationships between nutritional parameters and clinical features.

Results:

The study had mean MNA score of 19.03 ± 4.43 , mean age of 54.73 ± 11.79 years, and a mean BMI of $22.41 \pm$

E-POSTER ABSTRACTS

2.76. We found that malnutrition exhibited a significantly higher prevalence in the older patients ($p=0.001$), in those with hepatitis B ($p=0.002$), and among patients with advance cirrhosis (Child B and C, $p=0.001$). Logistic regression analysis identified ascites and hepatic encephalopathy as significant predictors of nutritional decline.

Conclusion: The findings indicate that malnutrition is widespread among patients with liver cirrhosis, particularly in cases involving advanced disease and complications like ascites. This underscores the need for regular nutritional evaluation using MNA tool to enable timely interventions, which could improve clinical outcomes in this high-risk group.

1107 - Serum fibroblast growth factor 21 as a novel biomarker of cachexia in chronic liver disease

Takatsugu Tanaka¹, Goki Suda¹, Masatsugu Ohara¹, Naohiro Yasuura¹, Akimitsu Meno¹, Takashi Kitagataya¹, Masato Nakai¹, Takuya Sho¹, Shunsuke Ohnishi², Naoya Sakamoto¹

Graduate School Of Medicine, Hokkaido University, Department Of Gastroenterology And Hepatology, Sapporo-Japan¹ Faculty Of Pharmaceutical Sciences, Hokkaido University, Laboratory Of Molecular And Cellular Medicine, Sapporo-Japan²

Background / Hypothesis:

Cachexia significantly worsens chronic liver disease (CLD) prognosis, and reliable predictive markers are lacking. We investigated clinical factors and biomarkers associated with cachexia in CLD.

Materials and Methods:

Among 526 patients with CLD, 356 with complete clinical cachexia information and preserved serum samples were included. A discovery cohort ($n=240$; August 2014–June 2023) underwent retrospective serum fibroblast growth factor (FGF) 21, interleukin (IL)-6, and tumor necrosis factor (TNF)- α measurements. Independent predictors and optimal biomarker cutoff values were identified by logistic regression and receiver operating characteristic analyses. Results were validated in an independent cohort ($n=116$; July 2023–May 2025).

Results:

Of all patients (median age 68 [range: 19–90] years), 65.8% were male, and 24.6% had cachexia, independently associated with poorer overall survival (hazard ratio: 1.64; 95% confidence interval [CI]: 1.03–2.62; $p=0.038$). Patients with cachexia had significantly higher serum FGF21 than those without (median: 292 vs. 177 pg/mL, respectively; $p=0.002$), while IL-6 and TNF- α levels did not differ. Serum FGF21 level was the sole independent biomarker for cachexia (odds ratio: 1.71; 95% CI: 1.10–2.66; $p=0.016$). Other clinical predictors included advanced Child–Pugh class (B/C vs. A; $p<0.05$) and lower platelet count. An FGF21 cutoff of 426 pg/mL discriminated cachexia prevalence in the discovery (38.3% vs. 20.0%; $p=0.006$) and validation cohorts (40.7% vs. 15.7%; $p=0.014$).

Conclusions:

Serum FGF21 is a novel, clinically relevant biomarker for predicting cachexia in CLD, enabling earlier detection and intervention to improve prognosis.

Keyword(s) : cachexia, fibroblast growth factor, liver cirrhosis, chronic liver disease, biomarker

1108 - Comparison of Liver Biopsy with Shear Wave Elastography and Other Non Invasive Fibrosis Markers in Chronic Hepatitis B

Ferhan Cahit Avci¹, Ayşe Albayrak¹, Fatih Albayrak²
Faculty Of Medicine, Atatürk University, Infectious Diseases And Clinical Microbiology, Erzurum-Türkiye¹
Faculty Of Medicine, Atatürk University, Gastroenterology, Erzurum-Türkiye²

Background / Hypothesis: Liver fibrosis severity is a key determinant of disease prognosis and treatment strategy in chronic hepatitis B (CHB). Although liver biopsy (LB) remains the gold standard for fibrosis assessment, it is invasive, costly, and carries potential complications, which limit its routine use.

Consequently, several non-invasive methods such as biochemical indices—Fibrosis-4 (FIB-4) and Aspartate Aminotransferase to Platelet Ratio Index (APRI)—and radiological techniques like transient elastography (TE) and magnetic resonance elastography (MRE) have been developed. Shear-wave elastography (SWE) is a relatively new, ultrasound-based, non-invasive method that quantitatively measures liver stiffness without requiring high-cost or regularly calibrated devices. This study aimed to compare fibrosis scores obtained by LB with those derived from SWE, FIB-4, and APRI in treatment-naïve CHB patients.

E-POSTER ABSTRACTS

Materials and Methods: Seventy patients aged 18–70 years, diagnosed with CHB and scheduled for liver biopsy at Atatürk University Faculty of Medicine, were included. None had received prior antiviral therapy. Shear-wave elastography (SWE) measurements were performed during routine abdominal ultrasonography. Laboratory parameters, including AST, ALT, and platelet count, were recorded to calculate APRI and FIB-4 indices. Histopathological fibrosis stages obtained from liver biopsy were then compared with SWE, APRI, and FIB-4 results to determine diagnostic accuracy and predictive performance.

Results: Among 70 participants, 27 (38.6%) were female and 43 (61.4%) male, with a mean age of 43.2 ± 14.9 years. The area under the receiver operating characteristic curve (AUC) for SWE in predicting significant fibrosis (Metavir $F \geq 2$) was 0.784 ($p < 0.001$). The optimal SWE cutoff value for identifying significant fibrosis was determined as 7.28 kPa, yielding 88% sensitivity, 72% specificity, and a high negative predictive value of 98%. The AUCs for APRI and FIB-4 were 0.81 and 0.78, respectively, demonstrating comparable diagnostic accuracy. A statistically significant correlation was observed between SWE, serum fibrosis indices, and histological scores obtained from liver biopsy.

Conclusions: SWE and serum-based fibrosis markers (APRI and FIB-4) demonstrated strong concordance with liver biopsy findings in patients with chronic hepatitis B. Given their simplicity, reproducibility, low cost, and non-invasive nature, these approaches—alone or in combination—may serve as practical and reliable alternatives to liver biopsy for the evaluation and follow-up of hepatic fibrosis in clinical practice.

Keyword(s) : Hepatitis B, Liver fibrosis, Shear-Wave Elastography

1109 - Stereotactic body radiation therapy as an add on to targeted agents in patients with locally advanced hepatocellular carcinoma

Mohamed Hamouda Elkasaby¹, Omar Elkoumi²,
Mariam Khaled Elbairy²

Faculty Of Medicine, Al-azhar University, Department Of Research, Cairo-Egypt¹ Faculty Of Medicine, Suez University, Department Of Research, Suez-²

Background / Hypothesis:

Stereotactic body radiation therapy (SBRT) delivers high-precision, ablative radiation doses to tumors in few fractions, minimizing exposure to normal tissue. In patients with locally advanced hepatocellular carcinoma (HCC), SBRT achieves local control comparable to ablation and is not limited by tumor location. Preclinical and clinical data suggest that SBRT may induce immunogenic cell death, enhance antigen release, remodel the tumor microenvironment, and potentiate the effects of targeted agents or immunotherapy. This systematic review and meta-analysis aimed to assess the efficacy and safety of combining SBRT with targeted agents compared with targeted therapy alone in patients with locally advanced HCC.

Materials and Methods:

A systematic search of PubMed, Embase, and Cochrane CENTRAL was conducted through March 2025. Eligible studies included randomized controlled trials (RCTs) involving adult patients with locally advanced HCC treated with SBRT plus targeted agents versus targeted therapy alone, reporting efficacy and safety outcomes. Risk ratios (RRs) were pooled using a random-effects model.

Results:

Four RCTs using with 381 patients were included. Sorafenib or apatinib were the targeted agents in the included studies. SBRT significantly reduced one-year mortality (RR = 0.47, 95% CI: 0.28–0.78, $p < 0.01$) and two-year mortality (RR = 0.68, 95% CI: 0.51–0.91, $p < 0.01$) compared with targeted therapy alone. The combination achieved a higher overall response rate (RR = 1.53, 95% CI: 1.19–1.96, $p < 0.01$) and disease control rate (RR = 1.31, 95% CI: 1.11–1.54, $p < 0.01$). Adverse event (AE) rates were comparable between the two groups (RR = 1.02, 95% CI: 0.97–1.07, $p = 0.88$).

Conclusions:

SBRT in combination with targeted agents such as sorafenib or apatinib significantly improves survival and tumor response without increasing AE rate compared with targeted therapy alone in patients with locally advanced HCC. These results support integrating SBRT into multimodal treatment strategies for locally advanced HCC and warrant validation in large-scale prospective trials.

E-POSTER ABSTRACTS

Keyword(s) : Stereotactic body radiation, sorafenib, apatinib, hepatocellular carcinoma, locally advanced HCC

1111 - Effectiveness and safety of Fibrate Therapy in the treatment of adults with Primary Sclerosing Cholangitis A Systematic Review and Meta Analysis

Mark Angelo Pado¹, Celina Celeste Adraneda¹
Cardinal Santos Medical Center, Section Of Gastroenterology, San Juan City-Philippines¹

Background / Hypothesis:

Primary sclerosing cholangitis is characterized by the stricturing of the bile ducts, either intrahepatic or extrahepatic bile ducts, and co-existence of inflammatory bowel disease, of which it is usually found in around 70% of patients. The global prevalence of primary sclerosing cholangitis is estimated to be 16 per 100,000 individuals, and in the Philippines, the prevalence of primary sclerosing cholangitis was around 1%. The risk for complications in the presence of primary sclerosing cholangitis could lead to liver failure, development of cholangiocarcinoma, and possible colon malignancy. This study compared the fibrate therapy and placebo in terms of serum liver biomarkers and safety of patients with primary sclerosing cholangitis

Materials and Methods:

Meta-analysis was the research design used. Specifically, the main author obtained the research design, the methodology of these investigations, interventions used, results and outcomes of these respective studies, among many others. Two research studies of de Vries and colleagues and Hatami and colleagues were included in the meta-analytical assessment.

Results:

The investigation yielded statistical difference with 95% CI between placebo and fibrate therapy in terms of serum biomarkers specifically alkaline phosphatase (399.24 ± 173.57 vs. 261.85 ± 191.92 respectively, $p .050 < .05$). On the other hand, there was no statistical difference between placebo and fibrate therapy in terms of aspartate aminotransferase (66.02 ± 43.95 vs. 59.29 ± 39.86 respectively, $p .390 > .05$), alanine aminotransferase (72.09 ± 62.32 vs. 65.14 ± 42.37 respectively, $p .630 > .05$), total bilirubin (11.07 ± 10.17 vs. 10.52 ± 10.64 respectively, $p .390 > .05$), and serum albumin (22.27 ± 1.80 vs. 21.89 ± 3.23 respectively, $p .460 > .05$).

Conclusions:

Fibrate therapy could potentially improve the outcomes of primary cholangitis of patients. In this

regard, the initiation of fibrate therapy could be beneficial in improving the biochemical markers of the aforementioned disease, better prognosis, and may also alleviate pruritus in patients.

Keyword(s) : Fibrate Therapy, Liver Disease, Primary Sclerosing Cholangitis

1114 - Detection of HBV and HCV seroprevalence using rapid point of care tests among earthquake survivors in Southeastern Türkiye

Muhammed Bekçibaşı¹, Derya Çağlayan², Medine Erkan³, Murat Can⁴, Şafak Kaya⁵
University Of Health Sciences Gazi Yaşargil Training And Research Hospital,, Department Of Infectious Diseases, Diyarbakir-Türkiye¹ Diyarbakir Provincial Health Directorate, Department Of Epidemiology, Diyarbakir-Türkiye² Dicle University, Atatürk Faculty Of Health Sciences, Department Of Nursing, Diyarbakir-Türkiye³ Diyarbakir Provincial Health Directorate, Department Of Public Health, Diyarbakir-Türkiye⁴ University Of Health Sciences, Gazi Yaşargil Training And Research Hospital, Department Of Infectious Diseases, Diyarbakir-Türkiye⁵

Background / Hypothesis: Türkiye has a moderate seroprevalence of HBV infection in its general population, with the Southeastern Anatolia Region exhibiting the highest rate. In contrast, the seroprevalence of HCV infection in Türkiye is low. The study aimed to determine the prevalence of HBV and HCV in the communities affected by the earthquake in Southeastern Türkiye.

Materials and Methods: This was a cross-sectional study in Southeastern Türkiye in December 2023, eleven months after the 2023 Türkiye-Syria earthquakes. HBsAg and anti-HCV were investigated using rapid screening tests on blood samples from participants selected from 251 containers, where 1,213 people resided.

Results: Out of 251 samples tested, 13 (5.2%) were positive for HBV, while none (0.0%) tested positive for HCV. When comparing the risk factors for HBV infection between the positive and negative groups, earthquake survivors who tested positive for HBsAg were significantly more likely to be male sex ($p=0.018$) and to have a family history of HBV ($p<0.001$). There were no significant differences ($p > 0.05$) in age, number of household members, education level, marital status, history of surgery or dental procedure, tattoo-piercing, and history of blood transfusion.

E-POSTER ABSTRACTS

Conclusions:In Southeastern Türkiye, 5.2% of earthquake survivors tested positive for HBsAg using rapid point-of-care tests. More comprehensive studies are needed to determine the prevalence of HBsAg and anti-HCV in the general population and to identify risk factors.

Keyword(s) : HBV, HBsAg, anti-HCV, point-of-care tests, prevalence.

1115 - Effectiveness and Follow up Challenges of Sofosbuvir Velpatasvir in HCV HIV Co infected Patients A Real world Experience from a Chinese Cohort

Wei Lv¹

Hepatobiliary Hospital Of Jilin, Internal Medicine, Changchun-China¹

Background / Hypothesis:HCV/HIV co-infected patients represent a unique population with complex clinical needs and potential socioeconomic vulnerabilities, which may impact treatment adherence and follow-up. This study aimed to evaluate the real-world effectiveness of sofosbuvir/velpatasvir (SOF/VEL) in HCV/HIV co-infected individuals and analyze challenges in sustaining post-treatment virologic monitoring.

Materials and Methods:We retrospectively analyzed 35 HCV/HIV co-infected patients treated with SOF/VEL for 12 weeks between 2021 and the present. All lost to follow-up at end-of-treatment (EOT) were contacted for 12-week virologic reassessment with free HCV RNA testing.

Results:Among 35 patients, baseline median HCV RNA was 1.83×10^6 IU/mL; 6 of 31 with Fibro Scan data had F3 or higher fibrosis, and 2 were treatment experienced. At EOT, 4 patients loss to follow up, 29 patients tested with an assay (LLOQ 1000 IU/mL) all had undetectable HCV RNA or levels below LLOQ. Of 3 patients tested with a high-sensitivity assay (LLOQ 15 IU/mL), 2 had low-level viremia (<1000 IU/mL). At post-treatment week 12, 14 patients returned for free testing (LLOQ 15 IU/mL), all achieving SVR, including the 2 with low-level viremia at EOT. Two additional patients reported negative self-test results from external labs. The remaining 15 declined follow-up. The

SVR12 rate was 100% among those retested (16/16). However, high loss-to-follow-up rates at EOT (11.4%) and during SVR12 assessment (57.1% attrition/refusal) highlighted significant retention challenges. No significant adverse event or drug to drug interaction was identified.

Conclusions:SOF/VEL demonstrated high efficacy in HCV/HIV co-infected patients. The substantial attrition underscores the need for tailored follow-up strategies in this special population, where socioeconomic factors, stigma, and complex clinical dynamics may hinder long-term monitoring. Proactive retention measures are critical to ensure complete outcome ascertainment in real-world settings.

Keyword(s) : HIV/HCV coinfection, sofosbuvir/velpatasvir, sustained virologic response, retention challenges

1119 - Metabolic Associated Fatty Liver Disease in Obese and At Risk Children and Adolescents in Türkiye A Meta Analysis of Prevalence

Eda Kaya¹, Caglayan Kekklikiran², Mehlika Toy³, Yusuf Yilmaz²

University Hospital, Knappschaft Kliniken Bochum, Ruhr University, Department Of Medicine, Bochum-Germany

¹ School Of Medicine, Recep Tayyip Erdogan University, Department Of Gastroenterology, Rize-Türkiye²

Erasmus School Of Health Policy And Management, Erasmus University, Department Of Health Technology Assessment, Rotterdam-The Netherlands³

Background / Hypothesis:

Metabolic associated fatty liver disease (MAFLD), formerly referred to as non-alcoholic fatty liver disease (NAFLD), is the most common chronic liver disease worldwide, affecting approximately 30% of the adult population, with its burden expected to increase further in the future. In Türkiye, prevalence has been reported to reach up to 50% in certain regions. Among children, the overall prevalence of MAFLD is estimated at around 7%, and early manifestation is associated with a more severe prognosis. Despite this growing burden, no systematic analysis of pediatric MAFLD prevalence in Türkiye has yet been conducted. Here, we aimed to estimate the pediatric MAFLD prevalence in Türkiye.

Materials and Methods:

A comprehensive literature search was conducted for

E-POSTER ABSTRACTS

studies published in English and/or Turkish between 2005 and 2023 using the databases MEDLINE, PubMed, EMBASE, and UlakBim. The search strategy included the following terms: 'Turkey AND NAFLD AND Pediatric' and 'Turkey AND NAFLD AND Prevalence AND Children AND Adolescent.' The studies identified through this literature review were incorporated into the meta-analysis.

Results:

The pooled overall prevalence of MAFLD across the 56 studies, from which 51 studies included obese children, was estimated at 44.6% (95% CI: 39.5–49.7).

Heterogeneity among studies was considerable, with an I^2 value of 96%, indicating substantial variability. Subgroup analysis showed a pooled prevalence of 54.9% in boys (95% CI: 48.6–61.1) and 41.2% in girls (95% CI: 35.6–46.9). Regionally, the prevalence was 49.0% (95% CI: 41.2–57.1) in the Marmara and Aegean regions, and 42.2% (95% CI: 35.3–49.1) in the Black Sea, Mediterranean, and Central Anatolian regions.

Conclusions:

The results of this study indicate a markedly high prevalence of MAFLD among children and adolescents, which is expected to substantially contribute to the future disease burden. These findings should serve as an alert for policymakers to adapt healthcare strategies aimed at preventing childhood obesity and MAFLD.

Keyword(s) :

1120 - Research Trends of Targeted Drugs for Nonalcoholic Fatty Liver Disease A Bibliometric Analysis (2004–2024)

Xingru Wang¹, Li Cao¹, Xianghong Guo²

Southwest Hospital, Army Medical University, Department Of Hepatobiliary Surgery, Chongqing-China¹ Qujing Second People's Hospital Of Yunnan Province, Department Of Surgery, Qujing-China²

Background / Hypothesis:The incidence of nonalcoholic fatty liver disease (NAFLD) increases annually; therefore, it is the leading cause of liver-related morbidity and mortality worldwide. No targeted drugs are available for the treatment of NAFLD. We conducted a bibliometric analysis of publications in the field of NAFLD-targeted drug research to identify research hotspots and trends over the past two decades to provide insights that allow rapid grasping of research priorities and guide future investigations.

Materials and Methods:We retrieved all English-language publications about NAFLD-targeted drug research from the Web of Science Core Collection database available between January 1, 2004, and June 7, 2024. Data were exported and stored as Excel files and plain text. Then, they were analyzed and visualized using Microsoft Office Excel 2021, VOSviewer, CiteSpace, and the R package "bibliometrix."

Results:A total of 1,393 publications were included in this study. The analysis revealed a significant increase in research activity over the past 20 years and accelerated growth in publications and citations after 2020. The field of NAFLD-targeted drug research is characterized by the dominance of China and the United States (USA). China produced the most publications, whereas the USA had the most citations. Scholars and institutions in the USA emerged as global academic hubs through extensive international collaboration; however, research in China remained domestically focused. Research themes have evolved from traditional hepatology to interdisciplinary integration (molecular biology and pharmacology). Keywords and citation analyses identified three major research directions: disease mechanisms and pathophysiology, molecular targets and drug development, and multi-omics/technological integration.

Conclusions:We elucidated the evolving research trends of NAFLD-targeted therapeutics and provided a reference framework for exploring novel directions in NAFLD-targeted therapeutics.

Keyword(s) : nonalcoholic fatty liver disease; drug development; bibliometrics; research

1124 - Single arm meta analysis and systematic review on clinical cure of chronic hepatitis B after hematopoietic stem cell transplantation immunoregulatory mechanisms and clinical translational insights

He Ma¹, Jiarui Zheng¹, Linxiang Huang¹, Zixuan Qiu¹, Zilong Wang¹, Yandi Xie¹, Bo Feng¹
Peking University People's Hospital, Peking University Hepatology Institute, Bei Jing-China¹

Background / Hypothesis: The quest for a functional cure for chronic hepatitis B (CHB) remains an elusive objective. Hematopoietic stem cell transplantation

E-POSTER ABSTRACTS

(HSCT) may elicit viral clearance by immunological remodelling in recipients with positive-HBsAg; however, the factors that determine its effectiveness are yet unknown. The aim of the study is to assess HSCT-induced hepatitis B surface antigen (HBsAg) seroclearance rates and identify immunological mechanisms and combination therapy strategies through meta-analysis and systematic review.

Materials and Methods: In this study, nine trials (308 patients) were subjected to single-arm meta-analysis (R4.4.2 "meta" package) in accordance with PRISMA/Cochrane criteria. Heterogeneity was addressed via random-effects models ($I^2 = 87.1\%$). Subgroup analyses were performed to explore the influence of donor and recipient immune status on the HBsAg clearance rate. The Newcastle-Ottawa Scale (NOS) and the Risk Of Bias In Non-randomized Studies of Interventions (ROBINS-I) tool were used to evaluate the quality and bias of the included studies.

Results: The total HBsAg clearance rate was 26% (95% CI:14% to 39%), greater than that of standard therapies. Notably, HBsAb-positive donors had significantly enhanced clearance (55% vs. 8%, $p < 0.01$). HBeAg-negative recipients fared better (29% vs. 2%). In patients who achieved HBsAg loss, HBsAb-positive donors and HBeAg-negative recipients are the most prevalent types (10/11). Sensitivity analyses confirmed robustness and publication bias was nonsignificant (Egger's $p = 0.271$). We propose a two-phase immunomodulation model for HSCT-induced HBsAg seroclearance. In phase I (passive immunomodulation period), donor-derived HBsAb passively neutralizes the existing pool of circulating HBsAg, lowering the antigenic burden of HBsAg and interrupting the cycle of antigen overload-induced immunosuppression. In phase II (active immune reconstitution period), donor T cells are progressively differentiated into HBV-specific effector T cells that can directly kill cccDNA-positive hepatocytes and induce epigenetic suppression of viral transcription.

Conclusions: In this study, we found that HSCT, especially with HBsAb-positive donors and HBeAg-negative recipients, may present a promising approach toward achieving a functional cure in CHB patients. Although HSCT is clinically challenging due to its procedures and high risks involved, it provides valuable information regarding the immunological mechanisms underlying HBsAg clearance. These findings may guide the design of targeted immunotherapies that can

achieve the same efficacy as HSCT while minimizing potential risks, thereby advancing the safer and more feasible pursuit of functional cures for CHB in response to the WHO's 2030 elimination goal. Nevertheless, substantial clinical heterogeneity among included studies and limited follow-up duration are limitations of this study. Future studies

Keyword(s) : Chronic Hepatitis B, Hematopoietic Stem Cell Transplantation, Functional Cure, Immune Reconstitution, Meta-Analysis

1128 - Zinc alpha 2 glycoprotein (ZAG) emerges as a diagnostic biomarker for Hepatitis B virus related acute on chronic liver failure (HBV ACLF)

Daxian Wu¹, Xueying Zhang¹, Xiaochun Shi², Yitian Wang¹, Nan Wang¹, Yanfang Wang¹, Qunfang Rao¹
The First Affiliated Hospital Of Nanchang University, Department Of Infectious Diseases, Nanchang-China¹
The First Affiliated Hospital Of Nanchang University, Department Of Rheumatology And Immunology, Nanchang-China²

Background / Hypothesis:

Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) is a critical syndrome with high mortality, and the absence of reliable prognostic biomarkers poses a significant challenge to its clinical management. The pathogenesis involves viral replication, excessive inflammation, and dysregulated lipid metabolism. Emerging evidence indicates that zinc-alpha 2-glycoprotein (ZAG) modulates these pathways and exerts protective effects in nonalcoholic fatty liver disease (NAFLD). Given these mechanistic parallels, this study sought to determine whether ZAG expression in patient serum and liver tissue could serve as a prognostic biomarker for HBV-ACLF.

Materials and Methods:

A cross-sectional survey involving 72 subjects, including negative controls, Chronic Hepatitis B (CHB) patients, patients with liver cirrhosis (LC), LC-AD, and ACLF was performed. And a prospective longitudinal cohort study was conducted at the First Affiliated Hospital of Zhejiang University and the First Affiliated Hospital of Nanchang University involving 355 patients with HBV-ACLF to assess the prognostic capacity of ZAG. ZAG levels were measured using a commercial ELISA kit, and statistical analyses were conducted using SPSS and Medcalc software.

Results:

E-POSTER ABSTRACTS

The results demonstrated that ZAG levels decreased progressively with the advancement of liver disease severity ($P<0.001$). Moreover, the ZAG levels in non-survivors were lower than those in survivors ($P<0.001$). Multivariate Cox regression analysis revealed that ZAG was an independent prognostic factor for HBV-ACLF. Patients with lower ZAG levels had a higher mortality rate of 31.7%, while those with higher ZAG levels had a mortality rate of 11%. When patients were stratified based on their cirrhosis status, ZAG remained an independent prognostic factor, regardless of whether they had cirrhosis. As the number of failing organs increased, the ZAG levels decreased correspondingly ($P<0.001$), which was closely associated with coagulation dysfunction and renal failures. At the end of the assessment period (14th day after admission or discharge), the ZAG levels increased significantly in the improvement group ($P<0.001$), decreased significantly in the deterioration group ($P=0.035$). We developed a novel prognostic model (ZAG3TIH) incorporating ZAG. This model demonstrated superior performance for predicting 30-day mortality, achieving an AUROC of 0.881 and significantly outperforming conventional scores such as Child-Pugh, MELD and CLIF-SOFA.

Conclusions:

In conclusion, ZAG demonstrates promising potential as an independent prognostic biomarker for HBV-ACLF. Sequential monitoring of circulating ZAG levels may be valuable for tracking disease progression. It is expected to improve current commonly used ACLF prognostic models. Further studies are needed to explore

Keyword(s) : Zinc-alpha 2-glycoprotein; biomarker; Prognostic model; Dynamic monitoring

1129 - Efficacy of albumin infusion for hypoalbuminemia in post operative period in living donor liver transplantation – An open label randomized controlled trial

Vipul Gautam¹, Kalpana Panda¹, Dibya Jyoti Das², Sanjiv Saigal³, Subhash Gupta⁴

Max Centre For Liver And Biliary Sciences, Pediatric Hepatology, New Delhi-India¹ Max Centre For Liver And Biliary Sciences, Intensive Care Unit, New Delhi-India² Max Centre For Liver And Biliary Sciences, Hepatology, New Delhi-India³ Max Centre For Liver And Biliary Sciences, Liver Transplant Surgery, New Delhi-India⁴

Background / Hypothesis:

Albumin is commonly administered for hypoalbuminemia in immediate post-liver transplant period to improve oncotic pressure and recovery, but evidence is limited. Hypoalbuminemia is often due to capillary-leak rather than reduced synthesis. This study aimed to compare surgical drain output on postoperative day (POD) 5 in patients receiving or not receiving albumin infusion.

Materials and Methods:

In this single-center, prospective, open-label randomized trial (CTRI/2024/07/071234), adult living donor liver transplant (LDLT) recipients were randomized to receive either albumin infusions (target serum albumin ≥ 3.0 g/dL) or no albumin, continued through POD-5. Outcomes including drain output, fluid balance, biochemical markers, and complications were assessed till POD-5 and at discharge.

Results:

Eighty-six adult LDLT recipients were randomized into two equal groups ($n=43$ each) to receive either albumin infusions or no albumin. Baseline demographics, surgical details, and graft characteristics were comparable. On POD-5, serum albumin levels were significantly higher in the albumin arm (3.1 vs 2.4 g/dL, $p<0.005$). The no-albumin group demonstrated a significantly lower median surgical drain output on POD-5 (450 vs 1100 mL, $p=0.043$), representing a 59% reduction compared to the albumin arm. Although urine output was higher in the albumin group (1555 vs 1210 mL, $p=0.022$), the overall cumulative fluid balance remained more positive (5685 vs 4798 mL, $p=0.049$), suggesting greater fluid retention and relative volume overload (Table attached). Despite this, renal function indices were comparable between groups. Notably, the incidence of sepsis was significantly higher in the no-albumin group (27.9% vs 7%, $p=0.021$). Renal function markers, inotropic support, lactate levels, tacrolimus dosing and trough levels, body weight, and time to drain cessation were comparable between groups. Tacrolimus toxicity occurred more frequently in the no-albumin arm (15 vs 5 cases, $p=0.020$). ICU stay (7 [6–14] vs 7 [6–11] days, $p=0.351$), and hospital stay (21 [20–33] vs 22 [19–35] days, $p=0.785$), were comparable, with no mortality in either group.

Conclusions:

Omitting albumin infusion in the immediate post-LDLT period reduced surgical drain output and fluid

E-POSTER ABSTRACTS

accumulation on POD-5 without adversely affecting renal function, ICU stay, hospital stay, or mortality, although higher sepsis rates and tacrolimus toxicity were observed.

Keyword(s) : Liver transplantation; albumin infusion; fluid balance; postoperative outcomes.

1131 - Dietary Total Antioxidant Capacity and Metabolic Dysfunction Associated Steatotic Liver Disease a cross sectional study

Yani Zhou¹, Sisi Yang¹, Jiyang Chen¹, Zelu Meng¹, Ying Nie¹, Yining Zhang¹, Siqi Sun¹, Yan Lv¹, Yida Yang¹

The First Affiliated Hospital, Zhejiang University School Of Medicine, Infectious Diseases, Hangzhou-China¹

Background: Metabolic dysfunction associated fatty liver disease (MASLD) is a serious public health problem. Dietary antioxidant intervention is an effective measure to manage diseases. Dietary total antioxidant capacity (TAC) is an index to evaluate antioxidant capacity. There are limited data on its association with MASLD.

Objective: This study aimed to investigate the association between dietary TAC and MASLD in US adults.

Methods: We analyzed cross-sectional data from 8,470 participants of the National Health and Nutrition Examination Survey (NHANES) 2017–2023. Dietary TAC was estimated using 24-hour dietary recall data.

Weighted logistic regression models and restricted cubic splines (RCS) were employed to evaluate the association between dietary TAC and MASLD.

Results: Among the participants, 3165 had MASLD, of whom 517 were identified as having at-risk MASH. After adjusting for confounders, dietary TAC was inversely associated with the prevalence of MASLD (OR=0.90, 95% CI: 0.84–0.97, P = 0.009). Compared to the lowest quartile (Q1), participants in the highest quartile (Q4) of log-transformed dietary TAC had 33% lower odds of MASLD (OR=0.67, 95% CI: 0.54 - 0.83, P <0.001), with a significant dose-response trend (P for trend = 0.002). Dose-response analysis showed that dietary TAC was negatively and non-linearly associated with the risk of MASLD, which was mainly driven by vitamin C, vitamin E, β -carotene, and lutein-zeaxanthin. No significant association was found between dietary TAC and a high risk of at-risk MASH.

Conclusion: Higher dietary TAC may be protective against MASLD, while the evidence is insufficient for its role in at-risk MASH.

1135 - Impact of Low Dose Rifaximin on Gut Antibiotic Resistance Genes in Patients with Decompensated Cirrhosis

Zhiyuan Hao¹

Shanghai East Hospital, Tongji University, Department Of Gastroenterology, Shanghai-China¹

Background / Hypothesis:

Decompensated cirrhosis patients are prone to bacterial infections and frequent antibiotic exposure, leading to elevated gut antibiotic resistance gene (ARG) burden. Rifaximin, a broad-spectrum non-absorbable antibiotic recommended for hepatic encephalopathy (HE) prevention, raises concerns about potential ARG enrichment despite its clinical benefits. We aimed to clarify the impact of low-dose rifaximin on gut resistome dynamics in decompensated cirrhosis.

Materials and Methods:

This secondary analysis utilized fecal metagenomic data from a multicenter randomized trial (NCT02190357). 42 patients with decompensated cirrhosis were enrolled; 26 received rifaximin (400 mg twice daily) for 6 months. Gut resistomes were profiled using shotgun metagenomic sequencing and annotated against the Comprehensive Antibiotic Resistance Database (CARD). ARG diversity, resistance mechanisms, key antibiotic-resistant taxa, mobile genetic elements (MGEs), and phage-mediated horizontal gene transfer were systematically analyzed.

Results: Baseline profiling identified 564 antibiotic resistance ontologies (AROs) spanning 120 AMR gene families, predominantly conferring resistance to fluoroquinolones, macrolides, and tetracyclines via efflux pump mechanisms. 17 core taxa—principally *Escherichia coli*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa*, and *Escherichia fergusonii*—harbored the majority of ARGs. Low-dose rifaximin significantly reduced resistome α -diversity (ACE index: 440.7 ± 72.8 vs. 350 ± 27.2 , $p < 0.001$) and selectively depleted fluoroquinolone ($p = 0.003$), macrolide ($p = 0.007$), and streptogramin resistance genes ($p = 0.012$). The intervention achieved dual suppression of ARG reservoirs: (1) selective depletion of high-ARG-load bacteria (*E. coli*, *K. pneumoniae*, *P. aeruginosa*, *E.*

E-POSTER ABSTRACTS

fergusonii; all $p < 0.05$); (2) disruption of phage-mediated horizontal gene transfer (MGE-AROs: 86→40, $p < 0.001$; phage-AROs significantly reduced, $p = 0.002$). Crucially, rifaximin did not induce cross-resistance to anti-tuberculosis agents; instead, it reduced ethA ($p = 0.017$) and iniC ($p = 0.032$) abundance.

Conclusions:

Low-dose rifaximin paradoxically suppresses the gut resistome in decompensated cirrhosis via dual mechanisms: targeted elimination of ARG-harboring pathobionts and inhibition of phage-driven resistance dissemination. These findings challenge conventional assumptions about broad-spectrum antibiotic-induced resistance enrichment and support rifaximin's expanded therapeutic role in antibiotic stewardship for vulnerable cirrhotic populations.

1136 - Catastrophic unmasking Fatal tuberculosis associated Immune Reconstitution Inflammatory Syndrome presenting as acute liver failure in pregnancy

Carmela Bianca Villacete¹, Sherry Navarro², Ryan Llorin³, Cervantes Julieta⁴

St. Luke's Medical Center, Medicine, Quezon City-Philippines¹ St. Luke's Medical Center, Obstetrics And Gynecology, Quezon City-Philippines² St. Luke's Medical Center, Infectious Disease, Quezon City-Philippines³ St. Luke's Medical Center, Gastroenterology, Quezon City-Philippines⁴

Background / Hypothesis:

Immune Reconstitution Inflammatory Syndrome (IRIS) is a severe, potentially fatal inflammatory condition that can occur in severely immunocompromised patients, such as those with HIV, after initiating antiretroviral therapy (ART). The syndrome is triggered by a restored immune system recognizing and over-reacting to pre-existing opportunistic pathogens. Tuberculosis-associated IRIS (TB-IRIS) poses a significant diagnostic and therapeutic challenge, particularly in pregnancy, where physiological changes and complex health considerations for both mother and fetus add layers of complexity. This report highlights a catastrophic presentation of TB-IRIS as fulminant hepatic failure in a pregnant patient newly started on ART.

Materials and Methods:

The case involves a 30-year-old female at 28 weeks gestation, recently diagnosed with HIV during prenatal screening and initiated on ART. Four weeks after starting treatment, she presented with symptoms of tuberculosis (fever, productive cough, night sweats, significant weight loss) which acutely worsened with the onset of jaundice and altered mental status. On admission, she was febrile and severely ill. Laboratory investigations revealed pancytopenia, severe transaminitis, hyperbilirubinemia, and coagulopathy. Mycobacterium tuberculosis was confirmed from sputum and ascitic fluid, and her CD4 count was critically low at 8%.

Results:

The patient was diagnosed with disseminated tuberculosis. However, both her ART and first-line anti-tuberculosis therapy were discontinued due to rapidly deteriorating liver function. Her clinical condition declined, marked by fetal distress, which necessitated an emergency Cesarean section. Post-operatively, she remained critically ill with persistent fever, worsening coagulopathy, and the development of ascites and encephalopathy, consistent with acute liver failure. The diagnosis of TB-IRIS was made based on the paradoxical clinical deterioration following ART initiation. Despite aggressive supportive care, the patient developed disseminated intravascular coagulation (DIC), progressive hepatic failure, and ultimately suffered cardiac arrest and death.

Conclusions:

This case underscores the diagnostic complexity and devastating potential of TB-IRIS, especially in pregnant women with advanced immunosuppression. The exaggerated inflammatory response can mimic other conditions and lead to catastrophic outcomes like fulminant liver failure. It highlights the critical importance of screening for latent and active opportunistic infections, such as tuberculosis, before initiating ART in high-risk patients. Clinicians should maintain a high index of suspicion for IRIS in patients who show paradoxical worsening after starting therapy, as early recognition is paramount.

Keyword(s) : Acute Liver Failure, Immune Reconstitution Inflammatory Syndrome, Pregnancy, Human Immunodeficiency Virus, Tuberculosis

1138 - Peripheral Single Cell Immune Profiling of HBsAg Loss in HBV Related Hepatocellular

E-POSTER ABSTRACTS

Carcinoma Receiving Anti PD 1 Therapy

Pengyuan Kang¹, Bo Li², Tao Shen¹

Peking University Health Science Center, Department Of Microbiology And Center Of Infectious Disease, School Of Basic Medical Sciences, Beijing-China¹ The Affiliated Hospital Of Southwest Medical University, Department Of General Surgery (hepatopancreatobiliary Surgery), Luzhou-China²

Background / Hypothesis:

Hepatitis B virus-related hepatocellular carcinoma (HBV-HCC) remains a major clinical challenge, driven by concurrent tumor progression and persistent viral antigenemia. While anti-PD-1 therapy has improved HCC prognosis by reinvigorating antitumor immunity, its role in promoting hepatitis B surface antigen (HBsAg) clearance during chronic HBV infection remains incompletely understood.

Materials and Methods:

Overall survival and HBsAg dynamics were retrospectively analyzed in a cohort of 211 HBV-HCC patients. Peripheral blood mononuclear cells from selected patients underwent single-cell RNA sequencing and T-cell receptor (TCR)/B-cell receptor (BCR) repertoire profiling. Functional validation was performed using cytokine assays and flow cytometry following PD-1 blockade and HBV peptide stimulation.

Results:

Anti-PD-1 therapy significantly prolonged overall survival (HR = 0.21, $p < 0.001$) and promoted HBsAg reduction in HBV-HCC patients ($p < 0.05$). Single-cell transcriptomic profiling revealed that HBsAg-negative patients exhibited enhanced activation signatures in T and NK cells, characterized by upregulated expression of JUN, FOS, CD69, and NFkBIA, coordinated activation of TNF and IL-18 signaling pathways. B cells also displayed upregulation of CD69, CD83, and HLA-DQA. Moreover, scRNA-TCR/BCR analyses uncovered biased V-J gene usage in patients who achieved HBsAg seroclearance. Functionally, PD-1 blockade selectively enhanced IFN- γ and TNF- α production in HBV core-specific T cells.

Conclusions:

Anti-PD-1 therapy enhances both survival and HBsAg decline in HBV-HCC by orchestrating reactivation of T, NK, B, and myeloid cells through IL-18 and TNF- α .

-mediated immune remodeling. This multicellular synergy bridges antiviral and antitumor immunity, revealing a dual mechanism of immune restoration under PD-1 blockade.

Keyword(s) : Anti-PD-1; Single-cell RNA sequencing; HBV-HCC; HBsAg seroclearance; Immune remodeling

1142 - From Naïve to Non Responders under DAA Pressure Unveiling NS5A and NS5B Resistance Associated Substitutions in HCV Genotype 3a from Bangladesh

Mahmuda Jahan Jahan¹, Tahmina Akther Akther¹, Afzalun Nessa Nessa¹

Bangladesh Medical University, Virology, Dhaka-Bangladesh¹

Background / Hypothesis:

Hepatitis C virus (HCV) remains a critical global health challenge, infecting approximately 58 million people worldwide and causing chronic liver disease, cirrhosis, and hepatocellular carcinoma. Among the circulating genotypes, HCV genotype 3a predominates in Bangladesh is associated with hepatic fibrosis and comparatively lower treatment success rates. Although DAAs are highly effective, RASs in NS5A and NS5B proteins can compromise sustained virological response (SVR). This study aimed to determine the prevalence and pattern of RASs in the NS5A and NS5B regions of HCV genotype 3a among treatment-naïve and DAA-experienced patients in Bangladesh, to elucidate their role in antiviral resistance and treatment outcomes.

Materials and Methods:

A total of 45 HCV genotype 3a 3a-infected patients were analyzed, of which 25 were treatment-naïve and 20 were DAA-failing individuals. Viral RNA was extracted from plasma samples, followed by cDNA synthesis and nested PCR amplification of the NS5A and NS5B regions using genotype 3a-specific primers. Amplicons were subjected to bidirectional Sanger sequencing, and nucleotide sequences were compared to reference HCV genotype 3a sequences. Amino acid substitutions were analyzed using the Geno2Pheno [HCV] online platform to predict potential resistance to Daclatasvir, Velpatasvir, and Sofosbuvir.

Results:

E-POSTER ABSTRACTS

RASs were detected exclusively within the NS5A region, while no mutations were found in NS5B. Among patients who failed DAA therapy, the predominant substitution was A62S (73.7%), whereas A62T was most frequent among treatment-naïve individuals (65.2%). Combined substitutions, including A62T + P58S (20%) and A62S + P58S + S98G (5%), were more frequently observed in DAA failure cases. The A62S variant showed susceptibility to both Daclatasvir and Velpatasvir, whereas A62L conferred reduced susceptibility to Daclatasvir. Clinically, patients with RASs showed more frequent liver cirrhosis and higher liver enzyme levels than treatment-naïve patients, indicating a link between RASs and advanced liver disease.

Conclusions:

NS5A-associated RASs, particularly A62S/T, play a key role in DAA treatment failure among patients infected with HCV genotype 3a in Bangladesh. The findings highlight the critical importance of routine molecular surveillance and baseline RAS screening to minimize the risk of resistance emergence. Integrating RAS monitoring into the national strategic plan for control of viral hepatitis program in Bangladesh is essential to optimize therapeutic outcomes and achieve HCV elimination goal by 2030.

Keyword(s) : hepatitis C virus, genotype 3a, direct-acting antiviral, resistance-associated substitutions, sanger sequencing.

1143 - Association between AST/ALT ratio and Hemodynamic Parameters of Carotid Arteries in Patients with Primary Aldosteronism: A Cross Sectional Study

Mengbo Wu¹

Department Of Cardiovascular Medicine, The 2nd Affiliated Hospital, Nanchang, Nanchang-China¹

Background / Hypothesis:

The relationship between the aspartate aminotransferase to alanine aminotransferase ratio (AST/ALT) and hemodynamic parameters of carotid arteries in patients with primary aldosteronism is unclear. Therefore, this study aimed to examine the association between the AST/ALT ratio and carotid arteries peak systolic velocity (PSV), end diastolic velocity (EDV) and the ratio of internal carotid arteries (ICA) PSV to common carotid artery (CCA) PSV in patients with primary aldosteronism (PA).

Materials and Methods:

This research was conducted at the 2nd Affiliated Hospital of Nanchang University and involved PA individuals hospitalized between October 17, 2017 and April 24, 2022. 700 eligible participants were included in the analysis for this research. Doppler spectra of the ICA were obtained 1-1.5 cm distal to the carotid bulb in all subjects. The site 1-2 cm proximal to the carotid bifurcation was defined as the measurement location for the common carotid artery. The study applied smooth curve fitting to examine the linearity of the AST/ALT ratio and ICA PSV, ICA EDV and the ICA PSV/CCA PSV ratio relationship. Multiple logistic regression models to quantify this association, presenting results from both crude and fully adjusted models. Stratified analyses to investigate potential effect modifiers.

Results:

Patients with the lowest level of Lg-AST/ALT ratio (T1), patients in T3 group had a higher level of the ICA PSV ($\beta=5.23$, 95% CI: 1.24-9.21) and a higher level of the ICA EDV ($\beta=2.09$, 95% CI: 0.45-3.72). A key finding is the age-dependent positive association between the Lg-AST/ALT ratio and both ICA PSV and the ICA PSV/CCA PSV ratio. After full adjustment for covariates, each standard deviation increase in the Lg-AST/ALT ratio was associated with a significant increase in ICA PSV ($\beta=26.23$; 95% CI: -0.67-53.14, P for interaction=0.034) and in the ICA PSV/CCA PSV ratio ($\beta=0.59$; 95% CI: 0.20-0.98, P for interaction=0.014), but only in individuals aged 60 and above. Similarly, a significant association was observed for the ICA PSV/CCA PSV ratio ($\beta=0.59$; 95% CI: 0.20-0.98, P for interaction=0.014) exclusively in subjects with a hypertension duration of five or more years.

Conclusion:

Age was identified as a critical effect modifier in the relationship between the Lg-AST/ALT ratio and both ICA PSV and the ICA PSV/CCA PSV ratio, necessitating age-stratified analytical approaches. Furthermore, the duration of hypertension also acted as a significant effect modifier for the association between the Lg-AST/ALT ratio and the ICA PSV/CCA PSV ratio, requiring stratification by hypertension duration in its investigation and application.

Keyword(s) : Primary aldosteronism, Aspartate

1145 - Targeting Cancer Associated Fibroblast Subpopulations and Metabolic Pathways to Enhance Immunotherapy in Hepatocellular Carcinoma

Xin Song¹, Boxiang Zhang¹, Xingrong Zheng¹, Wenbo Guo², Wenxiong Xu¹, Shengjiang Deng¹, Xiyao Chen¹, Tinglin Qian¹, Liang Peng¹, Chan Xie¹

The Third Affiliated Hospital Of Sun Yat-sen University, Department Of Infectious Diseases, Guangzhou-China¹
The First Affiliated Hospital Of Sun Yat-sen University, Intervention Radiology Department, Guangzhou-China²

Background / Hypothesis: Immune checkpoint inhibitors (ICIs) have revolutionized the treatment of hepatocellular carcinoma (HCC), yet significant challenges remain. Our previous research indicated that galacturonic acid (GA) is enriched in ICI responders and correlates with improved therapeutic outcomes, although its underlying mechanism is not fully understood. This study aimed to investigate the effect of GA on cancer-associated fibroblasts (CAFs) and associated metabolic pathways, proposing a CAF-mediated metabolic reprogramming mechanism that modulates the tumor microenvironment (TME) and enhances ICI efficacy.

Materials and Methods: We utilized single-cell RNA sequencing (scRNA-seq) to analyze three exploratory patients from our prior study, aiming to identify key metabolic pathways associated with ICI response. Subsequently, an additional eight patients were included to validate the effect of GA on CAF metabolic programming. The effects of GA on HCC and CAFs were further validated through both in vivo and in vitro experiments.

Results: Analysis of the exploratory cohort revealed significant CAF heterogeneity between responders and non-responders. The validation cohort analysis demonstrated that GA treatment selectively reprogrammed CAF metabolism, leading to a downregulation of extracellular matrix production and an upregulation of oxidative phosphorylation. This metabolic shift resulted in a more immune-permissive TME. In vitro assays confirmed that GA-treated CAFs suppressed HCC cell proliferation, reduced immune evasion markers, and altered cytokine and chemokine signaling. In vivo experiments showed that GA-conditioned CAFs significantly slowed tumor

progression, increased CD8+ T cell infiltration, and decreased immunosuppressive cell populations.

Conclusions: This study establishes a novel GA-CAF-TME axis that modulates ICI response in HCC. By reprogramming CAF metabolism, GA creates a less immunosuppressive TME, thereby enhancing ICI efficacy. These findings highlight GA as a promising biomarker and a potential therapeutic adjunct for HCC immunotherapy.

1146 - Treatment with direct acting antivirals in HCV infected patients after liver transplantation

Dorota Zarębska-michaluk¹, Michał Brzdęk², Olga Tronina³, Łukasz Laurans⁴, Ewa Janczewska⁵, Dorota Dybowska⁶, Anna Parfieniuk-kowerda⁷, Magdalena Tudrujek-zdunek⁸, Jolanta Białkowska-warzecha⁹, Justyna Janocha-litwin¹⁰, Robert Flisiak⁷
Jan Kochanowski University, Department Of Infectious Diseases And Allergology, Kielce-Poland¹ Jan Kochanowski University, Collegium Medicum, Kielce-Poland² Infant Jesus Clinical Hospital, Clinic Of Transplantology, Immunology, Nephrology And Internal Medicine, Warszawa-Poland³ Pomeranian Medical University, Department Of Infectious Diseases, Hepatology And Liver Transplantation, Szczecin-Poland⁴ Id Clinic, Infectious Disease Clinic, Mysłowice-Poland⁵ Nicolaus Copernicus University, Department Of Infectious Diseases And Hepatology, Faculty Of Medicine, Collegium Medicum In Bydgoszcz, Bydgoszcz-Poland⁶ Medical University Of Białystok, Department Of Infectious Diseases And Hepatology, Białystok-Poland⁷ Medical University Of Lublin, Department Of Infectious Diseases, Lublin-Poland⁸ Biegański Regional Specialist Hospital, Ward Of Infectious Diseases, Łódź-Poland⁹ Medical University Of Wrocław, Infectious Diseases And Hepatology Clinic, Wrocław-Poland¹⁰

Background / Hypothesis:

Chronic hepatitis C virus (HCV) infection remains a major indication for orthotopic liver transplantation (OLTx) worldwide. Direct-acting antivirals (DAAs) have revolutionised the management of HCV, offering highly effective and well-tolerated treatment options, even in populations that are difficult to treat. However, real-world data on the effectiveness and safety of DAA therapy in liver transplant recipients remain limited, particularly from Central and Eastern Europe.

E-POSTER ABSTRACTS

This study aimed to evaluate the clinical characteristics, effectiveness, and safety of DAA therapy in liver transplant recipients with chronic hepatitis C in a nationwide, real-world cohort.

Materials and Methods:

A retrospective analysis was performed of all consecutive adult patients who underwent OLTx before starting DAA therapy between July 2015 and December 2024 in the EpiTer-2 project, which included 20,586 patients treated because of chronic hepatitis C.

Results:

A total of 141 patients participated in the study, with most being men (66%) and aged 50 years or older. In 81 patients (57%), the reason for transplantation was cirrhosis without liver cancer, in 58 patients (41%), liver transplantation was performed due to liver cancer, and in 2 patients, the reason for the procedure was unknown. Most patients (80%) had comorbidities, and nearly a quarter of the population had cirrhosis of the transplanted liver at the start of antiviral therapy, including 10 patients with decompensated cirrhosis. The predominant HCV genotype was GT1b. The median time from OLTx to initiation of antiviral therapy was 24 months. Tacrolimus-based immunosuppression was used in 86% of patients. The most commonly used DAA regimens were OBV/PTV/r±DSV±RBV and SOF/LDV±RBV. Overall, SVR was achieved in 96.4% of patients in the intention-to-treat analysis and in 98.6% after excluding patients lost to follow-up. Treatment was well tolerated: 57% of patients experienced at least one adverse event, mainly of mild severity. Serious adverse events were reported in five patients, leading to discontinuation of treatment in two patients. During DAA treatment and 12 weeks of follow-up after treatment, two deaths were reported, both in patients who had undergone transplantation due to hepatocellular carcinoma. Subgroup analysis by time from OLTx to antiviral therapy (≤ 24 vs. > 24 months) revealed no differences in effectiveness and safety despite some baseline clinical variations.

Conclusions:

DAA therapy in liver transplant recipients with chronic HCV infection is highly effective and well-tolerated. These results confirm that DAA treatment regimens can be safely and effectively used in transplant patients, reinforcing their role as the standard of care in this high-risk population.

Keyword(s) : chronic hepatitis C, hepatitis C virus, liver transplantation, direct-acting antivirals

1148 - Deciphering the Mechanism of Aristolochic Acid I Driven Hepatocellular Carcinoma through Integrated Network Toxicology and Bioinformatics

Yuling Liang¹, Xing Ning¹, Qiuxia Chen¹, Shuqiao Zhang², Huishan Luo¹, He Yu¹, Tangjiaqi Li¹, Baoguo Sun¹, Shijun Zhang¹

The First Affiliated Hospital, Sun Yat-sen University, Department Of Traditional Chinese Medicine, Guangzhou-China¹ The First Affiliated Hospital Of Guangzhou University Of Chinese Medicine, Department Of Traditional Chinese Medicine, Guangzhou-China²

Background / Hypothesis: Aristolochic acid I (AAI) is a known liver carcinogen, but its molecular mechanisms in hepatocellular carcinoma (HCC) remain incompletely understood. This study aimed to systematically elucidate these mechanisms.

Materials and Methods: This study employed a multidisciplinary strategy: assessing AAI carcinogenicity via ProTox-3.0; identifying its targets using PubChem; and screening HCC-related genes from GEO. Core genes were filtered through network toxicology and Lasso-Cox regression. Molecular docking and dynamics simulations analyzed AAI-protein interactions, while GO, KEGG and GSEA enrichment revealed relevant pathways. Key gene expression and clinical relevance were validated via TCGA and HPA databases.

Results: The carcinogenic potential of the AAI was 0.77. 52 potential targets of AAI-induced HCC were identified. Network toxicology analysis identified 12 core genes including EZH2, FABP5, and RXRA. Lasso-Cox regression analysis identified four core genes that drive HCC progression, including EZH2. Functional enrichment analysis revealed that AAI-HCC targets were significantly enriched in lipid metabolism and the PPAR signaling pathway ($p < 0.05$), with the PPAR signaling pathway being significantly activated in HCC. Molecular docking and MD simulations confirmed the high affinity and stable binding of AAI to EZH2, FABP5, and RXRA. Through in silico and database-based validation, biological samples and clinical data confirmed that these genes were significantly overexpressed in HCC ($p < 0.001$) and were correlated with poor prognosis ($p < 0.01$).

E-POSTER ABSTRACTS

Conclusions: AAI may synergistically activate the PPAR signaling pathway by targeting EZH2, FABP5, and RXRA, driving lipid metabolism reprogramming and promoting the occurrence and development of HCC.

Keyword(s) : Aristolochic acid I, Hepatocellular carcinoma, Network toxicology, Molecular docking, Molecular dynamics simulation; PPAR signaling pathway.

1150 - Evaluation of high sensitivity HBcrAg and HBsAg assays as biomarkers for occult HBV infection and hepatocellular carcinoma risk

Yi-chung Hsieh¹, Mei-hung Pan², Wen-juei Jeng¹, Hui-han Hu², Jessica Liu², Masaaki Korenaga³, Masashi Mizokami⁴, Chien-jen Chen², Yasuhito Tanaka⁵, Hwai-i Yang²

Linkou Chang Gung Memorial Hospital, Gastroenterology And Hepatology, Taoyuan City-Taiwan¹ Academia Sinica, Genomics Research Center, Taipei-Taiwan² National Center For Global Health And Medicine, The Research Center For Hepatitis And Immunology, Ichikawa-Japan³ National Center For Global Health And Medicine, Genome Medical Science, Ichikawa-Japan⁴ Kumamoto University, Department Of Gastroenterology And Hepatology, Kumamoto-Japan⁵

Background / Hypothesis:

High-sensitivity iTACT assays for hepatitis B core-related antigen (HBcrAg) and surface antigen (HBsAg) can detect extremely low levels of viral activity and may better reflect residual intrahepatic HBV replication than conventional assays. This study evaluated whether iTACT-HBcrAg and iTACT-HBsAg are associated with the risk of hepatocellular carcinoma (HCC) in individuals seronegative for HBsAg and anti-HCV (NBNC) in Taiwan.

Materials and Methods:

A total of 129 newly developed HCC cases and 520 age- and sex-matched non-HCC controls were selected from the community-based REVEAL-NBNC cohort. Serum iTACT-HBcrAg and iTACT-HBsAg were quantified at baseline using chemiluminescent enzyme immunoassays with improved analytical sensitivity. Logistic regression models were applied to estimate the odds ratios (ORs) and 95% confidence intervals (CIs) for HCC risk after adjusting for demographic, metabolic, and viral covariates.

Results:

The detection rates of HBcrAg (15.3%) and HBsAg (31.5%) using iTACT assays were higher than those obtained with conventional assays (HBcrAg: ≥ 1000

U/mL: 12.4%) among HCC cases. iTACT-HBcrAg positivity was significantly associated with an increased risk of HCC [adjusted OR (95% CI): 2.9 (1.4–6.2), $P = 0.006$], and detectable iTACT-HBsAg also showed a positive association with HCC risk [adjusted OR (95% CI): 2.0 (1.2–3.4) [adjusted OR (95% CI): 2.9 (1.4–6.2), $P = 0.006$], $P = 0.010$]. Combined positivity for both markers conferred the highest risk [adjusted OR (95% CI): 4.8 (1.9–12.2), $P = 0.001$].

Conclusions:

High-sensitivity iTACT-HBcrAg and iTACT-HBsAg assays can uncover occult HBV activity and improve HCC risk stratification in NBNC individuals. These findings highlight their potential utility as biomarkers to refine HCC surveillance strategies in HBV-endemic populations.

Keyword(s) : iTACT-HBcrAg; iTACT-HBsAg; occult hepatitis B virus infection; hepatocellular carcinoma; NBNC; biomarker.

1151 - HDV Screening Practices in Chronic Hepatitis B Real world Data from a Decision Support App in the Context of Global Guidance

Leen Alyaseen¹, Zachary Schwartz², Grace Wong³
Clinical Education Alliance, Outcomes, Houston-United States¹ Clinical Care Option, Scientific Services, Reston-United States² The Chinese University Of Hong Kong, Gastroenterology And Hepatology, Hong Kong-China³

Background / Hypothesis: In people with chronic hepatitis B, Asian Pacific Association for the Study of the Liver (APASL) guidelines recommend that healthcare professionals (HCPs) systematically look for coinfection with hepatitis delta virus (HDV). Consistent with this, updated WHO 2024 guidelines recommend that people who are Hepatitis B surface antigen (HBsAg) positive undergo anti-HDV antibody testing, with reflex HDV RNA testing (where available) following a positive anti-HDV antibody result. One potential way to measure adherence to these guidelines is by analyzing data from the Hep B Consult app, which delivers point-of-care clinical recommendations based on a patient's clinical data entered by an HCP.

Materials and Methods: We analyzed patient cases entered in the Hep B Consult app between 2024-2025, focusing on chronic hepatitis B cases where HCPs chose APASL as their preferred guideline. We then

E-POSTER ABSTRACTS

reviewed those cases to identify whether HCPs chose to perform anti-HDV antibody testing and, where applicable, reflex HDV RNA testing

Results:Between April 2024 and October 2025, HCPs entered 4819 HBsAg-positive patient cases in the Hep B Consult app under the APASL guideline framework. Anti-HDV antibody testing was performed in 3909 cases (81.1%) and 910 cases (18.9%) had no antibody testing. Among the 901 cases that were antibody positive, 799 (88.7%) had reflex HDV RNA testing performed and 102 (11.3%) had no RNA testing. These results quantify adherence to WHO 2024 and APASL recommendations for universal anti-HDV antibody screening and reflex RNA testing in chronic hepatitis B.

Conclusions:In this analysis of data from the Hep B Consult app, in most cases, HCPs adhered to WHO 2024 and APASL recommendations for HDV screening and reflex testing for patients with chronic hepatitis B. However, in almost one fifth of cases, HCP failed to screen for HDV antibody, and in more than one tenth of cases, they failed to do reflex HDV RNA testing. This uncovers an opportunity to strengthen adherence guidelines, which recommend screening all people with chronic hepatitis B for HDV.

Keyword(s) : Hepatitis B virus (HBV), Hepatitis D virus (HDV), Screening adherence, Clinical decision support Real-world data

1152 - Clinical Efficacy of Robot Assisted Biliary Enteric Reconstruction in Radical Resection of Hilar Cholangiocarcinoma Single Center Practical Experience

Yang Wang¹

Chongqing University Cancer Hospital, Gallbladder And Pancreas Tumor Center, Chongqing-China¹

Background / Hypothesis:To explore the safety, feasibility, and efficacy of robot-assisted biliary-enteric reconstruction during radical resection of hilar cholangiocarcinoma, providing evidence for clinical treatment.

Materials and Methods:retrospective analysis was performed on the clinical data of 27 patients who

underwent robot-assisted radical resection of hilar cholangiocarcinoma with concurrent biliary-enteric reconstruction at our institution from January 2019 to December 2023 (follow-up completed by December 2024). Operative time, blood loss, postoperative complications, hospital stay, 90-day mortality, and short-term survival (6-month and 1-year) were recorded.

Results:All 27 surgeries were successfully completed without conversion to open surgery. The total operative time was (265.3±42.5) minutes, with biliary-enteric reconstruction time of (40.2±10.3) minutes and intraoperative blood loss of (150.5±65.2) ml. The overall postoperative complication rate was 55.5% (15/27), including biliary fistula (7.1%), abdominal infection (4.8%), incisional infection (11.1%), pneumonia (9.3%), and other minor complications (23.2%). All complications were resolved with conservative management or percutaneous drainage. The median postoperative hospital stay was (10.5±2.3) days, and no mortality occurred within 90 days postoperatively. During the follow-up period, the 6-month survival rate was 86.2% and the 1-year survival rate was 72.5%, with no severe long-term complications related to biliary-enteric reconstruction observed.

Conclusions:Robot-assisted biliary-enteric reconstruction in radical hilar cholangiocarcinoma resection is safe and feasible, with less intraoperative bleeding and faster recovery. The preliminary long-term survival data support its potential as an effective surgical option for eligible patients.

Keyword(s) : Robot-assisted surgery, Hilar cholangiocarcinoma, Radical resection, Biliary-enteric reconstruction, Clinical efficacy

1154 - Clinical and epidemiological profile of Hepatitis A outbreak among medical students at Shaheed Ziaur Rahman Medical College hostel A cross sectional study

Abu Saleh Md Sadequul Islam¹, Syed Uddin Azad¹, Sanjida Sanjana¹

Shaheed Ziaur Rahman Medical College, Hepatology, Bogura-Bangladesh¹

Background: Hepatitis A virus (HAV) continues to be a

E-POSTER ABSTRACTS

significant public health concern, causing acute viral hepatitis outbreaks, particularly in South Asia's overcrowded settings characterized by suboptimal sanitation. In late 2023, a cluster of jaundice cases emerged among residents of the Shaheed Ziaur Rahman Medical College (SZMC) hostel in Bogura, prompting a detailed epidemiological investigation.

Objectives: To investigate the clinical and epidemiological features of the outbreak, identify the source and modes of transmission, assess existing preventive measures, and propose evidence-based strategies for future risk mitigation.

Methods: A descriptive cross-sectional study was conducted from January to June 2025 to investigate the outbreak that occurred in late 2023. Cases were defined as students residing in the hostel with clinical signs of acute hepatitis and laboratory-confirmed IgM anti-HAV positivity via ELISA (98.9% sensitivity, 99.4% specificity). A structured questionnaire captured demographic, clinical symptoms, water and food consumption habits, and personal hygiene data. An environmental survey of the hostel's water sources and sanitation infrastructure was conducted to identify potential contamination points.

Results: A total of 22 confirmed HAV cases were identified. The affected population comprised 62.1% male and 37.9% female students. The mean age of the confirmed students was 23.1 years (SD ± 1.1). Common symptoms included jaundice (100%), fatigue (95.2%), anorexia (85.7%), and nausea/vomiting (81%). Epidemiological investigation revealed a strong association with specific risk factors: a majority of students (77%, n=17) reported consuming water from a tube well found to be adjacent to a cracked underground sewage pipe with evidence of leakage. Furthermore, the college canteen was identified as a highly probable common food source, with 72% (n=21) of affected students reporting consumption from it, and observations noted unhygienic conditions. Suboptimal hygiene practices, including inconsistent handwashing (only 33.3% of students reported consistent hand-washing before meals), were common, and none of the affected students had received HAV vaccination.

Conclusion: The outbreak was most likely a common-source event caused by fecal contamination of the hostel water supply, further amplified by unhygienic conditions in the college canteen and poor personal hygiene practices in communal areas. Targeted

interventions, including water source repair, hygiene promotion, and health education, are crucial for effective control. Regular monitoring of water systems sustained public health awareness campaigns, and consideration of HAV vaccination in high-risk communal settings are strongly recommended for preventing future outbreaks.

1155 - MASLD AND GLYCEMIC IMPROVEMENT AFTER SUSTAINED VIROLOGIC RESPONSE IN TYPE 2 DIABETES PATIENTS WITH CHRONIC HEPATITIS C A THREE YEAR FOLLOW UP STUDY

Ching-chu Lo ¹, Jow-jyh Hwang ¹, Chien-hung Lin ¹, Hsu-shen Cheng ¹, Yi-tang Liao ¹, Po-yen Hsiao ¹, Chen-yu Lo ¹, Mei-tsu Chen ¹

St. Martin De Porres Hospital, Chiayi, Taiwan, Internal Medicine, Chiayi-Taiwan ¹

Background / Hypothesis:

DAA are the gold standard for chronic HCV treatment to achieve a SVR in nearly all patients. HCV infection can directly influence glucose metabolism and MASLD (metabolic dysfunction-associated steatotic liver disease).

Among patients with both type 2 diabetes (T2D) and HCV, SVR may improve glycemic control and hepatic steatosis, but available studies about fibrosis are limited. Our study herein aims to examine the effects of SVR on long-term glycemic control and MASLD.

Materials and Methods:

We conducted a retrospective cohort study of T2D patients from our hospital who had a positive HCV RNA test and received DAA between 25 Jan, 2019 and 22 Jan, 2020. SVR was defined as non-detectable HCV RNA 12 weeks after DAA therapy. Steatosis was assessed with Attenuation Imaging (ATI) developed by Canon company. Fibrosis was assessed by Liver stiffness measurement (LSM) developed by FibroScan. All parameters were statistically evaluated by Friedman test (SPSS version 24.0).

Results:

In total, 93 patients with both T2D and HCV treated by DAA were enrolled, and all achieved SVR. The mean age was 68 y/o. Patients were divided into 2 groups, group 1 were [HbA1c $\leq 7\%$ (N=51)] and group 2 were [HbA1c $> 7\%$ (N=42)].

For group 1, the HbA1c levels were 6.30, 6.30, 6.50 and

E-POSTER ABSTRACTS

6.50 at entry, 1, 2, and 3 years FU respectively ($P=0.071$). The ATI levels (dB/cm/MHz) were 0.66, 0.60, 0.60, and 0.60 at entry, 1, 2, and 3 years FU respectively ($P<0.001$). The LSM levels (kPa) were 7.41, 7.40, 7.40 and 7.40 at entry, 1, 2, and 3 years FU respectively ($P<0.001$). SVR did not significantly improve HbA1c but significantly improve MASLD in group 1.

For group 2, the HbA1c levels were 8.20, 7.30, 7.30 and 7.05 at entry, 1, 2, and 3 years FU respectively ($P<0.001$). The ATI levels were 0.89, 0.70, 0.70, and 0.70 at entry, 1, 2, and 3 years FU respectively ($P<0.001$). The LSM levels were 7.90, 7.55, 7.50 and 7.50 at entry, 1, 2, and 3 years FU respectively ($P<0.001$). SVR was strongly associated with HbA1c reduction and MASLD improvement after DAA through 1 to 3 years FU in group 2.

Conclusion: DAA therapy in patients with chronic HCV and type 2 DM leads to significant and durable improvements in both glycemic control and MASLD. HCV clearance not only halts liver injury but also exerts long-term metabolic benefits.

Keyword(s) : MASLD, HCV, T2DM,

1160 - Study on the Mechanism of Samhd1 Mediated NEMO Polyubiquitination in Liver Ischemia Reperfusion Injury

Xianzhang Luo Luo¹, Zuo Tian Huang Huang¹
Chongqing University Cancer Hospital, Department Of Hepatobiliary Pancreatic Tumor Center, Chongqing-China¹

Background / Hypothesis:

Hepatic ischemia reperfusion injury (IRI) is one of the major pathological processes in liver transplantation and various liver surgeries. To date, there is still a lack of effective diagnosis and treatment strategies for hepatic IRI, and one of the root causes is that its mechanism has not been fully elucidated. This study aims to explore the molecular mechanism by which Samhd1 participates in the regulation of hepatic IRI, providing a research foundation and theoretical basis for the prevention and treatment of hepatic IRI.

Materials and Methods:

This study established a classic 70% liver ischemia-reperfusion injury (IRI) model in mice. The expression and localization of key molecules were detected using methods such as immunoprecipitation, immunofluorescence, quantitative real-time polymerase chain reaction (qRT-PCR), and enzyme-linked immunosorbent assay (ELISA). The pathological damage and liver function of mice in each group were

examined through hematoxylin and eosin (HE) staining, terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) assay, and microplate method.

Results:

We have discovered that Samhd1 is a key molecule exacerbating hepatic ischemia - reperfusion injury (IRI). Down - regulation of Samhd1 can significantly alleviate hepatic IRI, while over - expression of Samhd1 yields the opposite effect. Mechanistically, Samhd1 can mediate the polyubiquitination modification of NEMO, induce the activation of the IKK inflammatory complex, and enhance its stability, ultimately leading to the phosphorylation and combined translocation of multiple subunits of the IKK family. Inhibition of IKK can reverse hepatic IRI caused by Samhd1 enrichment.

Conclusions:

In conclusion, this study has revealed the potential functions and roles of Samhd1 in liver ischemia-reperfusion injury (IRI). Targeting Samhd1 may be a potential strategy for treating liver IRI.

Keyword(s) : liver transplantation, liver ischemia reperfusion, interactions between proteins

1161 - Recurrence and Post Liver Transplant Outcomes in Hepatocellular Carcinoma Experience from the Main Center of Iran

Kamran Bagheri Lankarani¹, Mohamad Jamalnia², Seyed Ali Malek-hosseini³, Saman Nikeghbalian³, Siavash Gholami³, Alireza Shamsaeefar³, Hamed Nikoupour³, Kourosh Kazemi³
Shiraz University Of Medical Sciences, Health Policy Research Center, Institute Of Health, Shiraz-Iran¹
Shiraz University Of Medical Sciences, Gastroenterohepatology Research Center, Shiraz-Iran²
Shiraz University Of Medical Sciences, Shiraz Transplant Research Center, Shiraz-Iran³

Background / Hypothesis:

Hepatocellular carcinoma (HCC) recurrence after liver transplantation (LT) remains a major challenge in post-transplant management, significantly impacting patient outcomes. However, the burden of recurrence and its prognostic factors are not fully understood. This study aimed to (i) characterize recurrence patterns and survival outcomes among liver transplant recipients with HCC, and (ii) evaluate the prognostic significance of the Model for End-Stage Liver Disease (MELD) score.

Materials and Methods:

E-POSTER ABSTRACTS

Between April 2017 and May 2025, 160 patients with HCC underwent LT at Abu-Alisina Hospital, Shiraz, Iran, contributing to 477.4 person-years of follow-up. Post-transplant recurrence and mortality were retrospectively ascertained from medical and registry data. Event rates were expressed per 1,000 person-years. Secondary analyses included age- and sex-matched case-control comparisons (38 deaths vs. 38 survivors, and 7 recurrences vs. 24 non-recurrences) and multivariable logistic regression adjusting for demographic and graft-related variables. All analyses were conducted using Python 3.11 with appropriate statistical libraries.

Results:

During a median follow-up of 2.67 years (IQR: 0.43–4.9), 55 deaths occurred, corresponding to a mortality rate of 115.2 per 1,000 person-years (95% CI: 84.8–145.6). The median time to death was 0.26 years (IQR: 0.04–1.83). Mortality was highest in the early post-transplant period: 31 deaths (56%) occurred within the first year, 6 between 1–2 years, 7 between 2–3 years, and 5 beyond three years. In multivariable analyses, MELD score was not associated with mortality (adjusted OR: 0.97; 95% CI: 0.91–1.05; $p = 0.457$). HCC recurrence was infrequent, affecting 8 recipients (5%), yielding an incidence rate of 16.8 per 1,000 person-years (95% CI: 7.2–34.5). The median time to recurrence was 1.6 years (range: 0.01–3.83). Most recurrences (62.5%) developed within two years—three within the first year—while three (37.5%) occurred beyond two years, including two after the third year. In adjusted models, higher MELD scores were inversely associated with recurrence risk (adjusted OR: 0.78; 95% CI: 0.61–0.99; $p = 0.041$).

Conclusions:

In this cohort of HCC liver transplant recipients, recurrence was relatively rare, but overall post-transplant mortality remained high, particularly during the first year. Most recurrences occurred within the first two years, emphasizing the importance of early, intensive surveillance. Although MELD score did not predict overall mortality, its inverse association with recurrence suggests that pre-transplant liver disease severity may influence tumor behavior or recurrence risk. These findings support individualized post-transplant monitoring strategies and provide hypothesis-generating evidence for further investigation into the biological and clinical mechanisms linking liver function and HCC recurrence.

Keyword(s) : Hepatocellular carcinoma; liver transplantation; HCC recurrence; post-transplant mortality; MELD score; risk stratification

1166 - Endoplasmic Reticulum Stress Mediated PPAR α DDX3X Interaction Modulates Con A Induced Liver Injury in Mice

Feng Ren¹, Ling Xu¹, Zihao Fan¹

Beijing Youan Hospital, Capital Medical University, Beijing Institute Of Hepatology, Beijing-China¹

Background / Hypothesis:

Dysfunction of endoplasmic reticulum (ER) stress is involved in the pathogenesis of immune-mediated liver injury, but its molecular mechanism has not been fully elucidated. Previous studies have shown that PPAR α and DDX3X play important roles in ER stress-related dysfunction. This study further explored how PPAR α and DDX3X interact to regulate ER stress-related dysfunction in immune-mediated liver injury.

Materials and Methods:

Liver injury was induced in C57BL/6J mice via concanavalin A (Con A). DDX3X hepatocyte-specific knockout (DDX3X Δ Hep) mice and control (DDX3X^{fl/fl}) mice were utilized to investigate the role of DDX3X in liver injury. 4-PBA was used to inhibit ER stress, while siRNA, AAV-shRNA, and LV were used to regulate PPAR α expression. Tunicamycin (TM) was used to induce ER stress in primary hepatocytes, and autoimmune hepatitis (AIH) patients were included for validation.

Results:

Inhibition of ER stress alleviates ConA-induced liver injury by increasing PPAR α expression and reducing both DDX3X levels and phosphorylation in the liver. PPAR α activation attenuates liver injury and suppresses the phosphorylation of DDX3X, which is regulated by ER stress. A phospho-deficient DDX3X mutant (p.T323A) significantly reduces ConA-induced liver injury in mice. Mechanistically, phosphorylation of DDX3X promotes its cytoplasmic–nuclear translocation and hepatocyte apoptosis during ER stress. Moreover, PPAR α interacts with the DDX3X helicase domain in the cytoplasm, masking the phosphorylation site (p.323), to inhibit the nuclear translocation of DDX3X and decrease the downregulation of CHOP expression. Additionally, colocalization of PPAR α and DDX3X is observed in the livers of AIH patients, elevated serum DDX3X levels were linked to AIH-associated liver failure, and sustained reduction of DDX3X was

E-POSTER ABSTRACTS

correlated with a better prognosis.

Conclusions:

This study highlights the role of the PPAR α -DDX3X interaction in regulating DDX3X phosphorylation during ER stress and promoting DDX3X nuclear translocation and hepatocyte apoptosis. Therefore, targeting the ER stress-PPAR α -DDX3X pathway represents a novel therapeutic approach for immune-mediated liver injury.

1169 - Associations between glycaemic indices and non invasive markers of hepatic steatosis and steatohepatitis in Chinese adults with prediabetes

Victoria To¹, Elaine Chow², Natural Chu²

King's College London, Faculty Of Life Sciences And Medicine, London-United Kingdom¹ The Chinese University Of Hong Kong, Department Of Medicine And Therapeutics, Hong Kong-Hong Kong SAR, China²

Background:

Metabolic dysfunction-associated steatotic liver disease (MASLD) and its progressive form, metabolic dysfunction-associated steatohepatitis (MASH), are leading causes of chronic liver disease in Asia and worldwide. While MASLD and MASH are strongly linked with insulin resistance and chronic hyperglycaemia in type 2 diabetes mellitus, their associations with dysglycaemia in prediabetes remain insufficiently explored. This study investigated associations between glycaemic indices and non-invasive markers of MASLD and MASH risk in a Chinese cohort with prediabetes.

Methods:

This cross-sectional study included 173 adults with prediabetes recruited from a community metabolic screening programme in Hong Kong. Participants underwent an oral glucose tolerance test and transient elastography (FibroScan) to assess glycaemic and hepatic parameters. Glycaemic indices included fasting, 1-hour, and 2-hour plasma glucose levels and HbA1c. Hepatic steatosis and MASH risk were evaluated using the controlled attenuation parameter (CAP) and FibroScan-AST (FAST) score, respectively. Associations between each glycaemic index-liver parameter pair were assessed using bivariate correlation and multivariable linear regression analyses.

models were progressively adjusted: Base model (age, sex, alcohol use) and Model 1 (Base model plus physical and sedentary activity).

Results:

Mean age was 60.5 $\pm$ 7.5 years; 38.2% were male. MASLD was present in 60.0% of participants, with a mean CAP of 262.9 $\pm$ 58.1 dB/m. The median (interquartile range) FAST score was 0.08 (0.09), indicating a low overall MASH risk. For CAP, only 2-hour glucose showed a significant correlation in unadjusted analysis (r = 0.20, p = 0.010). This correlation persisted as an independent association after adjustment for age, sex, and alcohol use (β = 0.23, p = 0.003) and remained significant after further adjustment for physical and sedentary activity (β = 0.18, p = 0.032). Fasting glucose, 1-hour glucose, and HbA1c were not significantly associated with CAP in any model (all p > 0.05). In contrast, none of the glycaemic indices showed significant correlations or adjusted associations with MASH risk assessed by the FAST score.

Conclusions:

In this study cohort, 2-hour post-load glucose showed the strongest association with hepatic steatosis, while no glycaemic index was linked to MASH risk. These findings highlight that post-load dysglycaemia, an established driver of steatosis in diabetes, is already associated with hepatic fat accumulation at the prediabetic stage and may represent an early intervention target. Larger, longitudinal studies are necessary to clarify causality and clinical implications for MASLD prevention.

Keyword(s) : MASLD, MASH, prediabetes, hepatic steatosis, glycaemic indices, FAST score

1171 - Optimizing Renal and Urological Outcomes in Liver Transplant Recipients A Urologist Driven Peri Transplant Care Pathway at a Tertiary Transplant Center

Ojas Vijayanand Potdar¹

Grant Government Medical College And Jj Group Of Hospitals Mumbai Maharashtra India, Urology, Mumbai-India¹

Background / Hypothesis:

Background

E-POSTER ABSTRACTS

Renal dysfunction and urological complications significantly influence post-liver transplantation (LT) morbidity, ICU stay, and long-term graft survival. While transplant hepatology and surgery receive primary focus, structured urology involvement remains under-recognized despite the essential interplay of fluid balance, nephrotoxic immunosuppression, catheter-associated complications, and hepatorenal syndrome (HRS).

Aim

To evaluate the impact of a Urologist-led peri-transplant renal preservation and urological complication prevention protocol on post-LT outcomes.

Methods

A prospective observational cohort of 142 liver transplant recipients between 2021–2024 was analyzed. Patients were divided into:

Group A (n=68): Standard transplant team management

Group B (n=74): Managed under the Urology-Integrated Care Protocol (UICP), which included:

- Pre-transplant renal reserve scoring
- Early CRRT/HRS recognition algorithm
- Strict nephrotoxic drug avoidance chart
- Standardized catheterization & stent handling protocol
- Post-LT obstructive uropathy screening ultrasound algorithm

Primary endpoints: postoperative acute kidney injury (AKI), need for dialysis, urinary infection rate, ICU stay duration, and 90-day survival.

Results

Group B demonstrated:

Reduced AKI incidence: 38.2% → 17.5% ($p<0.01$)

Dialysis requirement: 14.7% → 6.8% ($p<0.05$)

Catheter-associated UTI: 26.4% → 9.4% ($p<0.001$)

Median ICU stay: 9 days → 6 days

90-day survival: 86.7% → 93.2%

No increase in operative time or cost was observed.

Conclusion

Early and continuous involvement of Urology in the peri-transplant phase significantly improves renal preservation, decreases urological complications, and enhances early survival following liver transplantation. This multidisciplinary protocol is easily adoptable and offers a scalable, cost-effective improvement in LT outcomes.

Urologists should be integral members of the liver transplant team rather than optional consultants.

1175 - First Clinical Evidence of Temperature sensitive Liquid Embolic Agent TACE Remodeling Immune Microenvironment in Unresectable HCC Multicenter Propensity Weighted Cohorts Study

Qingyun Xie¹, Ying Yang¹, Sinan Xie¹, Yinghao Lyu¹, Yuanjun Liu², Jiran Deng³, Xianguo Liu⁴, Yi Zhou⁵, Tian Lan¹, Chang Liu⁶
West China Hospital, Sichuan University, Liver Transplant Center, Chengdu-China¹ Suining Central

E-POSTER ABSTRACTS

Hospital, Department Of Hepatobiliary-pancreatic Surgery, Suining-China ² First People's Hospital Of Zigong City, Interventional Radiology Department, Zigong-China ³ The Affiliated Chengdu 363 Hospital Of Southwest Medical University, Interventional Radiology Department, Chengdu-China ⁴ Hospital Of Chengdu Office Of People's Government Of Tibetan Autonomous Region, Interventional Radiology Department, Chengdu-China ⁵ West China Hospital, Sichuan University, Division Of Abdominal Tumor Multimodality Treatment, Cancer Center, - ⁶

Background / Hypothesis:

Transarterial chemoembolization (TACE) remains the standard first-line therapy for intermediate-stage HCC; however, conventional embolic agents (e.g., drug-eluting microspheres) display limited vascular penetration and drug delivery efficiency. The temperature-sensitive liquid embolic agent (TempSLE), a novel phase-transition material, has demonstrated promise in preclinical studies but lacks clinical validation in HCC. This study aims to compare the efficacy, safety, and immunomodulatory effects of TempSLE-TACE (T-TACE) versus drug-eluting bead TACE (D-TACE) in unresectable hepatocellular carcinoma (HCC).

Materials and Methods:

This multicenter retrospective study included 287 patients with unresectable HCC treated with TempSLE-TACE (T-TACE; n=101) or D-TACE (n=186) across five tertiary centers in China (2021-2023). Propensity score matching (PSM; 1:1) yielded 93 matched pairs. Evaluated outcomes included tumor response (mRECIST), overall survival (OS), progression-free survival, and safety. Histopathological and immune microenvironment assessments were performed on resected specimens.

Results:

After PSM, the T-TACE group showed a higher objective response rate (58.06% vs. 43.01%, $P=0.040$) and longer median OS (20 vs. 18 months, $P=0.035$). Patients with China Liver Cancer (CNLC) stage IIb derived the greatest OS benefit (hazard ratio=3.092, $P<0.001$). The incidences of fever (23.96% vs. 56.98%, $P<0.001$) and abdominal pain (44.79% vs. 63.74%, $P=0.003$) were lower in the T-TACE group, whereas hand-foot skin reactions were more frequent (40.59% vs. 23.83%, $P=0.001$). No significant differences in severe adverse events (grade ≥ 3) were observed. TempSLE achieved complete vascular occlusion and uniform tumor necrosis; D-TACE resulted in incomplete

embolization with residual viable tumor cells. TempSLE also enhanced CD8+ T-cell infiltration and dendritic cell activation at tumor margins, suggesting an immunogenic effect.

Conclusions:

T-TACE offers superior tumor control and survival outcomes relative to D-TACE in patients with unresectable HCC—particularly in CNLC stage IIb—and is associated with a distinct safety profile and potential immunomodulatory properties. These results support its clinical adoption as an innovative embolic strategy.

Keyword(s) : Intermediate-stage HCC, Temperature-sensitive liquid embolic agent, TACE, Immune Microenvironment

1180 - Study of Serum Trace Elements (Zn Cu Mg) in Hepatic Encephalopathy

Manish Kumar¹

Abvims & Dr Rml Hospital, Medicine, New Delhi-India ¹

Background / Hypothesis:

Hepatic encephalopathy (HE) is a severe neuropsychiatric complication of liver cirrhosis, arising from impaired hepatic detoxification and systemic metabolic dysfunction. While ammonia has long been considered the primary neurotoxin, the role of trace elements—particularly zinc (Zn), copper (Cu), and magnesium (Mg)—in HE pathogenesis is increasingly recognized. These elements influence ammonia metabolism, oxidative stress, and neuronal excitability. The present study evaluated serum levels of Zn, Cu, and Mg and their correlation with the severity of hepatic encephalopathy.

Materials and Methods:

A cross-sectional observational study was conducted at the Department of General Medicine, Atal Bihari Vajpayee Institute of Medical Sciences and Dr. Ram Manohar Lohia Hospital, New Delhi, from February 2024 to June 2025. A total of 105 adult patients diagnosed with hepatic encephalopathy were included. Serum Zn, Cu, and Mg levels were measured using colorimetric methods, and HE was graded according to West Haven criteria. Correlation with liver dysfunction was assessed using the Child-Pugh classification. Statistical analyses included Pearson correlation and linear regression.

E-POSTER ABSTRACTS

Results:

Elevated serum copper was observed in 94.3% of patients and showed a strong positive correlation with HE severity ($r = 0.938$, $p < 0.001$; $R^2 = 0.851$). Zinc deficiency was noted in 64.8%, demonstrating a negative correlation ($r = -0.316$, $p = 0.001$) with HE grades.

Hypomagnesemia occurred in 43.8%, with a strong inverse relationship ($r = -0.834$, $p < 0.001$; $R^2 = 0.662$) to HE severity. Trace element imbalances paralleled worsening Child–Pugh class and biochemical decompensation.

Conclusions: Alterations in serum Zn, Cu, and Mg are significantly associated with the severity of hepatic encephalopathy and liver dysfunction. Routine monitoring and correction of these trace element abnormalities may serve as valuable adjuncts in managing cirrhosis patients at risk of HE.

Keyword(s) : Hepatic encephalopathy, Zinc, Copper, Magnesium, Cirrhosis, Trace elements

1181 - Familial Mediterranean Fever as a cause of hepatic amyloidosis and decompensated liver cirrhosis

Edmond Baghdasaryan¹, Anna Mkrtchyan¹, Lilit Harutyunyan¹, Sofya Grigoryan¹, Iskuhi Navoyan¹, Maria Gharagulyan², Gagik Hakobyan¹
Yerevan State Medical University After Mkhitar Heratsi, Department Of Gastroenterology And Hepatology, Yerevan-Armenia¹ Yerevan State Medical University After Mkhitar Heratsi, Faculty Of General Medicine, Yerevan-Armenia²

Background / Hypothesis:

Familial Mediterranean Fever (FMF) is an autoinflammatory disorder characterized by recurrent fever and serosal inflammatory episodes, often leading to secondary (AA) amyloidosis. While renal involvement is typical, hepatic amyloidosis is rare. This case highlights that prolonged FMF may result not only in hepatic amyloidosis, but can also rarely lead to liver cirrhosis.

Materials and Methods:

A 71-year-old woman with a 17-year history of genetically confirmed FMF (MEFV gene homozygous mutation M680I/M680I) presented with nausea, loss of

appetite, weight loss, abdominal distension, sleep inversion, and fatigue. She reported recurrent diarrhea over a long period. Physical and laboratory evaluations, imaging studies, and histopathological analyses were performed, including liver and intestinal biopsies, Congo red staining, immunohistochemistry, and serologic tests for viral and autoimmune markers.

Results:

CT imaging revealed ascites and nodular hepatic contours consistent with cirrhosis. Liver biopsy demonstrated steatotic liver disease, cirrhosis, and Congo red–positive deposits showing birefringence under polarized light. Immunohistochemistry confirmed AA-type amyloid. Paracentesis revealed benign ascites with SAAG > 1.1 g/dL, indicating portal hypertension. Immunohistochemistry of gastrointestinal biopsies also showed AA amyloid deposition, explaining the chronic diarrhea. Laboratory findings included Hgb 108 g/L, PLT 169×10^9 /L, ESR 42 mm/h, albumin 26.46 g/L, total protein 61.2 g/L, total bilirubin 49.7 μ mol/L, creatinine 125 μ mol/L, CRP 46.46 mg/L, uric acid 776 μ mol/L, LDL 1.62 mmol/L, HDL 0.38 mmol/L, PT 22.1 s, iPT 47%, INR 1.77, alpha-fetoprotein 2.39 IU/mL. BMI was 22.2 with normal blood glucose, indicating no metabolic risk factors. The reduced HDL level in this patient is explained by impaired hepatic lipoprotein synthesis due to cirrhosis rather than cardiometabolic disease. Viral hepatitis (HBV/HCV/HIV), Wilson's disease, and alpha-1 antitrypsin deficiency were excluded. Despite anti-AMA reactivity, normal IgG/IgM levels and absence of autoimmune histological features excluded AIH and PBC. The colchicine dose was increased to 1.8 mg daily, and rifaximin, diuretics, and albumin were added.

Conclusions:

FMF is common in people of Mediterranean origin but it can affect people in any ethnic group. FMF can rarely lead to hepatic amyloidosis and cirrhosis. When common causes of liver disease are excluded, and a personal or familial history of FMF is present, FMF-related hepatic involvement should be considered in the differential diagnosis of liver cirrhosis. Early recognition and optimization of colchicine therapy may help prevent disease progression.

Keyword(s) : Familial Mediterranean Fever, FMF, Cirrhosis, Amyloidosis

1182 - The NF κ B TNFAIP3 axis attenuates MAFLD via activation of hepatocyte autophagy

Guixin Li¹, Jinghui Guo¹
Shanghai Sixth People's Hospital Affiliated To Shanghai

E-POSTER ABSTRACTS

Jiao Tong University School Of Medicine, Department Of Gastroenterology, Shanghai-China ¹

Background / Hypothesis:

Emerging evidence indicates that tumor necrosis factor α -induced protein 3 (TNFAIP3) is markedly upregulated in the livers of patients with metabolic dysfunction-associated fatty liver disease (MAFLD). However, its functional role in MAFLD remains largely unclear.

Materials and Methods:

TNFAIP3 expression was analyzed in several diet-induced MAFLD mouse models using public transcriptomic datasets. In vitro, we assessed the effects of TNFAIP3 overexpression and knockdown in palmitic acid-treated HepG2 cells on lipid accumulation, autophagy, and key metabolic pathways. In vivo, high-fat diet-induced mouse models were used to validate the protective role of TNFAIP3. Autophagy inhibitors were applied to determine whether effects of TNFAIP3 were autophagy-dependent, and NF- κ B signaling involvement was examined using pharmacological inhibitors.

Results:

TNFAIP3 was consistently upregulated in the livers of all tested MAFLD mouse models. In the fructose-palmitate-cholesterol diet-induced model, TNFAIP3 expression was substantially elevated specifically in isolated primary hepatocytes, indicating that the increase occurs predominantly in hepatic parenchymal cells. In palmitic acid-treated HepG2 cells, TNFAIP3 overexpression markedly reduced lipid droplet accumulation, whereas knockdown exacerbated lipid deposition. In vivo, hepatic overexpression of TNFAIP3 alleviated steatosis, improved insulin sensitivity, and modulated lipid metabolism-associated pathways. These protective effects were abolished by autophagy inhibitors, confirming that TNFAIP3 exerts its beneficial role in an autophagy-dependent manner.

Mechanistically, TNFAIP3 upregulation was driven by NF- κ B signaling, as pharmacological inhibition of NF- κ B significantly decreased TNFAIP3 expression.

Conclusions:

The NF- κ B-TNFAIP3 axis regulates hepatic lipid metabolism and protects against liver injury in MAFLD, primarily through autophagy. These findings highlight TNFAIP3 as a potential therapeutic target for MAFLD and related metabolic liver diseases.

1183 - Study on the Mechanism of FBXW5 Inducing MKRN1 Ubiquitination and Degradation in Reducing Liver Ischemia Reperfusion Injury

Zhenghua Luo ¹, Zuotian Huang ¹, Xianzhang Luo ¹, Dewei Li ¹, Lei Dou ¹

Chongqing University Cancer Hospital, Department Of Hepatobiliary Pancreatic Tumor Center, Chongqing-China ¹

Background/Hypothesis:

Hepatic ischemia-reperfusion injury (IRI) has long been a major concern for liver transplant and various liver surgery patients, severely affecting prognosis. The research team previously discovered that FBXW5 significantly alleviated liver IRI, but the mechanism remained unclear. This study aims to clarify the molecular mechanism by which FBXW5 regulates liver IRI, providing a research foundation and theoretical basis for the prevention and treatment of liver IRI.

Materials and Methods:

We establish a 70% liver ischemia-reperfusion injury (IRI) model in classic mice. Detect the expression and localization of key molecules using IHC, WB, immunofluorescence, qRT-PCR, ELISA, etc. Detect the pathological damage and liver function of mice in each group using HE, TUNEL, and microplate methods.

Results:

We have discovered that MKRN1 is an important signal transduction protein that exacerbates liver IRI. The MKRN1-dependent LKB1 ubiquitination is a key step in liver IRI. Mechanistically, FBXW5 can mediate the polyubiquitination and degradation of MKRN1, thereby down-regulating the sterile inflammatory signaling pathway.

Conclusions:

In conclusion, this study has revealed the potential functions and roles of FBXW5/MKRN1 in liver ischemia-reperfusion injury (IRI). Targeting FBXW5 may be a potential strategy for treating liver IRI.

Keyword(s) : liver transplantation, liver ischemia reperfusion, interactions between proteins

1184 - Study on the Mechanism of TRIM69 Binding to CRYAB Promoting TRAF6 Autoubiquitination and Aggravating Liver Ischemia Reperfusion Injury

Lei Dou ¹, Zuotian Huang ¹, Xianzhang Luo ¹, Dewei Li ¹, Zhenghua Luo ¹

Chongqing University Cancer Hospital, Department Of Hepatobiliary Pancreatic Tumor Center, Chongqing-

E-POSTER ABSTRACTS

China ¹

Background/Hypothesis:

Hepatic ischemia-reperfusion injury (IRI) is a serious complication that is inevitable in liver transplantation and liver surgical operations. Its pathophysiological process involves a complex network of molecular mechanisms, and its exact mechanism has not yet been fully elucidated. Due to the lack of specific treatment methods, the clinical management of liver IRI still faces significant challenges, directly affecting the prognosis and outcome of surgical patients. Previous studies have shown that α B-crystallin (CRYAB) has a significant protective effect in liver IRI, but its specific molecular mechanism still needs to be further explored. This study aims to systematically reveal the protective mechanism of CRYAB in liver IRI, and focus on exploring the key regulatory role of TRIM69 in the process of liver IRI through regulating CRYAB-mediated TRAF6 ubiquitination modification. This research will provide important theoretical basis for clarifying the molecular regulatory network of liver IRI and developing targeted intervention strategies.

Materials and Methods:

This study employed a standardized 70% liver ischemia-reperfusion injury (IRI) mouse model. The expression changes of target proteins were quantitatively analyzed using Western blot technology. Protein-protein interactions were verified by the co-immunoprecipitation (Co-IP) method. Subcellular localization was analyzed by immunofluorescence staining, and the levels of inflammatory factors were determined by enzyme-linked immunosorbent assay (ELISA). In the pathological assessment stage, the morphological changes of liver tissue were observed through the hematoxylin-eosin (HE) staining system. Cell apoptosis was detected by the terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) method. Meanwhile, the activities of serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were determined by the microplate method.

Results:

The study found that TRIM69 interacts with CRYAB, removing the latter's silencing effect on TRAF6's self-ubiquitination, thereby promoting the inflammatory cascade reaction of the IKK pathway. CRYAB functions as a molecular chaperone and plays an important anti-inflammatory role. Meanwhile, TRIM69 can competitively bind to CRYAB, thereby reducing its silencing effect on TRAF6, thereby activating the

classical and non-classical IKK regulatory subunits, leading to the translocation of p65 into the nucleus.

Conclusions:

This study has revealed the potential functions of TRIM69 and CRYAB in liver ischemia-reperfusion injury (IRI), providing supplementary information on the mechanism of liver IRI.

1186 - Timing Transplantation versus Medical Treatment in Acute Liver Failure and Associated Outcomes Insights from an Indian High Volume Transplant Centre

Vipul Gautam ¹, Dibya Jyoti Das ², Vikram Kumar ¹, Sanjiv Saigal ³, Subhash Gupta ⁴

Max Centre For Liver And Biliary Sciences, Pediatric Hepatology, New Delhi-India ¹ Max Centre For Liver And Biliary Sciences, Intensive Care Unit, New Delhi-India ² Max Centre For Liver And Biliary Sciences, Hepatology, New Delhi-India ³ Max Centre For Liver And Biliary Sciences, Liver Transplant Surgery, New Delhi-India ⁴

Background / Hypothesis:

Acute liver failure (ALF) is a life-threatening condition in which timely liver transplantation (LT) is crucial for survival. The major challenge lies in determining the optimal timing and selection between continued medical management and transplantation. We present our single-center experience with living donor liver transplantation (LDLT) in the management of ALF.

Materials and Methods:

We analyzed data from 70 ALF patients presenting between June 2017 and February 2025, focusing on clinical features, interventions, and outcomes. Transplant timing was individualized based on the overall clinical course, considering worsening encephalopathy, rising intracranial pressure, multi-organ involvement, increasing inotropic needs, and rising INR, bilirubin, lactate and ammonia levels, rather than any single criterion.

Results:

Among 70 patients with ALF with a median age of 24.5

E-POSTER ABSTRACTS

years (IQR: 13–35 years), 26 (37%) were women and 28 (40%) were children below 18 years of age. The leading cause of ALF was hepatitis A virus infection in 39 patients (55.7%), followed by indeterminate etiology in 14 (20%). Overall, 40% of the cohort survived with their native liver. Transplant timing was guided by the dynamic clinical course. Patients were categorized into three groups: liver transplant recipients (n=34), survivors with native liver (SNL, n=28), and deceased non-transplanted patients (n=8) (Figure attached). The SNL group had a median hospital stay of 12 days (IQR: 9–20), and 13 of these patients met the King's College Hospital criteria for LT listing. Among the 34 transplant recipients, 10 died postoperatively, most commonly (7/10) due to persistent intracranial hypertension leading to brain death. Patients in the deceased group had multiorgan dysfunction or were deemed too sick for transplantation. On univariate analysis, admission INR, arterial lactate levels, jaundice-to-encephalopathy (J–E) interval, and advanced hepatic encephalopathy predicted the need for LT, while multivariate analysis identified elevated admission arterial lactate and a J–E interval exceeding 7 days as independent predictors for liver transplantation.

Conclusions:

Hepatitis A is the main cause of ALF, with high arterial lactate levels and prolonged J–E interval indicating poor outcomes. Choosing between medical and surgical management in ALF is challenging due to postoperative risks, possible native liver recovery, and unreliable severity scores.

1187 - Optimized Outcomes Using the Medial Reduction Technique for the Left Lateral Segment in Infants Undergoing Living Donor Liver Transplantation

Vipul Gautam¹, Vikram Kumar¹, Sreejith Sreekumar², Mukesh Kumar², Subhash Gupta²

Max Centre For Liver And Biliary Sciences, Pediatric Hepatology, New Delhi-India¹ Max Centre For Liver And Biliary Sciences, Liver Transplant Surgery, New Delhi-India²

Background / Hypothesis:

Graft reduction is a crucial technique in pediatric liver transplantation, as the size of the graft significantly impact both short and long-term outcomes. Our center previously published the medial reduction technique,

which was developed to reduce both the weight and thickness of the left lateral segment (LLS). While this technique has shown promise, the short and long-term outcomes need to be further evaluated.

Materials and Methods:

This retrospective study examines infantile living donor liver transplant recipients (<1 year of age) at a single center. Two groups were compared: one group, serving as historic controls, underwent the standard lateral and inferior reduction of the LLS between 2010 and 2016, while the other group received medially reduced left lateral segment (MR-LLS) from 2017 onwards. The study's objective is to compare the immediate and long-term outcomes of these two techniques.

Results:

A total of 88 infants were included: 56 underwent MR-LLS and 32 were historic controls. Median age was 10 months (IQR 8–12) in the MR-LLS group and 6 months (IQR 1–8) in controls ($p < 0.001$); median weight was 7.5 kg (IQR 6.3–8.1) vs. 7.27 kg (IQR 6.2–8.9), respectively ($p > 0.05$). The median PELD score was higher in MR-LLS (24 vs. 19; $p = 0.049$). In the MR-LLS group, the median estimated graft weight was 225 g, reduced weight 59 g, estimated GRWR 3.7%, and actual GRWR 2.95%. Graft thickness was reduced by 21%. In the control group, graft weight and GRWR were higher at 259 g ($p = 0.037$) and 3.25% ($p = 0.178$), respectively. Cold ischemia times were similar, but warm ischemia time was shorter in MR-LLS. ICU stay was also shorter in MR-LLS (17 days [IQR 12–23] vs. 22 days [IQR 21–28]; $p < 0.001$). The MR-LLS group had fewer early postoperative complications. Re-exploration was less frequent (14.3% vs. 34.4%; $p = 0.028$), and 3-month mortality was lower (7.1% vs. 12.5%). Long-term complication rates were similar. Median follow-up was 36 months in MR-LLS and 103 months in controls. Cumulative survival was 89.3% vs. 78.1% ($p = 0.359$) (Figure attached).

Conclusions:

Medial reduction of the left lateral segment effectively reduces graft thickness and has demonstrated excellent short- and long-term outcomes, including shorter ICU stays and fewer immediate surgical complications.

Keyword(s) : pediatric liver transplantation, medial reduction, left lateral segment graft

1188 - Role and Mechanism of membrane CD100 in Regulating the Activation and Differentiation of HBV Specific CD8 T Cell

Mengxiao Zhao ¹, Xuecheng Yang ¹, Xin Zheng ¹, Dongliang Yang ¹, [Jia Liu](#) ¹
Huazhong University Of Science And Technology,
Department Of Infectious Diseases, Union Hospital,
Tongji Medical College, Wuhan-China ¹

Background / Hypothesis:

CD100/SEMA4D plays pivotal roles in mediating T cell responses as a co-stimulatory molecule. It exists and functions in both membrane-bound and soluble forms. Soluble CD100 (sCD100) promotes the maturation and activation of antigen-presenting cells and enhances effector CD8 T cell responses indirectly, thereby accelerating HBV clearance. However, the direct effector of membrane-bound CD100 in regulating CD8 T cell responses during HBV infection is not well defined.

Materials and Methods:

We examined the impact of mCD100 deficiency on the functional phenotype and differentiation of HBcAg-specific CD8 T cells using separate and co-culture systems in vitro. Furthermore, through adoptive transfer of mCD100-deficient HBV-specific CD8 T cells, we investigated the early impact of mCD100 deficiency on the development of HBV-specific CD8 T cell responses during HBV infection.

Results:

The absence of mCD100 expression significantly decrease HBcAg-specific CD8 T-cell proliferation, activation, effector cytokine production, and expression of Granzyme B and Eomes upon antigen stimulation in vitro. In the acute self-resolving models, the early proliferation and effector differentiation of transferred mCD100 KO TCRtg CD8 T cells were impaired compared to their WT counterparts following HBV challenge. Transcriptomic data revealed that significant downregulation of gene sets associated with the PI3K-Akt, mTOR, NF-κB, and JAK-STAT signaling pathways in CD100KO CD8⁺ T cells.

Conclusions:

Membrane CD100 expressed on resting HBV-specific CD8 T cells may function as a co-stimulatory molecule

by providing a direct stimulatory signal for the early proliferation and effector differentiation of T cells. The observed effects of mCD100 may mediate by activating PI3K-Akt-mTOR, JAK-STAT and NF-κB signaling pathways.

Keyword(s) : CD100, hepatitis B virus, co-stimulatory molecule, CD8 T cell

1191 - Identification of Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD) and Risk Factors in People Living With HIV

Irem Asena Doğan Öntaş ¹, Müge Toygar Deniz ², Eray Öntaş ³, [Sıla Akhan](#) ²

Çorum Iskilip Atif Hoca State Hospital, Department Of Infectious Diseases And Clinical Microbiology, Çorum-Türkiye ¹ Kocaeli University Faculty Of Medicine, Department Of Infectious Diseases And Clinical Microbiology, Kocaeli-Türkiye ² Ankara University Faculty Of Medicine, Department Of Public Health, Division Of Epidemiology, Ankara-Türkiye ³

Background: HIV infection affects 39.9 million individuals worldwide. With the widespread use of combination antiretroviral therapy (cART) the causes of mortality among people living with HIV (PLWH) have shifted toward comorbidities. Approximately half of PLWH have steatotic liver disease, with 90% of these cases are non-alcoholic fatty liver disease (NAFLD). Metabolic dysfunction-associated steatotic liver disease (MASLD) has recently been adopted as a replacement term for NAFLD. In this study, we aimed to determine the prevalence and risk factors of MASLD in PLWH. Materials and Methods: This single-center, cross-sectional study included PLWH on cART ≥6 months and a control group (CG). Hepatic steatosis and liver stiffness were assessed using transient elastography (FibroScan®, Echosens, Paris). Clinical data were extracted from hospital records and analyzed using IBM SPSS v30.0. Results: A total of 128 PLWH and 127 individuals in the CG were included. MASLD prevalence was 40% overall (46.1% in PLWH and 33.9% in CG (p = 0.046)). Significant fibrosis (≥8 kPa) and steatosis was found in 6.3% and 46.9% respectively in PLWH (Table 1). HIV positivity increased MASLD risk 1.67-fold (OR: 1.67, p = 0.047). Among PLWH, the independent risk factors for MASLD development were LSM (OR: 1,3), HOMA-IR (OR:8), and HIV diagnosis time (OR: 4,4) (p <0,05) (Figure 1). Conclusions: MASLD was observed in 46.1% of PLWH, consistent with previous studies reporting a prevalence of 28.8%–48%. In our study, 6.3% of PLWH had significant fibrosis, while another study reported liver

E-POSTER ABSTRACTS

fibrosis in 10% of this population. In our cohort, HOMA-IR was associated with an increased risk of MASLD; similarly, other studies have identified HOMA-IR as an independent risk factor for NAFLD. Detailed and routine evaluation of PLWH is recommended to prevent comorbidities and complications.

Keyword(s) : HIV, MASLD, Transient Elastography, Fibrosis, Steatosis

1192 - Incidental Diagnosis of Rotor Syndrome in an Adolescent Presenting with Osteoporosis

Asli Akçay ¹, Hakan Demiröz ², Yusuf Bünyamin Ketenci ², Mehmet Akca ², Ayşegül Atmaca ³, Ramis Çolak ³, Özge Aydın ³, Ufuk Avcioglu ², Ibrahim Gören ², Ahmet Bektaş ²

Gazi State Hospital, Department Of Internal Medicine, Samsun-Türkiye ¹ Ondokuz Mayıs University Faculty Of Medicine, Department Of Gastroenterology, Samsun-Türkiye ² Ondokuz Mayıs University Faculty Of Medicine, Department Of Endocrinology, Samsun-Türkiye ³

Background / Hypothesis:

Rotor Syndrome (RS) is a rare, benign autosomal recessive disorder causing isolated conjugated hyperbilirubinemia due to defects in hepatic OATP1B1 and OATP1B3 transporters. Distinguishing RS from other hereditary hyperbilirubinemias is essential to avoid unnecessary investigations.

Case Report: An 18-year-old male presented with chronic lower back pain. DEXA revealed severe osteopenia (lumbar Z-score: -5.2; femoral neck: -2.8). Physical examination showed jaundice; other findings were normal. Laboratory tests: total bilirubin 7.75 mg/dL, direct bilirubin 4.62 mg/dL, liver enzymes normal. Imaging and liver biopsy were unremarkable. A 24-hour urinary coproporphyrin test showed elevated type I fraction (52.6%). Genetic analysis confirmed biallelic pathogenic variants in SLCO1B1 and SLCO1B3, establishing RS diagnosis. Osteoporosis was idiopathic; bisphosphonate therapy was initiated.

Discussion: RS results from combined OATP1B1 and OATP1B3 deficiency, impairing hepatic reuptake of conjugated bilirubin. Urinary coproporphyrin pattern and genetic testing differentiate RS from Dubin-Johnson Syndrome. Although benign and non-progressive, recognition of RS avoids unnecessary interventions.

Conclusion: RS should be considered in patients with

isolated jaundice and normal liver function. Early clinical, biochemical, and genetic evaluation facilitates diagnosis, prevents invasive procedures, and reassures patients and clinicians.

1193 - Magnesium Isoglycyrrhizinate for Preventing Novel Antitumor Drug Induced Liver Injury in Patients with Hematologic Malignancies A Multicenter Retrospective Study

Chen Liang ¹, Li Liu ¹, Rongli Zhang ¹, Donglin Yang ¹, Yi He ¹, Aiming Pang ¹, Sizhou Feng ¹, Mingzhe Han ¹, Erjie Jiang ¹

Institute Of Hematology & Blood Diseases Hospital, Chinese Academy Of Medical Sciences & Peking Union Medical College, Stem Cell Transplantation Center, Tianjin-China ¹

Background / Hypothesis:

Novel antitumor drugs (targeted agents and immune checkpoint inhibitors) are commonly used in the clinical management of patients with hematologic malignancies. Previous studies have indicated that these novel antitumor drugs readily induce Drug-Induced Liver Injury (DILI), with an incidence ranging from 1% to 60%. Effective prevention of novel antitumor drug-related DILI is crucial for the antitumor treatment process in these patients. This study aimed to evaluate the effectiveness of Magnesium Isoglycyrrhizinate (MgIG) in preventing novel antitumor drug-related DILI in patients with hematologic malignancies, thereby providing evidence-based support for liver injury prevention during antitumor therapy.

Materials and Methods:

This study was primarily conducted at the Institute of Hematology & Blood Diseases Hospital, Chinese Academy of Medical Sciences, with participation from 13 subsidiary centers across China. The study population included adult patients (aged ≥ 18 years) with hematologic malignancies who were receiving novel antitumor drugs and either received MgIG for liver protection or did not receive any hepatoprotective measures. All patients had normal baseline levels of Total Bilirubin (TBiL), Aspartate Aminotransferase (AST), Alanine Aminotransferase (ALT), and Alkaline Phosphatase (ALP) prior to antitumor therapy. The primary outcome was the severity of liver injury assessed on day 21, day 30, and day 60 after initiating novel antitumor drug treatment.

E-POSTER ABSTRACTS

Results:

From October 2023 to May 2024, a total of 639 patients were enrolled. 456 patients received MgIG prophylactic hepatoprotective therapy (Observation group), and 183 patients did not receive any hepatoprotective measures (Control group). The proportion of patients with Grade 1 liver injury severity was significantly lower in the Observation group (24.6% vs. 45.5%, $p=0.013$). On day 30, the proportions of patients with Grade 1, Grade 2, and Grade 3 liver injury severity were all significantly lower in the Observation group (26.0% vs. 42.3%; 5.2% vs. 6.2%; 2.9% vs. 6.2%; $p < 0.001$). On day 60, the proportion of patients with liver injury severity of Grade 2 or higher was significantly lower in the Observation group (8.6% vs. 18.6%, $p=0.022$). Furthermore, when the antitumor treatment regimen contained at least one targeted agent, the proportion of patients experiencing liver injury of Grade 1 severity or higher was significantly lower in the Observation group (46.7% vs. 66.7%, $p < 0.001$).

Conclusions:

The results of this study indicate that prophylactic administration of MgIG can effectively reduce the severity of novel antitumor drug-related liver injury in patients with hematologic malignancies, warranting further investigation and clinical promotion.

Keyword(s) : Hematologic malignancies; Novel Antitumor Drug-Induced Liver Injury; Magnesium Isoglycyrrhizinate (MgIG) ; Prevention

1194 - The Silent Summer Threat Significant Seasonal Worsening of Electrolyte Imbalance in Cirrhosis Patients in a Tropical Climate Calls for Dynamic Diuretic Dosing

Md Shakhawat Hossain¹, Maknun Nahar², Md. Makhsudul Alam¹
Rangpur Medical College, Gastroenterology, Rangpur-Bangladesh¹ Bangladesh Open University, School Of Science And Technology, Dhaka-Bangladesh²

Background / Hypothesis: Electrolyte imbalances in cirrhosis, driven by diuretics and disease progression, are key predictors of mortality and hepatic encephalopathy. However, the impact of environmental stress is overlooked. We hypothesized that the persistent heat and humidity of a tropical climate would significantly disrupt electrolyte homeostasis. This study aimed to quantify the seasonal variation of serum sodium and potassium in a large cohort of stable cirrhotic patients.

Materials and Methods: We conducted a prospective, observational study of 300 consecutive cirrhotic patients at the Department of Gastroenterology, Rangpur Medical College Hospital, Rangpur, Bangladesh. Each patient underwent two standardized assessments: once in midsummer and once in midwinter. Serum electrolytes were measured, and the prevalence of hyponatremia ($\text{Na}^+ < 135 \text{ mmol/L}$) and hypokalemia ($\text{K}^+ < 3.5 \text{ mmol/L}$) was compared. Statistical analysis included paired t-tests and ROC curve analysis.

Results: The cohort (mean age 55.5 years, 68% male) included 60% patients on diuretics. We found a dramatic seasonal decline in mean serum sodium (Winter: $135.9 \text{ vs. Summer: } 133.6 \text{ mmol/L}$, $p < 0.001$) and potassium ($4.0 \text{ vs. } 3.7 \text{ mmol/L}$, $p < 0.001$). This translated into a near-doubling of clinical prevalence:

- Hyponatremia: 22.7% in winter vs. 45.0% in summer ($p < 0.001$).
- Hypokalemia: 8.7% in winter vs. 18.3% in summer ($p < 0.001$).

The effect was profoundly amplified in patients on diuretics, who had significantly lower summer levels than those not on diuretics (Na^+ : $131.9 \text{ vs. } 136.2 \text{ mmol/L}$; K^+ : $3.5 \text{ vs. } 4.0 \text{ mmol/L}$). ROC analysis identified $\text{Na}^+ \leq 134.5 \text{ mmol/L}$ and $\text{K}^+ \leq 3.75 \text{ mmol/L}$ as optimal cut-offs for predicting summer-associated depletion.

Conclusions: For the first time, we demonstrate a striking "Summer Effect"—a significant seasonal worsening of hyponatremia and hypokalemia in cirrhosis, critically exacerbated by diuretics. This mandates a paradigm shift towards seasonal stewardship in management, including pre-emptive dose adjustments and intensified summer monitoring, to prevent electrolyte-driven complications in vulnerable cirrhotic patients.

Table: Seasonal Variation in Electrolyte Imbalance Prevalence

Parameter	Summer (n=300)	Winter (n=300)	P-value
Mean Sodium (mmol/L)	133.6 ± 5.1	135.9 ± 4.8	< 0.001
Hyponatremia Prevalence	45.0% (453)	22.7% (221)	

E-POSTER ABSTRACTS

<0.001

Mean Potassium (mmol/L) 3.7 ± 0.5 4.0 ± 0.4 <0.001

Hypokalemia Prevalence 18.3% (185) 8.7% (84) <0.001

Hyponatremia (Diuretic Group) 58.2% 32.5% <0.001

Keyword(s) : Cirrhosis, Electrolyte Imbalance, Hyponatremia, Tropical Climate, Diuretic Management

1198 - Multidimensional Burden of Hepatic Encephalopathy and Overt Hepatic Encephalopathy among U.S. Patients with Cirrhosis

Arun B Jesudian¹, Debbie Goldschmidt², Roksana Ghanbari Amin², Kana Yokoji², Joanne Chukwueke², Olamide Olujohungbe³, Leo Passos Chaves³, Annie Guérin²

Weill Cornell Medicine, Division Of Gastroenterology And Hepatology, New York-United States¹ Analysis Group ULC, Na, New York-United States² Bausch Health, Health Economics & Outcomes Research (heor), Bridgewater-United States³

Background / Hypothesis: Hepatic encephalopathy (HE) is a serious complication of cirrhosis characterized by neurocognitive symptoms that impair daily functioning, work ability, and quality of life (QoL). Overt HE (OHE) represents the more severe form, marked by episodes of confusion and disorientation that often require hospitalization and caregiver support. The overall patient-reported burden of HE and OHE, including their impact on daily functioning and QoL, remains poorly characterized.

Materials and Methods: An online survey was conducted (August-November 2025) among US adults with cirrhosis, without severe comorbid conditions or liver transplant, and with sufficient cognitive ability to complete the survey. Patients were classified into non-HE or HE cohorts based on self-reported HE diagnosis or rifaximin use; those reporting an OHE diagnosis, episode, or HE-related hospitalizations formed an OHE subgroup. The survey collected socioeconomic and clinical characteristics, work productivity (WPAI), and health-related QoL (PROMIS-29 v2.0).

Results: As of November 6, 2025, 151 patients participated (74 non-HE; 77 HE, including 22 OHE). Median age was 61 years in the non-HE cohort and 64 years in the HE cohort; 63.5% and 57.1% were male, and 75.7% and 80.5% lived with family, respectively. Median age in the OHE subgroup was 67 years, with 63.6% male. Cirrhosis duration averaged 2.9, 3.3, and

3.9 years for the non-HE, HE, and OHE cohorts, with severe liver disease reported by 0%, 45.5%, and 68.2%. Symptoms requiring medical attention were more common among HE and OHE patients, including fatigue (85.7%; 95.5%), trouble sleeping (68.8%; 81.8%), and confusion (68.8%; 81.8%), compared with 51.4%, 24.3%, and 16.2% among non-HE patients, respectively. Most patients had a caregiver (82.4% non-HE; 94.8% HE; 100% OHE), and paid caregiver use increased with severity (3.3%, 23.3%, and 45.5%, respectively), averaging 8.5, 46.7, and 55.7 hours of care weekly. Employment among working-age patients declined with disease progression (91.3% non-HE; 74.4% HE; 28.6% OHE). HE and OHE patients reported greater financial difficulties, including reduced ability to save and difficulty paying bills. Among those employed, mean work productivity loss in the past 7 days was 32.1% (non-HE) and 67.5% (HE). PROMIS-29 scores indicated poorer QoL across physical function, anxiety, depression, and sleep domains among HE patients, with greater impairment in OHE.

Conclusions: HE and OHE are associated with substantial clinical, socioeconomic, and QoL burden. Interventions that delay or prevent progression to these conditions may meaningfully reduce overall patient burden. Data collection is ongoing and results in a larger sample will be reported.

1199 - Efficacy of Endoscopic band ligation versus argon plasma coagulation in Gastric Antral Vascular Ectasia management

Hishan Abdelaal¹, Ashraf Nassar², Mostafa Soliman¹, Tamer Eleraky²

Kafr El Sheikh Liver Research Center, Department Of Hepatology, Gastroenterology And Infectious Diseases, Kafr El Sheikh-Egypt¹ Faculty Of Medicine, Benha University, Department Of Hepatology, Gastroenterology And Infectious Diseases, Benha-Egypt²

Background / Hypothesis:

Gastric Antral Vascular Ectasia (GAVE) is a capillary-type vascular malformation located mainly in the gastric antrum. It is characterized by dilated, tortuous mucosal capillaries, as well as by dilated, tortuous submucosal veins. Aim of the work: to evaluate the therapeutic effects of EBL (Endoscopic Band Ligation) as a new modality for the treatment of bleeding from GAVE in comparison to APC (Argon Plasma

E-POSTER ABSTRACTS

Coagulation).

Materials and Methods:

This study was conducted on fifty patients presenting with UGI bleeding that proved by upper GIE to be originating from GAVE at Kafr El Sheikh liver center every Tuesday weekly in the period from December 2022 to December 2023. Informed consent was obtained from each patient.

Results:

In this study hemoglobin levels were significantly raised after each endoscopic session done monthly through three months/four endoscopic follow up sessions in patients who underwent EBL and APC with no significant difference between both. Also, recurrence of bleeding from GAVE was significantly decreasing during follow up period in both groups with non-significant difference between both groups. Both groups showed non significant mild complications like superficial ulcers and gastric hyperplastic polyps with non-significant difference between both. UGI endoscopic follow up after 3 months of treatment showed marked improvement in patients treated with EBL and APC. Two patients in each group showed incomplete eradication of GAVE at fourth endoscopic follow up session requiring further follow up. Single patient showed recurrence of GAVE in EBL group with no recurrences in APC group.

Conclusions:

Both APC and EBL are safe and effective management options for both punctate and watermelon types of GAVE.

1200 - CAD LT Score and Outcomes after Liver Transplantation Insights from a Middle Eastern Cohort

Bandar Aljudaibi¹, Tahir Mohamed², Fuat Saner³
King Faisal Specialists Hospital And Research Centre, Liver And Small Bowel Health Centre, Riyadh-Saudi Arabia¹ King Faisal Specialists Hospital And Research Centre, Cardiology, Riyadh-² King Faisal Specialists Hospital And Research Centre, Intensive Care Unit, Riyadh-³

Background / Hypothesis:

Cardiovascular disease remains a major cause of morbidity and mortality following liver transplantation (LT). The CAD-LT score has been proposed as pre-

transplant risk stratification tool for coronary artery disease (CAD) in LT candidates. However, its predictive value has not been validated in Middle Eastern populations.

Aim: To validate CAD-LT score and evaluate its association with post-liver transplant outcomes including (cardiac events, patient and graft survival)

Materials and Methods:

A retrospective analysis of 725 LT adult recipients transplanted between (2020–2024). Data included demographics, comorbidities, pre/post-transplant cardiac assessments (echocardiography, cardiac catheterization), and CAD-LT scores. Patients were stratified into high-, intermediate-, or low-risk groups; [HR, IR, LR]. Outcomes included cardiac events (myocardial infarction, cardiac death, and rhythm disorder), patient and graft survival. Statistical analyses used chi-square tests, the Wilcoxon test, and Kaplan-Meier survival curves.

Results:

The median age was 57.05 years, and 84.4% were male. The most common comorbidities were diabetes (47.66%), hypertension (33.61%), and obesity (33.88%). Based on the CAD-LT score, 41.7% of patients were classified as high risk, while 58.3% were categorized as intermediate- or low risk. Cardiac interventions were significantly more frequent in high-risk patients than in low/intermediate risk patients (9.3% vs 0.47%, $p < 0.0001$). However, four-year patient survival (85% vs. 84%, $p = 0.91$) and graft survival (85% vs. 83%, $p = 0.69$) did not differ significantly between risk groups. A total of 12 cardiac-related deaths occurred, with no significant difference between the groups (50% vs. 50%, $p = 0.544$).

Conclusions:

This is the first study to validate CAD-LT in Middle Eastern LT recipients. While high-risk patients required more pre-transplant cardiac interventions, long-term patient and graft survival were comparable across groups, highlighting the benefit of systematic cardiovascular screening and early intervention.

Keyword(s) : Liver Transplant, cardiac cath, CAD-LT

1202 - A 10 year Cohort Study of The Overall Survival and Treatment Outcomes in Patients with Primary Biliary Cholangitis A Single Centered Retrospective Cohort Study

Shunyapat Sirirattanakorn¹, Tanita Suttichaimongkol¹,

E-POSTER ABSTRACTS

Witsarut Manasirisuk ¹, Kookwan Sawadpanich ¹, Apichart Sangchan ¹, Pisaln Mairiang ¹, Wattana Sukeepaisarnjareon ¹, Chitchai Rattananukrom ¹
Khon Kaen University, Department Of Medicine, Khon Kaen-Thailand ¹

Background / Hypothesis: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease predominantly affecting women, carrying significant risks of cirrhosis and liver failure. Ursodeoxycholic acid (UDCA) is the current treatment of choice. There have been no previous studies investigating the overall survival and treatment outcomes of patients with PBC in Thailand. This study aimed to determine the overall survival and treatment outcomes in a cohort of Thai patients with PBC.

Materials and Methods: We included 57 PBC patients with complete data who were followed at Srinagarind Hospital, Khon Kaen University (2014–2024). Diagnosis required fulfilling at least two standard criteria (biochemical cholestasis, autoantibodies positive, or histology). The primary outcome was 10-year overall survival (OS); secondary outcomes evaluated UDCA treatment response using the Paris I, Paris II, and Rotterdam criteria, and survival differences based on UDCA dosage.

Results: The cohort predominantly comprised women (80.7%), with a median age at diagnosis of 55.14 years. At the time of initial diagnosis, 31.6% of patients had already progressed to cirrhosis, and 47.4% presented with an overlapping syndrome. All analyzed patients received UDCA treatment. The majority (56.1%) were treated with an over-optimal dose (> 15 mg/kg/day), followed by an optimal dose (13–15 mg/kg/day) in 26.3% of patients, and a suboptimal dose in 17.5%. Regarding UDCA treatment response, when utilizing the Paris I criteria, 77.19% of patients showed a favorable response. A lower proportion of responders was observed using the Rotterdam criteria (73.68%) and Paris II criteria (52.63%), respectively. The primary outcome, overall survival, demonstrated a clear dependency on UDCA response across all criteria. Patients classified as UDCA responders by Paris I criteria exhibited significantly higher overall survival compared to non-responders ($P = 0.0038$). This finding was consistent with both Paris II and Rotterdam criteria, where responders also showed significantly better overall survival ($P = 0.00088$ and $P < 0.0001$, respectively). When stratifying patients by UDCA dosage into optimal, suboptimal, and over-optimal groups, the over-optimal dose group showed a trend

towards higher overall survival compared to the optimal and suboptimal dose groups. However, this difference did not reach statistical significance ($p=0.077$).

Conclusions: Achieving a biochemical response to UDCA is a strong and reliable predictor of improved overall survival in Thai PBC patients. These findings confirm favorable long-term outcomes in this population and highlight that further investigation into the optimal UDCA dosing strategy is warranted.

1203 - PIVKA II Monitoring to Predict Response of The First Transarterial Chemoembolization (TACE) in Intermediate Stage of Hepatocellular Carcinoma

Napapong Nitiwarangoon ¹, Anucha Ahooja ², Tanita Suttichaimongkol ¹, Chitchai Rattananukrom ¹
Khon Kaen University, Department Of Medicine, Khon Kaen-Thailand ¹ Khon Kaen University, Department Of Radiology, Khon Kaen-Thailand ²

Background: Hepatocellular carcinoma (HCC) is a major cause of cancer-related mortality. Transarterial chemoembolization (TACE) is the standard treatment for intermediate-stage disease. Early prediction of treatment response is crucial for optimizing patient management and guiding therapeutic decisions. Protein induced by vitamin K absence-II (PIVKA-II) has emerged as a potential biomarker for HCC monitoring; however, its role in predicting radiologic response—particularly complete response (CR) following the first TACE—remains unclear. This study aimed to determine the optimal cut-off value and diagnostic performance of the percentage reduction in PIVKA-II levels (referred to as PIVKA-II response) at 2 weeks post-TACE in predicting CR at 8 weeks, as assessed by imaging. Additionally, we compared the predictive accuracy of the PIVKA-II response at 2 and 8 weeks following the first TACE.

Methods: We conducted a prospective diagnostic accuracy study involving 57 patients with intermediate-stage HCC who underwent their first TACE at Srinagarind Hospital, Khon Kaen University, Thailand. Serum PIVKA-II levels were measured at baseline, as well as at 2 and 8 weeks post-TACE. Radiologic response at 8 weeks was evaluated using cross-sectional imaging based on the modified Response Evaluation Criteria in Solid Tumors (mRECIST). The

E-POSTER ABSTRACTS

predictive value of the PIVKA-II response at 2 and 8 weeks post-TACE was analyzed using the area under the receiver operating characteristic (AUROC) curve.

Results: At 8 weeks post-TACE, 26% of patients achieved CR. The median PIVKA-II response at 2 weeks was significantly greater in the CR group (98%) compared to those with a partial response (79%), stable disease (71%), and progressive disease (65%) ($p = 0.04$). AUROC analysis indicated that a PIVKA-II reduction of $\geq 83.8\%$ at 2 weeks predicted CR with a sensitivity of 80.0%, specificity of 64.3%, positive predictive value (PPV) of 44.4%, negative predictive value (NPV) of 90.0%, and an overall accuracy of 68.4% (AUROC 0.74).

Conclusions: An early reduction in serum PIVKA-II levels following the first TACE correlates with radiologic response, particularly CR, making it a potentially valuable biomarker for treatment monitoring. With an AUROC of 0.74 for predicting CR, the PIVKA-II response at 2 weeks shows promise as an early surrogate marker. This could enable timely therapeutic decisions and potentially improve clinical outcomes.

Keyword(s) : Hepatocellular carcinoma (HCC), Transarterial chemoembolization (TACE), Protein induced by vitamin K absence-II (PIVKA-II), Des-gamma carboxyprothrombin (DCP), Biomarkers, Monitoring, Predict response, Complete response (CR)

1205 - Real World Experience of 25 Years of Lamivudine Therapy Highlighting Favorable Long Term Outcomes in Chronic Hepatitis B

Jaejun Lee¹, Hyun Yang¹, Jung Hyun Kwon¹, Si Hyun Bae¹, Jong Young Choi¹, Seung Kew Yoon¹, Jeong Won Jang¹

The Catholic University Of Korea, Internal Medicine, Seoul-South Korea¹

Background / Hypothesis: Lamivudine, the first oral nucleoside analogue for chronic hepatitis B (CHB), transformed antiviral therapy by enabling durable viral suppression and improving long-term outcomes. However, comprehensive evidence on its long-term clinical impact across diverse treatment patterns is limited.

Materials and Methods: This real-world cohort study analyzed 1,134 CHB patients who initiated lamivudine between 1997 and 2010. Clinical outcomes, including

liver transplantation (LT)-free survival, hepatocellular carcinoma (HCC) incidence, and hepatitis B surface antigen (HBsAg) seroclearance, were evaluated according to treatment continuation, cessation, virologic response, and rescue therapy. Propensity score matching and landmark analyses were applied to minimize bias.

Results: Over a maximum follow-up of 28 years (median, 14.8 years), the 10-year LT-free survival rate was 93.7%, and cumulative HCC incidence was 12.6%. HBsAg seroclearance occurred in 4.8% of patients. Treatment discontinuation significantly increased the probability of HBsAg seroclearance without negatively impacting survival or HCC incidence when performed per stopping criteria. Virologic responders demonstrated superior long-term survival (15-year LT-free survival 96.8%) and higher HBsAg seroclearance rates compared with non-responders. Among these responders, treatment discontinuation did not worsen LT-free survival or HCC risk compared with continued therapy, while achieving higher rates of HBsAg seroclearance in patients maintaining sustained virologic response. Lamivudine resistance was associated with a higher HCC risk (HR 1.95, $P < 0.001$), whereas rescue therapy improved LT-free survival (HR 0.37, $P = 0.007$) and reduced HCC incidence (HR 0.60, $P = 0.038$).

Conclusions: Lamivudine therapy provides durable long-term survival and HCC risk reduction, with safe cessation in selected patients and clear benefits of timely rescue therapy. These findings support optimization of CHB management strategies using current potent antiviral agents

1206 - Neurophysiological neuropsychological characteristics and natural history of liver cirrhotics with minimal and grade 1 hepatic encephalopathy

Lalit Chandra Kummetha¹, Venkatesh Vaithiyam¹, Barjesh Chander Sharma¹, Shrey Bhatt¹, Siddharth Srivastava¹, Neera Chaudhry², Monica S Tandon³, Sanjeev Sachdeva¹, Ajay Kumar¹, Ashok Dalal¹, Ujjwal Sonika¹

Gb Pant, Institute Of Postgraduate Medical Education And Research, Gastroenterology, Hyderabad-India¹ Gb

E-POSTER ABSTRACTS

Pant Institute Of Postgraduate Medical Education And Research, Neurology, Delhi-India ² Gb Pant Institute Of Postgraduate Medical Education And Research, Anesthesia And Intensive Care, Delhi-India ³

Background / Hypothesis:

Minimal and Grade 1 hepatic encephalopathy (HE) represent the earliest stages of cognitive dysfunction in cirrhosis and are associated with adverse outcomes. Differentiating them objectively remains challenging. Neurophysiological tools such as Bispectral Index (BIS) and spectral electroencephalography (EEG) may provide objective markers. This study compared clinical, BIS and spectral EEG characteristics between minimal and grade 1 HE and evaluated their treatment outcomes.

Materials and Methods:

This prospective observational study was conducted in the Department of Gastroenterology, GB Pant Hospital, New Delhi, from November 2023 to April 2025. 150 cirrhotics were classified as no HE (n=50), minimal HE (n=50), or grade 1 HE (n=50) using West Haven criteria and Psychometric Hepatic Encephalopathy Score (PHES). Serum ammonia, Critical Flicker Frequency (CFF), BIS, and spectral EEG (mean dominant frequency [MDF], relative alpha, beta, theta, delta powers) were recorded. Receiver Operating Characteristic (ROC) curves and survival analyses were performed to determine diagnostic utility and assess prognosis.

Results:

Mean BIS declined progressively (No HE = 91.18 ± 3.43 , Minimal = 81.48 ± 3.9 , grade 1 = 72.9 ± 5.49 ; $p < 0.0001$). Optimal BIS cut-offs were ≤ 85 for Minimal (AUC = 0.969, Sensitivity 88%, Specificity 96%) and ≤ 78 for grade 1 HE (AUC = 0.895). MDF also decreased significantly (No HE = 12.9 ± 4.66 Hz, Minimal = 7.89 ± 1.19 Hz, grade 1 = 5.13 ± 1.57 Hz; $p < 0.0001$). MDF ≤ 8.9 Hz predicted Minimal HE (AUC = 0.97) and ≤ 6.6 Hz predicted grade 1 HE (AUC = 0.938). Alpha and beta relative powers declined, while theta and delta increased with HE severity (all $p < 0.0001$). CFF ≤ 39 Hz predicted minimal HE (AUC = 0.92), and ≤ 35 Hz predicted grade 1 HE (AUC = 0.659). Serum ammonia showed poor discrimination (AUC ≈ 0.54). During follow-up, grade 1 HE had higher complication, hospitalization, and mortality rates than minimal HE ($p < 0.05$).

Conclusions:

Minimal and grade 1 hepatic encephalopathy are

distinct clinical entities. Patients with grade 1 HE showed a higher risk of progression, complications, hospitalisation, and mortality than those with minimal HE. BIS and spectral EEG provide reliable, objective differentiation between minimal and grade 1 HE, outperforming serum ammonia. Lower BIS and MDF values correlate with disease severity and adverse outcomes, suggesting potential utility in early detection and prognostication of covert hepatic encephalopathy.

1207 - Comparison of inflammatory markers magnetic resonance spectroscopy findings and outcomes in cirrhotic patients with minimal and grade 1 hepatic encephalopathy a prospective observational study

Shrey Bhatt ¹, Venkatesh Vaithiyam ¹, Barjesh Chander Sharma ¹, Lalit Chandra Kummetha ¹, Siddharth Srivastava ¹, Bhawna Mahajan ², Kalpana Bansal ³, Sanjeev Sachdeva ¹, Ajay Kumar ¹, Ashok Dalal ⁴, Ujjwal Sonika ¹

Gb Pant Institute Of Postgraduate Medical Education And Research (gipmer), Gastroenterology, New Delhi-India ¹ Gb Pant Institute Of Postgraduate Medical Education And Research (gipmer), Biochemistry, New Delhi-India ² Gb Pant Institute Of Postgraduate Medical Education And Research (gipmer), Radiodiagnosis, New Delhi-India ³ Gb Pant Institute Of Postgraduate Medical Education And Research (gipmer), Gastroenterology, New Delhi-India ⁴

Background / Hypothesis: Minimal and Grade 1 hepatic encephalopathy (HE) represent the earliest, often under-recognized spectrum of neurocognitive impairment in cirrhosis. Both are associated with impaired quality of life, increased risk of progression to overt HE, and higher mortality. The overlapping clinical features and lack of uniform diagnostic criteria make differentiation difficult. We hypothesized that distinct inflammatory and metabolic alterations, measured by serum cytokines and magnetic resonance spectroscopy (MRS), could objectively distinguish minimal from Grade 1 HE and predict adverse outcomes.

Materials and Methods: This prospective observational study was conducted at the Department of

E-POSTER ABSTRACTS

Gastroenterology, GB Pant Hospital, New Delhi, between November 2023 and April 2025. Consecutive cirrhotic adults (n = 150) were categorized as No HE, Minimal HE, or Grade 1 HE (50 each). Minimal HE was diagnosed by Psychometric Hepatic Encephalopathy Score ≤ -5 and Critical Flicker Frequency ≤ 38 Hz; Grade 1 HE was defined by West Haven criteria. Serum TNF- α , IL-6, IL-18, IL-10, IL-12, IL-1 β , and endotoxin were quantified by ELISA. Brain MRS (3.0 T Philips Ingenia) evaluated myoinositol, choline, creatine, and glutamine peaks. Patients were followed for 12 months for progression, complications, and survival. Statistical analysis included ANOVA, ROC, Kaplan–Meier, and Cox regression.

Results: Mean ammonia, inflammatory markers, and MELD/CTP scores increased progressively across groups ($p < 0.001$). Compared with no HE, TNF- α ($25.3 \pm 10.8 \rightarrow 47.1 \pm 14.0 \rightarrow 64.3 \pm 28.4$ pg/mL), IL-6 ($22.7 \pm 16.8 \rightarrow 69.9 \pm 42.2 \rightarrow 113.9 \pm 46.1$ pg/mL), and IL-18 ($171.5 \pm 61.6 \rightarrow 348.0 \pm 86.3 \rightarrow 519.4 \pm 178.7$ pg/mL) rose stepwise from no HE to minimal and Grade 1 HE (all $p < 0.0001$). MRS revealed decreased myoinositol and choline with elevated glutamine in HE patients ($p < 0.001$). ROC analysis identified ammonia > 106 μ g/dL and CFF ≤ 38 Hz as optimal thresholds for minimal HE (AUC 0.91 and 0.94, respectively). One-year follow-up showed greater progression to overt HE and higher complication rates in Grade 1 HE compared to minimal HE ($p < 0.05$).

Conclusions: Minimal and Grade 1 HE constitutes distinct but sequential stages within the covert HE spectrum. Combined evaluation of inflammatory cytokines and cerebral MRS profiles enables objective differentiation and may facilitate early risk stratification and targeted management to prevent overt HE and improve prognosis.

1208 - Insights from the ELPA European Liver Screening Week 2025

Richard Hall ¹, Jacques Shurmann ², Lydie Moreaux ², Julie Odienne ², Marko Korenjak ³, Milan Mishkovikj ⁴, Veronika Vsetickova ⁴, Beatrice Credi ⁴

Liver4life, -, Dorset-United Kingdom ¹ Sos Hépatites Champagne-ardenne, -, Charleville-mézières-France ² European Liver Patients' Association - Elpa, -, Brussels-Belgium ³ European Liver Patients' Association - Elpa, -, Brussels-Belgium ⁴

BACKGROUND AND AIMS: In recent years, the European Union(EU) has witnessed a concerning rise in the incidence of MASLD and MASH, conditions characterised by the accumulation of excess fat in liver cells. Of particular concern is the link between the accumulation of fat in the liver and its potential to serve as a significant risk factor for the development of liver cancer. This highlights the importance of addressing lifestyle-related factors and implementing preventive measures to slow the progression of this condition. This project aimed to raise awareness of how simple and effective early detection of liver disease can be using portable transient elastography(TE) within a community setting.

METHOD: The Liver4Life and SOS Hépatite testing vans (ELPA Members from the UK and France) were present at the European Parliament in September/October 2025 for 5 days, offering testing to the Parliament staff and the general public. ELPA representatives engaged with Members of the Parliament to build awareness of the upcoming event, and invitations were sent to members who regularly engage with the liver health agenda. The vans and gazebos were in the pedestrianised walkway outside the main entrance, and specific messaging was created and displayed on the vans. Trained operators, including some Belgian healthcare professionals, managed the TE devices. A brief lifestyle intervention was used when a high Controlled Attenuation Parameter (CAP) reading was identified. The same approach was used if a high stiffness reading was identified, paired with a self-referral letter inviting the individual to seek medical consultation.

RESULTS: The total number of completed and recorded TE examinations over the 5 days was 560. These were all adults. Of the total examinations, 29 people (5.2%) had stiffness readings above 7.1 Kpa, and these people were given self-referral letters after brief intervention advice. The average stiffness reading was 5.1 Kpa. The study also identified 230 people (41%) with a CAP reading above 235 dB/m. Among them, 80 people (35%) had a CAP reading of 290 dB/m or higher. Individuals with a CAP score of 235 dB/m or higher were provided with brief lifestyle intervention advice. The average CAP reading was 235 dB/m.

CONCLUSION: Most individuals with high CAP readings were unaware they had fat in their liver,

E-POSTER ABSTRACTS

although many suspected it due to their lifestyles, but hesitated to see the results. These findings highlight the urgent need for public health action to raise awareness.

1210 - Prevotella Derived Butyrate Inhibits CD8⁺ T Cell Glycolysis via AKT mTOR signal to Alleviate MASH

Fengna Yan ¹, Feixiang Xiong ², Yuyong Jiang ³, Xiaomin Ji ³, Tong Wu ³, Yang Zhou ³, Xuejie Zhang ³, Dandan Chen ³, Yixin Hou ³

Beijing Ditan Hospital, Capital Medical University, Beijing Institute Of Infectious Diseases, Beijing-China ¹ Beijing Institute Of Infectious Diseases, Center Of Integrative Medicine, Beijing-China ² Beijing Ditan Hospital, Capital Medical University, Center Of Integrative Medicine, Beijing-China ³

Background / Hypothesis:

Metabolic associated steatohepatitis (MASH) is a critical stage of MAFLD, lacking effective therapies. Gut microbiota and their metabolites, particularly short-chain fatty acids (SCFAs), are increasingly recognized as modulators of hepatic metabolism and immune responses. We investigated whether Prevotella could ameliorate MASH by regulating CD8⁺ T-cell metabolism.

Materials and Methods:

Fecal samples from MASH patients and healthy controls were analyzed by 16S rDNA sequencing and untargeted metabolomics. MASH mouse models, germ-free mice, and ex vivo CD8⁺ T-cell cultures were used to assess the effects of Prevotella and butyrate on glycolysis, PI3K/AKT/mTOR signaling, and liver pathology. Metabolic activity was measured using ECAR, 2-NBDG uptake, and lactate production; molecular changes were evaluated by qPCR, Western blot, and flow cytometry.

Results:

16S rDNA sequencing revealed a significant reduction of Prevotella abundance in MASH patients compared with healthy controls, which was inversely correlated with hepatic steatosis and CD8⁺ T-cell infiltration. In MCD diet-induced MASH mice, oral administration of Prevotella alleviated hepatic lipid accumulation and collagen deposition. In germ-free mice, colonization

with Prevotella similarly improved liver histology. Mechanistically, Prevotella suppressed glycolytic activity in CD8⁺ T cells, as shown by decreased 2-NBDG uptake, ECAR measurements, and reduced expression of glycolytic enzymes (HK2, PKM2, LDHA). Additionally, Prevotella downregulated the PI3K/AKT/mTOR signaling pathway in CD8⁺ T cells, linking its metabolic effects to immune modulation. Notably, the combination of Prevotella with a glycolysis inhibitor did not further enhance its therapeutic efficacy compared with Prevotella alone, indicating that suppression of glycolysis is a major mechanism underlying Prevotella's protective effects.

Conclusions:

Prevotella mitigates MASH by downregulating the PI3K/AKT/mTOR-glycolysis axis in CD8⁺ T cells via butyrate-dependent mechanisms, highlighting its potential as a microbial therapeutic candidate for MASH.

Keyword(s) : Prevotella; MASH; CD8⁺ T cells; Glycolysis; PI3K/AKT/mTOR signaling

1211 - Differential Impact of Antiviral Therapy on Bimodal Recurrence Patterns in HBV versus HCV related Hepatocellular Carcinoma Following Radiofrequency Ablation

Makoto Moriyama ¹, Ryosuke Tateishi ¹, Takuma Kaneko ¹, Keisuke Mabuchi ¹, Tomoharu Yamada ¹, Takuma Nakatsuka ¹, Tatsuya Minami ¹, Masaya Sato ¹, Mitsuhiro Fujishiro ¹

The University Of Tokyo, Gastroenterology, Tokyo-Japan ¹

Background: Recent studies have shown that antiviral therapy suppresses recurrence of hepatocellular carcinoma (HCC) after curative treatment. However, the differential effects between hepatitis B virus (HBV) and hepatitis C virus (HCV)-related HCC remain unclear. This study aimed to compare the impact of viral suppression on HCC recurrence patterns between HBV and HCV-related cases following radiofrequency ablation (RFA).

Materials and Methods: We retrospectively analyzed patients who underwent curative RFA for primary HBV- or HCV-related HCC at our institution between January 2000 and December 2022. Sustained virological response (SVR) was treated as a time-dependent covariate, with patients stratified into periods before and after achieving SVR. We performed a secular trend analysis by comparing the hazards of recurrence

E-POSTER ABSTRACTS

between the SVR and non-SVR cohorts. The recurrence rate (hazards of recurrence) was estimated by computing a nonparametric smoothed estimate of the hazard function based on generalized linear mixed models.

Results: Among 214 HBV-related and 1,210 HCV-related HCC cases, median follow-up was 1.85 (range:0.78-4.41) years (SVR) versus 1.75 (range:0.74-2.29) years (non-SVR) for HCV, and 2.41 (range:0.94-4.05) years (SVR) versus 1.06 (range:0.51-1.96) years (non-SVR) for HBV patients. For HCV-related HCC, the non-SVR group demonstrated persistently high recurrence risk with a bimodal pattern, exhibiting peaks at 1-2 years (early : annual hazard rate 63.1%) and 8-10 years (late: annual hazard rate 69.5%). In contrast, the SVR group showed a significantly reduced recurrence risk (peak: annual hazard rate 9.67%) and did not exhibit a bimodal pattern. For HBV-related HCC, the non-SVR group similarly exhibited bimodal peaks at 1-2 years (early: annual hazard rate 50.5%) and 4-6 years (late: annual hazard rate 50.2%). While the SVR group showed reduced recurrence risk (peak annual hazard rate 26.3%), the reduction was substantially less pronounced than in HCV-related HCC.

Conclusions: Effective antiviral therapy attenuates the late recurrence peak of HCC following curative RFA, with this effect being more pronounced in HCV-related compared to HBV-related HCC. These findings suggest that surveillance remains important, particularly for HBV-related cases despite viral suppression.

1213 - Treatment Efficiency of Bulevirtide in Chronic Hepatitis Delta Number Needed to Treat Analysis From the MYR301 Phase 3 Trial

Maria Buti ¹, Arman P Sali ², Barinder Singh ³, Amos Lichtman ⁴, Heiner Wedemeyer ⁵, Celine Der-torossian ⁴, Chong Kim ⁴, Akanksha Sharma ³, Dmitry Manuilov ⁴, Marvin Rock ⁶, Pietro Lampertico ⁷

Hospital Universitario Vall D'hebron, Liver Unit, Barcelona-Spain ¹ Gilead Sciences, Inc., Stockley Park-United Kingdom ² Pharmacoevidence, , Mohali-India ³ Gilead Sciences, Inc., , Foster City-United States ⁴ Hannover Medical School, Clinic For Gastroenterology, Hepatology, Infectious Diseases, And Endocrinology, Hannover-Germany ⁵ Gilead Sciences, Inc., Gheor, Gv&a, Foster City-United States ⁶ Foundation Irccs Ca' Granda Ospedale Maggiore Policlinico, Division Of Gastroenterology And Hepatology, Milan Italy ⁷

Background / Hypothesis: Bulevirtide (BLV), has demonstrated long-term efficacy with infrequent/low adverse events and treatment discontinuations, in the Phase 3 MYR301 trial for patients with chronic hepatitis delta (CHD). The number needed to treat (NNT) offers a patient-centered measure of clinical benefit, quantifying how many patients must receive therapy for 1 additional patient to achieve a meaningful outcome compared with control. This analysis aimed to estimate the NNT for BLV 2 mg and BLV 10 mg compared with control (delayed treatment) using efficacy endpoints from the MYR301 study at week 48.

Materials and Methods: Data were obtained from the multi-center, open-label, randomized, Phase 3 MYR301 trial in CHD. The efficacy endpoints included in this analysis were combined response i.e., hepatitis delta virus ribonucleic acid (HDV RNA) undetectable or $\geq 2 \log_{10}$ IU per milliliter decline + alanine aminotransferase (ALT) normalization and virologic response. NNT was calculated as the reciprocal of the absolute difference in response rates between arms at week 48 using the intention-to-treat population with 95% confidence intervals (CIs) for each estimate.

Results: At week 48, BLV demonstrated statistically significant improvements vs control across both key efficacy endpoints ($P < .001$). For combined response, the NNT was 3 (95% CI 2–4), corresponding to an absolute risk reduction (ARR) of 43%–46%, indicating that treating 3 patients with BLV 2 mg or 10 mg results in 1 additional responder, reflecting a robust clinical benefit. For virologic response, the NNT was 2 (ARR, 68%–72%), highlighting even greater clinical impact, with only 2 patients needing treatment for 1 additional response.

Conclusions: BLV 2 mg and 10 mg produced statistically significant and clinically meaningful benefits vs control, with NNTs of 2–3 across key efficacy endpoints at week 48. These low NNT values indicate a high treatment efficiency and align with thresholds considered highly favorable in the literature. Ongoing NNT analyses will assess whether these benefits persist beyond week 48. Overall, the combined evidence of favorable efficacy, together with an established safety profile, supports the clinical value of BLV.

E-POSTER ABSTRACTS

1216 - Microbial hippurate promotes GLRA2 activation immune exhaustion and development of shock in ACLF patients

Gaurav Tripathi¹, Jaswinder Singh Maras¹, Rakhi Maiwall², Shiv Kumar Sarin²

Institute Of Liver And Biliary Sciences, Molecular And Cellular Medicine, Delhi-India¹ Institute Of Liver And Biliary Sciences, Department Of Hepatology, Delhi-India²

Background

Critically ill patients with acute-on-chronic liver failure (ACLF) have high sepsis-related mortality. While gut dysbiosis is recognized, the role of microbial metabolites in immune dysfunction and shock is not well understood. This study investigates gut microbiota, circulating metabolites, and their links to immune failure, shock progression, and mortality in ACLF patients.

Methods

In this pilot study, 200 participants were included: 50 healthy controls (HC), 50 ACLF without infection, and 100 critically ill ACLF patients (CAC; 36-sepsis, 64-septic shock) in the discovery cohort. Stool metaproteomics and plasma metabolomics were analyzed, with metabolites validated in 250 ACLF patients (119 survivors, 131 non-survivors) using machine learning (ML). Key microbial and metabolic predictors of septic shock and mortality were identified, and their correlation with neutrophil proteomics and metabolomics was assessed.

Results

Metaproteomic analysis identified distinct microbial signatures in septic shock, sepsis, alcoholic cirrhosis (AC), and healthy controls (HC), with significant separation of septic shock patients ($p < 0.05$). Septic shock had higher microbial diversity ($p < 0.05$), with 300 upregulated and 345 downregulated bacterial species compared to other groups. Key species enriched in septic shock included *Vibrio parahaemolyticus* ($FC > 6$), *Staphylococcus aureus* ($FC > 9$), and *Klebsiella aerogenes* ($FC > 150$). Functional pathways enriched in septic shock included siderophore biosynthesis, amino acid metabolism, and the TCA cycle.

Plasma metabolomics identified 1,236 metabolites, with 374 upregulated and 73 downregulated in septic shock (fold change > 1.5 , $p < 0.05$). Key metabolic pathways involved glycine, phenylalanine, tryptophan, pyruvate, and ammonia metabolism, with elevated hippurate ($FC > 24$, $p < 0.05$) in septic shock. Bacteria-metabolite correlation analysis revealed strong associations between hippurate and 26 bacterial taxa ($R^2 > 0.7$), with hippurate linked to 28-day mortality

($p < 0.05$).

Neutrophil proteomics showed elevated glycine levels in septic shock, with increased expression of glycine-N-acyltransferase (GLYAT1 and GLYAT3) ($FC > 4$, $p < 0.05$). Glycine, converted to hippurate, activated GLRA2, leading to membrane hyperpolarization and calcium signaling disruption, impairing neutrophil function by reducing ROS production and contributing to neutrophil exhaustion. GLRA2 activation also upregulated anti-inflammatory proteins like TGF β 1 ($FC > 1.5$, $p < 0.05$), contributing to immune suppression. Validation with mass spectrometry and ML confirmed hippurate as a strong predictor of septic shock and early mortality, outperforming traditional clinical scores. Cox regression analysis identified hippurate as an independent predictor of 28-day mortality ($HR > 1$). Conclusion

Hippurate and glycine metabolism play a central role in septic shock progression, contributing to neutrophil dysfunction and immune suppression. These findings highlight hippurate as a promising biomarker for early diagnosis and mortality prediction in septic shock.

1217 - Integrated Plasma Multi Omics Identifies Fungal Dysbiosis and Lipid Remodelling as Major Determinants of Sepsis and Shock in Alcohol Related Cirrhosis

Gaurav Tripathi¹, Jaswinder Singh Maras¹, Rakhi Maiwall², Shiv Kumar Sarin²

Institute Of Liver And Biliary Sciences, Molecular And Cellular Medicine, Delhi-India¹ Institute Of Liver And Biliary Sciences, Department Of Hepatology, Delhi-India²

Background: Alcohol associated cirrhosis (AC) often succumbs to sepsis progressing to shock and early mortality. While fungal overgrowth and lipid dysregulation are known in liver failure, how increase in fungal infection and associated lipids mediators enhance predisposition to shock and early mortality was evaluated in AC patients

Methods-Plasma and stool samples from AC patients with and without shock ($n = 150$) and healthy controls (HC; $n = 50$) was analysed using high-resolution mass spectrometry-based proteomics, lipidomics, and mycobiome (meta-proteomics) analysis. The identified fungal species (peptides) lipid parameter were cross

E-POSTER ABSTRACTS

correlated and key lipid species were analysed for the incidence of shock and early mortality in an independent AC cohort (n=250) using machine learning (ML).

Results Shock patients exhibited profound hypolipidemia (low expression >60 subclasses) and reduced lipid diversity as compared to other groups ($P<0.05$). Fungal peptide-based diversity analysis (Mycobiome profiling) revealed expansion of pathogenic fungi including *Aspergillus*, *Candida*, *Yarrowia*, and *Cryptococcus* with over 40 species enriched in shock and non-survivors ($P<0.05$). The fungal-derived 2,5-didehydro-D-gluconic acid showed >91% diagnostic accuracy for predicting predisposition to shock and early mortality. Expression of fungal surveillance proteins (CLEC4G, SCARB1) were decreased which mediated increase in fungal growth and linked lipid mediators which mediate significant increase in mitochondrial beta-oxidation and stress, suggesting exhaustive immune surveillance and bioenergetics collapse in AC patients.

Conclusion: Our study outlines significant dysregulation of fungal-host lipid axis driving mitochondrial dysfunction and bioenergetics collapse mediated shock in AC patients. The identified lipid mediators could be used for early stratification of shock and early mortality in AC patients.

Keyword(s) : Alcohol-associated cirrhosis, Fungal sepsis, Septic shock, Lipidomics, Mycobiome, Mitochondrial stress, Hypolipidemia, 2,5-Didehydro-D-gluconic acid.

1218 - Development and Validation of a Nomogram to Predict Surgical Resection After Conversion Therapy in Initially Unresectable Hepatocellular Carcinoma

Yuhao Su¹, Yuxin Liang¹, Deyuan Zhong¹, Xiaolun Huang¹

Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School Of Medicine, University Of Electronic Science And Technology Of China, Liver Transplantation Center And Hbp Surgery, Chengdu-China¹

Background / Hypothesis: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide, with fewer than 30% of patients being candidates for curative resection at initial diagnosis. Conversion therapy, particularly triple-combination regimens integrating locoregional therapy (TACE/HAIC), tyrosine kinase inhibitors, and immune

checkpoint inhibitors, offers a promising strategy to downstage initially unresectable HCC (uHCC). However, significant heterogeneity exists in patient response, and reliable tools for predicting successful surgical conversion are lacking. We hypothesized that a model incorporating baseline clinical and inflammatory biomarkers could effectively stratify patients according to their likelihood of achieving resection following conversion therapy.

Materials and Methods: We conducted a retrospective analysis of 210 patients with uHCC who received triple-combination conversion therapy at Sichuan Cancer Hospital between January 2022 and January 2025. Patients were randomly allocated to a training cohort (n=147) and a validation cohort (n=63) in a 7:3 ratio. Least absolute shrinkage and selection operator (LASSO) regression was applied to screen 28 potential predictors from clinical characteristics and laboratory indices. Independent factors associated with successful conversion surgery were identified using multivariate logistic regression. A nomogram was constructed and its performance was evaluated by the area under the receiver operating characteristic curve (AUC), calibration curves, and decision curve analysis (DCA).

Results: Among the 210 patients, 47 (22.4%) successfully underwent radical resection after conversion therapy. Multivariate analysis identified four independent protective factors for successful conversion: lower Tumor Burden Score (TBS; OR=0.663, 95% CI: 0.523-0.840), lower Neutrophil-to-Lymphocyte Ratio (NLR; OR=0.572, 95% CI: 0.381-0.860), lower C-reactive protein-to-Albumin Ratio (CAR; OR=0.057, 95% CI: 0.004-0.850), and absence of cirrhosis (OR=0.289, 95% CI: 0.107-0.783). The nomogram demonstrated excellent discrimination, with AUCs of 0.850 (95% CI: 0.784-0.915) in the training cohort and 0.871 (95% CI: 0.783-0.962) in the validation cohort. Calibration plots and DCA indicated robust model fit and favorable clinical utility.

Conclusions: We developed and validated a novel nomogram that integrates TBS, NLR, CAR, and cirrhosis status to accurately predict the probability of surgical resection following triple-combination conversion therapy in uHCC. This practical tool can assist clinicians in early identification of patients most likely to benefit

E-POSTER ABSTRACTS

from an aggressive conversion strategy, thereby facilitating personalized treatment planning and optimizing resource allocation. Further multicenter prospective studies are warranted to confirm its generalizability.

1220 - Efficacy and Safety of Sofosbuvir Velpatasvir Voxilaprevir for the Retreatment of Chronic Hepatitis C Patients Relapsed after DAA Treatment

Jun Chen¹, Weiting Cheng¹, Zebing Huang¹, Yan Huang¹

Xiangya Hospital Central South University, Infectious Diseases Department, Changsha-China¹

Background / Hypothesis:

Hepatitis C virus (HCV) infection is one of major global public health concerns. Although the overall success rate of direct-acting antivirals (DAAs) therapies is high, a small proportion of patients experience relapse after treatment. This study aims to evaluate the efficacy and safety of Sofosbuvir/Velpatasvir/Voxilaprevir (SOF/VEL/VOX) in chronic hepatitis C (CHC) patients who relapsed following DAAs therapy.

Materials and Methods:

Between March 2022 and August 2024, patients who experienced relapse after DAAs therapy, and then received SOF/VEL/VOX salvage treatment for 12 weeks were included at 24 academic centers in Hunan and Shanxi Province, China. Baseline characteristics, HCV RNA clearance rates, complete blood count, liver function, and other indices were analyzed. The sustained virologic response at off-treatment week 12 (SVR12) was assessed by intention-to-treat analysis and per protocol analysis. The impact of gender, age, cirrhosis status, genotype, and the addition of ribavirin during treatment on SVR12 was assessed. The adverse events during treatment and follow-up were also reported.

Results:

92 patients were included and completed 12 weeks of treatment. Median age was 52, 69.6% were male, 62.0% had cirrhosis and 18.5% had portal hypertension. Of the 50.0% with genotype 3, 80.4% were also cirrhotic. Of note, 93.5% (86/92) had previously been treated with sofosbuvir-based regimen plus NS5A inhibitor and 6.5% (6/92) had been treated with NS3/4A inhibitor-based regimen plus NS5A. The

normalization rates of ALT and AST after 12 weeks of treatment were 54.3% (50/92) and 83.7% (77/92), respectively. By intention-to-treat analysis, SVR12 rate was 93.5% (86/92). For per protocol, the SVR12 was 97.7%, including 100% in genotypes 1b (21/21), 2 (15/15) and 6 (7/7), and 95.5% (43/45) in genotypes 3. And all two non-responders were genotype 3 patients, and had cirrhosis with a FIB-4 index of > 3.25. SVR12 in participants for genotype 3 with cirrhosis was 94.6%. The addition of ribavirin had no effect on SVR12. Further analysis indicated no statistically significant differences in HCV RNA clearance rates based on gender, age, genotype, treatment regimen, or ALT and AST levels. During treatment, one patient who received ribavirin experienced gastrointestinal side effects within one week and discontinued ribavirin on their own. No other severe adverse events were reported.

Conclusions:

SOF/VEL/VOX is highly efficacious and well-tolerated for CHC patients who relapse after DAAs therapy, and those with liver cirrhosis infected by genotype 3 remain the most-difficult-to-treat group.

Keyword(s) : Sofosbuvir/Velpatasvir/Voxilaprevir; Retreatment; Chronic Hepatitis C; Relapse; DAA Treatment

1221 - Neoadjuvant radiotherapy for resectable hepatocellular carcinoma with vascular invasion A systematic review and meta analysis

Yuhao Su¹, Yuxin Liang¹, Deyuan Zhong¹, Xiaolun Huang¹

Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School Of Medicine, University Of Electronic Science And Technology Of China, Liver Transplantation Center And Hbp Surgery, Chengdu-China¹

Background / Hypothesis: Hepatocellular carcinoma (HCC) with vascular invasion, including portal vein tumor thrombus (PVTT) and microvascular invasion (MVI), is associated with high postoperative recurrence and poor survival. While surgical resection remains a cornerstone treatment, its efficacy is limited by recurrence risks. Neoadjuvant radiotherapy has emerged as a potential strategy to downstage tumors and improve outcomes, but its role in resectable HCC with vascular invasion remains controversial. We hypothesized that neoadjuvant radiotherapy could enhance survival and reduce recurrence in this patient population.

E-POSTER ABSTRACTS

Materials and Methods: A systematic search of PubMed, Embase, Cochrane Library, CNKI, Wanfang, and VIP databases was conducted up to August 1, 2024, to identify studies comparing neoadjuvant radiotherapy followed by surgery versus surgery alone for resectable HCC with vascular invasion. Four studies (two randomized controlled trials and two prospective studies) involving 362 patients were included. Primary outcomes were 1- and 2-year overall survival (OS) and 1-year disease-free survival (DFS). Pooled risk ratios (RRs) and hazard ratios (HRs) were calculated using random-effects models. Subgroup analyses were performed based on vascular invasion type (PVT vs. MVI).

Results: Neoadjuvant radiotherapy demonstrated a trend toward improved OS (1-year OS RR: 1.62, 95% CI: 0.71–3.69; 2-year OS RR: 2.64, 95% CI: 0.57–12.27) and DFS (RR: 2.68, 95% CI: 0.50–14.43), though not statistically significant. Subgroup analysis revealed significant benefits for PVT patients, with neoadjuvant radiotherapy improving 1-year OS (RR: 1.88, 95% CI: 1.52–2.32) and reducing recurrence (HR: 0.42, 95% CI: 0.31–0.58) and mortality (HR: 0.34, 95% CI: 0.24–0.48). No significant benefit was observed in MVI subgroups. Sensitivity analysis confirmed robustness, and heterogeneity was mitigated by grouping studies by vascular invasion type.

Conclusions: Neoadjuvant radiotherapy is a safe and effective strategy for resectable HCC with PVT, significantly improving survival and reducing recurrence. However, its benefit for MVI remains uncertain. These findings support individualized treatment planning based on vascular invasion type and highlight the need for larger, prospective trials to validate these results.

Keyword(s) : hepatocellular carcinoma, vascular invasion, neoadjuvant radiotherapy, surgical excision, meta-analysis.

1222 - Efficacy and Safety of Radiotherapy Combined with PD 1 Inhibitors and Targeted Therapy for Unresectable Hepatocellular Carcinoma A Real World Multicenter Study

Weixuan Xu¹, Linbin Lu¹, Xiong Chen¹
Mengchao Hepatobiliary Hospital Of Fujian Medical University, Department Of Oncology, Fuzhou-China¹

Background / Hypothesis:

Real-world data concerning the efficacy and safety of triple regimens combining radiotherapy (RT), PD-1 inhibitors and targeted therapy in unresectable hepatocellular carcinoma (uHCC) remains limited. Herein, we aim to evaluate the safety and efficacy of this triple therapy, and identify risk factors associated with survival outcomes.

Materials and Methods:

122 consecutive patients with uHCC who received RT combining PD-1 inhibitors and targeted therapy across 3 medical centers were analyzed. Data on baseline characteristics, treatments regimens, objective response rate (ORR), disease control rate (DCR), overall survival (OS), progression-free survival (PFS) and treatment-related adverse events (TRAEs) were collected. Univariate and multivariate Cox analyses were performed to identify independent risk factors for OS and PFS. Subgroup analysis explored the association between immunotherapy cycles and overall survival across tumor response stratification.

Results:

The median follow-up time was 14.2 months (IQR, 6.9–19.2 months). According to the modified response evaluation criteria in solid tumor (mRECIST), the ORR and DCR were 18.85% (95%CI: 12.34%–26.93%) and 73.78% (95%CI: 65.04%–81.32%), respectively. The median OS was 19.0 months (95%CI: 17.8–23.4 months), and the median PFS was 7.2 months (95%CI: 5.5–10.9 months). TRAEs of any grade occurred in 93 patients (76.23%), with grade 3 or 4 TRAEs observed in 40 patients (32.79%). No treatment-related death was observed. Multivariate analysis identified elevated AFP (HR= 2.747), poor tumor response (HR=2.583) and fewer immunotherapy cycles (HR=0.903) as independent risk factors for shorter OS. Subgroup analysis indicated that fewer immunotherapy cycles was an independent prognostic factor only for patients in SD group (P=0.003). For PFS, higher mALBI grade (HR=1.816) and poor tumor response (HR=3.130) were observed.

Conclusions:

Exhibiting encouraging survival benefits and

E-POSTER ABSTRACTS

manageable safety profile, the triple therapy that combined radiotherapy plus PD-1 inhibitors and targeted agents provides a promising treatment option for uHCC. For patients within SD, appropriately extending the duration of immunotherapy may improve survival outcomes.

Keyword(s) : Unresectable hepatocellular carcinoma, radiotherapy, PD-1 inhibitors, targeted therapy, multicenter study

1223 - Prevalence and topographic extent of gastric intestinal metaplasia in cirrhosis versus dyspeptic controls Implications for premalignant risk

Aizirek Abdikaiyrova¹, Haldun Selçuk², Ahmet Sedat Boyacioğlu²

Başkent University Ankara Hospital, Internal Medicine, Ankara-Türkiye¹ Başkent University Ankara Hospital, Gastroenterology, Ankara-Türkiye²

Background / Hypothesis:

Liver cirrhosis is a chronic condition associated with high morbidity and mortality. In patients with cirrhosis, premalignant gastric lesions are reported in nearly one-third of cases, independent of portal hypertension severity. In addition, the risk of gastric cancer has been reported to be substantially higher in cirrhotic patients compared with the general population. This study aimed to compare the frequency and topographic extent of gastric intestinal metaplasia between individuals with cirrhosis and a control group of adults presenting with dyspeptic symptoms.

Materials and Methods:

A total of 115 patients with cirrhosis who underwent upper gastrointestinal endoscopy at Baskent University Gastroenterology Endoscopy Unit between 2011 and 2023 were retrospectively evaluated. The control group included 510 adults with dyspeptic symptoms.

Demographic features, comorbidities, endoscopic findings, and histopathological data were reviewed. Gastric intestinal metaplasia prevalence and extent were compared between the two groups.

Results:

Gastric intestinal metaplasia prevalence was 28.7% in patients with cirrhosis and 21.2% in controls ($p = 0.081$). *Helicobacter pylori* positivity was significantly higher in controls than in cirrhotic patients (26.7% vs. 17.3%, $p < 0.05$). Rates of focal gastric intestinal metaplasia were similar between groups (11.4% vs. 13.5%). However, extensive gastric intestinal metaplasia was significantly more common in patients with

cirrhosis compared with controls (16.6% vs. 7.47%, $p = 0.002$).

Conclusions:

This study is the first to evaluate the topographic extent of gastric intestinal metaplasia in individuals with cirrhosis. The findings demonstrate that extensive gastric intestinal metaplasia occurs more frequently in cirrhosis, indicating a higher premalignant potential in this population. According to international clinical guidelines, individuals with extensive or incomplete gastric intestinal metaplasia and those with a family history of gastric cancer require endoscopic surveillance. The present results highlight that patients with cirrhosis may constitute a high-risk group for progression to gastric malignancy. Regular endoscopic follow-up with adequate biopsy sampling is therefore essential for early identification and preventive management.

Keyword(s) : cirrhosis patients, gastric mucosal injury, frequency of atrophic gastritis

1224 - Clinical significance of *Helicobacter pylori* infection in cirrhotic patients Implications for the development of premalignant gastric lesions

Aizirek Abdikaiyrova¹, Haldun Selçuk², Ahmet Sedat Boyacioğlu²

Başkent University Ankara Hospital, Internal Medicine, Ankara-Türkiye¹ Başkent University Ankara Hospital, Gastroenterology, Ankara-Türkiye²

Background / Hypothesis:

Cirrhosis is associated with impaired gastric mucosal defense and an increased risk of gastric cancer, although the mechanisms underlying this elevated risk remain unclear. *Helicobacter pylori* (*H. pylori*) is the most important environmental factor in gastric carcinogenesis; however, its prevalence has paradoxically been reported as lower in cirrhotic patients than in the general population. Chronic atrophic gastritis (CAG) and gastric intestinal metaplasia (GIM), key stages of the Correa cascade, are well-recognized premalignant lesions. This study aimed to investigate the relationship between *H. pylori* infection and the development of GIM and CAG in patients with cirrhosis.

Materials and Methods:

A total of 685 cirrhotic patients and 1817 dyspeptic controls who underwent

E-POSTER ABSTRACTS

esophagogastroduodenoscopy were reviewed. After applying exclusion criteria, 115 cirrhotic patients (mean age: 54.6 ± 13.4 years) and 510 controls (mean age: 55.8 ± 14.6 years) were included in the analysis. Demographic characteristics, comorbidities, endoscopic findings, and histopathological outcomes were compared. *H. pylori* positivity was determined by histopathology. The presence of GIM and CAG was recorded in *H. pylori*-positive individuals.

Results:

H. pylori positivity was 17.3% in cirrhotic patients and 26.7% in controls ($p = 0.038$). Focal GIM was observed in 11.4% of cirrhotics and 13.5% of controls. Extensive GIM was significantly more frequent in cirrhotic patients (16.6%) than in controls (7.47%, $p = 0.002$). Atrophy was also significantly more common among cirrhotics (51.3% vs. 31.7%, $p < 0.001$). Among *H. pylori*-positive cirrhotic patients, 55% had GIM and 60% had atrophy, compared with 22.7% and 35.2% among *H. pylori*-positive controls, respectively (both $p < 0.05$).

Conclusions:

Although the overall prevalence of *H. pylori* infection was lower in cirrhotic patients than in dyspeptic controls, infected cirrhotic individuals demonstrated significantly higher rates of GIM and atrophy. These findings suggest that *H. pylori* infection accelerates the development of premalignant gastric lesions in cirrhosis and may further elevate their risk of gastric cancer. Identification and appropriate management of *H. pylori* infection should therefore be considered an essential component of gastric cancer prevention strategies in this high-risk population.

1227 - Comparative analysis of serum amino acid levels and their potential as biomarkers in liver cirrhosis A Systematic Review and Meta Analysis

Ying Xiao¹, Yadong Wang¹, Caiyan Zhao¹

The Hebei Medical University Third Hospital, Infectious Disease, Shijiazhuang-China¹

Background / Hypothesis: Early detection and precise prevention are crucial for reducing complications and mortality in liver cirrhosis (LC). The predictive value of amino acids profiles in monitoring the development of LC lacks consistent and comprehensive conclusions. This study aimed to review existing studies utilizing

metabolomics to detect serum amino acid levels in LC patients.

Materials and Methods: Meta-analysis was performed to identify potential biomarkers predictive of LC. Literature retrieved from eight databases between January 1, 2000 and August 1, 2025 was screened according to the inclusion criteria. The Newcastle-Ottawa Quality Assessment Scale (NOS) was used to assess the risk of bias in the included studies. A random-effects model for amino acid concentrations in the meta-analysis was used to calculate mean differences (MD) and 95% confidence intervals (95% CI). The I² statistic was used to measure study heterogeneity. This study has been registered with the PROSPERO.

Results: A total of 2125 records were retrieved, and 21 studies with 2254 individuals were included after screening, all of which were of high quality. Qualitative analysis of 21 studies including 23 amino acids. The meta-analysis of five studies showed that six amino acids (tyrosine, methionine, ornithine, threonine, citrulline and tryptophan) were significantly increased in the LC group, whereas two amino acids (arginine and valine) were significantly decreased. Subgroup analysis suggested that etiology and detection methods may be sources of heterogeneity in the results.

Conclusions: This manuscript will provide a comprehensive of differential expression of amino acid profiles and provide potential theoretical evidence to subsequently guide the assessment and treatment of LC.

Keyword(s) : liver cirrhosis, amino acids, metabolomics, meta-analysis

1228 - Role of Angiotensin Receptor Blockers in the Treatment of Hepatic Fibrosis in Patients with Metabolic Dysfunction Fatty Liver Disease A Meta Analysis

Jose Fernando Obillos¹, Diana Payawal²

Self Employed, Internal Medicine, Manila-Philippines¹
Hepatology Of The Philippines, Gastroenterology, Manila-Philippines²

Background / Hypothesis: Metabolic dysfunction fatty liver disease (MAFLD) impacts approximately 17% to 51% of adults globally, with a prevalence of 10% to 19% within the local population. Given its increasing incidence and the

E-POSTER ABSTRACTS

absence of approved pharmacologic therapies, there is an urgent requirement for innovative treatment options. Angiotensin receptor blockers (ARBs), integral components of the renin-angiotensin-aldosterone system (RAAS), have exhibited antifibrotic and anti-inflammatory effects, thereby positioning them as potential candidates for the management.

The objective of the study is to determine the therapeutic efficacy of angiotensin receptor blockers in liver fibrosis of patients with MAFLD liver cirrhosis by conducting a meta-analysis on different experimental studies randomized controlled trials, measuring changes in fibrosis scores, liver enzymes, and lipid profiles, and assessing its safety profile.

Materials and Methods:

A systematic investigation of databases including PubMed, ScienceDirect, PLOS ONE, and Google Scholar up to January 2025 identified 1173 relevant studies. Following the removal of duplicates and a meticulous screening process, five randomized controlled trials (RCTs) involving 642 patients were incorporated in accordance with PRISMA guidelines.

Results:

The meta-analysis indicated that ARB therapy significantly diminished fibrosis scores on liver biopsy compared to control groups (mean difference -0.38 ; 95% CI, -0.65 to -0.11 ; $p=0.006$) and enhanced MAFLD Activity Scores, especially in the domains of lobular inflammation and hepatocellular ballooning. Notable improvements were also recorded in hepatic serologic markers, including decreases in alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels. Significantly, the incidence of adverse events did not present significant differences between ARB and control groups, indicating a favorable safety profile.

Conclusions:

These results corroborate the potential role of ARBs in mitigating fibrosis progression and enhancing liver histology in NAFLD. Nonetheless, the relatively modest sample sizes, brief follow-up periods, and diversity among studies highlight the necessity for more extensive, rigorously designed trials with long-term endpoints to conclusively ascertain the efficacy and safety of ARBs as a therapeutic option for NAFLD.

Keyword(s) :

1230 - Treatment outcome of radiotherapy for elderly hepatocellular carcinoma patients with comorbidity

Sun Hyun Bae¹, Young Seok Kim², Sang Gyune Kim², Jeong-ju Yoo², Jae Myung Lee³, Sanghyeok Lim³, Jae Hong Jung⁴, Chan Kyu Kim⁵

Soonchunhyang University College Of Medicine, Bucheon, Radiation Oncology, Bucheon-si-South Korea

¹ Soonchunhyang University College Of Medicine, Bucheon, Division Of Gastroenterology And Hepatology, Department Of Internal Medicine, Bucheon-si-South Korea ² Soonchunhyang University College Of Medicine, Bucheon, Department Of Radiology, Soonchunhyang University College Of Medicine, Bucheon, Bucheon-si-South Korea ³ Soonchunhyang University College Of Medicine, Bucheon, Department Of General Surgery, Soonchunhyang University College Of Medicine, Bucheon, Bucheon-si-South Korea ⁴ Soonchunhyang University College Of Medicine, Bucheon, Division Of Hematology-oncology, Soonchunhyang University College Of Medicine, Bucheon-si-South Korea ⁵

Background / Hypothesis: The incidence of hepatocellular carcinoma (HCC) is increasing in elderly populations and the management in elderly patients is a globally emerging issue. Elderly patients tend to have several comorbidities affecting treatment tolerance and outcomes, and the optimal management in elderly patients has not been determined. Therefore, we assessed comorbidities in elderly patients and investigated treatment outcomes of radiotherapy (RT) to liver-confined HCC.

Materials and Methods: We retrospectively reviewed 40 elderly patients ≥ 70 years with liver-confined HCC, who were treated with RT between 2015 and 2023. Comorbidity was assessed by using the Charlson comorbidity index (CCI). Survivals were analyzed using the Kaplan-Meier method.

Results: The median age was 75 years (range, 70–87 years). The Barcelona Clinic Liver Cancer (BCLC) stage 0 was in 7 patients, A in 10 patients, B in 9 patients, and C in 14 patients. Most patients (85%) had Child-Pugh class A hepatic function before RT. The CCI scores ranged from 2 to 9 (median, 5). Various RT techniques were used according to patients' condition, tumor burden and treatment aim: 3-dimensional conformal radiotherapy in 4 patients; intensity modulated radiotherapy in 20 patients; and stereotactic body radiotherapy (SBRT) in 16 patients. RT was applied in 30 patients with radical intent and in 10 patients with

E-POSTER ABSTRACTS

palliative intent. The median biological effective dose (BED) using $\alpha/\beta = 10$ was 53.7 Gy10 (range, 39–134.4 Gy10), when the α/β ratio was assumed to be 10 Gy. The median follow-up period after RT was 18 months. The local progression-free survival and overall survival rates were 74% and 81% at 1 year, and 44% and 52% at 3 years, respectively. The CCI was not associated with survivals. On the other hand, the use of SBRT was the most significant parameter improving survivals.

Conclusions: Although elderly patients had several comorbidities, RT to liver-confined HCC seems to be tolerable, effective, and safe.

Keyword(s) : Charlson Comorbidity Index, Comorbidity, Elderly, hepatocellular carcinoma, radiotherapy

1231 - A Simplified HCV care whole pathway model improves HCV diagnosis and treatment rate in hyperendemic areas experience in Xing'an country from China

Huanwen Chen¹, Zengxue Lu², Chun Xia², Yanmei Zhou², Xianxin Tang²

The People's Hospital Of Xing'an Country, Infectious Department, Xin'an-China¹ The People's Hospital Of Xin'an Country, Infection Department, Xin-China²

Background / Hypothesis:

Hepatitis C virus (HCV) remains a major health burden, particularly in HCV hyperendemic, remote regions in China. Complicated pre-treatment assessments and follow-up procedures, as well as complex medical-insurance reimbursement processes, are main barriers leading to the low HCV diagnosis and treatment rate. We aims to evaluate the simplified HCV care whole pathway model on improving the HCV diagnosis and treatment rate of HCV-infected patients in Xing'an country which is HCV hyperendemic areas.

Materials and Methods:

A Simplified HCV care whole pathway model for the treatment of all patients infected with hepatitis C virus (HCV) was launched since January 2025. The simplified HCV care whole pathway includes: (i) Treat immediately upon HCV diagnosed by providing Pan-genotypic DAA regimen, without HCV genotype test. (ii) A "green reimbursement channel" was opened to patients undergoing HCV therapy directly supported by government policies. HCV antibodies positive patients in Xing'an country People's hospital will be informed and received education about the simplified HCV care whole pathway model to boost their confidence in subsequent diagnosis and therapy progress and benefit of HCV cure.

Results:

From January 2025 to October 2025, a total of 16585 people were screened, among whom 658 were HCV antibody positive. Encouraged by the simplified HCV care whole pathway model, the HCV RNA testing rate and the treatment rate were significantly improved to 73.7% (485/658) and 90.4% (198/219), respectively, much higher than the rates in the same period of 2024, (see Figure 1). Among the 198 patients who initiated therapy, 93.4% patients were initiated treatment on the day of diagnosis. Thirty-nine patients had decompensated cirrhosis, and 83.8% of HCV infected patients were aged 50–70 years (see Figure 2). All patients received sofosbuvir/velpatasvir for 12 or 24 weeks, The SVR12 were upto 100% (see Figure 3). Overall, the medication's safety and tolerability were good, with no serious adverse events reported.

Conclusions:

The simplified HCV care whole pathway model significantly increased the HCV RNA testing and treatment rate in HCV hyperendemic, remote regions in China. SOF-based regimen could achieve high SVR regardless of genotype testing. This model deserves promotion in remote areas to help accelerate HCV elimination target.

1234 - Associations of PNPLA3 and MBOAT7 Genetic Variants with Risk of Steatotic Liver Disease and Visceral Fat Accumulation in Adolescence

Akira Kado¹, Yukiko Inoue¹, Mitsuhiro Fujishiro¹, Shintaro Yanagimoto²

University Of Tokyo, Gastroenterology, Tokyo-Japan¹
University Of Tokyo, Health Service Promotion, Tokyo-Japan²

Background: Steatotic liver disease (SLD), predominantly metabolic dysfunction-associated steatotic liver disease (MASLD), is increasingly observed during adolescence as well as adulthood. Accumulation of body fat, particularly visceral fat, in association with SLD elevates the risk of lifestyle-related diseases and malignancies, underscoring the need to identify aggravating factors before adulthood. Variants in metabolic genes such as Patatin-like phospholipase domain containing 3 (PNPLA3) have been reported to influence SLD and lipid metabolism. Our previous report demonstrated associations between lipid changes and Membrane bound O-acyltransferase domain containing 7 (MBOAT7) variants in young individuals. However, the relationship

E-POSTER ABSTRACTS

between genetic variants and SLD or visceral fat accumulation in adolescence remains unclear. This study aimed to examine associations between selected metabolic gene variants and SLD as well as visceral fat accumulation using university health check-up data. Materials and Methods: Clinical data from 346 students aged 18–19 years (male: 183; female: 163) who underwent university health check-ups between 2024 and 2025 were analyzed. SLD and body fat were assessed by abdominal ultrasonography. Single-nucleotide polymorphism (SNP) genotyping was performed for PNPLA3 (rs738409), MBOAT7 (rs641738), Peroxisome proliferator activated receptor gamma (PPARG) (rs17036160), Lysophospholipase like 1 (LYPLAL1) (rs12137855), Transmembrane 6 superfamily member 2 (TM6SF2) (rs58542926), and Glucokinase regulatory protein (GCKR) (rs1260326). Associations between these genotypes and metabolic parameters were evaluated after stratification by SLD status. Results: In adolescents, among these 6 gene variants, PNPLA3, TM6SF2, and GCKR variants significantly increased SLD risk, with a stronger effect observed in males. MBOAT7 CC genotype did not show a significant difference in overall SLD risk; however, among SLD cases, CC genotype was associated with greater visceral fat thickness [5.8 mm (IQR: 4.1–8.5) vs 4.2 mm (2.9–5.6)]. PPARG and LYPLAL1 variants were not significantly associated with SLD or visceral fat accumulation, but in non-SLD individuals, PPARG CT genotype was associated with increased subcutaneous fat [3.9 mm (IQR: 2.5–5.2) vs 2.3 mm (1.6–3.6)]. Conclusions: PNPLA3, TM6SF2, and GCKR variants contribute to SLD risk in adolescence, whereas MBOAT7 variants may influence visceral fat accumulation in the presence of hepatic steatosis rather than directly increasing SLD risk. These findings suggest distinct metabolic and genetic backgrounds in adolescence compared to adulthood. Life stage-specific evaluation of SNPs may be critical for establishing precision medicine strategies for SLD.

Keyword(s) : SLD; visceral fat; adolescence; PNPLA3; MBOAT7

1235 - Comparative Efficacy of Emerging Metabolic Therapies for MASLD and MASH A Systematic Review and Network Meta analysis of Randomized Controlled Trials

Alaa Ramadan¹

Qena University Hospital, Internal Medicine, Qena-Egypt¹

Background / Hypothesis:

Metabolic dysfunction–associated steatotic liver disease (MASLD) and metabolic dysfunction–associated steatohepatitis (MASH) represent the fastest-growing causes of chronic liver disease worldwide. Multiple novel pharmacologic agents targeting metabolic and fibrotic pathways have emerged; however, their comparative efficacy remains unclear. A network meta-analysis allows indirect comparisons across drug classes to determine the most effective therapy for steatosis, inflammation, and fibrosis. This study aims to evaluate and rank the therapeutic efficacy of GLP-1 receptor agonists, dual GIP/GLP-1 agonists, SGLT2 inhibitors, FXR agonists, PPAR agonists, and FGF-21 analogues for the treatment of MASLD and MASH.

Methods:

A systematic search of PubMed, Embase, Cochrane CENTRAL, Web of Science, and ClinicalTrials.gov was completed from inception to January 2025. Randomized controlled trials enrolling adults with imaging-defined MASLD or biopsy-confirmed MASH and reporting outcomes on histology or validated non-invasive biomarkers were included. A Bayesian network meta-analysis was performed to compute pooled treatment effects and generate probability rankings (SUCRA values) for each intervention. Primary outcomes included resolution of MASH without fibrosis worsening and fibrosis improvement by at least one stage. Secondary outcomes included MRI-PDFF reduction, ALT and AST improvement, weight change, and glycemic outcomes. Study quality was assessed with the Cochrane RoB-2 tool.

Results:

Forty-six randomized trials involving 12,984 participants were included. Dual GIP/GLP-1 agonists demonstrated the highest probability of achieving MASH resolution without fibrosis worsening and were superior to GLP-1 receptor agonists, FXR agonists, and FGF-21 analogues. FGF-21 analogues ranked highest for fibrosis improvement, followed by PPAR agonists. GLP-1 receptor agonists produced the greatest reductions in MRI-PDFF, weight, and glycemic markers. SGLT2 inhibitors demonstrated modest but consistent biochemical improvements but ranked lower for histologic endpoints. FXR agonists improved biochemical inflammation but were limited by pruritus and lipid-related adverse effects. Treatment rankings remained stable across sensitivity analyses.

Conclusion:

This network meta-analysis demonstrates distinct therapeutic profiles among emerging metabolic agents for MASLD and MASH. Dual GIP/GLP-1 agonists appear most effective for resolving steatohepatitis, whereas

E-POSTER ABSTRACTS

FGF-21 analogues show superior impact on fibrosis improvement. GLP-1 receptor agonists remain highly effective for metabolic and steatosis-related outcomes, while PPAR agonists and SGLT2 inhibitors offer complementary benefits. These findings provide the most comprehensive comparative evaluation of MASLD pharmacologic therapies to date and may inform individualized, mechanism-based treatment strategies as these agents progress toward clinical implementation.

Keyword(s) : MASLD; MASH; network meta-analysis; GLP-1; dual incretin therapy; FGF-21; FXR agonists; PPAR agonists; SGLT2 inhibitors; fibrosis.

1236 - Multi center analysis of HDV seroprevalence and epidemiological profile in Chinese HBsAg positive inpatients

Huaguo Xu¹

The First Affiliated Hospital With Nanjing Medical University, Department Of Laboratory Medicine, Nanjing-China¹

Background / Hypothesis:

Hepatitis D virus (HDV) is a defective satellite virus that requires hepatitis B virus (HBV) for replication and exacerbates the severity of viral hepatitis. China carries a heavy burden of HBV, with an estimated 43.3 million infections in 2021. However, the national prevalence and clinical impact of HDV/HBV coinfection remains poorly defined. Accurate epidemiological data are essential to guide clinical and public health responses.

Materials and Methods:

From 2023 to 2025, we screened HBsAg-positive inpatients across nine medical centers representing northern, southern, eastern, and western China. Serum samples were tested for anti-HDV IgM and IgG using ELISA, and seropositive samples were further detected for HDV RNA via quantitative RT-PCR. Clinical and laboratory data were collected and analyzed.

Results:

The final analysis included 13,953 HBsAg-positive patients. Anti-HDV antibodies were detected in 0.57% of the cohort, with 0.29% positive for IgM and 0.31% for IgG. HDV RNA, indicating active viral replication, was detected in 5.06% of seropositive cases. Specifically, HDV RNA was positive in three of four patients with both IgM and IgG antibodies, and in one of 39 with IgG alone. Seroprevalence of HDV exhibited

regional variation ($p < 0.001$), ranging from 0% in Fujian to 0.96% in Guizhou. Higher rates of HDV seropositivity were observed in patients with HBsAb (0.75% vs 0.57%), HCV co-infection (2.47% vs 0.51%) or TP co-infection (0.56% vs 0.48%). Anti-HDV-positive patients were significantly older (57 vs 52 years, $p = 0.016$) and exhibited lower neutrophil (2.56 vs $3.09 \times 10^9/L$, $p = 0.023$) and lymphocyte counts (1.27 vs $1.50 \times 10^9/L$, $p = 0.005$), prolonged prothrombin time (13.1 vs 12.6 s, $p = 0.032$), and reduced fibrinogen levels (2.53 vs 2.74 g/L, $p = 0.004$) in peripheral blood compared to anti-HDV-negative individuals. Additionally, anti-HDV-positive patients had higher HBsAg levels (340.1 vs 250.1 COI, $p = 0.027$) and a non-significant trend toward lower HBV DNA loads (49.9 vs 69.1 IU/mL, $p = 0.101$).

Conclusions:

This multi-centre study provides an updated overview of HDV seroprevalence and active infection rates in China, which are substantially lower than previously reported. The findings highlight geographical disparities and high-risk groups of HDV infection, particularly those HBsAg-positive patients with HCV or TP co-infection or undetectable HBV DNA, providing valuable insights for targeted HDV surveillance and prevention strategies.

Keyword(s) : Hepatitis D virus, hepatitis B virus coinfection, multi-centre study, prevalence

1240 - Impact of Hand Grip Strength on the Clinical Course of Patients with Acute Variceal Bleeding A Single Center Prospective Observational Study

Hasan Eruzun¹, Hakan Demiröz²

Samsun Training And Research Hospital, Gastroenterology, Samsun-Türkiye¹ Ondokuz Mayıs University, Gastroenterology, Samsun-Türkiye²

Background / Hypothesis:

This study aimed to assess handgrip strength (HGS) in patients with acute variceal bleeding (AVB) following endoscopic therapy, compare it with compensated cirrhotic patients, and investigate its association with clinical outcomes, including rebleeding and short-term mortality.

Materials and Methods:

In this single-center, prospective observational study, 34 AVB patients and 21 compensated cirrhotics were enrolled between June 2024 and June 2025. Exclusion

E-POSTER ABSTRACTS

criteria included hepatocellular carcinoma, hepatic encephalopathy, malignancies, major organ failure, cerebrovascular disease, or neuromuscular disorders. HGS was measured using a digital dynamometer at discharge for AVB patients and during outpatient visits for controls. Baseline demographics, laboratory data, Child–Turcotte–Pugh (CTP) and MELD–Na scores, and 6-week outcomes were recorded. Statistical analyses compared HGS and clinical parameters between groups and evaluated correlations.

Results:

HGS was significantly lower in the AVB group compared with compensated cirrhotics ($p=0.0004$). Within six weeks, nine patients experienced rebleeding and seven patients died. Those with adverse outcomes demonstrated significantly reduced HGS, lower albumin, hemoglobin, and blood pressure, and higher MELD–Na and CTP scores. HGS negatively correlated with prognostic scores, hospital stay, INR, and bilirubin, while positively correlating with albumin.

Conclusions:

Handgrip strength is markedly reduced in patients with AVB and is associated with rebleeding, short-term mortality, and prolonged hospitalization. As a simple bedside measure of sarcopenia and nutritional status, HGS may serve as a valuable prognostic marker. Early identification of low HGS can guide nutritional and rehabilitative interventions to potentially improve outcomes in this high-risk patient population.

Keyword(s) : acute variceal bleeding, mortality, rebleeding, sarcopenia, hand dynamometer, muscle strength

1241 - Liquid Biopsy Based Detection Of TP53 And TERT Gene Mutations In HBV Induced Chronic Liver Disease and Hepatocellular Carcinoma Patients Evidence From Bangladesh

Sabinur Akter ¹, Sharmin Sultana ¹, Md. Zulqarnine Ibne Noman ², Ayesha Alam ¹, Afzalun Nessa ¹
Bangladesh Medical University, Virology, Dhaka-
Bangladesh ¹ Icdrr, b, Pei, Idd, Dhaka-Bangladesh ²

Background / Hypothesis:

The Tumor Protein 53 (TP53) and Telomerase Reverse Transcriptase (TERT) promoter genes are the most frequently mutated genes contribute to hepatocarcinogenesis in hepatitis B virus (HBV)

patients. Circulating cell free DNA (cfDNA) has emerged as a promising noninvasive 'liquid biopsy' tool for detecting tumor specific genetic mutations and monitoring disease progression. However, there are limited data about these gene mutations in HBV induced chronic liver disease (CLD) and Hepatocellular carcinoma (HCC) patients from Bangladesh that limits the development of precision diagnostics and targeted therapies. Therefore, we aimed to detect TP53 and TERT gene mutations from cfDNA in HBV induced CLD and HCC patients and determine association with liver enzymes and biochemical markers.

Materials and Methods:

This cross-sectional study was conducted among 80 participants where 30 had HCC, 30 CLD and 20 healthy controls. cfDNA was extracted from aseptically collected peripheral venous blood (10 mL) using the QIAamp Circulating Nucleic Acid Extraction Kit. Amplification of the TP53 (pR249S) and TERT (C228T and C250T) genes were performed using selected primers via conventional PCR, followed by visualization on 2% agarose gel with ethidium bromide. Positive samples underwent Sanger sequencing; mutation analysis conducted using MEGA 11 software comparing with the TP53 and TERT reference sequence. Statistical analysis was done using STATA 17.

Results:

TP53 mutations were detected in 3.3% (1/30) CLD and 23.3% (7/30) HCC patients and absent in healthy controls ($p=0.01$). Among HCC patients, the C228T mutation was identified in 3.3% (1/30) and C250T in 6.7% (2/30), with an overall TERT promoter gene mutation frequency of 10% (3/30) and none were found among CLD and healthy controls ($p=0.113$). Among all patients, TERT promoter mutations were significantly associated with low serum albumin (<3.4 g/dL) and elevated bilirubin (≥ 1.2 mg/dL) ($p<0.05$). TP53 mutations were strongly associated with elevated ALT and AST ($p<0.001$), low albumin ($p<0.05$), elevated bilirubin ($p<0.001$), and high AFP levels ($p<0.05$).

Conclusions:

TP53 and TERT gene mutations, detected from liquid biopsy may be used as biomarkers along with liver

E-POSTER ABSTRACTS

enzymes in HCC patients for early detection, management, and prognosis of HCC. These gene mutations can also be used in precision diagnostics and targeted therapies as personalized treatment plans.

Keyword(s) : TERT promoter mutation, TP53 mutation, cfDNA, liquid biopsy, hepatocellular carcinoma, hepatitis B, Bangladesh

1242 - Hormone therapy and metabolic risk interact to influence metabolic dysfunction associated steatotic liver disease incidence across the menopausal transition a 10 year longitudinal cohort study

I-jung Feng¹, Pei-chien Tsai², Ming-lun Yeh², Zih-chen Wong¹, Yung-chieh Tsai³, Ming-lung Yu²

National Sun Yat-sen University, Institute Of Precision Medicine, Kaohsiung-Taiwan¹ Kaohsiung Medical University Hospital, Kaohsiung Medical University, Hepatobiliary Division, Department Of Internal Medicine And Hepatitis Center, Kaohsiung-Taiwan² Chi-mei Medical Center, Center For Reproductive Medicine, Department Of Obstetrics And Gynecology, Tainan-Taiwan³

Background / Hypothesis:

Estrogen deficiency after menopause may increase hepatic vulnerability, particularly in women with clustered cardiometabolic risk factors. The hepatic safety of menopausal hormone therapy (MHT) in this context remains uncertain. We hypothesised that menopausal status, MHT use and cardiometabolic risk burden jointly influence the incidence of metabolic dysfunction associated steatotic liver disease (MASLD) and incident significant fibrosis.

Materials and Methods:

We analysed two parallel prospective cohorts of Taiwanese women aged 45–65 years who attended health examinations between 1996 and 2022: a MASLD free cohort (n=9,505) to evaluate incident MASLD, and a significant fibrosis free cohort (n=10,670; Fibrosis 4 [FIB 4] ≤ 1.3 at baseline) to evaluate incident significant fibrosis (FIB 4 > 1.3 during follow up). Menopausal status was classified as premenopausal, postmenopausal without MHT and postmenopausal with long term MHT. MASLD was defined using imaging and metabolic criteria. We estimated adjusted hazard ratios (aHRs) for incident MASLD and significant fibrosis using Cox models, controlling for age, lifestyle, education year, calendar year and cardiometabolic risk factors (body mass index, diabetes, hypertension and dyslipidaemia). Stratified analyses evaluated effect

modification by baseline cardiometabolic profiles.

Results:

Compared with premenopausal women, postmenopausal women without MHT had a higher risk of incident MASLD and a higher hazard of developing significant fibrosis; excess risks rose with the number of cardiometabolic risk factors. Overall, postmenopausal women using MHT showed MASLD and fibrosis risks broadly similar to those without MHT, and we did not observe a consistent protective effect of MHT. Across most cardiometabolic strata, MHT versus no MHT was not significantly associated with incident MASLD or significant fibrosis. However, in postmenopausal women with coexisting diabetes and hypertension, MHT use tended to associate with higher hepatic risk, with approximately 2.4 fold higher MASLD incidence and 2.7 fold higher hazard of significant fibrosis compared with non users, although confidence intervals were wide.

Conclusions:

Postmenopausal status is associated with increased incidence of MASLD and development of significant fibrosis, particularly in women with clustered cardiometabolic risk factors. In this cohort, MHT was predominantly prescribed as oral preparations, which undergo first pass hepatic metabolism. Long term oral MHT did not appear to confer uniform hepatic protection and may be associated with higher MASLD and fibrosis risk in women with combined diabetes and hypertension. These findings support integrating route of administration and cardiometabolic burden into MASLD risk stratification and individualising MHT decisions in midlife women.

Keyword(s) : menopause, menopausal hormone therapy, cardiometabolic risk factors, metabolic dysfunction-associated steatotic liver disease, hepatic fibrosis, cohort study

1244 - Cabozantinib as Third or Later Line Therapy After ICI Failure Real World Outcomes of Reduced Dose Strategies in Advanced HCC

Teiji Kuzuya¹, Hisanori Muto¹, Yoshihiko Tachi¹, Yoshiki Hirooka¹

Fujita Health University, Gastroenterology And Hepatology, Toyoake-Japan¹

Background / Hypothesis

Cabozantinib is commonly used as third- or later-line therapy for advanced hepatocellular carcinoma (HCC) following progression on immune checkpoint inhibitor (ICI)-based regimens. In routine practice, many patients begin cabozantinib at reduced doses because

E-POSTER ABSTRACTS

of impaired liver function or residual toxicities. The therapeutic relevance of these reduced-dose strategies remains unclear. We hypothesized that disease control (DC) could still be achieved at lower doses, and that hepatic reserve would be a key determinant of treatment outcomes.

Materials and Methods

We retrospectively analyzed 33 patients with unresectable HCC previously treated with at least one ICI-based regimen before receiving cabozantinib as third- or later-line therapy. Tumor response was assessed by RECIST v1.1 and categorized into DC (complete response, partial response, or stable disease) or non-DC (progressive disease or not evaluable). Initial dose, early dose modifications, and average daily dose during the first 6 weeks were examined.

Progression-free survival (PFS), overall survival (OS), and factors associated with outcomes were evaluated.

Results

Most patients (91%) initiated cabozantinib at reduced doses (20–40 mg/day), with only three patients starting at 60 mg/day. The objective response rate was 3%, and the DC rate was 52%. Compared with the non-DC group, the DC group had significantly longer median PFS (4.4 vs. 1.2 months; $p < 0.0001$), OS (10.7 vs. 3.0 months; $p = 0.0456$), and treatment duration (134 vs. 22 days; $p < 0.0001$). Time to first dose reduction and mean daily dose in the first 6 weeks were not significantly different between groups. Child–Pugh class A was independently associated with achieving DC and with better survival outcomes.

Conclusions

Cabozantinib is frequently started at reduced doses in later-line settings after ICI-based therapies for advanced HCC. Despite lower starting doses, meaningful and durable disease control (DC) can be achieved—even at approximately 20 mg/day—particularly in patients with preserved liver function. These findings support individualized dose-adjustment strategies and highlight the importance of hepatic reserve in optimizing cabozantinib treatment.

Keyword(s) : Cabozantinib, immune checkpoint inhibitor, hepatocellular carcinoma

1246 - TRENDS IN HEPATOCELLULAR CARCINOMA INCIDENCE IN MONGOLIA A DECADE OF NATIONAL DATA (2014–2024)

Daschirev Munkh-orshikh ¹, Purevsod Lkhagvasuren ², Jazag Amarsanaa ³, Oidov Batarkhuu ⁴
National Cancer Center, Department Of Surgery,
Ulaanbaatar-Mongolia ¹ Mongolian National University

Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia ² Mongolian Association For The Study Of Liver Disease, Hepatology, Ulaanbaatar-Mongolia ³ Mongolian National University Of Medical Sciences, Department Of Infectious Diseases, Ulaanbaatar-Mongolia ⁴

Background / Hypothesis:

Mongolia carries one of the highest liver disease burdens worldwide. Cancer is the second leading cause of death, accounting for nearly one-fifth of all mortality, and hepatocellular carcinoma (HCC) is the most prevalent cancer type, representing approximately 40% of all cancers in the country. The major etiologies of HCC in Mongolia include hepatitis C virus (HCV) infection (46%), hepatitis B virus (HBV) infection (34%), HBV–HCV co-infection (14.4%), and alcohol-related liver disease (5.6%). This study aims to compare the newly reported incidence of hepatocellular carcinoma in Mongolia over the last decade.

Materials and Methods:

This desk review examined reported hepatocellular carcinoma (HCC) cases by utilizing national statistical datasets and reviewing policy documents released by relevant governmental authorities.

Results:

Hepatocellular carcinoma (HCC) in Mongolia remains a major public health challenge. Between 2015 and 2024, the country has maintained some of the highest liver cancer rates in the world. The age-standardized incidence of liver cancer in Mongolia has been reported around 63.2 cases per 100,000 people, markedly higher than global averages. In terms of sex distribution, HCC morbidity is very high at 80.3 per 100,000 men and 60.3 per 100,000 women. Among newly reported liver cancer cases, 2,373 were diagnosed during a recent period, of which 56.4% were men and 43.6% women, making up 32.8% of all cancer diagnoses in the country. Viral hepatitis remains the primary driver: chronic HBV and/or HCV infections account for a large portion of HCC risk. In fact, over 95% of liver cancer cases in Mongolia are attributable to hepatitis B or C. Population-level surveys show a high seroprevalence: for example, HBsAg positivity among adults is around 9–11.8%, and anti-HCV antibodies appear in 11–16% of the general population. Survival remains poor: older reports suggest a 1-year survival rate of ~21–24%, dropping to 6–8% by five years, highlighting late-stage diagnosis as a key problem.

E-POSTER ABSTRACTS

Conclusions:

Hepatocellular carcinoma remains a critical health burden in Mongolia, with persistently high incidence driven largely by chronic hepatitis B and C infections. Despite national efforts in prevention and policy development, HCC rates have shown little reduction over the past decade, and survival outcomes remain poor due to late diagnosis. Strengthened screening programs, improved antiviral treatment coverage, and earlier detection strategies are essential to reduce HCC morbidity and mortality in the coming years.

Keyword(s) : HCC, cancer, HBV, HCV, incidence

1247 - Clinical characteristics and prognosis of patients with primary biliary cholangitis a single center experience in Lanzhou city China

Yuting Zhang ¹, Liting Zhang ¹, Junfeng Li ¹

The First Hospital Of Lanzhou University, Hepatology Department, Lanzhou-China ¹

Background:Information on the characteristics and prognosis of patients with Primary biliary cholangitis(PBC) in Lanzhou city,Gansu province,China,remains limited.This study aims to investigate the clinical characteristics and prognosis of patients with PBC in a single-center,retrospective cohort.

Materials and Methods:One hundred and nine PBC patients with complete data after one year or more of ursodeoxycholic acid (UDCA) treatment were selected finally.Data were collected at baseline and one year of treatment.Biochemical response was evaluated using the Barcelona criteria.Patients were divided into an IgM elevated group and an IgM control group according to whether the IgM level at baseline was a 15% higher than the upper limit of normal.The difference in prognosis between the two groups was evaluated using the UK-PBC score and GLOBE scores.

Results:The average age was 58.5 ± 10.7 years old,and the female-to-male ratio was approximately 4:1.The median values for the following were also recorded:alkaline phosphatase(ALP),181.0U/L(124.5U/L,265.0U/L),gamma-glutamyl transpeptidase(GGT),93.3U/L(35.8U/L,275.0U/L),alanine aminotransferase (ALT),36U/L (19.7U/L,70.0U/L),total bilirubin(TB),25.1umol/L(17.4umol/L,41.0umol/L),total bile acid(TBA),15.7umol/L(7.4umol/L,51.9umol/L),total cholesterol (TC),3.9 mmol/L(3.1mmol/L,5.0mmol/L),IgM level,2.5g/L(1.5g/L,4.0g/L).A complete biochemical response to UDCA was observed in 64 PBC

patients,accounting for a complete biochemical response rate of 58.7%.Anti-mitochondrial antibody M2 component(AMA-M2)-positive results were found in 72 patients.Fifty patients had elevated IgM, and 59 patients were in the IgM control group. Compared with the IgM control group,the IgM elevated group had higher TBIL,ALP,GGT and TBA, but lower ALB,this difference was statistically significant.($P < 0.05$). Correlation analysis showed that the IgM level was positively correlated with AST, ALP,GGT,TBIL and TBA,and negatively correlated with ALB in PBC patients.After one year of UDCA treatment,the patients in the IgM elevated group had a biochemical response rate than the IgM control group (48% vs 67.8%, $P < 0.05$) and a higher risk of liver transplantation within 5,10,15 years according to the UK-PBC score($P < 0.05$),although there was no significant difference in GLOBE score.

Conclusion: Among patients with simple PBC,elderly women predominate,while the male incidence is on the rise.The biochemical abnormalities of PBC patients with elevated IgM at baseline were more obvious.Current first-line UDCA therapy fails to meet clinical needs,particularly for patients with elevated IgM levels,who exhibit poorer treatment response and prognosis.There is an urgent need for safe and effective second-line medications for PBC in China.

Keyword(s) :

1248 - Progress Toward WHO 2030 Hepatitis B Mortality Target in the Asia-Pacific Region

Ying Shen ¹, Da Huo ², Quanyi Wang ³

Peking University,, School Of Public Health, Beijing-China ¹ Beijing Center For Disease Prevention And Control, Institute Of Infectious And Endemic Diseases, Beijing-China ² Beijing Center For Disease Prevention And Control, Beijing Center For Disease Prevention And Control, Beijing-China ³

Background / Hypothesis:

Hepatitis B virus (HBV) remains a major cause of mortality in the Asia-Pacific region, which bears a substantial proportion of the global HBV-related death burden. Monitoring long-term mortality trends and assessing progress toward the WHO 2030 elimination target—a 65% reduction in HBV deaths from 2015 levels—is essential for guiding regional hepatitis control strategies.

Materials and Methods:

Using Global Burden of Disease (GBD) 2023 estimates,

E-POSTER ABSTRACTS

we analyzed age-standardised HBV mortality rates (ASMRs) for 26 Asia-Pacific countries from 1990 to 2023 across the High-income Asia Pacific, East Asia, Southeast Asia, and selected South Asian and Oceania regions. "Liver cancer due to hepatitis B" and "Chronic hepatitis B including cirrhosis" were included in the analysis. Temporal trends were assessed using the Estimated Annual Percentage Change (EAPC) derived from log-linear regression. Progress toward the WHO 2030 targets was evaluated by the percentage change in ASMR between 2015 and 2023.

Results:

The regional ASMR declined by 39.8% from 1990 to 2023, decreasing from 15.4 to 9.28 deaths per 100,000 population (EAPC -2.53%, 95% CI -2.78 to -2.27). Mortality continued to fall through 2021 (9.14 per 100,000) but showed a modest increase thereafter, particularly in middle- and high-SDI countries. Progress toward the WHO 2030 target varied substantially across countries. None of the 26 countries was on track for the 2030 goal. Bangladesh, Singapore, Pakistan, India, and Mongolia achieved moderate reductions (mean ASMR decline: 26.8%), whereas 16 countries—including China, Indonesia, Viet Nam, Philippines and Malaysia—showed slow progress (mean decline: 7.22%). New Zealand, Japan, Myanmar, Papua New Guinea, and Brunei Darussalam experienced worsening trends, with ASMR increasing by an average of 3.57% since 2015.

Conclusions:

Although HBV mortality has declined markedly over the past three decades, the Asia-Pacific region remains collectively off track to meet the WHO 2030 mortality reduction target. The recent stagnation and reversals observed after 2021 highlight persistent challenges in HBV prevention and treatment coverage. Strengthening antiviral therapy uptake, maintaining continuity of essential HBV services, and prioritizing investments in under-performing countries will be critical to accelerate progress toward regional HBV elimination.

Keyword(s) : HBV, WHO 2030 target, Mortality

1249 - RE LIVE Study (Re Linkage to Pan Viral Hepatitis) Interim Results from a Multicenter Observational Study on Care Engagement in Chronic Viral Hepatitis

Jae Hyun Yoon¹, Young-sun Lee², Yang Jae Yoon², Yu Rim Lee³, Seul Ki Han⁴, Sun Young Chun⁵, Young Eun Seo⁶, Sung-bum Cho⁶

Chonnam National University Hospital, Gastroenterology, Gwangju-South Korea ¹ Korea University Hospital, Gastroenterology, Seoul-South Korea ² Kyungpook National University Hospital, Gastroenterology, Daegu- ³ Wonju Yonsei University Hospital, Gastroenterology, Wonju- ⁴ Chonnam National University Hospital, Internal Medicine, Gwangju- ⁵ Hwasun Chonnam National University Hospital, Gastroenterology, Hwasun- ⁶

Background / Hypothesis:

Despite the availability of highly effective antiviral therapies, linkage to care remains a key barrier to the global elimination of viral hepatitis. A considerable proportion of individuals with chronic hepatitis B, C, and D remain undiagnosed, untreated, or lost to follow-up, sustaining the burden of disease and transmission. In Korea, reimbursement criteria for HBV treatment were expanded in 2023; however, a substantial number of eligible patients remain untreated. This study aimed to evaluate systematic re-linkage strategies to re-engage these individuals in the continuum of care, with the goal of improving clinical outcomes and contributing to public health objectives.

Materials and Methods:

A retrospective chart review was conducted at four tertiary academic hospitals in Korea to identify candidates for antiviral treatment. HBV eligibility included (i) non-cirrhotic patients with HBV DNA >2,000 IU/mL and fibrosis stage ≥2, and (ii) cirrhotic patients with any detectable HBV DNA. For HCV, partially diagnosed-but-untreated (DBU) cases were defined as anti-HCV antibody positive with missing HCV RNA data; completely DBU cases were HCV RNA positive without prior antiviral therapy. HBV patients eligible for HDV screening underwent HDV PCR. All identified patients were re-contacted via text or phone for re-evaluation and potential treatment linkage.

Results:

Among 2,192 patient charts reviewed, 33 HBV and 127 HCV patients were enrolled in the call-back program. Among HBV patients, 21.2% (7) responded and agreed to further evaluation; 6.1% (2) initiated antiviral therapy, while 78.8% (26) did not respond to call-back. Of 92 partial HCV DBU cases, 13.0% (12) agreed to evaluation, 3.3% (3) had prior treatment, 3.3% (3) sought care elsewhere, 2.2% (2) refused, and 78.3% (72) did not respond. Among them, 2.2% (2) initiated treatment. Among 35 complete DBU cases, 2.9% (1) agreed to evaluation, 2.9% (1) sought care elsewhere, 5.7% (2) refused, and 88.6% (31) did not respond; only

E-POSTER ABSTRACTS

2.9% (1) initiated treatment. HDV RT-PCR was performed in 618 chronic HBV patients; 0.1% (1) tested positive but declined further management. In total, 3.1% (5) of 160 patients identified through the call-back program initiated antiviral therapy.

Conclusions:

Although effective antiviral treatments and expanded eligibility criteria are now available, many patients with viral hepatitis remain disconnected from care. Our re-linkage efforts showed limited success in bringing patients back into the treatment pathway. These findings emphasize the need for continued, practical strategies to improve access to care and support national and global goals for viral hepatitis elimination.

Keyword(s) : viral hepatitis, linkage to care, HBV, HCV, elimination

1251 - ANXA4 Deficiency Ameliorates Acetaminophen Induced Acute Liver Injury

Shengjiang Deng ¹, Xiyao Chen ¹, Xin Song ¹, Jia Chen ¹, Liang Peng ¹, Chan Xie ¹

The Third Affiliated Hospital Of Sun Yat-sen University, Department Of Infectious Diseases, Guangzhou-China ¹

Background: Acetaminophen (APAP) is widely used as an antipyretic and analgesic drug. However, APAP overdose is one of the leading causes of acute liver failure worldwide. Current therapeutic options for APAP-induced acute liver failure are limited. The severity of liver injury depends on the interconnection between metabolic detoxification and inflammatory signaling. Annexin A4 (ANXA4), a calcium-dependent phospholipid-binding protein, acts as a stress-responsive regulator that integrates metabolic and inflammatory pathways through its roles in membrane dynamics and signaling complex organization. This study aimed to elucidate whether ANXA4 deletion protects against acute liver failure and to define the molecular mechanisms underlying this effect.

Materials and Methods: We constructed mice with liver-specific knockout of ANXA4. Wild-type (WT) and ANXA4 knockout mice were administered APAP separately. Liver injury was assessed by serum liver function tests and histological evaluation. Oxidative stress indices and inflammatory mediators were quantified by biochemical assays and qPCR. Hepatic transcriptomic profiling was performed to identify genes associated with protective responses. Primary hepatocytes were used for mechanistic validation. Results: ANXA4 deficiency significantly alleviated APAP-induced liver injury and reduced mortality of

mice, as evidenced by lower serum aminotransferase, and attenuated centrilobular necrosis. The knockout livers exhibited lower reactive oxygen species accumulation and decreased activation of NF- κ B, accompanied by reduced expression of proinflammatory cytokines such as TNF- α and IL-6. Transcriptomic analysis revealed a pronounced increase in flavin-containing monooxygenase 3 (Fmo3), an enzyme involved in xenobiotic detoxification and redox regulation. Elevated Fmo3 expression correlated with improved oxidative balance and suppression of inflammatory signaling. In isolated hepatocytes, ANXA4 deletion enhanced resistance to APAP-induced mitochondrial dysfunction, supporting a direct cytoprotective mechanism linked to coordinated modulation of metabolic and inflammatory pathways. Conclusions: Inhibition of ANXA4 confers a protective effect against APAP-induced acute liver injury, not only by attenuating the immune response but also by effectively activating the APAP detoxification pathway through modulation of drug metabolism. Our findings suggest that ANXA4 may serve as a potential therapeutic target for the treatment of APAP-induced acute liver injury.

Keyword(s) : Liver injury, ANXA4, acetaminophen

1253 - Clinical Trajectories of Acute Decompensation in Cirrhosis The First Prospective PREDICT Based Study from India

Kapil Kumar ¹, Dr Ujjwal Sonika ¹, Dr Ajay Kumar ¹, Dr Ashok Dalal ¹, Dr Siddharth Srivastava ¹, Dr Sanjeev Sachdeva ¹

Govind Ballabh Pant Institute Of Postgraduate Medical Education And Research, Gastroenterology, New Delhi-India ¹

Background / Hypothesis:

Acute decompensation (AD) of cirrhosis is a heterogeneous clinical state with variable short-term outcomes. The PREDICT study identified three phenotypes—Stable Decompensated Cirrhosis (SDC), Unstable Decompensated Cirrhosis (UDC), and pre-Acute-on-Chronic Liver Failure (pre-ACLF)—driven largely by systemic inflammation. This study aimed to evaluate the clinical trajectories of AD based on the PREDICT framework in an Indian cohort and to identify inflammatory and biochemical predictors of progression to ACLF and 6-month mortality.

Materials and Methods:

This prospective observational study included 105 consecutive adults with cirrhosis admitted with AD to a

E-POSTER ABSTRACTS

tertiary-care center over 12 months. AD was defined by new or worsening ascites, hepatic encephalopathy (HE), gastrointestinal bleeding, or bacterial infection.

Patients with ACLF at presentation, immunosuppression, pregnancy, or post-transplant status were excluded. All participants were followed for 90 days to classify outcomes as SDC, UDC, or pre-ACLF, and for 6-month survival. Demographic, clinical, and laboratory parameters—including Hs-CRP, TNF- α , IL-6, and urinary NGAL—were recorded at baseline. Group comparisons were performed using appropriate statistical tests, and variables with $p < 0.1$ on univariate analysis were entered into multivariate logistic regression for prediction of ACLF and mortality. Prognostic accuracy of Hs-CRP was assessed using ROC analysis.

Results:

Of 105 patients (mean age 46.6 ± 10.9 years; 82.9% male), 57 (54.3%) were classified as SDC, 24 (22.9%) as UDC, and 24 (22.9%) as pre-ACLF at 90 days. Pre-ACLF patients had significantly higher prevalence of HE (54%), bacterial infections (46%), SBP (50%), sepsis (38%), renal dysfunction (creatinine 1.47 ± 0.33 mg/dL), and markedly elevated inflammatory markers (Hs-CRP 38.1 ± 14.6 mg/L; TNF- α 157 ± 50 pg/mL; IL-6 126 ± 45 pg/mL; all $p < 0.001$). Thirty-one patients (29.5%) died by 6 months. Non-survivors showed significantly higher baseline inflammation, organ dysfunction, and severity scores (MELD-Na 22.4 ± 5.8 vs 16.6 ± 5.6 , $p < 0.001$). On multivariate analysis, Hs-CRP independently predicted both ACLF (OR 1.057; $p = 0.04$) and 6-month mortality (OR 1.111; $p = 0.03$). Hs-CRP demonstrated excellent prognostic accuracy (AUC 0.92), with an optimal cut-off of 10.8 mg/L (90% sensitivity, 95% specificity).

Conclusions:

In this first Indian prospective validation of the PREDICT classification, inflammatory phenotype strongly determined clinical trajectory and survival in AD. Pre-ACLF was characterized by severe systemic inflammation and high early mortality. Hs-CRP emerged as a simple, robust, and independent predictor of ACLF and 6-month mortality. Routine CRP assessment may greatly improve early risk stratification in acutely decompensated cirrhosis.

1255 - Chenodeoxycholic Acid Modulation via *Bacteroides intestinalis* AM1 underscores a Novel Approach in Acute Liver Failure

Sushmita Pandey¹, Neha Sharma¹, Nupur Sharma¹, Gaurav Tripathi¹, Babu Mathew¹, Manisha Yadav¹, Vasundhra Bindal¹, Vipul Sharma¹, Sanju Yadav¹, Anju Katyal², Shvetank Sharma¹, Rakhi Maiwall³, Shiv Kumar Sarin³, Jaswinder Singh Maras¹
Institute Of Liver And Biliary Sciences, Mcm, New Delhi-India¹ Dr B R Ambedkar Center For Biomedical Research, Acbr, New Delhi-India² Institute Of Liver And Biliary Sciences, Hepatology, New Delhi-India³

Background / Hypothesis:

Acute liver failure (ALF) is associated with rapid and progressive hepatocellular injury, and severe metabolic-microbial derangements. We investigated early metabolic markers of non-survival, and a potential microbial intervention using *Bacteroides intestinalis*-AM1, to improve outcomes in ALF.

Materials and Methods: Plasma metabolomics and meta-proteomics were performed in 40 ALF patients and 5 healthy controls (training cohort). A non-survival marker panel was identified and validated in 270 ALF patients (test cohort) using high resolution mass spectrometry and machine learning. It was functionally validated in acetaminophen-induced ALF mouse model. *B. intestinalis*-AM1 was used to study alteration of gut bacteria and amelioration of liver injury.

Results: ALF non-survivors showed a distinct metabolomic signature with elevated primary bile acids, tryptophan, tyrosine, and enrichment of pathways linked to inflammation, cell death, and mitochondrial dysfunction ($p < 0.01$, FDR < 0.01 , FC > 1.5). Non-survivors had higher alpha/beta diversity ($p < 0.05$) with increase in Proteobacteria, Firmicutes, Actinobacteria ($p < 0.05$); functionally associated with energy, amino acid and xenobiotic metabolism ($p < 0.05$). A gut microbiota derangement in converting primary to secondary bile acids was evident as CDCA and cytotoxic metabolites (4-(2-Amino phenyl)-2,4-dioxobutanoate, L-Tyrosine) were higher. Elevated CDCA (logFC > 10) levels correlated with mortality in ALF patients as well as in mouse model. In this case, administration of *B. intestinalis*-AM1 bacteria (10^9 CFU/ml) reduced CDCA and CA levels by upregulating FXR, FGF15, and SLC10A1 gene expression. It also promoted glutathione synthesis through the activity of

E-POSTER ABSTRACTS

enzymes such as L-histidine amino ligase, GSH synthetase, and others ($FC > 1.5$; $P < 0.05$). As a result, inflammation was suppressed via inhibition of IL-1 β and TLR4 signaling. This treatment further enhanced glutathione-dependent oxidative repair, mitigated mitochondrial dysfunction, and ultimately improved necroptosis outcomes.

Conclusions: Elevated chenodeoxycholic acid (CDCA) levels are associated with poor prognosis in ALF patients. B. intestinalis-AM1, a primary-to-secondary bile acid converter, effectively lowers CDCA levels, activates FXR, enhances glutathione production, and reduces inflammation and mitochondrial dysfunction, thereby protecting hepatocytes and underscoring its therapeutic potential in ALF.

1256 - Evaluation of Information Quality and Reliability of Chronic Hepatitis B Related Short Videos on TikTok and Bilibili

Yu Huang¹, Liwei Zeng¹, Xi Wang¹

Hebei University Of Chinese Medicine, Institute Of Traditional Chinese Medicine, Shijiazhuang-China¹

Background / Hypothesis:

Chronic hepatitis B (CHB) is a globally prevalent infectious liver disease. The scientific dissemination of knowledge regarding its prevention and management is critical for reducing incidence and improving rates of accurate diagnosis and appropriate treatment. With the widespread adoption of short video platforms, TikTok and Bilibili have become core channels for the Chinese public to access CHB-related information; however, systematic evaluations of the quality and reliability of CHB-focused short videos on these two platforms remain scarce.

Materials and Methods:

A total of 149 valid videos were retrieved from TikTok and Bilibili using "乙肝" as the keyword. Three validated tools—Global Quality Score (GQS), Modified DISCERN, and Journal of the American Medical Association (JAMA) Benchmark Criteria—were employed to assess the information quality of the videos. Video characteristics were analyzed, and differences between the two platforms as well as across uploader identities were compared.

Results:

The overall quality of CHB science popularization short videos on both platforms was low, with the following median (interquartile range) scores: GQS 3 (2, 4), Modified DISCERN 2 (1, 2), and JAMA 2 (1, 2). TikTok outperformed Bilibili significantly in terms of quality scores, and also exhibited advantages in interaction metrics (likes, comments, favorites, shares) and uploader certification rates; in contrast, Bilibili videos had a significantly longer duration. Regarding uploader identity, videos posted by hepatology specialists achieved significantly higher quality scores than those by non-specialist uploaders. Correlation analysis revealed that all interaction metrics exhibited little to no correlation with quality scores.

Conclusions:

The information quality and reliability of CHB-related short videos on TikTok and Bilibili are both poor and need to be improved; platform attributes and uploaders' professional backgrounds are closely related to the quality of short videos; the interaction rate is not proportional to the quality of short videos, and videos with a high interaction rate do not necessarily have good quality and reliability.

Keyword(s) : Chronic Hepatitis B; TikTok; Bilibili; Short Videos; Information Quality; Reliability

1258 - The Liver in Systemic Diseases A Key Metabolic Regulator

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The liver plays a central role in systemic metabolism, immune regulation, and detoxification. We hypothesize that liver dysfunction significantly contributes to the progression of extrahepatic diseases, including metabolic syndrome, cardiovascular disorders, and systemic inflammation.

Materials and Methods:

We conducted a retrospective cohort study including 1,200 patients with documented liver conditions (NAFLD, ALD, viral hepatitis) and matched controls. Serum biomarkers, imaging studies, and histopathological data were analyzed. Multivariate regression models were used to assess associations between liver function and systemic disease outcomes.

E-POSTER ABSTRACTS

Results:

Patients with advanced liver disease showed a higher prevalence of type 2 diabetes (42% vs. 18%, $p < 0.01$), coronary artery disease (28% vs. 12%, $p < 0.05$), and chronic kidney disease (19% vs. 7%, $p < 0.01$). Liver stiffness and elevated ALT levels were independent predictors of systemic morbidity.

Conclusions:

The liver is critically involved in the pathogenesis and progression of multiple systemic diseases. Early detection and management of liver disorders may reduce the burden of extrahepatic complications and improve overall patient outcomes.

Keyword(s) : Liver Involvement, Systemic Diseases, Extrahepatic Manifestations, Metabolic Dysfunction, Biomarkers

1259 - The Central Role of Liver Dysfunction in Systemic Metabolic and Cardiovascular Diseases Remaining characters

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

The liver is a pivotal metabolic and immunomodulatory organ, yet its systemic influence beyond classical hepatology is underestimated. We hypothesized that the severity of liver fibrosis, measured non-invasively, is an independent predictor for the incidence and progression of key extrahepatic diseases, including type 2 diabetes (T2D), atherosclerotic cardiovascular disease (ASCVD), and chronic kidney disease (CKD). A prospective, multicenter cohort study was conducted from 2020 to 2024, enrolling 2,850 adults with varying degrees of non-alcoholic fatty liver disease (NAFLD). All participants underwent comprehensive assessment at baseline: clinical evaluation, laboratory tests (including liver enzymes, lipid profile, and HbA1c), vibration-controlled transient elastography (VCTE) to determine liver stiffness measurement (LSM), and abdominal ultrasound. They were followed annually for the primary endpoints: new-onset T2D, major adverse cardiovascular events (MACE), and progression of CKD. Over a median follow-up of 3.5 years, 289 (10.1%) participants developed T2D, 156 (5.5%) experienced a MACE, and 203 (7.1%) showed significant CKD progression. Multivariable Cox regression analysis, adjusted for age, sex, BMI, and traditional risk factors, revealed that elevated baseline LSM was a powerful independent risk factor. Each 1-kPa increase in LSM was associated with a 15% higher risk for T2D (HR 1.15,

95% CI 1.09-1.22), an 18% higher risk for MACE (HR 1.18, 95% CI 1.10-1.27), and a 12% higher risk for CKD progression (HR 1.12, 95% CI 1.05-1.19). Participants with LSM ≥ 10.0 kPa (indicating advanced fibrosis) had a 3.2-fold increased risk for the composite endpoint compared to those with LSM < 7.0 kPa.

Liver fibrosis severity is a robust, independent predictor for the development of critical systemic diseases. Our findings compellingly argue for the integration of liver health assessment, particularly non-invasive fibroscan, into the routine risk stratification for T2D, ASCVD, and CKD. Proactive management of liver disease may not only prevent hepatic complications but also mitigate the global burden of major extrahepatic morbidity and mortality.

1260 - Mitochondrial Dysfunction in NAFLD A Public Health Perspective Remaining characters

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

Non-alcoholic fatty liver disease (NAFLD) is a burgeoning public health crisis, yet the underlying pathological mechanisms driving its progression remain incompletely understood. We hypothesized that hepatic mitochondrial dysfunction is a critical early event in NAFLD pathogenesis, and that quantifying this dysfunction could serve as a novel biomarker for disease progression and systemic metabolic complications, informing public health screening strategies.

We conducted an integrated study combining in vitro and clinical cohorts. In vitro, we exposed human HepG2 hepatocytes to free fatty acids and assessed mitochondrial function via Seahorse Analyzer, oxidative stress markers, and apoptosis. In vivo, we analyzed a prospective community-based cohort of 1,500 individuals with ultrasonographically confirmed NAFLD. Peripheral blood mononuclear cells (PBMCs) were isolated as a surrogate tissue to measure mitochondrial DNA (mtDNA) copy number and respiratory complex activity. All participants were followed for 3 years for the primary outcome of fibrosis progression (measured by FIB-4 index increase ≥ 0.5) and incident type 2 diabetes (T2D).

In vitro, fatty acid-overloaded hepatocytes exhibited significant mitochondrial depolarization, reduced ATP production, and increased ROS, culminating in cell death. In vivo, patients in the lowest tertile of PBMC

E-POSTER ABSTRACTS

mtDNA copy number at baseline had a significantly higher risk of fibrosis progression (HR: 2.8, 95% CI: 1.9-4.1, $p < 0.001$) and new-onset T2D (HR: 2.1, 95% CI: 1.5-3.0, $p < 0.001$), independent of age, BMI, and HOMA-IR. A combined model integrating low mtDNA copy number and high FIB-4 index showed superior predictive accuracy for 3-year metabolic deterioration (AUC=0.82) compared to either marker alone. Our findings from bench to population demonstrate that mitochondrial dysfunction is a cornerstone of NAFLD pathology. Critically, we establish that a simple, measurable biomarker of this dysfunction (PBMC mtDNA copy number) holds significant prognostic value for predicting liver fibrosis and diabetes risk. This presents a compelling public health opportunity: incorporating mitochondrial health assessment into NAFLD management protocols could enable earlier identification of high-risk individuals, facilitating targeted interventions and alleviating the future healthcare burden.

1261 - Single Cell Atlas Reveals Immunometabolic Drivers of NAFLD HCC Transition Remaining characters

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

Hepatocellular carcinoma (HCC) arising from non-alcoholic fatty liver disease (NAFLD) is becoming a leading cause of liver-related mortality worldwide. A critical gap exists in understanding the pre-malignant immune microenvironment. We hypothesized that a specific, metabolically reprogrammed CD8⁺ T cell subset accumulates in advanced NAFLD, fostering an immunosuppressive niche that licenses hepatocarcinogenesis.

We employed an integrated approach. A novel murine model of NAFLD-driven HCC (fed a high-fat, high-cholesterol, high-fructose diet) was utilized. Liver immune cells from pre-malignant (6-month) and tumor-bearing (12-month) stages were analyzed using single-cell RNA sequencing (scRNA-seq) coupled with Cellular Indexing of Transcriptomes and Epitopes (CITE-seq). Key findings were validated in a human cohort using multiplex immunofluorescence on liver biopsies from 60 patients with NAFLD, with or without HCC.

scRNA-seq of 45,000 murine liver cells unveiled a trajectory of CD8⁺ T cell exhaustion, culminating in a previously unrecognized subset termed "metabolically

exhausted" CD8⁺ T cells (Tmet-ex). These Tmet-ex cells, enriched in pre-malignant livers, exhibited a unique dual signature: high expression of exhaustion markers (e.g., PD-1, TOX) and a dysregulated metabolic profile with impaired mitochondrial fatty acid oxidation and increased glycolytic dependency. In vivo depletion of this subset significantly reduced subsequent tumor incidence ($p < 0.01$). Crucially, we identified the surface protein Folate Receptor beta (FR β) as a specific marker for Tmet-ex cells. In human NAFLD biopsies, the density of FR β ⁺ CD8⁺ T cells was significantly higher in patients who progressed to HCC within 3 years (AUC=0.88 for prediction).

Our study provides the first single-cell resolution atlas of the immunosuppressive transition from NAFLD to HCC, identifying a metabolically distinct, protumorigenic CD8⁺ T cell subset. The discovery of FR β as a surface marker offers a direct translational path. This opens a novel avenue for public health strategy: targeting FR β ⁺ Tmet-ex cells could serve as a chemopreventive measure for high-risk NAFLD patients, potentially halting HCC development before it begins.

1262 - Gut Microbiota Derived Metabolites Predict Advanced Fibrosis in MAFLD A Machine Learning Approach Remaining characters

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

Metabolic dysfunction-associated fatty liver disease (MAFLD) poses a massive disease burden, with rapid identification of advanced fibrosis being a critical public health priority. The gut-liver axis is implicated in pathogenesis, but its translational potential for community screening remains untapped. We hypothesized that a signature of circulating gut microbiota-derived metabolites, integrated with clinical data via machine learning, could non-invasively and accurately identify patients with advanced fibrosis, outperforming current biomarkers.

We conducted a multi-stage, cross-sectional study. In the discovery phase, untargeted metabolomics was performed on plasma from 400 well-phenotyped MAFLD patients (derivation cohort). Significant metabolites were validated using targeted LC-MS/MS in an independent cohort of 800 MAFLD patients (validation cohort). All participants underwent liver

E-POSTER ABSTRACTS

stiffness measurement (LSM) by VCTE as the reference standard (advanced fibrosis: LSM ≥ 10.0 kPa). A machine learning model (XGBoost) was trained to predict advanced fibrosis using the metabolite panel and routine clinical variables (e.g., age, BMI, platelets, AST/ALT). Its performance was compared to FIB-4 and NFS.

Untargeted metabolomics identified 12 metabolites significantly associated with advanced fibrosis, primarily belonging to bile acid and aromatic amino acid pathways. Three key metabolites—phenylacetylglutamine (PAGln), a secondary bile acid (isoDCA), and indole-3-propionic acid (IPA)—were consistently validated. The XGBoost model, incorporating these three metabolites and clinical data, dramatically outperformed traditional tests. In the validation cohort, it achieved an AUC of 0.94 (95% CI: 0.91-0.97), with a sensitivity of 92% and specificity of 88%. In contrast, FIB-4 and NFS achieved AUCs of 0.78 and 0.75, respectively. The model also accurately reclassified 35% of FIB-4 indeterminate cases. This study establishes a robust link between specific gut microbiota-derived metabolites and MAFLD severity. More importantly, we demonstrate that a machine learning model leveraging this "metabolic fingerprint" provides a superior, non-invasive tool for detecting advanced fibrosis at the population level. This AI-powered approach represents a paradigm shift in public health strategy, enabling high-throughput, accurate risk stratification that could transform MAFLD screening and direct resources to those at greatest need.

1264 - Efficacy of Percutaneous Microwave Ablation in Exophytic Hepatocellular carcinoma

Hishan Abdelaal¹, Ebada Said², Mohamed El Shewy², Mahmoud Salah¹

Kafr El Sheikh Liver Research Center, Department Of Hepatology, Gastroenterology And Infectious Diseases, Kafr El Sheikh-Egypt¹ Faculty Of Medicine Benha University, Department Of Hepatology, Gastroenterology And Infectious Diseases, Benha-Egypt²

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is the commonest

primary cancer of the liver. HCC location is a critical factor for local recurrence following percutaneous ablation. Exophytic HCC is a challenging location with high risk of tumor rupture. HCCs in these locations are more prone for residual disease or local progression owing to creation of suboptimal ablation volume. The aim of this study was to evaluate the efficacy of percutaneous microwave ablation (MVA) for exophytic (HCC) and outcome after 6 months follow up.

Materials and Methods:

A prospective study was conducted on 40 cases with exophytic HCC. Microwave ablation was performed percutaneously for all patients. Artificial ascites was made in sub-diaphragmatic lesions & Exophytic lesion adjacent to bowel. Patients were followed for 1, 3, and 6 months postoperatively.

Results:

The complications of MVA were reported by 7.5 % of cases and were minor complications. 80 % of cases showed complete ablation while 20 % of cases have incomplete ablation. There was significant decrease in Alpha fetoprotein before and after MVA.

Conclusions:

Percutaneous microwave ablation showed a good result for treating exophytic hepatocellular carcinoma with little complications.

Keyword(s) : Percutaneous microwave ablation, Exophytic hepatocellular carcinoma, Alpha fetoprotein.

1267 - Clinical Characteristics and Prognostic Analysis of Patients with Primary Biliary Cholangitis Complicated with Hepatic Granulomas

Wen Gao¹, Chunyang Huang¹, Bin Xu¹

Beijing Youan Hospital Affiliated To Capital Medical University, Department Ii Of Liver Diseases, Beijing-China¹

Background / Hypothesis: Primary biliary cholangitis (PBC) is an autoimmune liver disease characterized by intrahepatic small bile duct inflammation, progressive fibrosis, and potential progression to cirrhosis or liver failure. With globally rising incidence and prevalence, its burden is increasing. Ursodeoxycholic acid (UDCA) is first-line therapy but fails to cure, with 30-40% of patients showing inadequate response. The need to optimize PBC management is unmet. Hepatic granuloma is observed in many PBC patients, but the association of hepatic granuloma with PBC and its

E-POSTER ABSTRACTS

impact remain unclear.

Methods: A retrospective analysis was conducted on 319 patients diagnosed with PBC and undergoing liver biopsy at Beijing You'an Hospital, Capital Medical University, from 2014 to 2024. Histological staging was performed using the Ludwig classification system (Stage I–IV). Serum immunological markers, pathological features, and GLOBE scores were compared between the two groups.

Results: Among the 319 PBC patients, hepatic granulomas were detected in 79 PBC patients (24.8%). Compared with the non-granulomatous group, the granulomatous group exhibited significantly higher globulin (GLB) [(34.40±5.23) g/L vs (32.95±4.81) g/L] and lower total bile acid (TBA) [(11.7±8.5) µmol/L vs (16.0±12.3) µmol/L] (both $P < 0.05$). The positive rate of anti-centromere antibody (ACA) in the granulomatous group (27.9%) was significantly higher than that in the non-granulomatous group (17.2%), with a statistically significant difference ($P=0.028$).

GLOBE scores showed no significant difference between groups [(0.49±0.12) vs (0.58±0.15), $P=0.075$]. Among 79 PBC patients with hepatic granulomas, epithelioid granulomas were observed in 65 cases (82.3%), microgranulomas in 13 cases (16.5%), and mixed granulomas in 1 case (1.3%); 65 cases (82.3%) were located in the portal area, 11 cases (13.9%) in the lobule, and 3 cases (3.8%) in cross-regional distribution. Histological staging revealed that among the 79 PBC patients with hepatic granulomas, 78.5% (62/79) were in stages I–II, which was significantly higher than the proportion of stages I–II in overall PBC patients (63.0%, 201/319). Furthermore, the detection rate of granulomas showed a decreasing trend with advancing disease stage (detection rate of stage I: 32.1%; stage II: 38.5%; stage III: 18.6%; stage IV: 5.9%), with a statistically significant difference ($P < 0.05$).

Conclusion: Hepatic granulomas are more prevalent in the early stages of PBC, diminishing progressively with disease progression, suggesting they may represent a transitional pathological manifestation within the PBC disease course. PBC with hepatic granulomas may denote a distinct disease subtype, and its prognostic implications warrant validation through larger sample cohorts.

Keyword(s) : Primary biliary cholangitis; Hepatic granuloma; Clinical features; Pathological staging; GLOBE score

DATA

Enkhtaivan Odmaa¹, Ganbaatar Khorolgarav², Jazag Amarsanaa³, Oidov Baatarkhuu²
National Center For Communicable Diseases, -, Ulaanbaatar-Mongolia¹ Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia² Mongolian Association For The Study Of Liver Disease, -, Ulaanbaatar-Mongolia³

Background / Hypothesis:

Mongolia has implemented several key policies to reduce the incidence of viral hepatitis, including the National Program for the Prevention and Control of Infectious Diseases and the Whole Liver Program (Hepatitis Prevention, Control, and Elimination Program). This study aims to estimate the new incidence of viral hepatitis in Mongolia and evaluate the impact of these policy measures in combating the disease.

Materials and Methods:

This desk review examined reported hepatocellular carcinoma (HCC) cases by utilizing national statistical datasets and reviewing policy documents released by relevant governmental authorities.

Results:

As of 2025, 270 cases of acute hepatitis virus infection have been registered nationwide, equating to 0.8 cases per 10 000 population. Compared to last year, there were 49 additional cases, resulting in an increase of 0.1 case per 10 000 population. In the last decade, the incidence of acute hepatitis virus infection at the national level was highest in 2015, with a rate of 4.0 cases per 10 000 population, and has been steadily decreasing since 2016. As of 2024, the breakdown of hepatitis virus infections is as follows: hepatitis A virus infection accounts for 0.7% of all cases, hepatitis B virus infection for 46.3%, hepatitis C virus infection for 44.5%, and other hepatitis virus infections for 8.5%. In 2024, 54.1% of acute hepatitis virus infection cases were male, and 45.9% were female. Age distribution showed that 30.4% of the cases were individuals aged 20–29 years, and 32.6% were aged 30–39 years. Outpatient services diagnosed 88.9% of all infections, and there were 8 reported deaths due to viral hepatitis infection.

Conclusions:

Last decades, Mongolia has been reducing the

E-POSTER ABSTRACTS

incidence of new infections through HPCE programs, public awareness campaigns, and new antiviral medicines have been introduced into chronic viral hepatitis treatment.

Keyword(s) : Acute viral hepatitis, HCC, HBV, HCV, Mongolia

1269 - RISK FACTORS AND CLINICAL FEATURES OF ACUTE HEPATITIS D IN MONGOLIA

Badamnachin Batsukh¹, Ganbaatar Khorolgarav², Vangan Nyamtsengel², Oidov Baatarkhuu²
National Center For Communicable Diseases, Emergency Department, Ulaanbaatar-Mongolia¹
Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia²

Background / Hypothesis:

Hepatitis D virus (HDV) infection is associated with more severe liver disease, including cirrhosis and hepatocellular carcinoma (HCC). Mongolia has one of the highest prevalence rates of viral hepatitis worldwide, with over 15% of the population infected with HCV, more than 10% with HBV, and HDV detected in 75–100% of HBsAg carriers. This study aims to investigate the clinical prognosis and risk factors of acute hepatitis D in Mongolia.

Materials and Methods:

A total of 172 patients diagnosed with acute viral hepatitis D were enrolled in the study, and their demographic, clinical, and laboratory data were collected between 2021 and 2024. Patients were evaluated for risk factors, disease severity, serological markers (anti-HDV IgM and total anti-HDV antibodies), and follow-up outcomes, including viral persistence and HBsAg clearance.

Results:

The mean age of patients was 29.7 ± 7.2 years, with 104 males (60.4%) and 68 females (39.6%). Reported risk factors included unprotected sexual contact (82, 47.7%), hospitalization (84, 48.8%), sharing nail clippers (154, 86%), family contact with hepatitis B (46, 26.7%), dental procedures (22, 12.8%), history of surgery (26, 15.1%), tattooing (16, 9.3%), and acupuncture (24, 13.9%). Serological testing showed that both anti-HDV IgM and total anti-HDV antibodies were positive in 68 of 172 patients. Anti-HDV IgM alone was positive in 130 patients, while total anti-HDV antibodies alone

were positive in 122 patients. During follow-up, among 10 patients with co-infection (HDV + HBV), 3 (30%) achieved HBsAg clearance. In contrast, all 116 patients with superinfection demonstrated persistent HBV and HDV viremia, indicating chronic infection

Conclusions:

Risk factors for hepatitis D virus infection were unprotected sexual contact, admitted hospital, share with nail clipper and family contacts with viral hepatitis. During follow-up, three of 10 (60%) patients with co D infection showed HBsAg loss and 116 patients with super D infection (100%) showed persistent hepatitis B and D viremia.

Keyword(s) : Hepatitis D virus infection, HBsAg, anti-HDV, anti-HDV IgM, Mongolia

1270 - Treatment Outcomes of HCV Genotype 1b with Ledipasvir Sofosbuvir and the Role of Resistance Associated Substitutions in Mongolia

Lkhagvasuren Purevsod¹, Jazag Amarsanaa², Oidov Baatarkhuu¹
Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia¹
Mongolian Association For The Study Of Liver Disease, Ulaanbaatar, Mongolia, Ulaanbaatar-Mongolia²

Background / Hypothesis:

Mongolia ranks among the countries with the highest hepatitis C virus (HCV) prevalence worldwide. Ledipasvir/sofosbuvir (LDV/SOF) has been introduced in Mongolia since 2016 to support national efforts to eliminate HCV. In studies from Western populations, resistance-associated substitutions (RASs) in HCV have been shown to compromise the effectiveness of LDV/SOF therapy in chronic hepatitis C (CHC) patients. This study aims to assess the treatment efficacy of LDV/SOF and examine the impact of RASs on therapeutic outcomes in Mongolian patients with CHC.

Materials and Methods:

HCV genotype 1b (GT1b) patients were prospectively enrolled in Mongolia and treated with a 12-week course of ledipasvir/sofosbuvir (LDV/SOF). Pre-treatment NS5A Y93H resistance-associated substitutions (RASs) in viral quasiespecies were analyzed using next-generation sequencing. Treatment effectiveness was assessed by the sustained virological response at 12 weeks post-treatment (SVR12).

E-POSTER ABSTRACTS

Results:

A total of 94 patients with chronic hepatitis C (CHC) were included in the analysis. The baseline proportion of the NS5A Y93H resistance-associated substitution (RAS) was <1% in 74 patients, 1–15% in 7 patients, 15–50% in 2 patients, and ≥50% in 11 patients. All participants completed the 12-week course of ledipasvir/sofosbuvir (LDV/SOF), achieving an overall sustained virological response at 12 weeks (SVR12) rate of 90.4%. The likelihood of failing to achieve SVR12 increased with higher baseline Y93H levels: 0% in patients with <1%, 14.3% in those with 1–15%, and 61.5% in patients with ≥15% Y93H (p for trend <0.001). In univariable analysis, treatment failure was associated with older age, baseline alanine transaminase (ALT) <40 U/mL, and a higher proportion of Y93H. However, multivariable analysis identified only a higher baseline proportion of Y93H as an independent predictor of treatment failure ($p = 0.022$).

Conclusions:

LDV/SOF therapy demonstrates a high sustained virological response (SVR) rate in Mongolian CHC patients with genotype 1b who lack baseline Y93H resistance-associated substitutions (RASs). Conversely, a higher baseline proportion of Y93H can substantially reduce the effectiveness of LDV/SOF treatment.

Keyword(s) : Chronic hepatitis C; Resistance-associated substitution; Ledipasvir; Sofosbuvir; Mongolia

1271 - CLINICAL AND LABORATORY CHARACTERISTICS OF CHRONIC HEPATITIS D VIRUS INFECTION IN MONGOLIA

¹ Mongolian National University Of Medical Sciences, Emergency Department, Ulaanbaatar-Mongolia
² National Center For Communicable Disease, -, Ulaanbaatar-Mongolia
³

Background / Hypothesis:

Hepatitis D virus (HDV) infection progresses more aggressively than hepatitis B virus (HBV) mono-infection. Within two years, 10–15% of patients develop severe liver disease, and 70–80% progress to cirrhosis within 5–10 years. The risk of hepatocellular

carcinoma (HCC) is approximately three times higher than in HBV mono-infected patients. This study aimed to evaluate the clinical characteristics and laboratory profiles of patients with chronic HDV infection in Mongolia.

Materials and Methods:

From October 2024 to October 2025, laboratory and clinical data of patients with chronic HDV infection attending the outpatient department of the National Center for Communicable Diseases (NCCD) were analyzed. Data were processed and analyzed using SPSS 25 software.

Results:

A total of 252 patients with chronic HDV infection were included. Among them, 197 (78.2%) had chronic hepatitis, while 55 (21.8%) had liver cirrhosis. The mean age was 48.4 ± 0.66 years, with 151 (59.9%) males and 101 (40.1%) females. Prior HBV antiviral therapy was reported in 112 patients (44.4%), including tenofovir (72.5%), entecavir (27.1%), and adefovir (0.4%). Two patients initiated bulevirtide therapy for HDV in 2023. The mean duration of HBV antiviral therapy was 2.9 ± 0.3 years (range 3 months–10 years). Liver function tests showed elevated transaminase levels: ALT 63.1 ± 5.5 U/L, AST 60.7 ± 38.7 U/L, bilirubin 21.6 ± 3.8 $\mu\text{mol/L}$, and platelet count $194.4 \pm 6.5 \times 10^3/\mu\text{L}$. Serological testing revealed a mean qHBsAg of $7,029.5 \pm 926.6$ IU/mL. Among 67 patients tested for HBeAg, 62 (92.5%) were negative and 5 (7.5%) positive. HBV-DNA levels averaged $11,157,679.2 \pm 7,889,122.6$ IU/mL. HDV-RNA quantification showed 15.3% of patients with levels $>10^7$, 29.6% at 10^6 , 31.6% at 10^5 , 7.1% $<10^4$, and 16.3% with undetectable levels. The mean APRI score for liver fibrosis was 1.0 ± 0.1 .

Conclusions:

Chronic HDV infection in Mongolia predominantly affects middle-aged adults, with 21.8% already presenting with cirrhosis. Laboratory findings indicate elevated transaminases and high viral replication, with 44.9% of patients exhibiting HDV-RNA levels above 10^6 . These findings underscore the aggressive nature of HDV and the need for early diagnosis and therapeutic interventions.

E-POSTER ABSTRACTS

1273 - Community based interventions for hepatitis C virus elimination among people who use drugs in Shanghai China

Xiaoxiao Yu ¹, Yingqiu Shen ¹, Jiayi Wang ², Guichun Ji ³, Qiuli Xu ⁴, Yumeng Gao ⁴, Zhenglan Zhang ⁵, Xingyi Chen ⁶, Xin Xin ⁴, Lihong Qu ¹

Shanghai East Hospital, School Of Medicine, Tongji University, Department Of Infectious Diseases, Shanghai-China ¹ Shanghai East Hospital, School Of Medicine, Tongji University, Department Of Public Health, Shanghai-China ² Beicai Community Health Service Center, Pudong New Area, Department Of Public Health, Shanghai-China ³ Shanghai Pudong New Area Centre For Disease Control And Prevention, Department Of Aids Prevention, Shanghai-China ⁴ Shanghai Pudong Hospital, Fudan University, Department Of Infectious Diseases, Shanghai-China ⁵ Shanghai East Hospital, School Of Medicine, Tongji University, Department Of Medical Administration, Shanghai-China ⁶

Background:

The prevalence of hepatitis C virus (HCV) infection among people who use drugs (PWUD) in China remains high, yet diagnosis and treatment rates are low. Strategies are urgently needed to achieve the World Health Organization's goal of eliminating HCV as a public health threat by 2030.

Aim: To improve HCV diagnosis and treatment rates among PWUD in Pudong New Area, Shanghai, China.

Materials and Methods:

A retrospective and prospective study was implemented among individuals with substance addiction history in Pudong New Area, Shanghai, China. Three models were explored in our study. In the Self-Referral (SR) model, HCV antibody-positive individuals relied on their own initiative to seek medical services. In the Standard Intensive Referral (SIR) model, managerial supervision was strengthened. The Active Intensive Referral (AIR) model placed greater emphasis on managerial proactivity, enhancing screening and treatment for high-risk populations.

Results:

A total of 3926 PWUD from 36 communities in Pudong New Area underwent rapid HCV antibody testing in the SR model. These numbers were 1973 and 191, respectively, in the SIR and AIR models. Only 18.9% population completed HCV RNA testing in the SR model compared with 100.0% in both the SIR and AIR models ($P < 0.001$). Overall, 70/146 (48.0%) PWUD in the SR model were identified with HCV RNA consistent

with the SIR and AIR models [339/916 (37.0%) and 74/191 (38.7%), $P > 0.05$]. Only 73 (21.5%) patients received DAAs treatment. In terms of treatment, 47/74 (63.5%) of patients in the AIR model initiated treatment, significantly higher than the 15/70 (21.4%) in the SR model and 73/339 (21.5%) in the SIR model ($P < 0.001$). Genotype 3, particularly subtype 3b, was the most prevalent genotype among PWUD in our study, respectively accounting for 23/38 [60.5%] in the AIR model and 112/166 [67.5%] in the SIR model. In the AIR model, all participants received a liver stiffness test. Fifty-two (27.2%) patients had a liver stiffness of more than 12.5kPa. One hundred and eighty-one persons completed the questionnaire in the AIR model. The results revealed that few people had high educational attainment. More than half (52.5%) of the population had no stable marital relationship.

Conclusions:

A multidisciplinary community-based approach significantly improved HCV diagnosis and treatment among PWUD, offering a scalable model for achieving the WHO elimination targets in China.

1274 - Constructing a dual dimensional scoring system by integrating tertiary lymphoid structures and monocyte lymphocyte ratio to optimize recurrence risk stratification in hepatocellular carcinoma a multicenter cohort study

Jia-yong Su ¹, Xiao-ling Xu ², Shao-ping Liu ³, Yi-man Li ⁴, Shu-chang Chen ², Jun-jie Ou ², Xiao-ming Li ⁴, Wei Chen ⁴, Liang Ma ¹, Yi-li Ma ¹, Jian-hong Zhong ¹

Guangxi Medical University Cancer Hospital, Department Of Hepatobiliary Surgery, Nanning-China ¹ The People's Hospital Of Wuzhou, Department Of Hepatobiliary Surgery, Wuzhou-China ² Guigang City People's Hospital, Department Of Hepatobiliary Surgery, Guigang-China ³ Southwest Hospital, Army Medical University (third Military Medical University), 7t Magnetic Resonance Translational Medicine Research Center, Department Of Radiology, Chongqing-China ⁴

Background / Hypothesis: The monocyte/lymphocyte ratio (MLR) reflects systemic inflammatory-immune status, while tertiary lymphoid structures (TLS) reflect local anti-tumor immunity. Both markers are associated with hepatocellular carcinoma (HCC) prognosis. This study aims to evaluate a dual-dimensional scoring system integrating TLS and MLR for accurately predicting HCC recurrence risk, and to assess their interaction with adjuvant PD-1 inhibitors.

E-POSTER ABSTRACTS

Materials and Methods: A total of 1,139 patients who underwent curative resection for HCC without adjuvant therapy were retrospectively enrolled from 4 institutions in China between January 2019 and December 2023. These patients were stratified based on their TLS and MLR status. Additionally, 195 patients who received adjuvant PD-1 inhibitor therapy were prospectively recruited to validate the clinical utility of the scoring system. The X-tile software was employed to determine the optimal cutoff value for MLR (defined as MLR-high if >0.27 and MLR-low otherwise). Recurrence-free survival (RFS) and overall survival (OS) were evaluated. Fifty-five patients in the prospective cohort underwent bulk RNA sequencing to explore underlying mechanisms.

Results: Patients were categorized into four subgroups: 382 (33.5%) TLS+ /MLR-low, 282 (24.8%) TLS+ /MLR-high, 244 (21.4%) TLS- /MLR-low, and 231 (20.3%) TLS- /MLR-high in the retrospective cohort; and 62 (31.8%) TLS+ /MLR-low, 47 (24.1%) TLS+ /MLR-high, 49 (25.1%) TLS- /MLR-low, and 37 (19.0%) TLS- /MLR-high in the prospective cohort. In the retrospective cohort, TLS+ /MLR-low had the best prognosis (median RFS: 25.6 months; median OS: not reached), while TLS- /MLR-high had the poorest (median RFS: 14.5 months; median OS: 41.3 months). Prognoses were comparable between TLS+ /MLR-high and TLS- /MLR-low (median RFS: 19.3 vs. 20.8 months; median OS: 58.0 vs. 61.6 months), with significant differences in RFS and OS across all four subgroups (both $P < 0.001$). In the prospective cohort, TLS+ /MLR-low showed significantly better RFS (median: 43.3 months; $P = 0.043$) and OS (median: not reached; $P = 0.045$) versus other subgroups. Bulk RNA sequencing revealed differentially expressed genes between TLS+ and TLS- cases were primarily associated with the T-cell-inflamed tumor microenvironment and anti-tumor immunity, corroborated by peripheral inflammatory-immune status reflected by MLR. These results indicate the combined score predicts HCC recurrence risk more accurately than either indicator alone.

Conclusions: We developed a novel scoring system refining postoperative recurrence risk stratification, identifying patients more likely to benefit from

adjuvant PD-1 inhibitors, with potential to guide personalized therapy.

E-POSTER ABSTRACTS

Hepatobiliary Surgery, Nanning-China ¹⁶ The Seventh Affiliated Hospital Of Guangxi Medical University, Department Of Hepatobiliary Surgery, Wuzhou-China ¹⁷

Background / Hypothesis:Identifying the optimal patient subpopulation for benefiting from adjuvant immune checkpoint inhibitors is crucial. This study aims to develop and validate an explainable machine learning model for predicting recurrence in hepatocellular carcinoma (HCC) patients receiving adjuvant PD-1 inhibitors who are at high risk of recurrence after curative resection.

Materials and Methods:This study included retrospective and prospective datasets from 16 medical centers in China, collected from January 2019 to December 2024. Patients who received adjuvant therapy in the prospective cohort were randomly split into the training set and internal validation set, while the retrospective cohort served as the external validation set. Eight machine learning models were employed to predict recurrence in HCC patients. Model performance was evaluated using the area under the receiver operating characteristic curve (AUC), C-index, calibration curve, Brier score, and decision curve analysis (DCA). Additionally, the performance of traditional models was compared to that of time-dependent machine learning models in predicting HCC recurrence. The optimal model was interpreted via SHapley Additive exPlanations (SHAP).

Results:A total of 2,680 patients were included in this study, including 1,649 in the prospective cohort and 1,031 in the retrospective cohort. Adjuvant therapy significantly improved patient prognosis in both cohorts. A total of 910 patients (465 in the prospective cohort and 441 in the retrospective cohort) who received adjuvant PD-1 inhibitor therapy were included in the model analysis. Five key features were selected for model development: tumor size, tumor number, BCLC stage, macrovascular invasion, and microvascular invasion (MVI). Of the eight machine learning (ML) models evaluated, the gradient boosting machine (GBM) model exhibited superior performance. In the external validation cohort, the GBM model achieved 1-, 2-, and 3-year AUC values of 0.831, 0.750, and 0.712, respectively, with corresponding C-indices of 0.800, 0.737, and 0.711—all superior to those of conventional

postoperative recurrence prediction models in predicting recurrence after adjuvant therapy. The GBM model could effectively identify patients with still high recurrence risk after adjuvant therapy; these patients showed no significant difference in prognosis compared with those under active surveillance in both the prospective and retrospective cohorts. Additionally, we developed an online calculator to facilitate easy clinical application.

Conclusions:We constructed a new recurrence risk prediction model for patients with HCC who received adjuvant PD-1 inhibitor therapy after curative resection, which can effectively identify patients who benefit from adjuvant therapy, providing potential guidance to support clinicians in establishing personalized and precision treatment decisions.

1276 - Autoimmune hepatitis triggered by acute Coxiella burnetii infection a case report

Yusuf Bünyamin Ketenci ¹, Hakan Demiröz ¹, Mehmet Akca ¹, Gökçen Ayçe Yilmaz ², Ufuk Avcioğlu ¹, Ibrahim Gören ¹, Talat Ayyildiz ¹, Müge Ustaoglu Dede ¹, Ahmet Bektaş ¹

Ondokuz Mayıs University, Gastroenterology, Atakum-Türkiye ¹ Ondokuz Mayıs University, Internal Medicine, Samsun-Türkiye ²

Background:

Q fever, caused by *Coxiella burnetii*, is associated with autoimmune phenomena; however, biopsy-proven autoimmune hepatitis (AIH) developing sequentially after acute Q fever has not been reported to date. We present the first documented case of acute AIH emerging shortly after acute Q fever, suggesting infection-triggered loss of immune tolerance.

Case Presentation:

A 58-year-old livestock farmer presented with nausea, dark urine, jaundice, and acute hepatitis (ALT 552 U/L, AST 352 U/L, direct bilirubin 10 mg/dL). Serologies for hepatitis A–E, EBV, CMV, and other viral causes were negative. *Coxiella burnetii* phase II IgM and IgG were positive; Brucella serology was negative. MRI/MRCP revealed hepatomegaly and periportal edema. Doxycycline was initiated, with initial improvement.

E-POSTER ABSTRACTS

Following completion of therapy, liver enzymes rose again, raising suspicion for autoimmune hepatitis. Autoimmune workup revealed ANA 1:320 (homogeneous), elevated IgG (25 g/L), with negative ASMA, AMA, and LKM. Liver biopsy demonstrated interface hepatitis, prominent portal mononuclear infiltrates, venulitis, cholestatic pseudorosettes, and rare emperipolesis (Ishak HAI 15; fibrosis stage 2), consistent with acute AIH with cholestatic features.

Treatment and Outcome:

Prednisolone (60 mg/day) followed by azathioprine resulted in rapid biochemical improvement. At 4-month follow-up, ALT decreased to 96 U/L and bilirubin normalized. Clinical course strongly supported infection-triggered AIH.

Discussion:

This case highlights a unique temporal association where acute Q fever appears to precipitate autoimmune hepatitis. Although autoantibody induction during Q fever has been described, progression to biopsy-proven AIH immediately after acute infection has not been previously reported. Proposed mechanisms include molecular mimicry, epitope spreading, IL-10-mediated immune dysregulation, and DAMP-induced loss of self-tolerance.

Conclusion:

Acute Q fever may act as a potent environmental trigger for autoimmune hepatitis, especially when liver tests exhibit a biphasic pattern after antibiotic therapy. Awareness of this rare but clinically significant association is essential for timely diagnosis and management.

Background / Hypothesis: Adjuvant PD-1 inhibitors may significantly improve recurrence-free survival (RFS) in hepatocellular carcinoma (HCC) patients at high risk of recurrence after curative resection. This study aims to evaluate the impact of such therapy on early recurrence (defined as recurrence within 12 months after therapy) and late recurrence.

Materials and Methods: This study compared RFS and overall survival (OS) among patients with HCC who received adjuvant PD-1 inhibitor therapy or active surveillance. These patients were prospectively recruited from 14 medical centers in the same province and retrospectively collected from 2 medical centers in other provinces between January 2019 and December 2024. Propensity score matching was used to balance baseline characteristics. Landmark analysis was further performed to evaluate the impact of adjuvant therapy

E-POSTER ABSTRACTS

on early or late recurrence.

Results: A total of 2,680 patients were included, with 1,649 in the prospective cohort (465 received adjuvant therapy and 1,184 underwent active surveillance) and 1,031 in the retrospective cohort (441 received adjuvant therapy and 590 underwent active surveillance). In the prospective cohort, the median RFS in the adjuvant therapy group was 28.4 months (95% CI 27.4-32.1), significantly longer than the 23.0 months (95% CI 20.3-25.7) in the active surveillance group (HR 0.72; 95% CI 0.69-0.92). Median overall survival was not reached in the adjuvant group, whereas it was 68.3 months (95% CI 54.3-82.3) in the surveillance group, suggesting a significant survival benefit (HR 0.61; 95% CI 0.50-0.75). Landmark analysis further revealed that adjuvant PD-1 inhibitors significantly reduced the risk of early recurrence (HR 0.69; 95% CI 0.58-0.83) but showed limited efficacy against late recurrence (HR 0.97; 95% CI 0.78-1.21). In the retrospective cohort, adjuvant therapy significantly improved RFS (35.6 vs. 21.9 months; HR 0.78; 95% CI 0.66-0.93) and OS (median OS not reached in either group; HR 0.73; 95% CI 0.58-0.91). However, this benefit also appeared to be confined to early recurrence (HR 0.72; 95% CI 0.58-0.90), not late recurrence (HR 0.87; 95% CI 0.67-1.13). Similar results were observed after propensity score matching.

Conclusions: Adjuvant PD-1 inhibitor therapy significantly improves prognosis in HCC patients at high risk of recurrence after curative resection, but its efficacy demonstrates time dependence, with the benefit may be primarily confined to reducing early recurrence.

Keyword(s) : Adjuvant PD-1 inhibitor, curative resection, early recurrence, hepatocellular carcinoma

1282 - Understand Current Treatment Experience Unmet Needs and Attitudes Toward Functional Cure in China Among Patients With Chronic Hepatitis B

Guanzhu Lu¹, Jing Wang¹, Wei Chen¹, Xiaoling Yuan¹, Yujie Bao¹, Jie Xu¹

Shanghai Ninth People's Hospital School Of Medicine, Department Of Infectious Disease, Shanghai-China¹

Background/ Hypothesis:

Chronic hepatitis B (CHB) continues to pose a substantial public health burden in China. Although recent years have seen significant advances in screening, diagnosis, and antiviral therapy, aligning with progress toward the WHO 2030 elimination goals. However, limited data are available on patients' perspectives regarding current antiviral treatment experiences and understanding of functional cure. This study aimed to characterize their real-world treatment experiences, perceptions of functional cure, and to explore unmet needs and expectations for novel therapies through a mixed qualitative and quantitative design.

Materials and Methods:

A mixed-methods design was adopted. In the qualitative phase, in-depth interviews were conducted with 10 adult CHB patients to explore their lived experiences, challenges, and motivations regarding current therapies and pursuit of a functional cure. In the quantitative phase, an anonymous online questionnaire using a 6-section questionnaire (covering treatment experience, awareness of functional cure, and new-therapy preference etc.) was distributed to CHB patients residing in mainland China.

Results:

In total, 97 respondents completed the quantitative survey. The mean age was 52.4 years. Educational backgrounds were diverse, with 36.1% holding a bachelor's degree.

Most participants viewed the goal of antiviral therapy as preventing progression to cirrhosis or hepatocellular carcinoma, yet 57.7% had never heard of "functional cure (FC)" and only 10.3% reported clear understanding. Among those who are clear about the definition, patients across all age groups expressed desire for FC, though motivations varied by age: younger patients sought to remove the CHB label and return to a "normal social and family life", while older participants aspired to "live longer and healthier". Although Peg-IFN therapy was perceived as a possible way to FC, its adverse events were described as "unbearable". Patients' perceptions of side effects differed markedly from physicians'; for example, hair loss, considered mild and reversible by clinicians, while was viewed by patients as an outward stigma of illness. With respect to expectations for emerging therapies, patients placed high value on treatment regimens that are shorter, safer, and more predictable in efficacy, while maintaining manageable requirements for clinical monitoring. The majority preferred patient support programs led by healthcare professionals rather than

E-POSTER ABSTRACTS

peer-led communities.

Conclusions:

This mixed-methods study offers novel insights into the real-world treatment experiences of Chinese CHB patients. Although Awareness and understanding of functional cure remain limited, patients demonstrated strong motivation to achieve HBsAg loss and a strong preference for finite, tolerable regimens under physician guidance. Collectively, these findings underscore the importance of incorporating patient perspectives.

1285 - Safety and Outcomes of Allogeneic Hematopoietic Stem Cell Transplantation from HBsAg Positive Donors A Case Control Study from a Tertiary Care Centre.

Saleh Alghaythi ¹, Faisal Aba-alkhail ¹, Ahmad Alotaibi ², Musthafa Peedikayil ¹

King Faisal Specialist Hospital & Research Centre, Medicine, Riyadh-Saudi Arabia ¹ King Faisal Specialist Hospital & Research Centre, Oncology Centre, Riyadh-Saudi Arabia ²

Background / Hypothesis:

Hematopoietic stem cell transplantation (HSCT) from HBsAg-positive donors represents a strategy to expand the donor pool particularly in endemic regions. However, this practice may carry risks of HBV transmission and hepatic complications. The available literature is limited, conflicting, and based on low-scale protocols without standardized guidelines for managing such cases. The aim of this study is to evaluate HBV transmission risk, clinical outcomes, and the impact of current prophylactic strategies in recipients of HSCT from HBsAg-positive donors.

Materials and Methods:

We conducted a retrospective matched case-control study. Sixteen HSCT recipients aged >14 years who received grafts from HBsAg-positive donors between 2000 and 2024, were compared with 32 recipient controls matched 2:1 based on age, sex, disease, transplant year, donor type, and HBV status. Detailed donor, recipient, and HBV-related variables were collected, including laboratory data, clinical outcomes, and prophylactic interventions. Hepatic events—including HBV-related hepatitis, hepatic failure, VOD, and hepatic GVHD—were defined using standardized

criteria. Univariate analysis and descriptive analyses were used to identify predictors of HBV transmission and hepatic complications.

Results:

Baseline characteristics were well-matched between the case and control groups. Among the 16 case patients, only two (12.5%) developed post-transplant hepatitis, with both cases being acute. Strikingly, the incidence of hepatitis was lower in the HBsAg-positive donor group (12.5%) compared to the control group (31.2%), though this difference was not statistically significant ($p=0.157$). The absolute risk difference was -18.8% (95% CI -45.1% to +18.1%). Serological analysis revealed Only one (1/8) HBsAg-negative recipients (12.5%, 95% CI) developed de novo persistent HBsAg antigenemia post-transplant. A key finding was the successful implementation of a tailored prophylactic protocol, with the most common regimen being a combination of recipient and donor anti-HBV prophylaxis (50% of patients). An undetectable HBV DNA PCR was achieved in 11/16 pairs (68.8%) post-prophylaxis.

Conclusions:

With a structured, multi-modal prophylactic strategy, allogeneic HSCT from HBsAg-positive donors was not associated an apparent increase of HBV transmission, HBV-related hepatitis, or liver-related mortality compared with matched controls. Only one HBsAg-negative recipient (12.5%) developed persistent antigenemia, and two of the sixteen total recipients (12.5%) experienced HBV-related hepatitis. These descriptive results support the cautious use of HBsAg-positive donors in allogeneic HSCT programs which can safely expand the donor pool when managed with vigilant monitoring and comprehensive prophylaxis. However, the small sample size necessitates confirmation in larger studies.

Keyword(s) : Hematopoietic Stem Cell Transplantation, Hepatitis B Virus, HBsAg-Positive Donors, HBV Transmission, Liver Complications

1287 - Using Community Partnerships to Achieve HCV Micro elimination in Vancouver's Inner city

Christina Wiesmann ¹, Shana Yi ², David Truong ², Brian Conway ¹

Simon Fraser University, Faculty Of Health Sciences, Burnaby-Canada ¹ Vancouver Infectious Diseases Centre, N/a, Vancouver-Canada ²

E-POSTER ABSTRACTS

Background / Hypothesis:

The individuals living in Vancouver's inner city have some of the highest rates of hepatitis C virus (HCV) Canada, and the Vancouver Infectious Diseases Centre (VIDC) is working towards eliminating HCV in this population. The VIDC does this using an approach involving regular community pop-up clinics, or CPCs, at various inner-city locations. At each event, point-of-care HCV antibody testing is offered to up to 30 individuals. Individuals testing positive for HCV antibodies often have their blood drawn on site and those confirmed to be viremic are followed up with by outreach individuals and engaged in treatment under a multi-disciplinary model of care. We aimed to determine whether VIDC is achieving a reduction in the prevalence of HCV viremia in Vancouver's inner-city.

Materials and Methods:

As part of a partnership with Atira housing society, since 2022 CPCs have regularly been held in the common spaces of Atira inner-city buildings with the goal of achieving elimination of HCV infection among the individuals living in these spaces. We determined the proportion of individuals testing positive for HCV antibodies, and those viremic, at CPC events held at 4 different Atira buildings in 2022 through 2024. We then averaged the proportion of individuals testing positive at each location in 2022 and in 2024. We were able to determine if there was a significant reduction in the proportion of individuals residing in these four buildings living with HCV in 2024 relative to 2022.

Results:

We saw a clear reduction in the proportion of viremic individuals tested over time at all four locations. We performed a more detailed analysis of the individuals testing positive at pop-up events at the Luugat and saw that the reduction in viremic individuals over time largely due to the previous treatment of viremic individuals living in that building. Overall, we did not see a reduction in the proportion of individuals with HCV antibodies in these four buildings (32% in 2022 vs. 26% in 2024). However, we saw a clear reduction in the proportion of individuals residing in these residences who were viremic for HCV (14% in 2022 vs. 4% in 2024; $p = 0.1$).

Conclusions:

This study demonstrates that while PWID may be a

particularly difficult demographic to target for HCV treatment, with the help of community partnerships, a multidisciplinary approach to care, and continued testing and follow-up, we are on our way to achieving micro-elimination of HCV among the residents of Vancouver's inner-city.

Keyword(s) : HCV, micro-elimination, PWID, inner-city

1288 - Strategies for reducing the time from HCV diagnosis to treatment initiation Lessons from Vancouver BC Canada

Christina Wiesmann ¹, Shana Yi ², David Truong ², [Brian Conway](#) ¹

Simon Fraser University, Faculty Of Health Sciences, Vancouver-Canada ¹ Vancouver Infectious Diseases Centre, N/a, Vancouver-Canada ²

Background / Hypothesis:

The eradication of HCV infection as a public health concern requires targeted initiatives. In Canada, approximately 35% of people who use drugs are infected with HCV, representing more than 60,000 individuals. The Vancouver Infectious Diseases Centre (VIDC) runs pop-up clinics in Vancouver's inner-city to test for HCV antibodies. Anecdotally, we identify numerous individuals who have documented HCV viremia and who state they have never been offered treatment. There is an urgent need to meaningfully re-engage these individuals in an accessible and timely manner. Reducing the time from HCV antibody diagnosis to treatment initiation is thought to be a key strategy for increasing HCV treatment uptake.

Materials and Methods:

Between August of 2023 and June of 2024, many measures were put in place to help reduce the time from point-of-care testing to initiation of treatment. These included on-site medical records look-up and phlebotomy, immediate special authority (SA) application, assistance attending required medical appointment(s), and partnership with a pharmacy providing daily HCV medication delivery. We measured the effect of these measures on time from initial contact to treatment initiation.

Results:

The median time from initial contact to treatment initiation was reduced from 6 weeks to approximately 3.5 weeks, with a range from 4 days to 57 days. The

E-POSTER ABSTRACTS

median from initial patient contact to SA application being sent was 2 days (range from 0 to 33 days), and the median number of days for SA approval was 1 day (range from 1 to 22 days). The median number of days from SA approval to prescription being written was 5 days (range from 0 to 40 days), and the median number of days from the prescription being written to the patient receiving their first dose of medication was 7 days (range from 0 to 25 days).

We identified a number of facilitators and barriers to timely treatment initiation. Facilitators included on-site phlebotomy, telehealth assistance for appointments, pharmaceutical delivery, and dispensation with other medications. Barriers included follow-up with individuals without a fixed address, lengthy SA approval times for complex cases, requirement for a fibroscan in some cases, and wait times for HCV medication or pharmaceutical delivery services.

Conclusions:

We have identified many different interventions which have helped to decrease the time between initial contact and treatment start date. We believe that many of these interventions are accessible and can be implemented in similar communities around the world.

1290 - Safety and Tolerability of SIRT and Sorafenib in Advanced Hepatocellular Carcinoma in Mongolia

Khasbazar Ariunaa ¹, Yalhgarg Bolormaa ², Altankhuyag Tuyatsetseg ², Oidov Baatarkhuu ³
Mongolian National University Of Medical Sciences, Cancer Department, Ulaanbaatar-Mongolia ¹ National Cancer Center, , Ulaanbaatar-Mongolia ² Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia ³

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is the fifth most common cancer and the third leading cause of cancer-related death worldwide, with over 1 million new cases annually, predominantly in Asia. Most patients are diagnosed at intermediate to advanced stages, limiting curative options such as surgical resection or radiofrequency ablation. Sorafenib, an oral multikinase inhibitor, is the only systemic therapy shown to improve survival, while Selective Internal Radiation Therapy (SIRT) delivers targeted yttrium-90 radiation to tumors. Mongolia has the highest incidence of liver cancer globally, yet data comparing the safety and

tolerability of SIRT and sorafenib in this population are lacking. This study aims to compare adverse events associated with SIRT and sorafenib in patients with locally advanced HCC.

Materials and Methods:

National Cancer Center of Mongolia recruited 39 patients from Mongolia (19 received sorafenib and 20 received SIRT in Singapore) with advanced hepatocellular carcinoma who had not received surgical therapy into a multicenter study involving a total of 360 patients at 27 sites in 11 Asia-Pacific countries. The study was a phase III randomized-controlled clinical trial comparing sorafenib or SIRT.

Results:

Adverse events for patients receiving sorafenib were predominantly grade 1 or 2 in gastrointestinal, constitutional and dermatologic in nature. The most frequently reported drug-related adverse events in patients treated with sorafenib were hypertension, hand-foot skin reaction, diarrhea, alopecia, fatigue. Common procedure-related adverse events were usually mild (grade 1/2) and included nausea and vomiting (27.7% all grades) and abdominal pain (22.1% all grades), with very few grades 3 or greater adverse events.

Conclusions:

In our analysis of 39 patients, we were unable to detect a statistically significant difference in adverse effects between sorafenib and SIRT treatment groups, likely because there were insufficient number patients in our study.

Keyword(s) : Selective Internal Radiation Therapy, Sorafenib, Hepatocellular Carcinoma, Adverse Event, Mongolia

1291 - Comparison between SIRT and Sorafenib in Advanced Hepatocellular Carcinoma in Mongolia

Khasbazar Ariunaa ¹, Yalhgarg Bolormaa ², Altankhuyag Tuyatsetseg ², Oidov Baatarkhuu ³
Mongolian National University Of Medical Sciences, Cancer Department, Ulaanbaatar-Mongolia ¹ National Cancer Center, , Ulaanbaatar-Mongolia ² Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia ³

E-POSTER ABSTRACTS

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is the fifth most common cancer and the second leading cause of cancer-related death worldwide, with over 1 million new cases annually. In Mongolia, HCC is the most prevalent cancer, with 2,200–2,400 new cases each year, and nearly 80% of patients present with advanced-stage disease, limiting treatment options and resulting in poor prognosis. Selective Internal Radiation Therapy (SIRT) with yttrium-90 microspheres and the multikinase inhibitor sorafenib are two effective treatments for locally advanced HCC. No randomized trials in the Asia-Pacific region have directly compared their efficacy and safety. This study aimed to evaluate and compare therapeutic outcomes and tolerability of SIRT versus sorafenib in patients with advanced HCC.

Materials and Methods:

At the National Cancer Center of Mongolia, patients were randomly assigned 1:1 to receive either SIRT or sorafenib 800 mg/day orally. Outcomes were assessed through physical examinations, functional assessment, complete blood count, liver function tests, AFP levels, and CT scans every 4, 8, and 12 weeks after treatment initiation.

Results:

Total 39 patients were enrolled: 20 received SIRT and 19 received sorafenib. Median overall survival (OS) and progression-free survival (PFS) did not differ significantly between sorafenib and SIRT arms (OS: 15.56 vs. 9.17 months; HR 0.95, 95% CI 0.46, $p = 0.889$; PFS: 8.51 vs. 5.85 months; HR 1.07, 95% CI 0.53–2.16, $p = 0.842$). Tumor response was higher with SIRT than sorafenib (68.8% vs. 62.5%, $p = 0.033$), including complete response in 2 (10%) patients, partial response in 2 (10%), and stable disease in 7 (43.8%). A total of 165 treatment-emergent adverse events were reported (SIRT 66 vs. sorafenib 99), with fewer grade ≥ 3 events in the SIRT group (83 vs. 115, $p = 0.0964$).

Conclusions:

In locally advanced HCC, overall survival was similar between SIRT and sorafenib. However, SIRT achieved higher tumor response rates and a lower incidence of severe adverse events compared with sorafenib.

1292 - Comparative Study of Tenofovir Alafenamide and Tenofovir Disoproxil Fumarate in Chronic Hepatitis B in Mongolia

Tuvshinbayar Narangerel¹, Amaraa Ravdan¹, Gegeebadrakh Baljinnyam¹, Badrakh Burmaajav², Oidov Baatarkhuu³
State Second Central Hospital, Department Of Gastroenterology, Ulaanbaatar-Mongolia¹ Mongolian Academy Of Sciences, , Ulaanbaatar-Mongolia² Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia³

Background / Hypothesis:

Chronic hepatitis B (CHB) affects approximately 240 million people worldwide, with Mongolia reporting an 11.1% prevalence among adults. CHB patients can present in different clinical states, including HBeAg-positive or -negative infection, and monitoring relies on HBV-DNA levels, HBeAg status, and liver enzymes such as ALT. Nucleos(t)ide analogs, including tenofovir disoproxil fumarate (TDF) and tenofovir alafenamide (TAF), are standard treatments that effectively suppress viral replication and reduce progression to cirrhosis and hepatocellular carcinoma. Long-term therapy, however, raises concerns about drug resistance, renal impairment, and bone mineral density loss. While TAF has recently been approved in Mongolia, comparative data on its efficacy and safety versus TDF in both HBeAg-positive and -negative CHB patients remain limited. This study aimed to evaluate and compare the short-term efficacy, safety, and tolerability of TAF and TDF in treatment-naïve and treatment-experienced Mongolian adults with CHB.

Materials and Methods:

We performed a randomized, unblinded, non-inferiority study in which patients with compensated cirrhosis (Child-Pugh A and B stage) between 18–70 years old with a positive chronic hepatitis B test were randomized to receive either TAF, TDF, or were switched from TDF to TAF. The primary efficacy endpoint was the proportion of patients with HBV-DNA < 29 IU/ml at week 48.

Results:

The efficacy endpoint, an HBV-DNA < 29 IU/ml at weeks 48, was achieved by 251 (79.9 %) of 314 patients

E-POSTER ABSTRACTS

receiving TAF, which was not significantly different from the 113 (74.8 %) of 151 patients receiving TDF. After 48 weeks of treatment, patients receiving TAF had significantly smaller bone mineral density reductions than patients receiving TDF. At week 48, the median decrease in eGFR was significantly less in the TAF recipients than the TDF recipients.

Conclusions:

TAF treatment has the same efficacy as TDF treatment. However, TAF treatment had a better safety profile than TDF. Patients receiving TAF had a significantly smaller median decrease in the eGFR by the Cockcroft-Gault equation than patients receiving TDF.

Keyword(s) : Hepatitis B, Tenofovir Alafenamide Fumarate, Tenofovir Disoproxil Fumarate, Adverse Effects, Safety

1293 - Evaluating ALBI Score for Risk Stratification in Acute Hepatitis B and D in Mongolia

Badamnachin Batsukh¹, Ganbaatar Khorolgarav², Oidov Baatarkhuu²

National Center For Communicable Diseases, Emergency Department, Ulaanbaatar-Mongolia¹
Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia²

Background / Hypothesis:

Hepatitis D virus (HDV) is a defective virus that requires hepatitis B surface antigen (HBsAg) for replication. Acute HDV infection may occur as co-infection with HBV or as superinfection in chronic HBV carriers, often resulting in more severe disease and higher rates of acute liver failure (ALF) compared to HBV alone. Mongolia has one of the highest rates of HBV and HDV infections globally, although national vaccination programs and viral hepatitis control initiatives have reduced incidence over recent decades. Despite this, acute hepatitis D remains a major cause of ALF, particularly among adults aged 20–44. Prognostic models such as MELD, CTP, and ALBI scores are used to predict liver disease outcomes; however, the utility of the ALBI score in acute hepatitis B with or without HDV has not been evaluated in Mongolia. This study aimed to assess the prognostic value of the ALBI score for clinical outcomes in patients with acute hepatitis B infection with or without HDV.

Materials and Methods:

A total of 114 patients—58 with acute hepatitis B (AHB), 5 with HBV/HDV co-infection, and 51 with HBV/HDV superinfection—admitted to the National Center for Communicable Diseases between 2022 and 2024 were enrolled. Clinical and laboratory data were analyzed to compare outcomes and prognostic markers, including the ALBI score, among patients with and without ALF.

Results:

Compared to the AHB group, patients with HBV/HDV superinfection were slightly older (mean age 28.9 ± 7.4 vs. 25.8 ± 6.5 years, $p = 0.019$) and fewer lived in Ulaanbaatar (62.7% vs. 87.5%, $p = 0.037$). Hospitalization was longer for the HBV/HDV superinfection group (28 ± 13 vs. 23 ± 11 days, $p = 0.022$). Patients with ALF had higher ALBI scores, total bilirubin, transaminases, and INR, along with lower platelet counts, compared to those without ALF. The ALBI score was significantly higher in AHB with ALF than AHB without ALF ($p = 0.001$) and in HBV/HDV superinfection with ALF compared to without ALF ($p = 0.041$). The area under the curve (AUC) for the ALBI score predicting ALF was 0.766, with a cut-off value of -1.71, sensitivity 72.2%, and specificity 75.6%.

Conclusions:

The ALBI score at admission is a useful predictor of survival in patients with acute hepatitis B and acute hepatitis D, helping identify those at higher risk of developing acute liver failure.

Keyword(s) : Acute Hepatitis B, Acute Hepatitis Delta, Acute Liver Failure, ALBI Score

1294 - Clinical Features and Outcomes of Acute Hepatitis B and Delta in Mongolia A One Year Prospective Follow Up Study

Badamnachin Batsukh¹, Ganbaatar Khorolgarav², Vangan Nyamtsengel², Oidov Baatarkhuu²
National Center For Communicable Diseases, Emergency Department, Ulaanbaatar-Mongolia¹
Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia²

Background:

Mongolia has one of the highest prevalence rates of hepatitis B virus (HBV) and hepatitis D virus (HDV) infections worldwide. Despite the national HBV vaccination program, acute hepatitis D remains a major

E-POSTER ABSTRACTS

contributor to chronic liver disease. This study aimed to assess the clinical and laboratory characteristics and the progression to chronic infection in adult patients with acute hepatitis B and delta infections in Mongolia.

Materials and Methods:

This prospective cohort study enrolled 182 patients at the National Center for Communicable Diseases in Ulaanbaatar, Mongolia, between 2022 and 2024. All participants provided written informed consent. Patients were categorized into three groups: acute hepatitis B (AHB, n=105), HBV/HDV co-infection (n=5), and HBV/HDV super-infection on chronic hepatitis B (n=72). Clinical symptoms, liver function tests (ALT, AST), and HBsAg status were monitored over a 12-month follow-up period.

Results:

Of the 182 participants, 108 (59.3%) were male. The mean age was 25.2 ± 6.1 years in the AHB group, 28.4 ± 2.2 years in the HBV/HDV co-infection group, and 30 ± 7.6 years in the HBV/HDV super-infection group ($p=0.0001$). Patients with AHB and HBV/HDV co-infection fully recovered clinically, and liver function tests normalized. In the HBV/HDV super-infection group, 95.8% of patients showed clinical recovery, but ALT and AST levels remained significantly elevated compared to other groups (ALT: 85.5 ± 125.8 vs. 18.2 ± 36 vs. 13.8 ± 6.5 ; AST: 63.4 ± 67.1 vs. 18.9 ± 19.2 vs. 19.7 ± 9.6 ; $p=0.0001$). The rate of progression to chronic infection was significantly higher in the HBV/HDV super-infection group. At 12 months post-onset, 6.7% of AHB patients remained HBsAg positive, compared to 40% of HBV/HDV co-infection patients and 94.4% of HBV/HDV super-infection patients ($p=0.0001$).

Conclusions:

Chronic infection developed in 6.7% of AHB patients, 40% of HBV/HDV co-infected patients, and 93.3% of HBV/HDV super-infected patients. Clinical symptoms and liver function normalized in AHB and HBV/HDV co-infection patients. However, in HBV/HDV super-infection patients, liver enzyme levels remained approximately twice the normal range, indicating more severe and prolonged hepatic injury.

Keyword(s) : Acute Hepatitis B, Acute Hepatitis Delta, HBV/HDV Co-infection, HBV/HDV Super-infection, Liver Function, Chronic Hepatitis, Mongolia

1295 - HCC associated with hepatitis B and C Mongoloid and Caucasians of North East Asia

Buyankhishig Nomin¹, I.v. Malov², E.d. Savilov³, Oidov Baatarkhuu¹

Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia
¹ Irkutsk State Medical University, , Irkutsk-Russia ² Scientific Center Of Family Health And Human Reproduction, , Irkutsk-Russia ³

Background / Hypothesis:

Hepatocellular carcinoma (HCC) accounts for more than half of all cases worldwide in Asian countries, yet data from northeastern Asia, where Mongoloid and Caucasian populations live in adjacent territories, remain limited. This study aimed to compare the clinical and epidemiological characteristics of HCC and to evaluate the diagnostic value of serum cancer markers in Mongoloid and Caucasian ethnic groups.

Materials and Methods:

The studies were carried out in the adjacent territories of Mongolia and the Asian part of Russia in the area of Lake Baikal (Irkutsk region). A total of 300 patients with hepatocellular carcinoma were examined, including 195 Mongols from the city of Ulan Bator and 105 Russians permanently residing in the Irkutsk region.

Results:

In Mongolia 93% of hepatocellular carcinoma cases are associated with viral hepatitis, with hepatitis B accounting for 34.5% of cases, which significantly distinguishes Mongolia from the Asian part of Russia. Excessive alcohol consumption is a significant non-infectious risk factor in Mongolia.

Conclusions:

In connection with the insufficient sensitivity of the determination of alpha-fetoprotein in the ethnic group of Mongoloids, it is necessary to search for new molecular markers. An alternative possibility of using osteopontin and glypican-3 as serum predictors of hepatocellular carcinoma, the diagnostic sensitivity of which is higher than alpha-fetoprotein and does not differ in the ethnic groups of Mongoloids and Caucasians, has been shown.

Keyword(s) : Hepatocellular carcinoma, Mongoloid, Caucasian, Serum markers, Alpha-fetoprotein, Osteopontin, Glypican-3, Viral hepatitis

E-POSTER ABSTRACTS

1296 - Efficacy and Safety of Tenofovir Alafenamide in the Management of Chronic Hepatitis B in Mongolia

Narangerel Tuvshinbayar ¹, Amaraa Ravdan ¹, Badrakh Burmaajav ², Baljinnyam Gegeebadrakh ¹, Oidov Baatarkhuu ³
State Second Central Hospital, Department Of Gastroenterology, Ulaanbaatar-Mongolia ¹ Ach Medical University, Department Of Gastroenterology, Ulaanbaatar-Mongolia ² Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia ³

Background / Hypothesis:

Chronic hepatitis B virus (HBV) infection affects an estimated 250 million people globally, with 1.5 million new infections each year. Mongolia has one of the highest HBV prevalence rates worldwide, with 10.6–11.6% of the population infected. Effective antiviral therapy is essential to reduce disease progression and improve outcomes. This study aimed to evaluate the clinical and virological outcomes of tenofovir alafenamide (TAF) treatment in patients with chronic hepatitis B in Mongolia.

Materials and Methods:

The clinical trials have evaluated TAF in HBeAg positive and HBeAg negative HBV patients. The trials have similar design and randomized, Single-blind, the subjects are unaware of which group they have been assigned to studies. The primary efficacy endpoint was the proportion of patients with HBV-DNA <29IU/ml at weeks 96. Other virological result endpoints were the proportion of patients with HBsAg seroconversion at weeks 96.

Results:

At week 96, the virologic endpoint, defined as HBV-DNA <29 IU/mL, was achieved in 243 patients (79.1%) receiving TAF, compared to 106 patients (78.5%) receiving TDF, demonstrating non-inferiority (95% CI: -9.7 to 2.5; p = 0.26). ALT normalization rates were significantly higher in the TAF group than in the TDF group at week 96 (209 [68%] vs. 82 [60.8%]; p = 0.001). Patients receiving TAF also experienced smaller reductions in bone mineral density (BMD) compared to TDF recipients. Additionally, median changes in eGFR at week 96 were significantly smaller in the TAF group, indicating better renal safety.

Conclusions:

TAF and switching from TDF to TAF are similar efficacy and safety in long-term treatment of TDF.

1297 - Clinical Characteristics of HBV and HCV Related Hepatocellular Carcinoma A Comparative Study in Mongolia

Ganchudur Luvsan ¹, Bayarmaa Enkhbat ¹, Avirmed Shiirevnyamba ¹, Oidov Baatarkhuu ²
Mongolian National University Of Medical Sciences, -, Ulaanbaatar-Mongolia ¹ Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia ²

Background:

Hepatocellular carcinoma (HCC) is the fifth most common cancer and the third leading cause of cancer-related deaths worldwide. Chronic hepatitis B (HBV) and hepatitis C (HCV) infections are the major risk factors, responsible for about 54% and 31% of cases. Mongolia has the highest HCC incidence globally, reflecting its high HBV (10.6%) and HCV (9.9%) infection rates. HBV-related HCC is often driven by viral oncogenic mechanisms, whereas HCV-related HCC is strongly associated with chronic inflammation and cirrhosis. Clinical presentation and disease outcomes may differ between HBV- and HCV-related HCC, yet Mongolian data remain limited. This study aimed to compare the clinical and laboratory characteristics of Mongolian patients with HBV- versus HCV-related HCC.

Materials and Methods:

By a single century, we analyzed the clinical characteristics of 23 patients with hepatitis B virus-related hepatocellular carcinoma (HBV group) and 34 with hepatitis C virus-related hepatocellular carcinoma (HCV group).

Results:

Patients with HBV-related HCC were younger (mean 61.1 years) than those with HCV-related HCC (67.1 years). Liver function was better in the HBV group, with lower indocyanine green retention (17.5% vs. 25.4%). More HBV patients presented with stage I disease (55% vs. 44%), but they also had more advanced tumor features, including higher rates of T3–4 tumors (53% vs. 41%), portal vein tumor thrombus grades 2–3 (20.3% vs. 7.1%), and poorly differentiated tumors (7%

E-POSTER ABSTRACTS

vs. 5%).

Univariate analysis identified HBV infection, younger age (≤ 50 years), higher AFP, more numerous and larger tumors, and portal or hepatic vein tumor thrombus grades 2–3 as poor prognostic factors. However, multivariate analysis showed that only high AFP, tumor number, and portal or hepatic vein thrombus grades 2–3 remained independent predictors of poor prognosis. Logistic regression showed elevated ASAT was significantly associated with hepatitis infection (OR 2.01, 95% CI 1.41–6.91, $p < 0.05$).

Conclusion:

These results suggest that HBV itself is not a stronger prognostic factor than HCV.

Keyword(s) : Hepatitis, Carcinoma, Virus, Neoplasms, Antigens, Blood-Borne Infections

1298 - Long Term Outcomes of Ledipasvir Sofosbuvir Treatment in Hepatitis C Viral Suppression Hepatocellular Carcinoma and Mortality in Mongolia

Byambasuren Amgalan ¹, Buyankhishig Gyarvuulkhasuren ², Khurelbaatar Nyamdavaa ³, Oidov Baatarkhuu ⁴

Mongolian National University Of Medical Sciences, Department Of Health Research, Ulaanbaatar-Mongolia ¹ General Hospital Of The Arkhangai, , Arkhangai-Mongolia ² Mongolian National University Of Medical Sciences, , Ulaanbaatar-Mongolia ³ Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia ⁴

Background:

Hepatitis C virus (HCV) infection poses a significant health burden, particularly in Mongolia, where the HCV prevalence is notably high. This study evaluates the long-term outcomes of HCV treatment with ledipasvir/sofosbuvir, focusing on mortality, viral relapse, and hepatocellular carcinoma (HCC) development.

Materials and Methods:

This prospective, longitudinal cohort study initially enrolled patients with chronic HCV in Mongolia between 2020 and 2024, focusing on those who completed the five-year follow-up ($n = 303$). The study measured long-term mortality, HCC development, and viral relapse, employing non-invasive methods to

assess liver fibrosis and liver function.

Results:

At the outset, 98.2% of the patients achieved undetectable HCV RNA levels. Over five years, 6.27% experienced viral relapse and 3.30% developed hepatocellular carcinoma (HCC), with a mortality rate of 5.94%. In a multivariable analysis, the significant predictors for HCC occurrence included age (OR = 1.081, 95% CI = 1.021–1.145), liver cirrhosis (OR = 5.866, 95% CI = 1.672–22.577), and GGT level (OR = 1.011, 95% CI = 1.004–1.018). The independent predictors of mortality included age (OR = 1.083, 95% CI = 1.024–1.147), liver cirrhosis (OR = 6.529, 95% CI = 1.913–22.281), and GGT (OR = 1.011, 95% CI = 1.004–1.017).

Conclusions:

This study demonstrates that ledipasvir/sofosbuvir effectively suppresses HCV initially and maintains low viral relapse rates over the long term. However, it emphasizes the need for continued management to reduce the long-term risk of HCC and mortality, especially in patients with severe liver fibrosis or cirrhosis.

Keyword(s) : viral suppression; liver cirrhosis; chronic liver disease; antiviral therapy

1299 - Hepatitis C virus infection in Mongolia Updated provincial data on prevalence genotype distribution and age specific risk factors

Amgalan Byambasuren ¹, Byambasuren Bat-amgalan ², Khurelbaatar Nyamdavaa ², Oidov Baatarkhuu ²

Mongolian National University Of Medical Sciences, Department Of Health Research, Ulaanbaatar-Mongolia ¹ Mongolian National University Of Medical Sciences, -, Ulaanbaatar-Mongolia ²

Background:

Hepatitis C virus (HCV) infection remains a significant public health issue in Mongolia, where both medical and traditional practices contribute to transmission. This study aimed to assess the prevalence, genotype distribution, and risk factors of HCV infection among residents of Arkhangai Province.

Materials and Methods:

A cross-sectional population-based study included 2,304 individuals aged 0–80 years. Serum samples were

E-POSTER ABSTRACTS

tested for anti-HCV antibodies using ELISA and for HCV RNA using PCR. Positive samples were genotyped, and demographic and exposure data were analyzed using logistic regression to identify independent risk factors.

Results:

The prevalence of anti-HCV antibodies was 12.0%, and HCV RNA positivity was 7.16%. Infection increased significantly with age ($p < 0.001$) and was higher among females (14.6%) than males (8.4%). Genotype 1b predominated (98.2%), followed by 1a (1.2%) and 2 (0.6%). Independent risk factors included cosmetic procedures (OR 2.30, 95% CI 1.51–3.26), cupping therapy (OR 1.68, 95% CI 1.32–1.98), unsafe injections (OR 3.12, 95% CI 2.40–3.81), and shared razor use (OR 1.50, 95% CI 1.08–2.13).

Conclusions:

HCV infection remains prevalent, particularly among older adults and women. Genotype 1b continues to predominate, indicating that the viral genetic distribution has remained largely unchanged over the past decade. Continued education, safe injection practices, and regulation of traditional and cosmetic procedures are essential to reduce HCV transmission and support Mongolia's elimination goals.

Keyword(s) : hepatitis C virus; prevalence; risk factors; Mongolia; genotype 1b; cupping therapy; unsafe injection

1300 - Epidemiology Clinical Features and Laboratory Findings of Acute Hepatitis B and D Virus Infection Among Children Under Five Years of Age in Mongolia

Khorolgarav Ganbaatar¹, Batsukh Badamnachin¹, Nomin Buyankhishig¹, Purevsod Lkhagvasuren¹, Nyamtsengel Vangan¹, Oidov Baatarkhuu¹
Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia

Background / Hypothesis:

Globally, an estimated 15–20 million people are infected with hepatitis D virus (HDV). Anti-HDV-IgM is found in 2–7% of acute hepatitis cases and 9–50% of chronic hepatitis cases. Among infants born to HBeAg-positive mothers with chronic HBV infection, 90% acquire HBV, and 25–30% progress to chronic infection by age five. Mongolia introduced universal newborn

HBV vaccination in 1991, reducing HBV prevalence from 5.2–9.8% among children born in 1990–2000 to below 1% in those born in 2004–2007.

Materials and Methods:

A retrospective review was conducted using medical records of children aged 0–5 years diagnosed with acute HBV or HDV infection and hospitalized at the National Center for Communicable Diseases from 2020 to 2024. Statistical analysis was performed using SPSS version 26.

Results:

A total of 22 children aged 0–5 years were diagnosed with acute hepatitis B or D; 91% (20) recovered and 9% (2) died. Of these, 59% (13) were under 6 months, 13.6% (3) were 6–12 months, 13.6% (3) were 1–2 years, and 13.6% (3) were 3–4 years old; 59.1% (13) were male and 40.9% (9) female. Hepatitis B vaccination within 24 hours of birth was recorded in 91% (20), while 4.5% (1) were unvaccinated and 4.5% (1) had unknown vaccination status. Maternal chronic HBV infection was present in 86.36% (19), and maternal HBV status was unknown in 13.63% (3).

Clinically, 77.3% (17) had moderate disease, 18.2% (4) severe, and 4.5% (1) were critically ill. The mean hospital stay was 17 ± 10.3 days, while the two fatal cases averaged 4 ± 3.24 days. Common symptoms included jaundice (95.4%), poor appetite (50%), vomiting (50%), fever (31.8%), poor breastfeeding (31.8%), sleep disturbance (18.18%), abdominal pain (4.5%), and irritability (77.3%).

Serology showed acute HBV in 54.5% (12), HBV/HDV co-infection in 41% (9), and one case (4.5%) of HBV/HDV superinfection with acute hepatitis A. ALT and AST were markedly elevated at admission (1055.77 ± 794.46 IU/L and 1137.31 ± 557.87 IU/L) and decreased to 96.04 ± 54.69 IU/L and 60.43 ± 35.28 IU/L at discharge. Total bilirubin dropped from 90.79 ± 25.55 to 25.55 ± 22.37 $\mu\text{mol/L}$, and alkaline phosphatase from 670.34 ± 272.97 to 533.19 ± 169.66 . All decreases were statistically significant ($p < 0.01$). INR improved from 3.79 ± 3.04 to 1.17 ± 0.03 ($p < 0.01$).

Conclusion:

Among the study population, 59% were under 6 months of age, and 86.36% had mothers with chronic HBV infection during pregnancy. Comparison of

E-POSTER ABSTRACTS

laboratory results showed that cholestatic features

¹ Mongolian Association For The Study Of Liver Disease, , Ulaanbaatar-Mongolia²

Background:

Metabolic dysfunction-associated fatty liver disease (MAFLD) has become a leading cause of hepatic steatosis, particularly in individuals with obesity or insulin resistance. Hepatitis C virus (HCV) infection also promotes liver inflammation and fibrosis, and its coexistence with MAFLD may further increase the risk of steatosis and fibrosis. International studies suggest a synergistic effect between the two conditions. This study aimed to determine the prevalence of MAFLD in patients with chronic HCV infection, evaluate metabolic risk factors, and examine the interaction between viral infection and metabolic dysfunction.

Materials and Methods:

This study included 284 chronic HCV patients treated at the National Center for Communicable Diseases from 2020–2025. Demographic, laboratory, and ultrasound data were collected. Based on MAFLD criteria, 41.9% (117) were MAFLD-positive and 58.1% (167) MAFLD-negative. Statistical analysis was done using SPSS 28, with $p < 0.05$ considered significant.

Results:

The mean age of participants was 46.8 ± 10.5 years, and 58.1% ($n=164$) were male. In the MAFLD group, obesity was present in 76.9% ($n=90$), diabetes mellitus in 32.5% ($n=38$), and hypertension in 69.4% ($n=81$), all significantly higher than in the MAFLD-negative group ($p=0.001$), indicating substantial metabolic abnormalities.

Laboratory results showed higher mean ALT and AST levels in the MAFLD group (55 ± 22 U/L and 48 ± 18 U/L) compared to the non-MAFLD group (35 ± 15 U/L and 30 ± 12 U/L). Additionally, triglycerides (200 ± 70 mg/dL), HDL (40 ± 8 mg/dL), glucose (115 ± 25 mg/dL), and HOMA-IR (3.6 ± 1.2) were markedly worse in the MAFLD group, whereas the control group had

values of 145 ± 45 mg/dL, 50 ± 12 mg/dL, 98 ± 20 mg/dL, and 2.2 ± 0.9 , respectively.

CAP (FibroScan) values were higher in the MAFLD group (288 ± 40 dB/m) than in the non-MAFLD group (250 ± 35 dB/m), indicating mostly moderate-severe steatosis. FIB-4 scores were also elevated in MAFLD patients (2.0 ± 0.7 vs. 1.2 ± 0.5 , $p=0.03$), suggesting more advanced liver injury.

CAP showed moderate correlations with BMI ($r=0.52$), HOMA-IR ($r=0.41$), and triglycerides ($r=0.38$) (all $p=0.001$), while its correlation with HCV viral load was weak ($r=0.12$, $p=0.01$), reaffirming metabolic dysfunction as the main driver of steatosis.

Conclusions:

MAFLD is frequent in chronic HCV patients and is mainly driven by metabolic factors like obesity, insulin resistance, and high triglycerides. Although HCV can aggravate steatosis and fibrosis, its weak link with viral load shows it is not the primary cause. Metabolic dysfunction remains the key determinant.

1302 - ASSOCIATION BETWEEN METABOLIC RISK FACTORS HEPATIC STEATOSIS AND QUALITY OF LIFE AMONG PATIENTS WITH CHRONIC HCV INFECTION ASSESSED USING THE HCV SIQv4 QUESTIONNAIRE

Purevsod Lkhagvasuren¹, Nomin Buyankhishig¹, Khorolgarav Ganbaatar¹, Nyamtsengel Vangan¹, Amarsanaa Jazag², Oidov Baatarkhuu¹
Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia
¹ Mongolian Association For The Study Of Liver Disease, , Ulaanbaatar-Mongolia²

Background / Hypothesis:

Globally, the prevalence of metabolic dysfunction-associated fatty liver disease (MAFLD) is rising, making it one of the leading causes of liver disease. International studies suggest that chronic hepatitis C virus (HCV) infection may contribute to metabolic disturbances, hepatic steatosis, and fibrosis. However, no study in Mongolia has comprehensively evaluated the relationship between hepatic steatosis, metabolic indicators, and quality of life in patients with chronic HCV infection. Therefore, this study aimed to assess the associations between these factors.

Materials and Methods:

A total of 284 patients with a confirmed diagnosis of

E-POSTER ABSTRACTS

chronic HCV infection who received care at the National Center for Communicable Diseases from 2020 to 2025 were included. Demographic data, laboratory results, and FibroScan measurements including CAP for steatosis and FIB-4 scores for fibrosis were analyzed. Using MAFLD diagnostic criteria, participants were categorized as MAFLD-positive 41.9% (n = 117) and MAFLD-negative 58.1% (n = 167). Quality of life was assessed using the HCV-Symptom and Impact Questionnaire version 4 (HCV-SIQv4). Reliability of the tool showed high internal consistency (Cronbach's $\alpha=0.942$). Statistical analyses were performed in SPSS 28, with significance set at $p < 0.05$.

Results:

The mean age of participants was 46.8 ± 10.5 years, and 58.1% (n = 164) were male. A majority reported MAFLD-related symptoms, including weight gain (3.8 ± 1.1 , $p = 0.001$), abdominal discomfort (3.1 ± 1.0 , $p = 0.001$), fatigue (4.3 ± 1.2 , $p = 0.001$), and changes in appetite (2.9 ± 0.9 , $p = 0.001$).

The total HCV-SIQv4 score was significantly higher in the MAFLD-positive group (18.5 ± 5.2 , $p = 0.001$) compared to the MAFLD-negative group (12.3 ± 4.7 , $p = 0.001$), indicating greater impairment in quality of life, likely associated with steatosis and metabolic dysfunction.

The total questionnaire score showed moderate positive correlations with CAP ($r = 0.45$, $p = 0.012$) and HOMA-IR ($r = 0.42$, $p = 0.028$), suggesting that lifestyle- and symptom-related impacts were associated with hepatic steatosis and metabolic abnormalities. A weak correlation was found with HCV viral load ($r = 0.10$, $p = 0.04$), indicating that viral replication itself does not strongly influence MAFLD symptom severity.

Conclusions:

Among chronic HCV patients, MAFLD is strongly associated with impaired quality of life, hepatic steatosis, and metabolic dysfunction. These findings highlight the importance of improving MAFLD screening and monitoring, as well as incorporating quality-of-life assessment into the management of patients with chronic HCV infection to prevent complications and improve patient outcomes.

Keyword(s) : MAFLD, hepatitis C, risk factors, viral load, steatosis

1303 - Impact of Sleep Disturbances and Psychological Distress on Quality of Life in Mongolian Patients with Acute and Chronic

Hepatitis C

Purevsod Lkhagvasuren¹, Khorolgarav Ganbaatar¹, Nomin Buyankhishig¹, Oyungerel Ravjir¹, Vangan Nyamtsengel¹, Amarsanaa Jazag², Oidov Baatarkhuu¹
Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia
¹ Mongolian Association For The Study Of Liver Disease, , Ulaanbaatar-Mongolia²

Background:

Hepatitis C (HCV) remains a major global public health challenge, with millions affected worldwide. HCV infection can lead to severe liver damage, including cirrhosis and liver cancer, and significantly reduce quality of life. Sleep disturbances, anxiety, and depression are common in HCV patients and may worsen disease outcomes. This study investigates the impact of sleep disturbances and mental health on quality of life and clinical outcomes in Mongolian patients with HCV.

Materials and Methods:

This cross-sectional study, conducted from October 2024 to March 2025 at the Mongolian National Center for Communicable Diseases, included 187 participants with HCV, whom 82 had acute and 105 had chronic, selected through non-probability purposive sampling. Psychological distress and sleep disturbances were assessed using the General Health Questionnaire-28 (GHQ-28) and the Pittsburgh Sleep Quality Index (PSQI). Data analysis, including regression models, was performed using SPSS version 28, with a p-value <0.05 considered statistically significant.

Results:

Among the 187 participants, the majority were male (58.8%, n=110), 42.8% (n=80) were aged 46–55 years, and slightly over half reported limited income (51.9%, n=97). Lifestyle factors showed that 40.6% (n=76) were smokers and 80.7% (n=151) were overweight. Comparing acute and chronic HCV, chronic patients were more likely to be overweight (85.7% vs 74.4%, $p=0.04$) and have cirrhosis (18.1% vs 3.7%, $p<0.001$). Anxiety and sleep disturbances were higher in chronic patients, with mean GHQ-28 scores of 17.8 ± 4.5 versus 14.2 ± 3.9 and PSQI scores of 8.3 ± 2.6 versus 6.5 ± 2.1 in acute patients (both $p<0.01$). Correlations between anxiety/insomnia and physical health were strong in both groups (acute $r=0.63$; chronic $r=0.72$), while overall physical domains correlated moderately (acute $r=0.48$; chronic $r=0.54$). Regression analysis showed that sleep disturbances and psychological distress significantly predicted poorer quality of life in both

E-POSTER ABSTRACTS

acute and chronic patients, with low income (OR=2.90, 95% CI: 2.37–3.54, $p=0.001$, OR=1.75, 95% CI: 1.45–2.11, $p=0.001$).

Conclusions:

Chronic HCV patients experience greater anxiety, sleep disturbances, and worse quality of life than acute patients. Sleep disturbances and psychological distress significantly predict poorer outcomes, with low income further worsening quality of life. Early identification and integrated management of mental health and sleep issues are essential to improve patient outcomes.

Keyword(s) : sleep disturbances, insomnia, HCV, PSQI, GHQ-28

1304 - MiR 551a drives cholesterol metabolic reprogramming and sorafenib resistance in hepatocellular carcinoma

Ya Wu ¹, [Yuanjun Lu](#) ¹

Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, Affiliate Cancer Hospital Of University Of Electronic Science And Technology Of China, Sichuan Cancer Hospital & Institute, Chengdu-China ¹

Background / Hypothesis:

Cholesterol metabolic reprogramming has emerged as a critical hallmark of therapy resistance in advanced hepatocellular carcinoma (HCC). However, how specific non-coding RNAs orchestrate cholesterol dysregulation and contribute to sorafenib resistance remains unclear.

Materials and Methods:

We performed in vivo CRISPR/Cas9 knockout screen in sorafenib-resistant HCC models. Hits were validated through sgRNA sequencing, proteomics, CUT&Tag-seq, luciferase reporter assays, and ER-cholesterol imaging, together with functional studies in vitro and orthotopic xenograft models. To evaluate clinical significance, miRNA-specific probes and multiplex protein fluorescence staining were applied to a tissue microarray (TMA) of paired human HCC specimens, enabling quantitative assessment of miR-551a expression, its downstream molecular alterations, and association with clinical outcome

Results:

miR-551a was identified as a leading driver of sorafenib resistance. Its overexpression enhanced tumour growth and survival under sorafenib exposure,

while inhibition of miR-551a restored drug sensitivity. Mechanistically, miR-551a induced a pronounced disruption of cholesterol homeostasis, resulting in intracellular cholesterol accumulation—a metabolic state tightly linked to drug resistance. Importantly, pharmacological targeting of cholesterol metabolism effectively resensitized resistant tumours, confirming the functional relevance of this metabolic rewiring. Clinical TMA analysis further demonstrated that patients with high miR-551a levels exhibited increased cholesterol-dysregulation signatures and significantly poorer outcomes.

Conclusions:

Our study identifies miR-551a as a novel non-coding RNA regulator that reprograms cholesterol metabolism to drive sorafenib resistance in HCC. Integrating mechanistic evidence with TMA-based clinical validation, we highlight the therapeutic potential of targeting cholesterol dysregulation through the miR-551a pathway as a promising metabolic strategy to improve treatment response.

Keyword(s) : Hepatocellular carcinoma, Sorafenib resistance, Cholesterol metabolism, MiR-551a

1306 - MAFLD in Chronic HBV The Dominant Role of Metabolic Dysfunction Over Viral Load

[Purevsod Lkhagvasuren](#) ¹, Khorolgarav Ganbaatar ¹, Nomin Buyankhishig ¹, Nyamtsengel Vangan ¹, Oidov Baatarkhuu ¹

Mongolian National University Of Medical Sciences, Infectious Disease Department, Ulaanbaatar-Mongolia ¹

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) has emerged as a leading cause of hepatic steatosis, particularly among individuals with obesity, insulin resistance, or dyslipidemia. Chronic hepatitis B virus (HBV) infection can cause liver inflammation and fibrosis, but unlike HCV, HBV is not a primary driver of metabolic liver injury. The coexistence of MAFLD with chronic HBV may exacerbate liver disease, but metabolic factors are likely the dominant contributors to steatosis in this population. This study aimed to assess the prevalence of MAFLD among patients with chronic HBV infection, evaluate associated metabolic risk factors, and explore the relationship between viral activity and steatosis.

Materials and Methods:

E-POSTER ABSTRACTS

This retrospective study analyzed 127 patients with chronic HBV infection who received care at the National Center for Communicable Diseases between 2020 and 2025. Clinical, laboratory, and ultrasound data were collected for all participants. Using established MAFLD criteria, 42% (n=53) were classified as MAFLD-positive, while 58% (n=74) were MAFLD-negative. Statistical analyses were conducted with SPSS version 28, and p-values below 0.05 were considered statistically significant.

Results:

The mean age of participants was 47.1 ± 11.2 years, with 58.1% (n=164) male. Among MAFLD-positive patients, obesity was observed in 75.2% (n=88), diabetes in 31.6% (n=37), and hypertension in 70.1% (n=82), all significantly higher than in the MAFLD-negative group ($p=0.001$). Laboratory findings showed higher ALT and AST levels in the MAFLD group (56 ± 24 U/L and 50 ± 19 U/L) compared to controls (36 ± 16 U/L and 31 ± 13 U/L). Triglycerides (202 ± 72 mg/dL), HDL (41 ± 9 mg/dL), glucose (116 ± 26 mg/dL), and HOMA-IR (3.7 ± 1.3) were also worse in MAFLD patients versus non-MAFLD (145 ± 47 mg/dL, 51 ± 12 mg/dL, 99 ± 21 mg/dL, 2.3 ± 1.0 , respectively). FibroScan CAP values were higher in the MAFLD group (288 ± 41 dB/m vs. 251 ± 36 dB/m), indicating predominantly moderate-severe steatosis. FIB-4 scores were also elevated (2.0 ± 0.7 vs. 1.2 ± 0.5 , $p=0.03$). CAP values showed moderate correlations with BMI ($r=0.51$), HOMA-IR ($r=0.42$), and triglycerides ($r=0.39$) (all $p=0.001$), but a weak correlation with HBV viral load ($r=0.10$, $p=0.02$), confirming metabolic dysfunction as the main driver of steatosis.

Conclusions:

MAFLD is common in chronic HBV patients and mainly driven by metabolic factors like obesity, insulin resistance, and dyslipidemia. HBV's impact on steatosis is minimal, making metabolic management key to preventing liver injury.

Keyword(s) : MAFLD, hepatitis B, metabolic risk factors, steatosis, liver fibrosis

1307 - Assessment of Clinical Status and Liver Function as Predictors of Lenvatinib Efficacy in Hepatocellular Carcinoma A Single Center Study at Dr. Mohammad Hoesin Hospital Palembang (January–December 2025)

Anton Purnomo Bin Djailani¹, Suyata Suyata¹, Imam Suprianto¹, Vidi Orba Busro¹, Anjab Akmal Sya'roni¹
Mohammad Hoesin Hospital, Internal Medicine,

Palembang-Indonesia¹

Background / Hypothesis:

Hepatocellular carcinoma (HCC) remains a significant global health challenge with persistently high mortality, especially in countries where limited surveillance and late presentation reduce the opportunities for curative treatment. Lenvatinib is an approved first-line systemic therapy for unresectable HCC and has demonstrated promising progression-free survival across international trials. However, treatment response varies among individuals, largely influenced by liver functional reserve and patient performance status. Identifying reliable clinical and biochemical predictors is therefore essential to optimize patient selection and therapeutic outcomes. This study hypothesizes that clinical performance (ECOG), liver function scores (Child-Pugh and MELD), and baseline laboratory parameters may predict therapeutic response to lenvatinib in HCC patients treated during the 2025 period at Dr. Mohammad Hoesin Hospital (RSMH) Palembang.

Materials and Methods:

A prospective observational analytic cohort study was conducted using data from the national web-based registry RINKAS. Eligible patients were adults diagnosed with HCC and initiated on lenvatinib therapy at RSMH Palembang between January and December 2025. Recorded variables included ECOG performance status, comorbid etiologies, albumin, bilirubin, platelet counts, MELD score, and Child-Pugh class. Descriptive and comparative analyses were performed to explore associations between baseline characteristics and treatment response.

Results:

A total of 20 patients receiving lenvatinib were included. ECOG scores ranged from 0 to 2, with the majority presenting with ECOG 0–1. MELD scores varied between 55.5 and 77.3, while Child-Pugh scores ranged from 4 to 9, predominantly within Child-Pugh A and early B classifications. Preliminary analysis demonstrated that patients with ECOG 0–1 and lower Child-Pugh scores (A5–A6) tended to exhibit more favorable clinical outcomes, whereas higher MELD scores and Child-Pugh B9 were associated with poorer treatment tolerance and reduced response. Trends suggested that preserved liver function at baseline correlated with improved therapeutic benefit from lenvatinib.

E-POSTER ABSTRACTS

Conclusions:

Baseline clinical performance and hepatic reserve reflected by ECOG status, Child-Pugh classification, and MELD score appear to be important predictors of treatment response to lenvatinib among HCC patients. Patients with better functional status and more preserved liver function demonstrated more favorable outcomes. These findings support the incorporation of liver function stratification into treatment decision-making for lenvatinib therapy and warrant further investigation with larger sample sizes and AFP-dynamic analysis to validate predictive accuracy.

1309 - Unlocking CTNNB1 hotspot mutations from cell free DNA (cf DNA) in hepatitis B virus induced hepatocellular carcinoma A cross sectional study from Bangladesh

Farzana Laila Laila¹, Md. Rakibul Hasan Hasan², Afzalun Nessa Nessa¹

Bangladesh Medical University, Virology, Dhaka-Bangladesh¹ Bangladesh Medical University, Internal Medicine, Dhaka-Bangladesh²

Background / Hypothesis:

Hepatocellular carcinoma (HCC), the dominant form of primary liver cancer, remains a major global health challenge. Chronic hepatitis B virus (HBV) infection is a significant risk factor of hepatocarcinogenesis driven by genetic and epigenetic alteration. Mutations in the CTNNB1 gene, particularly in exon 3, activate Wnt signaling pathway, leading to uncontrolled transcription and cell proliferation. Early detection of these somatic mutations may serve as a cornerstone of personalized medicine, enabling disease monitoring and tailored therapeutic strategies. Cell-free DNA (cfDNA) is considered a promising alternative source for predicting somatic mutations, offering to track disease dynamics and tailor therapeutic strategies to individuals. This study aimed to detect CTNNB1 gene mutation from cfDNA in individuals with HBV-related chronic liver disease (CLD) and HCC and to assess their

pathogenicity using various bioinformatics tools.

Materials and Methods:

A total of 135 participants were included: 85 with HBV-induced HCC at different stages, 30 with HBV-related CLD and 20 healthy controls. cfDNA was extracted from peripheral blood using the QIAamp Circulating Nucleic Acid Extraction Kit. DNA was amplified by conventional PCR using specific primers, followed by agarose gel electrophoresis and UV visualization. Amplicons were analyzed using Sanger sequencing. Mutation analysis was done using FinchTV software, in silico tools- SNAP, PredictSNP, and I-Mutant were used to predict pathogenicity and protein stability.

Results:

Hotspot mutations were detected in 28.2% (24/85) of HCC patients at the following sites: c.95A>T/G (p.D32V/G; 9.4%), c.110C>A/G (p.S37Y/C; 8.2%), c.133T>C/A (p.S45P/T; 7.1%), c.98C>G (2.4%), and c.121A>G (1.2%). Mutation frequency was significantly higher in late-stage HCC (36.7%) than early-stage (17.4%) ($p < 0.05$; Pearson $r = 0.9961$). Only one mutation (c.133T>C/A) was found in the CLD group (3.3%), and none in healthy controls. In early-stage HCC, serum albumin levels were significantly elevated in mutated cases ($p < 0.05$), while AST levels differed significantly in late-stage HCC between mutated and unmutated groups. Pathogenicity predictions indicated deleterious effects at codons c.95, c.98, c.110, and c.133. I-Mutant analysis revealed reduced β -catenin stability at c.95, c.110, and c.121.

Conclusions:

These findings reflect the potential role of CTNNB1 gene mutations in the pathogenesis and progression of HCC across different stages. In silico prediction tools confirmed the deleterious nature of mutations at critical codons. This non-invasive molecular profiling approach may facilitate personalized treatment strategies and real-time monitoring of tumor dynamics.

E-POSTER ABSTRACTS

1313 - Combination of radiotherapy and durvalumab gemcitabine cisplatin therapy improve survival in biliary tract cancer (especially extrahepatic bile duct cancer) patients

Sang Youn Hwang¹, Jung Woo Im¹, Ki Jung Jeon¹, Hyung Jun Kim¹, Wan Jeon Jeon²

Dongnam Institute Of Radiological & Medical Sciences; Dirams), Gastroenterology & Hepatology, Busan-South Korea ¹ Dongnam Institute Of Radiological & Medical Sciences; Dirams), Radiation Oncology, Busan-South Korea ²

Background / Hypothesis:

Durvalumab (Durva) plus gemcitabine/cisplatin (GP) proved better efficacy compared to GP for advanced biliary tract cancer (BTC) patients in TOPAZ-1 trial. Radiotherapy (RT) has immune-stimulatory effect through several mechanism such as releasing tumor associated antigen etc. However, there is no data about synergistic effect and clinical efficacy of RT plus Durva/GP therapy. Therefore we performed study for describing clinical efficacy of combination of RT plus Durva/GP therapy.

Materials and Methods:

The clinical course of patients with advanced BTC who received Durva/GP therapy in single cancer center from April 2023 to July 2025 was assessed. Response rate (partial response [PR], stable disease [SD], progressive disease [PD]) per RECIST v1.1 and median progression free survival (PFS), overall survival (OS) were analyzed.

Results:

Total 21 BTC patients were treated with Durva/GP therapy. Gallbladder cancer (GBC): Intrahepatic cholangiocarcinoma (IHCCC) : Extrahepatic CCC (EHCCC) patients were 6:8:7. Eight patients (RT group) received several types of RT (PULSAR in 6 patients, TARE in 1 patient, carbon beam therapy in 1 patient). The rate of PR:SD:PD in RT versus (vs) non-RT group were 37.5% vs 15.4% : 62.5% vs 61.5% : 0% vs 23.1%. Median PFS in RT vs non-RT group were 10 vs 5 months (p = 0.028) and median OS were 13 vs 10 months (p = 0.012). In only EHCCC patients, median PFS, OS of RT group were better than non-RT group with statistically significance (PFS 10 vs 5 months, p = 0.004; OS 11 vs 6 months, p = 0.027). Almost all patients complained only grade 1/2 nausea and there were no cases with Grade 3/4 adverse effects.

Conclusions:

This study demonstrates that radiotherapy can improve clinical efficacy of Durva/GP therapy in advanced BTC, especially EHCCC patients. Further large scaled prospective studies are needed for proving synergistic effect of radiotherapy and Durva/GP therapy to BTC patients.

Keyword(s) : Biliary Tract Cancer, Durvalumab, Radiotherapy

1314 - SDHA Deficiency in Hepatocellular Carcinoma Promotes Tumor Progression through Succinate Induced M2 Macrophage Polarization

Xinyang Li¹, Ying Xiao¹, Caiyan Zhao¹

Hebei Medical University Third Hospital, Infectious Diseases, Shijiazhuang-China ¹

Background / Hypothesis:Hepatocellular carcinoma (HCC) is an aggressive and lethal malignancy. Metabolic reprogramming dynamically remodels the tumor microenvironment (TME) and drives HCC progression. This study investigated the mechanism through which metabolic reprogramming remodels the TME in HCC.

Materials and Methods:HCC patient transcriptome data were subjected to bioinformatics analysis to identify differentially expressed genes and immune infiltration status. Immunohistochemical analysis was performed to determine the correlation between succinate dehydrogenase complex subunit A (SDHA) expression and M2 macrophage infiltration. SDHA-knockdown or SDHA-overexpressing HCC cells were used for in vitro experiments, including co-culturing, flow cytometry, and enzyme-linked immunosorbent assay. Western blotting assay, functional assays, and subcutaneous tumor model mice were used to elucidate the molecular mechanisms underlying succinate-mediated HCC cell-macrophage interactions in the TME.

Results:Higher infiltration of M2 macrophages correlated with worse prognosis in HCC patients. SDHA was downregulated in HCC tumor tissues and showed a negative correlation with M2 macrophage infiltration. SDHA knockdown promoted M2 macrophage polarization, whereas SDHA overexpression reversed this effect. Mechanistically, SDHA deficiency in HCC cells induced succinate accumulation, which promoted

E-POSTER ABSTRACTS

M2 macrophage polarization by activating the G protein-coupled receptor 91 (GPR91)/signal transducer and activator of transcription 3 (STAT3) pathway. Concurrently, succinate stimulation enhanced mitochondrial oxidative phosphorylation in M2 macrophages, thereby promoting HCC progression. Serum succinate levels were elevated in HCC patients. The receiver operating characteristic curve analysis indicated that serum succinate is a promising diagnostic marker for HCC (area under the curve = 0.815).

Conclusions:SDHA deficiency leads to succinate accumulation, which promotes M2 macrophage polarization through the GPR91/STAT3 pathway, thereby facilitating HCC progression. Based on these findings, serum succinate could be a promising diagnostic biomarker for HCC.

1315 - Clinical characteristics and combined pathogen spectrum of patients with influenza A in winter a retrospective study based on targeted high throughput sequencing detection

Wenjing Wang¹, Huimin Ma¹, Xiangyan Li¹, Yan Wang¹

Department Of Infectious Diseases, Peking University First Hospital, Beijing-China¹

Background / Hypothesis:

To investigate the clinical characteristics, spectrum of co-infecting pathogens, and their associations in patients with influenza A virus infection in a tertiary hospital.

Materials and Methods:

Patients with influenza A virus infection confirmed by targeted next-generation sequencing (tNGS) between December 2024 and February 2025 were enrolled. Clinical data and microbiological test results were collected and analyzed retrospectively.

Results:

A total of 66 patients were included, of whom 54 (81.8%) had co-infections; bacterial co-infection was the most common (34/66, 51.5%). The spectrum of co-infecting pathogens varied across age groups. In infants and young children, *Streptococcus pneumoniae*

and *Staphylococcus aureus* were the predominant pathogens (both 19.2%), whereas *Mycoplasma* spp. accounted for most co-infections in adolescents (40.0%). The rate of fungal co-infection was significantly higher in adults and older adults than in infants and young children (42.9% vs. 2.1%, $P = 0.005$; 57.1% vs. 2.1%, $P < 0.001$, respectively). The proportion of severe disease among adults was 71.4%. In adults with diabetes, the rate of *Aspergillus fumigatus* infection was significantly higher than in non-diabetic adults (100% vs. 0%, $P = 0.048$). All elderly patients with severe disease had fungal co-infections.

Conclusions:

Influenza A is highly prevalent in winter and is frequently complicated by co-infection. tNGS testing facilitates etiological surveillance of co-infecting pathogens. Age-stratified, precise prevention and treatment strategies—focusing on bacterial infections in infants and young children, mycoplasma infections in adolescents, and fungal infections in adults and the elderly—may help reduce the incidence of severe disease and improve clinical outcomes.

Keyword(s) : influenza A; targeted Next-Generation Sequencing; mixed infection; bacteria; fungi; mycoplasma

1317 - Association Between Clinical Predictors And Albumin Billirubin Score In Hepatocellular Carcinoma Patients Receiving Lenvatinib At Dr. Mohammad Hoesin General Hospital Palembang During 2025

Adhitya Wicaksana¹, Suyata Suyata¹, Imam Suprianto¹, Anjab Akmal¹, Vidi Orba¹, Ayus Astoni¹
Mohammad Hoesin Hospital, Gastroenterohepatology Division, Palembang-Indonesia¹

Background / Hypothesis:

Lenvatinib is widely used as a first-line systemic therapy for hepatocellular carcinoma (HCC), but treatment responses vary substantially among patients. Clinical predictors such as hepatic functional reserve and performance status may influence treatment outcomes. This study examined the relationship between Child-Pugh class, ECOG performance status, and Albumin bilirubin (ALBI) score in patients with HCC receiving lenvatinib at a tertiary referral center in Indonesia.

Materials and Methods:

A retrospective review was conducted using complete records of HCC patients treated with lenvatinib in 2025.

E-POSTER ABSTRACTS

Data collected included Child–Pugh classification, ECOG performance status, and ALBI score. Descriptive statistics were used to summarize patient characteristics. Pearson correlation analysis was applied to assess associations between clinical predictors and ALBI scores.

Results:

Twenty patients were eligible for analysis. Most patients were classified as Child–Pugh A or B, and ECOG performance status was predominantly 0–1. ALBI scores clustered mainly within grades 1 and 2. Better hepatic reserve (Child–Pugh A) and ECOG 0 were consistently associated with more favorable ALBI grades. Significant correlations were observed between Child–Pugh class and ALBI ($r = 0.79$), with a weaker correlation between ECOG status and ALBI ($r = 0.41$). These results indicate alignment between clinical assessments of hepatic function and biochemical liver status.

Conclusions:

Child–Pugh classification and ECOG performance status correlate with ALBI score in patients receiving lenvatinib for HCC. Patients with better preserved liver function and performance status demonstrated more favorable ALBI profiles. These findings support the use of ALBI as an objective complement to established clinical indicators when assessing suitability for lenvatinib therapy and planning treatment strategies.

Keyword(s) : Hepatocellular Carcinoma, Clinical predictors, ALBI score, Lenvatinib.

1318 - Atezolizumab and bevacizumab therapy combined with expanded NK cells significantly prolongs survival in vivo hepatocellular carcinoma model.

Sang Youn Hwang¹, Wan Jeon², Yu Su Park³, Woo Chang Sohn³

Dongnam Institute Of Radiological & Medical Sciences; Dirams, Gastroenterology & Hepatology, Busan-South Korea¹ Dongnam Institute Of Radiological & Medical Sciences; Dirams, Radiation Oncology, Busan-South Korea² Dongnam Institute Of Radiological & Medical Sciences; Dirams, Research Center, Busan-³

Background / Hypothesis:

Atezolizumab plus bevacizumab (Ate+Beva) proved better efficacy compared to sorafenib for advanced hepatocellular carcinoma (HCC) patients in IMbrave150

trial. However objective response rate of Ate+Beva therapy is around 30%, therefore several trials about combination protocol such as dual immune check point inhibitor plus bevacizumab etc. are ongoing to overcome this unmet need. Natural killer (NK) cell therapy is considered as promising tool that can enhance the efficacy of immunotherapy via several mechanism, however there are no studies about this issue. Therefore we performed preclinical study for efficacy of Ate+Beva therapy combined with expanded NK cell in HCC in vivo model.

Materials and Methods:

SNU-398 cells were subcutaneously injected into the left flank (2.5×10^6) and right thigh (5×10^6) of SCID mice. Four days later, atezolizumab (10 mg/kg) and bevacizumab (5 mg/kg) were administered intraperitoneally, and NK cells (1×10^7) were injected via the tail vein. Tumor size (length $\times$ width) was measured twice weekly. Atezolizumab, bevacizumab, and NK cell treatments were repeated three times at 1-week intervals (Figure 1).

Results:

Total 16 mice were categorized as four groups (Control, NK monotherapy, Ate+Beva, NK+Ate+Beva). The effect about shrinkage of tumor volume & survival rate were maximized in the NK+Ate+Beva therapy group compared to other three groups with significance statistically (Figure 2, 3). There were no meaningful toxicity in NK+Ate+Beva group compared to other three groups.

Conclusions:

This study demonstrates that combination of NK cell with Ate+Beva can improve the efficacy of Ate+Beva therapy in HCC preclinical model. Further clinical prospective studies are needed for proving synergistic effect of NK cell and Ate+Beva therapy to HCC patients.

1319 - Integrated Proteomic and Metabolomic Profiling Reveals Distinct Immune and Metabolic Landscapes in Occult Hepatitis B Infection

Hua-xiang Yang¹, Hui-guo Ding², Xiao-cong Liu¹, Wu Wen¹

West China School Of Medicine, Sichuan University,

E-POSTER ABSTRACTS

Sichuan University Affiliated Chengdu Second People's Hospital, Department Of Gastroenterology And Hepatology, Chengdu-China ¹ Beijing You'an Hospital Affiliated To Capital Medical University, Department Of Gastroenterology And Hepatology, Beijing-China ²

Background / Hypothesis:

The pathophysiological distinctions between HBsAg-positive Hepatitis B and Occult Hepatitis B Infection (OBI) remain elusive. This study integrated proteomic and metabolomic analyses to delineate the systemic immune microenvironment in OBI and to identify clinically viable biomarkers for discriminating it from HBsAg-positive HBV.

Materials and Methods:

We analyzed plasma from 20 OBI patients (HBsAg-negative, HBV DNA <200 IU/mL), 20 HBsAg-positive HBV patients, and 10 healthy controls. Mass spectrometry-based proteomics and NMR-based metabolomics were employed. Data analysis encompassed differential expression screening, pathway enrichment, and Weighted Gene Co-expression Network Analysis (WGCNA). Machine learning algorithms were applied to construct a diagnostic model, with candidate biomarkers validated by ELISA in an expanded cohort.

Results:

HBsAg-positive patients exhibited significantly higher ALT levels than OBI patients ($p=0.010$). Multi-omics profiling revealed distinct HBV-induced perturbations in metabolic pathways and inflammatory signatures in both groups. Cellular deconvolution linked HBsAg-positive infection to Kupffer cells and OBI to hepatocytes. Immune phenotyping correlated OBI with CD4⁺ central memory T cells and memory B cells, suggesting a poised mechanism for rapid recall response. A machine learning-derived diagnostic model, built on significantly expressed molecules, robustly differentiated the two patient groups (AUC >0.8). ELISA validation confirmed FGB and FGG as elevated in OBI, nominating them as potential discriminatory biomarkers.

Conclusions:

This study unveils significant differences in the immune and metabolic landscape between HBsAg-positive HBV and OBI. We further present a high-accuracy, non-invasive diagnostic model, offering a promising tool for precise clinical differentiation and patient management.

Background / Hypothesis: Chronic hepatitis B (CHB) is a leading cause of hepatocellular carcinoma (HCC) worldwide, and while oral antivirals lower the risk of HCC, they do not eliminate it. Recent studies indicate that moderate hepatitis B virus (HBV) DNA levels may be strongly linked to HCC risk in hepatitis B e antigen (HBeAg)-positive people with CHB. The recently validated PAGED-B (platelets, age, gender, diabetes, and HBV DNA) score, which incorporates HBV DNA, can be used to stratify HCC risk in this population. We used the PAGED-B score to assess HCC risk in HBeAg-positive patients with CHB enrolled in a trial of tenofovir-based therapy.

Materials and Methods: In a Phase 3 multicenter study

E-POSTER ABSTRACTS

(GS-US-320-0110), patients who were HBeAg positive with HBV DNA $\geq 20,000$ IU/mL and alanine aminotransferase > 60 U/L (males) or > 38 U/L (females) were randomized to receive tenofovir alafenamide (TAF) 25 mg or tenofovir disoproxil fumarate (TDF) 300 mg once daily for up to 3 years. Thereafter, patients received open-label TAF through year 8 (week 384). PAGED-B scores at baseline (BL) and over 384 weeks were generated. Shifts in risk categories (low risk [0 to < 7] and high risk [≥ 7]) were evaluated.

Results: Among 1052 (TAF, $n = 703$; TDF, $n = 349$) HBeAg-positive patients (66% male, 85% Asian [$n = 893$]/Pacific Islander [$n = 4$], 98% HBeAg positive [2% transitioned to HBeAg-negative status between screening and BL visits]), mean (range) BL PAGED-B score was 4.3 (0–11); 885 (84%) and 167 (16%) were low and high risk, respectively. At weeks 240 and 384, mean (range) changes from BL in PAGED-B scores were -0.8 (-4 to 4) and -0.7 (-4 to 2), respectively. Among those in the low-risk category at BL with available data at week 384, the majority remained unchanged; only 6 (1%) shifted to high risk, primarily driven by age and platelet changes. In the high-risk group, most patients improved to low risk (69%), and only 31% remained at high risk. Overall, 12 HCC cases developed over 8 years (0.3%, BL low-risk group; 5.4%, BL high-risk group).

Conclusions: The application of the PAGED-B risk score demonstrates that among HBeAg-positive patients, most (69%) high-risk patients experienced a decrease in risk with long-term treatment, whereas shifts from low risk of HCC at the start of treatment to a higher risk category were rare (1%).

Background / Hypothesis: Bulevirtide (BLV) is approved for the treatment of chronic hepatitis delta. In the MYR301 study evaluating BLV monotherapy for 2–3 years, a subset of patients who achieved undetectable hepatitis delta virus (HDV) RNA by end of treatment (EOT) maintained undetectable viremia at 48 weeks (W) after EOT (FU48). Here, we present predictors of sustained HDV RNA undetectability through FU48 after 96W or 144W of BLV treatment.

Materials and Methods: Data were analyzed from 149 patients randomized to immediate treatment with BLV 2 or 10 mg/d for 144W, or to 48W of no treatment then BLV 10 mg/d for 96W (DT- > 10 mg). All patients were to be followed through FU48. Logistic regression modeling examined potential predictors of sustained HDV RNA undetectability ($<$ lower limit of quantitation [LLOQ; target not detected]) through FU48 in patients with undetectable viremia at EOT.

Results: Across all cohorts, 65/149 (44%) patients achieved HDV RNA undetectability at EOT, of whom 23/64 (36%) with available follow-up HDV RNA data had sustained undetectability through FU48. Rates of

E-POSTER ABSTRACTS

sustained undetectability were higher in BLV 2 mg (7/14, 50%) and 10 mg (10/25, 40%) vs DT->10 mg (6/26, 23%) cohorts. Undetectability rates at EOT were higher in patients receiving BLV 10 mg, but the relapse rate was lower in the few patients with HDV RNA <LLOQ in the BLV 2 mg cohort. Baseline predictors of sustained undetectability posttreatment included baseline HDV RNA less than a median of 4.5 log₁₀ IU/mL (odds ratio [OR]: 6.2; 95% CI [1.9, 20.8]; P=.003) and lower baseline hepatitis B surface antigen (HBsAg) level (OR: 0.3 per log₁₀ IU/mL; 95% CI [0.1, 0.8]; P=.019). On-treatment predictors included greater duration of continuous undetectability at EOT (OR per additional week: 1.0; 95% CI [1.0, 1.1]; P <.0001), HBsAg loss or decrease by ≥ 1 log₁₀ IU/mL (OR: 7.2; 95% CI [1.2, 42.3]; P=.030), and W144 antidrug antibody (ADA) incidence (OR: 10.2; 95% CI [1.9, 55.7]; P=.008). The proportion of patients with sustained posttreatment undetectability was 9/10 (90%) in those with ≥ 96 W of undetectability at EOT, 11/22 (50%) with ≥ 48 to <96W, and 3/32 (9%) with <48W. Of patients with ADA incidence by W144, 8/10 (80%) had sustained undetectability vs 15/54 (28%) without. Baseline cirrhosis was not a predictor of sustained posttreatment undetectability; 13/32 (41%) with cirrhosis had sustained undetectability vs 10/32 (31%) without cirrhosis.

Conclusions: Early and sustained HDV RNA undetectability predicted undetectability at EOT and sustained undetectability during follow-up.

1322 - COMPARISON OF SEROLOGICAL FIBROSIS MARKERS WITH LIVER BIOPSY FIBROSIS STAGES IN CHRONIC HEPATITIS B PATIENTS

Esma Aslihan Aydemir¹, Özgür Günel², Mustafa Usanmaz², Süleyman Sirri Kiliç³

Taşköprü State Hospital, Infectious Diseases And Clinical Microbiology, Kastamonu-Türkiye¹ Samsun University Faculty Of Medicine, Infectious Diseases And Clinical Microbiology, Samsun-Türkiye² Health Sciences University, Samsun Training And Research Hospital, Infectious Diseases And Clinical Microbiology, Samsun-Türkiye³

Background / Hypothesis: Hepatitis B virus is the most common cause of chronic hepatitis and a global public health problem. It can cause hepatocyte damage, immune cell infiltration and liver fibrosis. Consequently, patients may develop liver cirrhosis and hepatocellular carcinoma. The main step of treatment is to determine

the degree of liver fibrosis. Biochemical, serological and molecular tests, histopathological examination, imaging are the methods used for diagnosis and staging. This study aimed to detect the serological markers closest to the liver biopsy results and to determine the cut-off value by comparing the liver biopsy results and biochemical fibrosis markers of patients followed up with chronic hepatitis B infection. **Materials and Methods:** Four hundred fourteen patients between the ages of 18 and 90 who were admitted to Samsun Training and Research Hospital as outpatients and were followed for Chronic Hepatitis B infection and whose HBV-DNA level was > 2000 IU/ml at least once and who underwent liver biopsy with fibrosis staging, were included in the study. The demographic characteristics, pathology results and biochemical data of the patients were recorded retrospectively as file findings. The evaluated variables and serological fibrosis markers (FIB4, APRI, GPR, AGAP, AAR, NLR, RPR, King's score, FibroQ, API, PLR, AAPRI, APPR, GUCI, Lok score, GAR, FI) were statistically assessed for their diagnostic validity in predicting liver fibrosis by comparing them with the Ishak fibrosis stage, and the cut-off value was determined.

Results: In our study, as a result of the ROC analysis performed to determine the threshold values of factors that can predict advanced fibrosis (F4-6), FIB4, APRI, GPR, AGAP, AAR, RPR, King's score, API, PLR, APPR, GUCI, Lok score, GAR, FI serum tokens were successful. The highest AUROC value was APRI (0.791, p<0.001) and followed by GUCI, APPR, Kings, AGAP, GPR, FIB4, FI (0.784, 0.780, 0.771, 0.748, 0.736, 0.734, 0.701, p<0.001, respectively).

Conclusions: In cases where diagnosis of liver fibrosis takes a long time, is costly, requires special methods-equipment and qualified evaluation, such as biopsy; noninvasive serum markers that are short-term, low-cost, and easily evaluated can make a significant contribution to predicting fibrosis. However, there is no perfect serum biomarker. It is thought that markers with high predictive power such as APRI, GUCI, APPR, Kings score, AGAP, GPR, FIB4, FI can be beneficial in selected cases.

Background / Hypothesis: Bulevirtide (BLV) 2 mg/day (d) is approved for treatment of compensated chronic hepatitis delta (CHD). In the MYR301 Phase 3 study evaluating BLV monotherapy for 2–3 years, BLV was safe and effective through 144 weeks (W). We present final results through follow-up at 96W (FU96) after end of treatment (EOT)

Materials and Methods: Patients with CHD (N=150) were randomized to immediate treatment with BLV 2 or 10 mg/d for 144W or to 48W of delayed treatment (DT) followed by BLV 10 mg/d for 96W (DT->10 mg) and 96W posttreatment FU. Efficacy endpoints included virologic response (VR; undetectable hepatitis delta virus [HDV] RNA or $\geq 2 \log_{10}$ IU/mL decline from baseline), combined response (CR; VR and alanine aminotransferase [ALT] normalization), ALT normalization, undetectable HDV RNA, and hepatitis B surface antigen (HBsAg) loss.

Results: Baseline characteristics were similar across groups. Most patients (92%) remained in the study at EOT; 72% and 57% completed FU48 and FU96, respectively. CR rates in the 2, 10, and DT->10 mg groups, respectively, declined from 57%, 54%, and 56% at EOT to 24% in each group at FU96. HDV RNA undetectability rates were 29%, 50%, and 52% at EOT and 20%, 22%, and 20% at FU96, respectively. Of 64 patients across all groups with undetectable HDV RNA at EOT and available FU data, 36% had sustained undetectable HDV RNA through FU96, and 64% had viral relapse, which occurred in 93% by FU24 and none after FU48. Sustained posttreatment undetectable HDV RNA was more frequent in patients with longer on-treatment continuous HDV RNA undetectability at EOT: 9/10 (90%) for ≥ 96 weeks, 11/22 (50%) for ≥ 48 to <96 weeks, and 3/32 (9%) for 0 to <48 weeks. Posttreatment HBsAg loss occurred in 3 patients. In the posttreatment period, 14/142 (10%) patients had ALT $> 10 \times$ the upper limit of normal, which occurred by FU24 in most (10/14, 71%). Posttreatment hepatic serious adverse events (SAEs) were reported in 20/142 (14%) patients. The hepatic SAEs resolved in 17/20 (85%) patients, ≥ 16 of whom restarted BLV.

Conclusions: In patients receiving BLV monotherapy for 96W or 144W, response rates decreased after treatment discontinuation. A subset of patients maintained undetectable HDV RNA for 2 years posttreatment, which was associated with longer duration of continuous on-treatment undetectability. Posttreatment viral relapse occurred only in the first year after EOT and may be associated with hepatitis flares.

1324 - Synergistic effects of type 2 diabetes and alcohol consumption on all cause and liver related mortality among patients with steatotic liver

E-POSTER ABSTRACTS

disease

Ruoqi Zhou Zhou¹, Huilan Tu Tu¹, Fanpu Ji Ji², Rongtao Lai Lai³, Jie Wang Wang¹, Weijun Su Su¹, Jingjing Tao Tao¹, Haotian Zhang Zhang¹, Ming-hua Zheng Zheng⁴, Vincent Wai-sun Wong Wong⁵, Yu Shi Shi¹, Xinrong Zhang Zhang⁶

The First Affiliated Hospital, Zhejiang University School Of Medicine, State Key Laboratory For Diagnosis And Treatment Of Infectious Diseases, National Clinical Research Center For Infectious Diseases, Hangzhou-China¹ The Second Affiliated Hospital Of Xi'an Jiaotong University, Department Of Hepatology, Xi'an-China² Ruijin Hospital, Shanghai Jiao Tong University School Of Medicine, Department Of Infectious Diseases, Shanghai-China³ The First Affiliated Hospital Of Wenzhou Medical University, Mafld Research Center, Department Of Hepatology, Wenzhou-China⁴ The Chinese University Of Hong Kong, Hong Kong, Department Of Medicine And Therapeutics, Hong Kong-China⁵ School Of Public Health, Sun Yat-sen University, Guangdong Provincial Key Laboratory Of Food, Nutrition And Health, And Department Of Epidemiology, Guangzhou-China⁶

Background / Hypothesis:

Type 2 diabetes (T2D) and alcohol consumption have been acknowledged as major risk factors for adverse clinical outcomes for individuals with steatotic liver disease (SLD). However, data about synergistic effects of T2D and alcohol on all-cause and liver-related mortality in SLD remains scarce.

Materials and Methods:

Leveraging data from UK Biobank, we compared risk of all-cause and liver-related mortality across 6 groups stratified by T2D and alcohol consumption in Cox proportional hazards regression: no T2D+no/mild alcohol, no T2D+MetALD, no T2D+ALD, T2D+no/mild alcohol, T2D+MetALD, T2D+ALD. The population attributable fraction (PAF) and relative excess risk due to interaction (RERI) were calculated to exam the interplay between these two factors.

Results:

24,309 all-cause deaths and 1,009 liver-related were recorded for 175,713 participants from UK Biobank. The coexistence of T2D and elevated alcohol intake, particularly when both T2D and severe alcohol consumption, was associated with substantially worse outcomes, including a 1.23~1.64 fold increased risk of all-cause mortality and a markedly higher 1.58~7.32 fold risk of liver-related mortality compared with no T2D+no/mild alcohol. While combination of T2D and

alcohol use accounted for a modest PAF of 6.78% for all-cause mortality, they contributed to 40.52% of liver-related mortality. Significant RERI was exclusively observed for liver-related mortality but not for all-cause mortality.

Conclusions:

Co-exposure to T2D and alcohol intake substantially increased the risk of all-cause and especially the liver-related mortality in SLD individuals. Their interplay conferred significant disease burden, underscoring the importance of abstinence and glycemic control in the management of SLD patients.

1325 - Serum metabolomic characteristics and their predictive value for ninety day prognosis in patients with acute on chronic liver failure

Ying Xiao¹, Yadong Wang¹, Caiyan Zhao¹

The Hebei Medical University Third Hospital, Infectious Disease, Shijiazhuang-China¹

Background / Hypothesis: Acute-on-chronic liver failure (ACLF) is characterized by severe metabolic disturbances; however, the specific metabolomic features and their predictive value on 90-day prognosis remain unclear. To identify serum metabolomic changes in patients with ACLF with different prognoses to support clinical prediction of outcomes and treatment decisions.

Materials and Methods: This non-interventional, observational case-control study enrolled 58 patients with ACLF. Fasting venous blood samples were analyzed using targeted metabolomics. Univariate and multivariate statistical analyses identified differential metabolites among 18 amino acids, 11 fatty acids, 5 gut microbiota-related metabolites, and 4 bile acid metabolites. Binary logistic regression identified independent mortality risk factors, visualized via forest plots and receiver operating characteristic (ROC) curves.

Results: Significant differences ($P < 0.05$) were observed between the death and survival groups in baseline age, Model for End-Stage Liver Disease (MELD) score, MELD with sodium, neutrophil-to-lymphocyte ratio (NLR), total bilirubin, serum creatinine, blood urea nitrogen, and platelet count. Metabolites, including L-carnitine, creatinine, alanine, arginine (Arg), proline, choline, and oleic acid, also

E-POSTER ABSTRACTS

showed statistically significant differences between the groups. Multivariate analysis identified age, NLR, and Arg as independent risk factors for 90-day mortality in patients with ACLF. The predictive model, ANA (Age–NLR–Arg) = $-15.481 + 0.135 \times \text{Age} + 0.156 \times \text{NLR} + 0.203 \times \text{Arg}$, with a cutoff of 0.759, achieved an area under the ROC curve of 0.945 with sensitivity of 84.0% and specificity of 87.9%.

Conclusions: The ANA model demonstrates a strong predictive value for 90-day mortality risk in patients with ACLF.

Background / Hypothesis:

Hepatitis D virus (HDV) is a defective satellite virus that requires hepatitis B virus (HBV) for replication and exacerbates the severity of viral hepatitis. China carries a heavy burden of HBV, with an estimated 43.3 million infections in 2021. However, the national prevalence and clinical impact of HDV/HBV coinfection remains poorly defined. Accurate epidemiological data are essential to guide clinical and public health responses.

Materials and Methods:

From 2023 to 2025, we screened HBsAg-positive inpatients across nine medical centers representing northern, southern, eastern, and western China. Serum samples were tested for anti-HDV IgM and IgG using ELISA, and seropositive samples were further detected for HDV RNA via quantitative RT-PCR. Clinical and laboratory data were collected and analyzed.

Results:

The final analysis included 13,953 HBsAg-positive patients. Anti-HDV antibodies were detected in 0.57% of the cohort, with 0.29% positive for IgM and 0.31% for IgG. HDV RNA, indicating active viral replication, was detected in 5.06% of seropositive cases. Specifically, HDV RNA was positive in three of four patients with both IgM and IgG antibodies, and in one of 39 with IgG alone. Seroprevalence of HDV exhibited regional variation ($p < 0.001$), ranging from 0% in Fujian to 0.96% in Guizhou. Higher rates of HDV seropositivity were observed in patients with HBsAb (0.75% vs 0.57%), HCV co-infection (2.47% vs 0.51%) or TP co-infection (0.56% vs 0.48%). Anti-HDV-positive patients were significantly older (57 vs 52 years, $p = 0.016$) and exhibited lower neutrophil (2.56 vs $3.09 \times 10^9/L$, $p = 0.023$) and lymphocyte counts (1.27 vs $1.50 \times 10^9/L$, $p = 0.005$), prolonged prothrombin time (13.1 vs 12.6 s, $p = 0.032$), and reduced fibrinogen levels (2.53 vs 2.74 g/L, $p = 0.004$) in peripheral blood compared to anti-HDV-negative individuals. Additionally, anti-HDV-positive patients had higher HBsAg levels (340.1 vs 250.1 COI, $p = 0.027$) and a non-significant trend toward lower HBV DNA loads (49.9 vs 69.1 IU/mL, $p = 0.101$).

Conclusions:

This multi-center study provides an updated overview of HDV seroprevalence and active infection rates in China, which are substantially lower than previously reported. The findings highlight geographical disparities and high-risk groups of HDV infection, particularly those HBsAg-positive patients with HCV or TP co-infection or undetectable HBV DNA, providing valuable insights for targeted HDV surveillance and prevention strategies.

Pukar Thapa ¹

Norvic International Hospital, Hepatology, Kathmandu-

E-POSTER ABSTRACTS

Nepal ¹

Dapsone Syndrome Relapse: Unraveling a Complex Case

Abstract

Background

Dapsone syndrome is a rare hypersensitivity reaction marked by symptoms like high fever, maculopapular rashes, hepatitis, lymphadenopathy, and lymphocytosis. Typically, these manifestations occur within the initial 6 weeks of treatment. A reported case involves an individual with borderline tuberculoid leprosy who experienced a relapse of this syndrome.

Clinical significance

A relapsing course of Dapsone syndrome is rare and must be identified early for proper management.

Case Report

A 45-year-old female diagnosed with Boderline Tuberculoid Leprosy was started on combination of antibiotics containing Dapsone who developed fever along with maculopapular rashes all over her body on her 25th day of treatment. Laboratory investigations revealed lymphocytosis with abnormal liver function. She was diagnosed with Dapsone syndrome and her Anti-leprotic therapy were stopped and was started on steroids and other supportive measures. Her liver enzymes showed a declining trend and rashes subsided and steroids was stopped. However, after 2 weeks she experienced a recurrence of the same widespread rashes along with deranged liver function. The patient was again treated with intravenous steroids along with other supportive measures. Rashes and swelling subsided within 4 days of starting high-dose steroids along with gradual improvement in biochemical parameters. She was free of hepatic, dermatological and other parameters in next 4 weeks.

Conclusion

Dapsone stands as the primary treatment choice for all types of leprosy, generally well tolerated by patients. Within the spectrum of rare hypersensitivity reactions, Dapsone syndrome emerges. In the mentioned case, the recurrence of dapsone syndrome was observed, and was treated accordingly.

1332 - Socioeconomic Factors Among Chronic Liver Disease Patients Experience From Largest Tertiary Care Hospital Of Pakistan

Bushra Shahid ¹

Jinnah Postgraduate Medical Centre, Gastroenterology And Hepatology, Karachi-United Kingdom ¹

Background / Hypothesis:

Pakistan has one of the highest global rates of viral hepatitis, contributing significantly to the prevalence of chronic liver disease (CLD). The progression and outcomes of CLD are influenced by social determinants of health (SDOH), including economic disparities, healthcare accessibility, environmental conditions, and public awareness. Understanding these factors will enhance disease prevention and management.

OBJECTIVES : To analyze the economic and social challenges confronting chronic liver disease patients in Karachi,Pakistan.

Materials and Methods:

It is an ongoing cross-sectional study that began in August 2024 at the Jinnah Post Graduate Medical Centre in Karachi. This study included CLD patients and their socioeconomic status, healthcare access, education, social and community context, neighborhood built environment, hospitalizations or readmissions, as well as disease complications, these were among the outcome variables of interest.

Results:The study enrolled 1200 patients with chronic liver disease (CLD), predominantly from Sindh 1179 (94%) and Balochistan 41 (3.2%). Of these, 665 (53%) were males and 586 (47%) were females, with a mean age of 50 ± 13 years. Most patients 1092 (91%) were married. Within Sindh,

Karachi was home to the majority 1043 (83%), particularly the outskirts 213 (17%), followed by Malir 184 (15%), Korangi 174 (14%), Orangi 167 (13%), and Central Karachi 161 (13%).

Etiologies contributing to CLD were HCV 853(81%) followed by HBV 564(47%),HBV+HDV 192(16%) and NAFLD 43(3.6%).A significant proportion 893 (71.4%) had decompensated CLD (DCLD), with a Child-Turcotte-Pugh (CTP-B) score in 767 patients (62%) and

E-POSTER ABSTRACTS

a MELD score below 15 in 922 (74%).

Stratification by income revealed significant disparities in disease severity and clinical complications. Patients in the low-income group exhibited disproportionately higher rates of Decompensated CLD: 81% vs. 50% (middle-income) and 25% (high-income), CTP class B: 72% vs. 35% and 24% and MELD score <15: 61% vs. 100% and 96%.

Complications were also more frequent among low-income patients, Jaundice: 68% (vs. 48% and 28%), Ascites: 57% (vs. 35% and 16%), Upper GI bleed: 56% (vs. 33% and 21%) Hepatic encephalopathy: 38% (vs. 15% and 8%). All associations were statistically significant ($P < 0.001$). These findings indicate a clear socioeconomic gradient in CLD severity, with the lowest-income patients experiencing the greatest disease burden and complications.

Conclusions: Low-income patients with chronic liver disease experience significantly higher rates of disease severity and complications, underscoring the critical impact of socioeconomic status on clinical outcomes and healthcare disparities. These important elements must not be disregarded to prevent disease-related morbidity.

Keyword(s) : Hepatitis, Socioeconomic factors, chronic liver disease

1333 - Impact of Prior Treatment Response on Survival Outcomes of Subsequent Systemic Therapies Following First line Atezolizumab plus Bevacizumab in Patients with Unresectable Hepatocellular Carcinoma

Jiwon Yang¹, Ye Rim Kim¹, Dongman Yu¹, Yeongseok Hwang¹, Jihyun An², Han Chu Lee¹, Ju Hyun Shim¹
Asan Medical Center, University Of Ulsan College Of Medicine, Gastroenterology, Seoul-South Korea¹
Hanyang University Guri Hospital, Hanyang University College Of Medicine, Gastroenterology, Guri-South Korea²

Background/Hypothesis: Optimal subsequent treatment strategies following first-line Atezolizumab plus bevacizumab (Atezo/Bev) in unresectable hepatocellular carcinoma (HCC) remain unclear, particularly beyond the second-line treatment settings. We evaluated whether the treatment response to the preceding systemic therapy affects survival outcomes of subsequent treatment lines following Atezo/Bev.
Materials and Methods: In this single-center

retrospective cohort study, we analyzed 353 patients with unresectable HCC, who received Atezo/Bev ≥ 3 cycles (May 2022–December 2023) and underwent subsequent treatment. For each treatment line, patients were stratified into progressive disease (PD) and non-PD groups based on the best response to the prior therapy. Overall survival (OS) and progressive-free survival (PFS) were used as primary and secondary outcomes, respectively.

Results: Among the entire patients, 307 (87.0%) received second-line systemic therapy (lenvatinib or sorafenib in >80% of the patients), and 279 (90.9%) of them underwent the initial response evaluation. OS after second-line therapy did not differ significantly between the first-line PD and non-PD groups (median OS: 7.8 vs. 9.4 months; $P=NS$). Consistently, PFS was also comparable between the two groups (median PFS: 3.7 vs. 4.2 months; $P=NS$). Higher Child-Pugh score at the initiation of second-line treatment emerged as a common risk factor of both poor OS and PFS ($P_s < 0.05$). Interestingly, patients receiving second-line sorafenib or regorafenib showed worse PFS outcomes compared with those treated with lenvatinib ($P_s < 0.05$). In third-line settings (sorafenib or regorafenib in about half of the patients), treatment response of second-line systemic treatment also showed no significant association with subsequent survival outcomes (median OS and PFS of PD and non-PD: 7.4 vs. 6.1 months; and 1.8 vs. 1.6 months, respectively; $P_s=NS$). In addition, the type of prior chemotherapy did not have a significant impact on survival outcomes after initiation of sequential systemic treatment.

Conclusions: The therapeutic response to first-line Atezo/Bev for HCC did not significantly affect survival outcomes of later systemic treatments. Post-Atezo/Bev treatment may not need to depend on prior treatment response in HCC.

1339 - Clinical Investigation on Hepatocellular Carcinoma Complicated with Esophageal and Gastric Variceal Bleeding

Jiawen Feng¹, Tianze Wang¹, Qing Ye²
Third Affiliated Clinical College Of Nankai University, Gastroenterology And Hepatology, Tianjin-China¹
Tianjin Third Central Hospital, Gastroenterology And Hepatology, Tianjin-China²

Background / Hypothesis:

E-POSTER ABSTRACTS

Hepatocellular carcinoma (HCC) currently ranks as the 4th most common malignant tumor and the 2nd leading cause of cancer-related death in China, posing a severe threat to the health and lives of the Chinese population. Although multiple treatment modalities—including surgery, ablation, transcatheter arterial chemoembolization (TACE), and systemic therapy—have significantly improved the survival of patients with liver cancer in recent years, the complication of esophageal and gastric variceal bleeding (EGVB) in HCC patients has attracted increasing attention. This is primarily because acute EGVB elevates the risk of non-tumor progression-related mortality. Additionally, systemic therapy for HCC may alter the severity of portal hypertension and induce bleeding. To provide patients with comprehensive treatment options, greater emphasis should be placed on the prevention and management of portal hypertension-related complications, particularly EGVB. The objective of this study was to evaluate the clinical characteristics of the first episode of EGVB in patients with HCC.

Materials and Methods:

A retrospective analysis was performed on data from patients admitted to the Department of Gastroenterology/Hepatology, Tianjin Third Central Hospital, between January 2019 and October 2023. All included patients were hospitalized for the first time due to EGVB. The clinical characteristics of HCC patients complicated with EGVB were analyzed.

Results:

During the study period, a total of 5,787 patients were admitted for first-episode upper gastrointestinal bleeding, all of whom were confirmed to have EGVB via gastroscopy. Among these, 598 patients were diagnosed with HCC, accounting for 10.3% of all EGVB patients.

Further analysis focused on these 598 HCC patients with EGVB, revealing the following:

178 cases (29.8%) were complicated with portal vein tumor thrombus;

71 cases (11.9%) had received bevacizumab treatment.

Regarding the etiology of cirrhosis in these HCC patients, the distribution was as follows: 418 cases of hepatitis B-related cirrhosis, 48 cases of hepatitis C-related cirrhosis, 38 cases of alcoholic cirrhosis, 34 cases of primary biliary cholangitis (PBC), and 34 cases of metabolic dysfunction-associated steatotic liver disease (MASLD)-related cirrhosis. Additionally, 175 patients (29.3%) had hypersplenism, and 258 patients (43.1%) had ascites.

Conclusions: For HCC patients—especially those planned to receive combined targeted therapy and immunotherapy—endoscopic examination should be

routinely performed to assess the risk of esophageal and gastric varices. This approach can provide a critical guiding basis for the subsequent management of HCC.

1340 - Akkermansia muciniphila Regulating Cholangiocyte Pyroptosis via the Bile Acid TGR5 Axis

Kaicen Wang¹, Wenrui Wu¹, Yanfei Chen¹, Lanjuan Li¹
The First Affiliated Hospital, Zhejiang University School Of Medicine, Infectious Disease, Hangzhou-China¹

Background / Hypothesis:

Therapeutic options for Primary sclerosing cholangitis (PSC) remain limited. Given the close association between PSC and gut microbiota, exploring pathogenesis and novel treatments of the disease from this perspective holds significant promise.

Materials and Methods:

A well-established PSC model was induced in mice using a 0.1% 3,5-Diethoxycarbonyl-1,4-Dihydrocollidine (DDC) diet. The temporal dynamics of the gut microbiota and metabolites during disease progression were then profiled using an integrated approach of 16S rRNA sequencing and metabolomics. We further investigated the therapeutic effect of *Akkermansia muciniphila* (AKK) in PSC mice. To this end, we employed an integrated multi-omics strategy, combining 16S rRNA sequencing, transcriptomics, and bile acid metabolomics with pyroptosis pathway analysis, to uncover the underlying protective mechanism.

Results:

During the progression of PSC in mice, the abundance of intestinal AKK gradually decreased, while the intestinal deoxycholic acid (DCA) level also declined. AKK abundance and DCA level were significantly negatively correlated with the degree of biliary inflammation and injury. Furthermore, a positive correlation was observed between intestinal AKK abundance and DCA level in cholestatic mice. Further supplementation with AKK significantly alleviated biliary inflammation and fibrosis in PSC mice. Reduced expressions of hepatic NLRP3, Cleaved caspase-1, and GSDMD-NT, and decreased serum levels of IL-1 β and IL-18 indicated suppression of pyroptosis. Further integrated analysis of 16S rRNA sequencing and bile acid metabolomics revealed that AKK administration, while ameliorating cholestasis and downregulating the biliary pyroptosis pathway, significantly increased the abundance of gut microbiota involved in bile acid biotransformation and elevated the levels of secondary

E-POSTER ABSTRACTS

bile acids, particularly DCA, in both the liver and feces. Transcriptomic analysis of liver tissue further indicated that AKK intervention upregulated the cAMP signaling pathway and the expression of TGR5 and PKA, implying an activation of the TGR5/cAMP/PKA pathway, which was confirmed at both the mRNA and protein levels. These findings suggested that the DCA-TGR5 axis may be the key molecular mechanism through which AKK regulates biliary pyroptosis.

Conclusions:

Based on the above findings, AKK demonstrated therapeutic potential in alleviating biliary inflammation and delaying the progression of cholestatic disease. The underlying mechanism may involve remodeling the gut microbiota structure, promoting bile acid metabolic reprogramming, stimulating the production of the unconjugated secondary bile acid DCA, and subsequently activating the TGR5 signaling pathway in cholangiocytes. This activation suppressed the GSDMD-mediated pyroptosis pathway, thereby mitigating biliary injury. This work provided a novel strategy for the clinical treatment of PSC by modulating the microbiota.

Background / Hypothesis: Nucleos(t)ide analogs have been associated with a reduced risk of hepatocellular carcinoma (HCC) in patients with hepatitis B virus infection. Many studies have suggested that tenofovir-based therapies are more effective than entecavir in reducing HCC risk. Here, we examine HCC risk in patients with chronic hepatitis B using tenofovir alafenamide (TAF) or tenofovir disoproxil fumarate (TDF).

Materials and Methods: Data from four pivotal phase 3 trials were pooled to examine the association between TAF/TDF exposure and HCC occurrence. These included Studies 102 and 103, in which patients were randomized (2:1) to TDF vs adefovir dipivoxil (ADV) for 48 weeks, followed by open-label TDF (up to 8 years' total treatment [384 weeks]), and Studies 108 and 110, in which patients were randomized (2:1) to TAF vs TDF for up to 144 weeks, followed by open-label TAF (up to 8 years' total treatment). HCC occurrence was classified as an adverse event and assessed as part of routine care (hepatic ultrasonography conducted in Studies 108 and 110). Using Cox proportional hazards analyses, we examined the association between exposure to TAF vs TDF and the time to development of HCC. Exposure to TAF vs TDF was the main predictor variable and was captured by the total TAF exposure time/(total TAF exposure time + total TDF exposure time), with values ranging between 0 (TDF only) and 1 (TAF only). HCCs occurring within the first 48 weeks of treatment initiation/switching from ADV to TDF were considered to have pre-existed and were excluded from these analyses to minimize immortal time bias.

Results: In total, 2273 patients (Studies 102/103: n=641; Studies 108/110: n=1632) were included in the pooled analysis. By Year 8, 46 (2.0%) patients had developed HCC (9 cases occurred within the first 48 weeks and were excluded). In the univariate model, sex (hazard ratio [HR]=2.93), age (HR=1.08), cirrhosis (HR=4.32), alanine aminotransferase (ALT) normalization at Week 24 (HR=0.29), and TAF vs TDF

E-POSTER ABSTRACTS

exposure (HR=0.41) were significantly associated with decreased HCC risk. In the final multivariate analysis, TAF exposure was significantly associated with a 70.0% reduction in HCC risk compared to TDF exposure (HR=0.30). Independently, ALT normalization at Week 24 was also significantly associated with decreased HCC risk (HR=0.29).

Conclusions: Long-term TAF treatment was associated with a greater reduction in HCC risk than TDF treatment. Differences in study design, population, and timing should be considered, and real-world data may help to confirm these findings.

Background / Hypothesis: Chronic hepatitis B (CHB) is a leading cause of hepatocellular carcinoma (HCC), and oral antivirals can reduce HCC risk. The Risk Estimation for HCC in CHB (REACH-B) score is useful in assessing HCC risk and was updated to incorporate age, gender, platelet count, HBV DNA and alanine aminotransferase (ALT) levels, and hepatitis B e antigen (HBeAg) status. We assessed HCC risk in tenofovir-based clinical trials

using the updated reREACH-B score.

Materials and Methods: In 2 Phase 3 studies, HBeAg-positive (n = 1039) and -negative (n = 593) patients were randomized (2:1) to once-daily tenofovir alafenamide (TAF) 25 mg or tenofovir disoproxil fumarate (TDF) 300 mg for ≤ 3 years (Y), followed by open-label TAF through Y8. reREACH-B scores at baseline and over 8Y (384 weeks [W]) were generated. HCC was assessed throughout and hepatic ultrasonography was introduced at W96 and used every 6 months. Patients were stratified into low (<0.01) and high (≥ 0.01) reREACH-B HCC risk categories, reflecting an annual incidence of 0.2%, the cost-effectiveness threshold for HCC surveillance.

Results: Through 8Y of follow-up, HCC occurred in 26/1632 (1.6%) patients (TAF, 14/1093 [1.3%]; TDF, 12/539 [2.2%]). Nine of 26 (35%) patients had cirrhosis at baseline. Patients who developed HCC were older (median age 52Y vs 39Y; $P<.0001$), more often male (89% vs 65%; $P=.0119$), and more likely to have baseline cirrhosis (FibroTest score ≥ 0.75 ; 35% vs 9%; $P<.0001$). At baseline, 547 and 1084 were categorized as low and high risk. Those at high risk and low risk respectively had median age 43Y vs 32Y; 74% vs 47% were male; 57% vs 77% were HBeAg positive; median platelet counts were 174 vs 233 $\times 10^3/\mu\text{L}$; median HBV DNA was 6.7 vs 8.2 log₁₀ IU/mL; and median baseline ALT levels were 89 vs 70 U/L. Over 8Y, 24/1084 (2.2%) baseline high-risk and 2/547 (0.4%) baseline low-risk patients developed HCC. At Y8, mean (range) change from baseline in reREACH-B score was -0.1 (-1.0, 0.1). Notably, 58% and 52% of baseline high-risk patients with available data at Y5 and Y8 transitioned to low risk; only 5% and 8% shifted from low to high risk at Y5 and Y8.

Conclusions: Application of reREACH-B risk scores to data of patients receiving tenofovir-based therapy supports that few patients at low risk for HCC at treatment initiation developed HCC, while many high-risk patients decreased in risk after long-term treatment.

tenofovir alafenamide (TAF), tenofovir disoproxil fumarate (TDF)

1345 - Association of MASLD with Prevalence and Severity of GERD in Primary Care

Minseong Kim¹

Millenium Seoul Im Clinic, Internal Medicine, Incheon-South Korea¹

Background / Hypothesis: Metabolic dysfunction-associated steatotic liver disease (MASLD) is strongly linked to metabolic syndrome, and its association with gastroesophageal reflux disease (GERD) is increasingly reported. Despite shared risk factors, studies directly comparing GERD occurrence and severity in MASLD versus normal liver patients within a single primary care clinic setting using abdominal ultrasound remain limited. This study aimed to investigate the association between MASLD and GERD in a primary care patient cohort.

Materials and Methods: A cross-sectional study was conducted on patients from the Millennium Seoul IM Clinic in Incheon who were diagnosed with MASLD (n=23) by abdominal ultrasound or confirmed to have a normal liver (Control group, n=23). Participants completed a validated questionnaire assessing the prevalence and severity of GERD symptoms. Endoscopic findings were also retrospectively analyzed from medical records.

Results: The MASLD group exhibited a significantly higher overall prevalence of GERD symptoms (60.9% vs. 26.1%, $P=0.020$) compared to the Control group, with significant differences in typical symptoms, including heartburn ($P=0.038$) and acid regurgitation ($P=0.016$). A trend towards greater GERD symptom severity was also noted in the MASLD group ($P=0.014$).

Conclusions: MASLD, diagnosed by abdominal ultrasound in the primary care setting, may represent a significant risk factor for the development of GERD. These findings highlight the need for increased clinical vigilance regarding GERD in MASLD patients and provide foundational evidence for assessing this association in primary care.

Keyword(s) : MASLD, GERD, Primary Care

1347 - Efficacy and safety of tenofovir amibufenamide in patients with chronic hepatitis B An observational study

Jiarui Zheng¹, Yuxuan Song¹, Bo Feng¹, Yandi Xie¹
Peking University Hepatology Institute, Peking University People's Hospital, Beijing-China¹

Background / Hypothesis:

Tenofovir amibufenamide (TMF) is a newly recommended first-line nucleos(t)ide analogues for chronic hepatitis B (CHB) in China. However, real-world evidence on its safety and effectiveness are limited. This research sought to assess the short-term virological efficacy, biochemical response, as well as safety profile of TMF over 24 and 48 weeks in a real-world cohort of CHB individuals.

Materials and Methods:

In this single-center retrospective analysis, 119 treatment-naïve CHB patients were administered TMF at 25 mg daily. Clinical, virological, and biochemical parameters were gathered at baseline and at weeks 12, 24, and 48 for evaluation. The primary effectiveness endpoint was virological response (VR, HBV DNA <10 IU/mL) after 24 weeks of treatment. Secondary endpoints included VR at other timepoints, alanine aminotransferase (ALT) normalization, and changes in renal parameters and lipid levels.

Results:

At week 24, 68.9% (82/119) of patients achieved VR. Multivariate analysis identified lower baseline HBsAg levels and non-cirrhotic status as independent predictors for achieving VR. The ALT normalization rate was 69.5% at week 24, with lower baseline HBsAg and liver stiffness measurement (LSM) being significant associated factors. One patient achieved HBsAg seroclearance. Regarding safety, no adverse events linked to the medication were observed. There were no statistically significant alterations in serum phosphorus, estimated glomerular filtration rate (eGFR), serum creatinine, or lipid levels (triglycerides, total cholesterol, high-density lipoprotein and low-density lipoprotein) from baseline to week 48.

Conclusions:

This real-world cohort analysis showed that TMF treatment achieved effective virological suppression and high ALT normalization rates by week 24, with its efficacy being influenced by baseline HBsAg levels and liver fibrosis status. Furthermore, TMF exhibited a favorable safety profile, characterized by stable renal parameters and lipid levels over 48 weeks. These findings support TMF as a safe and effective treatment alternative in CHB management.

1348 - Activation of the 5 lipoxygenase in myeloid immune cells is associated with systemic inflammation in acute on chronic liver failure

Huilan Tu¹, Ruoqi Zhou¹, Xia Yu¹, Xianbin Xu¹, Xinyi Xu¹, Jiyang Chen¹, Xiuding Zhang¹, Xinxin Liu¹, Ying Hu¹, Jifang Sheng¹, Yu Shi¹

The First Affiliated Hospital, Zhejiang University School Of Medicine, Hangzhou, China, Department Of Infectious Diseases, Hangzhou-China¹

Background / Hypothesis:

Profound systemic inflammation is a hallmark of acute-on-chronic liver failure (ACLF), yet upstream inflammatory circuits remain incompletely defined. 5-Lipoxygenase (5-LOX) and its oxylipin products, including 5-hydroxyeicosatetraenoic acid (5-HETE) and leukotrienes, are emerging mediators of myeloid cell-driven inflammation. We examined whether 5-LOX activation and its metabolites link hepatic and systemic inflammation in ACLF.

Materials and Methods:

We enrolled 26 healthy controls (Ctrl), 31 patients with chronic liver disease (CLD), 33 with decompensated cirrhosis (DC) and 55 with ACLF. Bulk RNA-sequencing of whole-blood leukocytes, purified neutrophils and liver tissue, and liver single-cell RNA-seq in 3 controls, 3 DC and 6 ACLF patients were performed. Targeted oxylipin metabolomics quantified 5-LOX-derived lipid mediators in plasma. 5-LOX pathway score were calculated in deconvoluted leukocyte subsets. Intrahepatic co-localization of 5-LOX+ monocytes/macrophages and neutrophils were assessed by multiplex immunofluorescence. The efficacy of zileuton, an inhibitor of 5-LOX, was tested in a mouse model of liver failure induced by lipopolysaccharide plus D-Galactosamine. The effect of 5-HETE on macrophage polarization were assessed in THP-1-derived macrophages.

Results:

Whole-leukocyte and neutrophil transcriptome showed stepwise increases in 5-LOX related gene set (ALOX5, ALOX5AP, LTA4H, LTC4S, LTB4R) and leukotriene receptor genes with worsening disease and being highest in ACLF. GSVA scores for arachidonic acid and leukotriene pathways displayed similar trends. 5-LOX related gene set was enriched in neutrophils and monocytes/macrophages and strongly correlated with activation markers (S100A8/A9), pro-inflammatory cytokines (IL-1B, TNF, CXCL8) and ACLF severity. Plasma 5-HETE and leukotrienes were markedly

elevated in ACLF and correlated with liver injury and systemic inflammation. A significantly higher level of 5-LOX pathway activation was also seen in the liver of patients with ACLF compared to those of DC and controls, as indicated by hepatic transcriptome and validated by multiple approaches including immunohistochemistry, RT-PCR and Western blotting. The liver of ACLF patients also displayed significantly higher number of 5-LOX+CD14⁺/CD68⁺ macrophages and 5-LOX+MPO⁺ neutrophils as shown by multiplex immunofluorescence. In mice of liver failure, hepatic 5-LOX expression and levels of 5-HETE both in liver and serum were up-regulated. Oral administration of zileuton, an inhibitor of 5-LOX, reduced serum 5-HETE, hepatic 5-LOX and IL-6/IL-1 β expression, as well as liver injury markers and histological damage. In vitro, 5-HETE promoted M1-like polarization and pro-inflammatory cytokine production (IL-6, IL-1 β , TNF- α) in THP-1-derived macrophages.

Conclusions:

5-LOX activation in myeloid immune cell is tightly linked to systemic inflammation and disease severity in ACLF. 5-LOX represents a promising therapeutic target for ameliorating systemic inflammation in ACLF.

Keyword(s) : Acute-on-chronic liver failure; 5-lipoxygenase; 5-HETE; Innate immunity.

1351 - Evaluation Of Hepatitis B Recurrence In Liver Transplant Recipients In Vietnam

Cam Linh Le¹, Van Quang Vu¹, Van Thanh Le¹, Van Linh Ho¹, Hoang Ngoc Anh Nguyen¹

108 Military Central Hospital, Hepato-biliary And Pancreatic Surgery, Ha Noi-Vietnam¹

Background / Hypothesis:

Hepatitis B virus (HBV) is a global public health challenge and a leading cause of end – stage liver disease requiring transplantation. However, HBV recurrence after transplantation can significantly compromise graft function and patient survival. In the context of limited healthcare resources, evaluating the recurrence rate and the current status of prophylactic strategies is essential.

Materials and Methods:

A cross-sectional descriptive study was conducted at the 108 Military Central Hospital (Vietnam) involving 126 patients who underwent LT due to HBV-related liver diseases. Data collected included pre- and post-transplant laboratory results (HBsAg, HBeAg, Anti-HBs, Anti-HBc IgG/IgM, and HBV-DNA) and information regarding prophylactic regimens (use of Hepatitis B Immunoglobulin [HBIG] and nucleos(t)ide analog [NA]).

E-POSTER ABSTRACTS

Results:

Male patients accounted for 89.7%, with a mean age of 54.2 ± 10.8 years. The average follow-up duration after transplantation was 34.4 ± 20.1 months. HCC was the most common indication for LT (48.4%). The HBV recurrence rate was 11.1%. Short-term HBIG prophylaxis following transplantation, in combination with long-term NA therapy, has demonstrated effectiveness in preventing HBV recurrence in this patient population. Notably, only 25.4% of patients were Anti-HBs positive, raising concerns about long-term immunological protection. The use of appropriately dosed HBIG in combination therapy, tailored according to high- and low-risk HBV recurrence groups, should be considered to optimize antibody levels in this patient population, as maintaining HBIG therapy remains a major challenge due to financial burden and supply shortages in Vietnam.

Conclusions:

Oral NA therapy remains an effective prophylactic approach for preventing HBV recurrence after LT, particularly in the context of significant challenges associated with HBIG availability in Vietnam. Strategies to enhance post-transplant Anti-HBs titers – such as selective dosing of HBIG administration – should be considered in long-term post-transplant care.

Keyword(s) : Hepatitis B virus, Liver transplantation, Recurrence, Hepatitis B immunoglobulin, Nucleos(t)ide analog, Prophylaxis.

1354 - Prognostic value of alpha fetoprotein and hepatic reserve in hepatocellular carcinoma patients receiving lenvatinib real world evidence from Dr. Mohammad Hoesin Hospital Palembang

Anton Purnomo¹, Suyata Suyata¹, Imam Suprianto¹, Vidi Orba Busro¹, Muhammad Ayus Astoni¹
Mohammad Hoesin Hospital, Internal Medicine, Palembang-Indonesia¹

Background

Lenvatinib is an established first-line systemic therapy for advanced hepatocellular carcinoma (HCC). Baseline tumor biology and hepatic functional reserve — commonly assessed using alpha-fetoprotein (AFP), Child–Pugh, and ALBI scores — substantially influence treatment tolerance and early disease trajectory. Evidence describing these prognostic markers in Indonesian HCC populations remains limited. This study aimed to characterize baseline AFP status and hepatic reserve among HCC patients who received lenvatinib at Dr. Mohammad Hoesin Hospital

Palembang in 2025, and to examine the relationship between AFP elevation and other clinical or laboratory predictors. We hypothesized that AFP-positive patients constitute the majority and demonstrate poorer pretreatment profiles.

Materials and Methods

Nineteen consecutive HCC patients receiving lenvatinib between January and December 2025 were included. Extracted variables comprised Child–Pugh score, ECOG performance status, MELD score, ALBI score, and serum AFP level. Data cleaning involved conversion of comma-based decimals and exclusion of clearly non-numeric AFP or MELD entries. AFP positivity was defined as ≥ 200 ng/mL. Descriptive analyses were performed due to the absence of radiologic or survival outcomes in the dataset. MELD values were interpreted cautiously because several entries appeared in a nonstandard numerical format.

Results

Of the 19 patients analyzed, AFP values were available for 16 (84%). All evaluable patients exhibited AFP ≥ 200 ng/mL (16/16, 100%), indicating a fully AFP-positive, high-risk biological profile. Median AFP concentration was approximately 2,820 ng/mL, with extreme right-skewed distribution due to very high outliers (two patients with 80,000 ng/mL and one with 2,365,547 ng/mL). Child–Pugh scores demonstrated broad variation: 4 (n=2, 11%), 5 (n=4, 21%), 6 (n=5, 26%), 7 (n=4, 21%), and 9 (n=4, 21%). Most patients had preserved functional status (ECOG 0: 37%; ECOG 1: 53%). Mean ALBI score was -1.92 , reflecting moderate hepatic impairment across the cohort. Excluding the non-numeric entry, MELD values averaged approximately 65.7, though interpretation was limited by the atypical scale recorded in source data. Overall, patients demonstrated a combination of markedly elevated AFP and variable but frequently diminished hepatic reserve.

Conclusions

This real-world lenvatinib cohort from Dr. Mohammad Hoesin Hospital Palembang was characterized by universally elevated AFP, substantial AFP heterogeneity, and moderate hepatic dysfunction at baseline. These features collectively suggest a high-risk population in whom therapeutic response and survival may be strongly influenced by biomarker-driven tumor biology and hepatic reserve. Future studies incorporating radiologic response, adverse events, and survival outcomes are warranted to clarify the prognostic impact of AFP and liver function indices in

1355 - Adipocyte derived Extracellular Vesicles Propagate Hepatic Metabolic Inflammation Remaining characters

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

The progression of metabolic dysfunction-associated fatty liver disease (MAFLD) is driven by complex organ crosstalk. While adipose tissue inflammation is a known key driver, the precise mechanisms by which it instigates hepatic injury remain elusive. We hypothesized that adipocyte-derived extracellular vesicles (Ad-EVs) serve as critical "messengers" transporting pro-inflammatory and pro-fibrotic cargos from adipose tissue to the liver, thereby accelerating MAFLD pathogenesis.

We employed a translational approach. In vitro, Ad-EVs were isolated from the supernatant of TNF- α -treated 3T3-L1 adipocytes and applied to primary mouse hepatocytes and hepatic stellate cells (HSCs). In vivo, we utilized a diet-induced obesity mouse model, administering fluorescently labelled Ad-EVs to track their hepatic uptake. A prospective human cohort of 120 individuals with obesity and varying degrees of MAFLD severity (assessed by biopsy/VCTE) was enrolled. Plasma Ad-EVs were isolated, quantified by nanoparticle tracking analysis, and their miRNA cargo was profiled by sequencing.

In vitro, Ad-EVs from inflamed adipocytes were readily taken up by hepatocytes and HSCs. This triggered hepatocyte insulin resistance and apoptosis, and activated HSCs into a pro-fibrotic phenotype. In vivo, injected Ad-EVs preferentially accumulated in the liver. Mice receiving Ad-EVs from obese donors developed significantly worse hepatic steatosis, inflammation, and fibrosis compared to controls ($p < 0.01$). In the human cohort, plasma levels of Ad-EVs were significantly elevated in patients with steatohepatitis (NASH) and advanced fibrosis ($p < 0.001$). miRNA sequencing identified a specific signature, most notably a high miR-155-5p cargo in Ad-EVs, which strongly correlated with histological severity ($r = 0.67$, $p < 0.001$) and was an independent predictor of fibrosis stage in multivariable analysis.

Our findings establish adipocyte-derived extracellular vesicles as a novel and critical pathway in the liver.

adipose tissue axis, directly propagating metabolic inflammation and fibrosis in MAFLD. The identification of a specific Ad-EV miRNA signature, particularly miR-155-5p, offers a novel mechanistic insight and a promising, accessible liquid biopsy biomarker. This discovery paves the way for novel public health strategies targeting inter-organ communication to prevent and halt MAFLD progression in at-risk populations.

1357 - Expression of the FCGBP Gene in Hepatocellular Carcinoma Tissues and Its Role in Prognostic Assessment

Hang Wang¹, Bobin Hu¹, Jianning Jiang¹

The First Affiliated Hospital Of Guangxi Medical University, Department Of Infectious Diseases, Nanning-China¹

Background / Hypothesis:

[Abstract] Objective: To investigate the expression of the Fc fragment of IgG-binding protein (FCGBP) gene in hepatocellular carcinoma (HCC) and its impact on clinical prognosis, as well as to preliminarily analyze FCGBP variations and molecular biological functions.

Materials and Methods:

Methods: FCGBP expression data and clinical information of HCC patients were obtained from the TCGA database, and the expression levels in tumor, adjacent non-tumor, and normal tissues were compared. Cox regression analysis was used to identify risk factors affecting the prognosis of HCC patients, and the Kaplan-Meier method was applied to analyze the relationship between FCGBP expression levels and prognosis in HCC patients. Log-rank test was used to examine survival differences between high and low FCGBP expression groups. cBioPortal online software was used to analyze FCGBP mutations, and a protein-protein interaction network for FCGBP was constructed using the STRING database, followed by GO and KEGG enrichment analyses to elucidate its molecular biological functions.

Results:

Results: FCGBP expression levels were higher in liver cancer tissues than in adjacent non-tumor and normal tissues ($P < 0.05$); FCGBP levels were also higher in

E-POSTER ABSTRACTS

hepatitis B virus (HBV)-related liver cancer compared to non-HBV-related liver cancer ($P < 0.05$). FCGBP expression levels were associated with tumor histological grade, vascular invasion, prognostic outcome, and primary tumor stage ($P < 0.05$). Primary tumor stage, tumor size, and FCGBP expression levels were independent prognostic factors for HCC patients, with higher FCGBP expression associated with poorer prognosis (HR=1.47, 95%CI: 1.04–2.08, $P < 0.05$). The mutation rate of FCGBP in HCC patients was 3.4%, with poorer prognosis observed in mutated cases. Enrichment results indicated that FCGBP mainly participates in biological functions such as cell proliferation and division, cell-matrix adhesion, and transcriptional regulation. Immune infiltration analysis showed that FCGBP is associated with the infiltration of various immune cell types.

Conclusions:

FCGBP expression is upregulated in HCC, with notably high expression specifically in HBV-related liver cancer. HCC patients with high FCGBP expression and FCGBP mutations have poorer prognosis. FCGBP may serve as a potential biomarker for poor prognosis in HCC patients.

1358 - CORRELATION OF INTERLEUKIN 17 SERUM LEVELS WITH DEGREE OF LIVER FIBROSIS IN CHRONIC HEPATITIS B PATIENTS AT MOHAMMAD HOESIN HOSPITAL PALEMBANG

Lingga Gumelar¹, Suyata Suyata¹, Imam Suprianto¹, Vidi Orba Busro¹, Ayus Astoni¹, Anjab Sya'roni¹, Fahri Indra²
Sriwijaya University, Gastroenterohepatology, Palembang-Indonesia¹ Sriwijaya University, Internal Medicine, Palembang-Indonesia²

Background / Hypothesis:

Chronic hepatitis B (CHB) is a major global cause of progressive liver disease, and immune-mediated hepatic inflammation plays a critical role in driving fibrosis. Interleukin-17 (IL-17), a key cytokine produced by Th17 cells, has been implicated in hepatocellular inflammation, fibrogenesis, and disease progression in chronic liver disorders. However, data on the association between circulating IL-17 levels and liver stiffness in CHB patients remain limited. This study aimed to evaluate the correlation between serum IL-17 levels and the degree of liver fibrosis assessed using

transient elastography

Materials and Methods:

We conducted an analytical observational study with a cross-sectional design among patients with CHB at Dr. Mohammad Hoesin Hospital Palembang. Subjects were enrolled through consecutive non-probability sampling. Serum IL-17 levels were quantified, and liver fibrosis was measured using FibroScan®. Continuous variables were summarized as means and ranges. The correlation between IL-17 serum levels and liver stiffness values was analyzed using Spearman's rank correlation coefficient

Results:

A total of 40 patients were included, with a mean age of 37 years (range 22–60 years). The majority were male (75%). Serum IL-17 levels and liver stiffness values were both treated as numerical variables. Spearman's analysis demonstrated a statistically significant positive correlation between serum IL-17 concentration and liver stiffness ($r = 0.388$; $p = 0.013$).

Conclusions:

Serum IL-17 levels show a significant positive correlation with liver fibrosis severity in patients with chronic hepatitis B. IL-17 may serve as a useful non-invasive biomarker to complement elastography in assessing fibrotic progression, especially in patients in whom liver biopsy is not feasible.

Keyword(s) : interleukin-17; liver fibrosis; chronic hepatitis B; transient elastography; FibroScan

1360 - Gender specific clinical characteristics and care cascade of HCV in east China a multicenter retrospective study

Honglian Gui¹, Junyan Hu¹, Ziqiang Li¹, Ruidong Mo¹, Qing Xie¹

Ruijin Hospital, Shanghai Jiao Tong University School Of Medicine, Department Of Infectious Diseases, Shanghai-China¹

Background / Hypothesis:

Gender equality and women's empowerment is one of WHO's commitment. Data on the current health care status in HCV-infected women is limited. We aimed to figure out gender-specific clinical characteristics and cascade of HCV care in east China, which is crucial for

E-POSTER ABSTRACTS

individualized diagnosis and treatment cascade in all HCV patients.

Materials and Methods:

A multicenter, retrospective study was conducted on HCV-infected adults in east China, enrolling patients who tested positive for HCV RNA from three tertiary hospitals between Jan. 2021 and Dec. 2023. Individuals with HBV/HCV co-infection, a history of hepatic decompensation or HCC, other types of carcinomas, severe comorbidities, prior exposure to NS5B/NS5A inhibitors, or incomplete key data were excluded. The characteristics, time interval from diagnosis to treatment, treatment rates, and sustained virologic response at 12 weeks among eligible female and male patients were utilized to analyze the cascade of care.

Results:

A total of 1,052 cases were analyzed: 456 females and 596 males. HCV genotypes were identified in 976 cases: 52.5% of females had genotype 1, while males predominantly had non-1 genotypes, including 29.9% type 3 and 22.5% type 6. The severity of liver disease assessed by the fibrosis-4 score was comparable between genders. Treatment rates were nearly identical, with 96.9% of females and 95.8% of males. Notably, asymptomatic individuals not receiving antiviral therapy were largely unaware of their risk for disease progression. Among those treated, 10.2% of females and 10.3% of males experienced a delay exceeding six months from diagnosis to treatment. Furthermore, the proportion of females who delayed treatment due to specific objective factors—such as childbirth, relapse following interferon therapy, and the COVID-19 pandemic—was higher than that of males (37.8% vs. 15.3%). The incidence of premature therapy discontinuation was lower among females compared to males (2.3% vs. 10.7%). Consequently, the SVR12 rate was higher in females than in males, at 97.3% versus 89.3%. The follow-up rate of post-SVR in specialty clinics and/or health examination centers was also higher among females compared to males (89.8% vs. 79.0%).

Conclusions:

Women with HCV infection can access the same healthcare services as men in east China. The treatment willingness is similar across genders; however, women are more prone to postponing treatment due to specific objective factors. Upon treatment initiation,

women show higher rates of disease control and follow-up compared to men. These findings may indicate differences in health literacy levels, which influence disease outcomes and treatment adherence.

Keyword(s) : HCV infection; gender-specific; care cascade; clinical characteristic; treatment adherence

1363 - Combination therapy with HT 101 and HT 102 achieves rapid and progressive HBsAg loss in HBeAg negative nucleos(t)ide analogues suppressed patients 24 week results from an ongoing multicentre open label phase Ib/IIa study

Xieer Liang ¹, Liang Chen ², Jianmei Lin ³, Bei Zhong ⁴, Huiqing Liang ⁵, Wen Xie ⁶, Yujuan Guan ⁷, Zhihong Liu ¹, Xun Qi ², Dong Wang ⁸, Zhipeng Zhang ⁸, Lijuan Ding ⁸, Zhiping Cui ⁸, Huaie Song ⁸, Kun Yue ⁸, Jinlin Hou ¹
Nanfang Hospital, southern Medical University, Department Of Infectious Diseases, Guangzhou-China ¹ Shanghai Public Health Clinical Centre, Liver Disease Department, Shanghai-China ², Sichuan Provincial People's Hospital, Infectious Diseases Department, Chengdu-China ³ Qingyuan People's Hospital, Infectious Diseases Department, Qingyuan- ⁴ Xiamen Traditional Chinese Medicine Hospital, Infectious Diseases Department, Xiamen- ⁵, Beijing Ditan Hospital, Liver Disease Department, Beijing- ⁶, Guangzhou Eighth People's Hospital, Liver Disease Department, Guangzhou- ⁷ Hepa Thera Biotech Company, , Shangghai- ⁸

Background / Hypothesis:

HT-101 is an N-acetylgalactosamine (GalNAc)–conjugated small interfering ribonucleic acid (siRNA) targeting the S-region of the HBV genome that demonstrated durable reductions in hepatitis B surface antigen (HBsAg) in phase 1 study. HT-102 is a human monoclonal antibody against the antigenic loop of HBsAg that achieved rapid serum HBsAg decline in phase 1. We report 24-week on-treatment data from an ongoing phase Ib/IIa study in China (NCT07183306/CTR20244730) evaluating the safety and efficacy of HT-101 and HT-102 combination treatment, compared with monotherapy.

Materials and Methods:

This multicentre, open-label, partial dose-escalation study enrolled HBeAg-negative patients with stable nucleos(t)ide analogue (NA) background treatment with serum HBsAg 100–3,000 (Median 671) IU/mL. Participants were assigned to five groups: A, HT-101

E-POSTER ABSTRACTS

400 mg alone; B, Sequential HT-102 300mg followed by HT-101 400 mg; C, HT-101 100mg+HT-102 300mg; D, HT-101 200mg+HT-102 300mg and E, HT-101 400mg+HT-102 300mg. HT-101 and/or HT-102 were administered subcutaneously every 4 weeks for at least 24 weeks. Follow-up planned to 48 weeks post-therapy. Primary endpoint was the incidence of treatment-emergent adverse events (TEAEs). Secondary endpoints included HBsAg kinetics, virological and pharmacodynamics markers, pharmacokinetics, and immunogenicity.

Results:

All participants (Groups A-E) completed 24 weeks of treatment with HT-101 and/or HT-102 (Figure A). At Week 24, HBsAg seroclearance was achieved in 4/20 (20%) participants in group A, 0/8 (0%) in Group B, 5/8 (63%) in Group C, 8/10 (80%) in Group D and 9/10 (90%) in Group E, respectively (Figure B). Among all subjects with combination therapy (Groups C-E), at Week 24 end of treatment (EOT), 22/28 (79%) achieved HBsAg loss. EOT response rates were associated with baseline HBsAg levels: 14/14 (100%) of participants with baseline HBsAg <1,000 IU/mL achieved HBsAg loss, compared with 8/14 (57%) of those with baseline HBsAg ≥1,000 IU/mL, in which HBsAg loss showed a clear dose-dependent effect: Group C: 1/4 (25%), Group D: 2/4 (50%), and Group E: 5/6 (83%). Notably, One additional subject in each of Groups B and C attained HBsAg loss by Week 28. Treatment was well-tolerated: most TEAEs being Grade 1–2 (e.g., injection site reactions). No drug-related serious AEs, grade ≥3 events, ALT flares, or other safety signals were observed.

Conclusions:Combination therapy with HT-101 and HT-102 in CHB patients achieved rapid serum HBsAg reduction and a high rate of HBsAg loss at EOT with a favourable safety profile. These findings support continued development of HT-101 and HT-102 as a promising strategy toward achieving functional cure of HBV.

1364 - Exploring the Impact of Gut Microbiota on Itch in Cholestasis

Chengxuan Yao¹, Xiangji Guo², Rui Zhao¹, Shuiweizhi Dai¹, Huaibin Zou³, Yu Chen³

Beijing Youan Hospital, Capital Medical University, Beijing Key Laboratory Of Liver Regeneration And Artificial Liver Transformation Research, Beijing-China¹

Basic Medical Sciences, Chinese Academy Of Medical Sciences And School Of Basic Medicinepeking Union Medical College, Molecular Biology And Biochemistry, State Key Laboratory Ofcommon Mechanism Research For Major Diseases, Beijing-China² Beijing Youan Hospital, Capital Medical University, Fourth Department Of Liver Disease Center, Beijing-China³

Background / Hypothesis:In cholestatic liver disease, pruritus is one of the most common symptoms in chronic patients, which significantly reduces the quality of life, and even has adverse consequences such as depression and suicide. The role of gut microbiota in this process cannot be ignored. The role of intestinal flora cannot be ignored. The purpose of this study was to explore the potential mechanism of intestinal flora in cholestasis-related pruritus.

Materials and Methods:Fecal samples were collected from 13 patients with cholestasis (6 patients with pruritus and 7 patients without pruritus) for metagenomic sequencing and bioinformatics analysis.

Results:Principal coordinates analysis (PCoA) showed that there was a significant difference in microbial composition between the pruritus group and the non-pruritus group. Compared with the non-pruritus group, the microbial diversity of the pruritus group was significantly increased. Further focusing on the species, we identified two groups of species with significant differences at the species level ($P < 0.05$), and selected the top 20 species with the most significant differences to perform correlation analysis with the patient 's serum total bile acid (TBA). It can be seen that coprococcus sp. Am11-30b is significantly negatively correlated with TBA, while multiple species of veillonella are significantly positively correlated with TBA . In order to clarify the mechanism pathway, we enriched and compared the differential strains of the two groups, and found that the key pathways of bile acid metabolism increased significantly in the pruritus group, which was consistent with the functional spectrum of the identified differential strains.

Conclusions:In summary, in the environment of cholestasis, the intestinal flora of some patients showed structural remodeling and increased diversity, which may be a key factor in the occurrence of pruritus in patients. The correlation between different strains and TBA showed that gut microbiota may lead to pruritus through bile acid regulation, which was supported by the enrichment of bile acid metabolic pathway in pruritus group. Future studies can further

E-POSTER ABSTRACTS

explore the specific mechanism of these metabolic pathways in the occurrence of pruritus and provide new biomarkers or therapeutic targets.

1365 - Sequential combination therapy of PD1 antibody and PEG IFN α promotes HBsAg clearance and the restoration of specific T cell response

Hongmin Wang¹, Xin Zhang², Kaili Wang³, Sa Lv³, Fusheng Wang², Junliang Fu²

University Of Science And Technology Of China, The First Affiliated Hospital Of Ustc, Hefei-China¹ The Fifth Medical Center Of Chinese PLA General Hospital, Senior Department Of Infectious Diseases, Beijing-China² The Fifth Medical Center Of Chinese PLA General Hospital, Senior Department Of Hepatology, Beijing-China³

Background / Hypothesis:

While PD-1/PD-L1 blockade is a promising therapeutic strategy for chronic hepatitis B (CHB), its efficacy in achieving functional cure remains limited. This study aimed to evaluate the novel combination strategy—PD-1 antibody combined with PEG-IFN α therapy—to promote functional cure through restoration of HBV-specific immune responses.

Materials and Methods:

In this single-arm trial (NCT06457477), 10 CHB patients with HBsAg ≤ 200 IU/ml were received PD-1 antibody monotherapy for 12 weeks. PEG-IFN α was added if HBsAg declined <1 log from baseline, and continued until week 48. The maximum duration of PD-1 antibody treatment was 24 weeks. HBV-specific T-cell responses were assessed ex vivo using three-color FluoroSpot (IFN- γ , IL-2, TNF- α). Plasma inflammation-related proteins were quantified by Olink proximity extension assay.

Results:

A total of 10 patients were enrolled in this study. Among them, 9 patients completed the protocol, while 1 patient withdrew at week 6. Three patients achieved HBsAg loss at week 9 after PD-1 antibody monotherapy (Group A). Six were added PEG-IFN α in treatment at week 12; among them, three achieved HBsAg loss at week 24–30 (Group B), while three remained HBsAg-positive (Group C). Throughout the study period, no fatal adverse events were recorded. In Group A, ALT showed a sharply flare and was associated with HBsAg rapidly clearance or decline during PD-1 antibody monotherapy, and accompanied

by significant increased HBsAg-specific IL-2 response. In Group B and C, PEG-IFN α treatment shows a gradual and sustained ALT elevation, and was not related to HBsAg changes. In Group B, HBV-specific T-cell responses increased during PD-1 monotherapy and were maintained after PEG-IFN α addition, while in Group C, patients showed minimal improvement in HBV-specific T cell response. Plasma cytokine levels were remained stable during PD-1 monotherapy but increased (e.g., TNF, IL-6, IL-10, IL-18) following PEG-IFN α combination.

Conclusions:

PD-1 antibody added in PEG-IFN α treatment enhances HBV-specific T-cell responses and promotes HBsAg loss, providing a promising immunomodulatory strategy toward CHB functional cure.

Keyword(s) : PD-1 antibody, PEG-IFN α , HBsAg clearance, Specific T-cell response

1366 - Spatial Transcriptomics Uncovers Niche Driving Liver Fibrosis Remaining characters

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

Liver fibrosis is a reversible yet critical pathological stage in chronic liver disease progression. The complex cellular ecosystem and spatial interactions that dictate the transition from inflammation to fibrosis remain poorly mapped. We hypothesized that a specific periportal inflammatory niche, characterized by unique intercellular communication, is a critical driver of progressive fibrosis and holds actionable targets for intervention.

We integrated spatial transcriptomics (10x Genomics Visium) with single-cell RNA sequencing (scRNA-seq) on liver biopsies from a prospective cohort of 60 patients with Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) across the fibrosis spectrum (F0-F4). Cell-cell communication was computationally inferred and validated by multiplex immunofluorescence (mIF) and in situ hybridization. Functional validation was performed in a carbon tetrachloride (CCl₄)-induced murine fibrosis model using targeted cytokine blockade.

Spatial transcriptomics revealed a previously unrecognized "Fibrogenic Niche" enriched in portal tracts of progressive fibrosers. This niche was defined by the colocalization of a specific subset of PDGFR α + fibroblasts, *S100A9+* pro-inflammatory macrophages, and *CXCR6+* T cells. scRNA-seq deconvolution identified a distinct fibroblast

E-POSTER ABSTRACTS

subpopulation, termed "Niche Anchor Cells (NACs)", which highly expressed COMP and POSTN. NACs were the hub of a pro-fibrotic signaling network, primarily through a strong spatial interaction with macrophages via the *MDK-SORL1* ligand-receptor pair. In the murine model, disruption of this axis using a Midkine (MDK) neutralizing antibody significantly attenuated collagen deposition and reduced myofibroblast activation compared to controls ($p < 0.005$). In our cohort, the spatial signature of this niche strongly predicted 3-year fibrosis progression (AUC=0.91). Our study provides the first high-resolution spatial map of human liver fibrosis, identifying a pathogenic peri-portal niche that acts as an engine for disease progression. We functionally validate the *MDK-SORL1* axis as a novel and targetable driver of fibrogenesis. From a public health perspective, this spatial signature offers a powerful prognostic tool for risk stratification, while the identified targets pave the way for developing precise, niche-directed anti-fibrotic therapies to alleviate the growing burden of chronic liver diseases.

Keyword(s) : Spatial Transcriptomics, Fibrogenic Niche, Cell-Cell Communication, MASLD, Precision Medicine, Anti-fibrotic Therapy

1367 - TCM Constitution Types Predict MAFLD Risk and Pathology Remaining characters

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

Traditional Chinese Medicine (TCM) constitution theory postulates that individuals with specific innate body types (e.g., Dampness-Heat, Phlegm-Dampness, Qi Deficiency) are predisposed to certain diseases. We hypothesized that these TCM constitution types can serve as novel, holistic risk indicators for Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD), correlating with distinct clinical and pathological features.

A multi-center, cross-sectional study was conducted. 1,200 participants were recruited and classified into one of the nine TCM constitution types using the standardized Constitution in Chinese Medicine Questionnaire (CCMQ). All participants underwent comprehensive assessment: abdominal ultrasonography for hepatic steatosis, liver stiffness measurement (LSM) via VCTE for fibrosis, and detailed serum metabolomic profiling. Multivariate logistic regression was used to analyze the association between constitution types and MAFLD, adjusting for age, sex, and BMI.

The Phlegm-Dampness (odds ratio [OR]=3.52, 95% CI: 2.41-5.15) and Dampness-Heat (OR=2.85, 95% CI: 1.98-4.10) constitutions were identified as strong independent risk factors for MAFLD. Participants with these constitutions exhibited significantly higher LSM values ($p < 0.01$) and a greater prevalence of advanced fibrosis (LSM ≥ 10 kPa) compared to the Balanced (Gentle) constitution. Metabolomic analysis revealed distinct serum profiles: the Phlegm-Dampness type was characterized by elevated branched-chain amino acids and dysregulated bile acid metabolism, while the Dampness-Heat type showed signatures of heightened inflammation and oxidative stress. A model integrating TCM constitution with BMI demonstrated superior predictive power for MAFLD (AUC=0.84) compared to BMI alone (AUC=0.76).

This study provides the first large-scale evidence that TCM constitution types are robustly associated with MAFLD risk, severity, and specific metabolic disturbances. It validates traditional wisdom with modern scientific data, positioning TCM constitution as a valuable, low-cost tool for public health. Integrating constitutional assessment into primary care could enable early, personalized risk stratification and lifestyle interventions for MAFLD prevention, embodying a truly holistic and predictive healthcare model.

Keyword(s) : Traditional Chinese Medicine, Constitution Types, MAFLD, Risk Prediction, Precision Prevention, Metabolomics

1368 - Phlegm Dampness Constitution Alters Gut Microbiome in MAFLD

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

The Phlegm-Dampness (PD) constitution in Traditional Chinese Medicine (TCM) is strongly associated with metabolic disorders, including Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD). We hypothesized that the PD constitution harbors a distinct gut microbiome profile that contributes to MAFLD pathogenesis through altered gut-liver axis signaling, providing a mechanistic link between TCM theory and modern pathophysiology.

We conducted a case-control study nested within a prospective cohort of 850 adults with MAFLD. Participants were rigorously classified into TCM constitutions using the Constitution in Chinese Medicine Questionnaire (CCMQ). Fecal samples from 150 PD and 150 Balanced (BL) constitution individuals, matched for age, sex, and BMI, underwent shotgun

E-POSTER ABSTRACTS

metagenomic sequencing. Serum was analyzed for metabolomics. All participants underwent vibration-controlled transient elastography (VCTE) to assess liver stiffness.

Individuals with PD constitution had significantly higher liver stiffness measurements (6.8 kPa vs 5.1 kPa, $p < 0.001$) and higher rates of significant fibrosis (LSM ≥ 8 kPa) compared to the BL group (22% vs 8%, $p < 0.01$). Metagenomic analysis revealed a robust PD-associated gut microbiome signature characterized by:

1. Enrichment of pro-inflammatory species (*Escherichia coli*, *Klebsiella pneumoniae*).

2. Depletion of beneficial, short-chain fatty acid producers (*Faecalibacterium prausnitzii*, *Akkermansia muciniphila*).

This dysbiotic PD signature was associated with: Reduced microbial gene richness and butyrate synthesis capacity.

Increased serum levels of lipopolysaccharide (LPS) and bile acids.

A machine learning model based on 15 microbial species accurately discriminated PD from BL constitution (AUC=0.82). Mediation analysis confirmed that the gut microbiome composition significantly mediated the association between PD constitution and liver fibrosis severity ($p < 0.05$).

Our findings provide the first evidence that the TCM Phlegm-Dampness constitution is characterized by a pro-inflammatory, dysbiotic gut microbiome that contributes to MAFLD severity via the gut-liver axis. This bridges TCM theory with molecular pathogenesis, identifying the gut microbiome as a potential therapeutic target for individuals with PD constitution. It paves the way for a novel, microbiota-based precision medicine approach to MAFLD management rooted in TCM principles.

1369 - Qi Stagnation Constitution Primes Pro inflammatory Liver Macrophages Remaining characters

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

The Qi-Stagnation (QS) constitution in Traditional Chinese Medicine reflects a state of chronic stress and emotional dysregulation, clinically associated with chronic inflammatory conditions. We hypothesized that individuals with QS constitution exhibit a primed,

hyper-inflammatory state in hepatic macrophages, creating a permissive microenvironment for accelerated liver injury in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD). In a multi-center cohort of 680 biopsy-proven MASLD patients, TCM constitution was assessed via the standardized CCMQ. Peripheral blood mononuclear cells (PBMCs) and liver biopsy samples were analyzed using single-cell RNA sequencing (scRNA-seq) from matched QS (n=35) and Balanced (BL, n=35) individuals. Macrophage subsets were characterized, and their inflammatory responses to LPS stimulation were assessed. Serum neuro-immune markers (e.g., substance P, NPY) were quantified.

The QS constitution was independently associated with higher NAFLD Activity Scores (NAS) and more severe lobular inflammation ($p < 0.01$). scRNA-seq of liver tissues revealed a significant expansion of a specific macrophage subcluster, termed "Inflammation-Primed Macrophages" (IPM), in QS individuals. IPMs exhibited a unique transcriptomic signature with upregulated genes in both inflammatory pathways (e.g., NFKB1, IL1B) and neurotransmitter signaling (e.g., TACR1, encoding substance P receptor). In vitro, PBMC-derived macrophages from QS subjects showed heightened IL-6 and TNF- α production upon LPS challenge. Serum levels of substance P were elevated in the QS group and positively correlated with IPM abundance in the liver ($r = 0.72$, $p < 0.001$). A neural-liver axis was suggested by the co-localization of substance P-positive nerve fibers and IPMs in portal areas.

This study provides pioneering evidence that the TCM Qi-Stagnation constitution is linked to a primed, hyper-reactive macrophage phenotype in MASLD, potentially mediated by neuro-immune crosstalk. It mechanistically connects emotional stress-related constitution with liver inflammation, offering a novel biological basis for personalized management strategies that incorporate mind-body interventions and neuro-immune modulation for MASLD patients with this specific constitution.

1370 - Qi Stagnation Constitution Primes Pro inflammatory Liver Macrophages Remaining characters

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

The Qi-Stagnation (QS) constitution in Traditional

E-POSTER ABSTRACTS

Chinese Medicine reflects a state of chronic stress and emotional dysregulation, clinically associated with chronic inflammatory conditions. We hypothesized that individuals with QS constitution exhibit a primed, hyper-inflammatory state in hepatic macrophages, creating a permissive microenvironment for accelerated liver injury in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD).

In a multi-center cohort of 680 biopsy-proven MASLD patients, TCM constitution was assessed via the standardized CCMQ. Peripheral blood mononuclear cells (PBMCs) and liver biopsy samples were analyzed using single-cell RNA sequencing (scRNA-seq) from matched QS (n=35) and Balanced (BL, n=35) individuals. Macrophage subsets were characterized, and their inflammatory responses to LPS stimulation were assessed. Serum neuro-immune markers (e.g., substance P, NPY) were quantified.

The QS constitution was independently associated with higher NAFLD Activity Scores (NAS) and more severe lobular inflammation ($p < 0.01$). scRNA-seq of liver tissues revealed a significant expansion of a specific macrophage subcluster, termed "Inflammation-Primed Macrophages" (IPM), in QS individuals. IPMs exhibited a unique transcriptomic signature with upregulated genes in both inflammatory pathways (e.g., NFKB1, IL1B) and neurotransmitter signaling (e.g., TACR1, encoding substance P receptor). In vitro, PBMC-derived macrophages from QS subjects showed heightened IL-6 and TNF- α production upon LPS challenge. Serum levels of substance P were elevated in the QS group and positively correlated with IPM abundance in the liver ($r = 0.72$, $p < 0.001$). A neural-liver axis was suggested by the co-localization of substance P-positive nerve fibers and IPMs in portal areas. This study provides pioneering evidence that the TCM Qi-Stagnation constitution is linked to a primed, hyper-reactive macrophage phenotype in MASLD, potentially mediated by neuro-immune crosstalk. It mechanistically connects emotional stress-related constitution with liver inflammation, offering a novel biological basis for personalized management strategies that incorporate mind-body interventions and neuro-immune modulation for MASLD patients with this specific constitution.

1371 - 消耗流量 707字 单词846 5000 字符 Multi omics analysis reveals key mediators of 90 day prognostic predictive value in patients with acute

on chronic liver failure

Ying Xiao¹, Yadong Wang¹, Caiyan Zhao¹

The Hebei Medical University Third Hospital, Infectious Disease, Shijiazhuang-China¹

Background/Hypothesis: Acute-on-chronic liver failure (ACLF) is a critical clinical syndrome regulated by many molecules, but the effect of gene and metabolite interaction on 90-day prognosis and predictive value are not clear. In this study, based on multi-omics integration strategy, we screened and validated the expression changes of key molecules in ACLF patients with different prognoses, providing a reference basis for clinical prediction of clinical outcomes and targeted intervention of ACLF.

Materials and Methods: In this study, gene expression Omnibus (GEO) dataset was used to select differentially expressed genes (DEGs) significantly associated with the prognosis of ACLF patients, and untargeted metabolomics was used to detect differentially expressed metabolites (DEMs) in 17 ACLF patients hospitalized in our hospital from January 2023 to December 2024 to construct DEG-DEM co-expression network, and core association pairs and regulatory pathways were identified in combination with functional enrichment analysis. Fasting venous blood was collected from 58 patients with ACLF during the same period. DEG expression was detected by ELISA, and DEM content was quantitatively analyzed by amino acid-targeted metabolomics technique. Patients were divided into survival group and death group according to their survival status at 90 days after ACLF diagnosis, and receiver operating characteristic (ROC) curves were plotted, combined with binary logistic regression to analyze the predictive value of influencing factors for the risk of 90-day death in ACLF patients.

Results: A total of 102 DEGs associated with ACLF prognosis were screened from two public datasets, and 302 serum DEMs were identified by untargeted metabolomics. Combined transcriptome and metabolome analysis confirmed that MAPK14 and L-arginine were differentially expressed in the ACLF group compared with the cirrhotic group and were co-enriched in the TNF signaling pathway. The results of clinical validation showed that 23 of 58 patients (39.66%) with ACLF died within 90 days, and the serum MAPK14 level (18.84 ± 12.87 pg/mL) and L-arginine content (22.81 ± 11.93 μ mol/L) in this group were significantly higher than those in the good prognosis group (AUC = 0.720/0.871, $P < 0.05$), and multivariate analysis confirmed that both were independent risk

E-POSTER ABSTRACTS

factors for 90-day death in ACLF patients.

Conclusions: MAPK14 and L-arginine are independent predictors of 90-day mortality risk in patients with ACLF, which may be involved in the inflammatory imbalance and disease progression of ACLF by synergistically regulating the function of the funeral pathway.

1372 - Survival Outcomes and Prognostic Nomogram in Primary Hepatic Angiosarcoma Insights From a Population Based Analysis

Ahmed Almezaine¹, Safaa Abdelhalim²

Tanta General Hospital, Internal Medicine, Tanta-Egypt

¹ Menia University, Git & Tropical, Menia-Egypt ²

Background: Primary hepatic angiosarcoma (PHA) represents an exceptionally rare malignant liver tumor, accounting for nearly 1% of primary hepatic cancers. Its aggressive biological behavior, vague clinical presentation, and rapid progression contribute to its extremely poor prognosis, with median survival typically under six months. Owing to the scarcity of cases, comprehensive survival-related evidence remains limited. This study aims to characterize the demographic and tumor-related features of PHA and to construct a predictive nomogram to estimate overall survival (OS) and disease-specific survival (DSS).

Materials and Methods: Data for patients diagnosed with PHA between 2000 and 2021 were retrieved from the Surveillance, Epidemiology, and End Results (SEER) database. Individuals with incomplete or missing vital-status information were excluded. Patients were stratified based on demographic characteristics, tumor features, and treatment modalities. Kaplan–Meier methods were used to assess differences in OS and DSS, while univariate and multivariate Cox analyses identified independent prognostic variables. A nomogram predicting 6-month and 1-year survival was developed from the final multivariate model.

Results: A total of 316 patients with PHA were included, with a mean age of 62.2 years. Males constituted 35% of the cohort and demonstrated significantly higher 5-year OS compared with females (11.1% vs. 3.4%, $P < .001$). In older adults, survival among patients treated

with combined surgery and chemotherapy was comparable to those receiving chemotherapy alone. However, patients who did not undergo chemotherapy had markedly worse survival than those who did (5-year OS: 3.7% vs. 9.9%, $P < .001$). Sex, age, race, and tumor grade were independently associated with OS and DSS. The constructed nomograms showed reliable discrimination, with C-index values of 0.654 for OS and 0.662 for DSS, supported by well-aligned calibration curves.

Conclusions: PHA continues to carry an extremely poor prognosis. Chemotherapy and surgery appear to offer survival advantages in selected patient groups. The prognostic nomograms developed in this study provide a practical and accurate tool for estimating individualized survival probability and may support clinical decision-making for this rare and aggressive malignancy.

1373 - Constructing and Implementing a New Model for Viral Hepatitis Screening in Guangzhou's Primary Communities

Bo Li¹, Aiqi Lu¹, Ze Huang¹, Ying Tan¹, Lihua Lin¹, Songlian Liu¹, Ganqiu Lin¹, Qikai Ning¹, Jiewei Liu², Huanhui Liang², Jianping Li¹, Yujuan Guan¹

Guangzhou Eighth People's Hospital, Guangzhou Medical University, Center For Liver Disease, Guangzhou-China ¹ Baiyun Guangzhou Center For Disease Control And Prevention, , Guangzhou-China ²

Background / Hypothesis:

The study aimed to establish and evaluate a novel community-based screening and management model in Guangzhou, focusing on improving early detection and standardized treatment for hepatitis B (HBV) and hepatitis C (HCV). A novel grass-root community screening and management model of hepatitis B (HBV) and hepatitis C (HCV) was developed in order to improve the diagnosis and treatment rate of HBV and HCV in Guangzhou city.

Materials and Methods:

A three-tier collaborative framework [tertiary hospitals-center for disease control and prevention (CDC) -primary care clinics] implemented dual-track screening (fixed-site+mobile units) using rapid screening through HBsAg/HCV-Ab dual testing and structured surveys. Digital closed-loop management integrated screening, referral, and follow-up. Data

E-POSTER ABSTRACTS

were analyzed via SPSS 26. 0.

Results:

Among 30012 community-dwelling adults screened (Male:Female=1:1.68), overall positivity rate was 5.61% (1,669/30,012), peaking in the 50-59-year cohort ($\chi^2=321.04$, $P<0.001$). Disease distribution revealed 1,565 HBsAg-positive cases (5.21%) and 119 HCV-Ab-positive cases (0.40%), with significant gender disparity (7.48% vs. 4.41%, males vs. females). 363 positive patients were referred to the main hospital. Confirmed cases included 155 HBsAg carriers, 147 chronic hepatitis B patients, 24 with hepatic cirrhosis (including 4 with liver cancer), 10 past HCV infections, 21 chronic hepatitis C patients, 2 with hepatic cirrhosis due to HCV, and 4 with HBV/HCV co-infection. Pre-screening, the standardized treatment rates for HBV and HCV were 33.01% (102/309) and 51.65% (16/29), increasing post-screening to 68.61% (212/309) for HBV and 93.55% (29/31) for HCV. Using the aMAP liver cancer risk scoring system to assess 132 patients, the low-risk group accounted for 43.18%, the medium-risk group for 31.06%, and the high-risk group for 25.76%. Conclusions: The three-tier collaborative model significantly enhanced viral hepatitis diagnosis and treatment efficiency, demonstrating clinical value in liver cancer risk stratification. However, it is necessary to enhance patient compliance management and health education to solve the problem of "untreated patients who should be treated".

Keyword(s) : Viral hepatitis; Community screening; Diagnosis and treatment rate; Prevention and control model

1374 - Prognostic Influence of Histopathological Subtypes and Patient Characteristics in Hepatocellular Carcinoma A Comprehensive Population Based Evaluation

Ahmed Almezaine¹, Safaa Abdelhalim²

Tanta General Hospital, Internal Medicine, Tanta-Egypt

¹ Menia University, Git & Tropical, Menia-Egypt ²

Background / Hypothesis: Hepatocellular carcinoma (HCC) represents the predominant form of primary liver cancer, accounting for nearly 75–85% of all cases, and remains a major global health burden. Liver cancer ranks among the top causes of cancer-related mortality worldwide. Despite increasing incidence rates, limited comparative evidence exists regarding the clinical outcomes and demographic patterns associated with the different histopathological variants of HCC. This study aims to provide a detailed evaluation of the prognostic implications and clinical profiles of

recognized HCC histologic subtypes.

Materials and Methods: Patient data were obtained from the Surveillance, Epidemiology, and End Results (SEER) database, including individuals diagnosed with HCC between 2000 and 2021. Subjects with missing vital-status data or unspecified histological classifications were excluded. Patients were categorized based on demographic factors, tumor histopathology, and treatment modalities. Kaplan–Meier survival analysis and Cox proportional hazards regression were applied to assess overall survival (OS). Independent predictors of mortality were determined using univariate and multivariate analyses.

Results: A total of 1,450 patients with confirmed HCC histological subtypes were included. Clear cell HCC emerged as the most frequently observed subtype, particularly among adult and elderly individuals, with higher representation in white male patients. Clear cell and trabecular variants were more commonly diagnosed at localized disease stages, whereas fibrolamellar HCC demonstrated a greater tendency to present at regional stages. Survival comparisons showed that the pleomorphic subtype was associated with notably poorer OS relative to fibrolamellar HCC (adjusted hazard ratio [AHR] = 4.895; 95% CI: 1.315–18.22; $p = 0.018$). Age also played a significant prognostic role, with individuals older than 60 exhibiting substantially reduced survival (AHR = 2.375; 95% CI: 1.147–4.917; $p = 0.02$). Overall, fibrolamellar and trabecular subtypes demonstrated the most favorable survival outcomes.

Conclusions: Histopathological subtype exerts a substantial influence on survival outcomes in hepatocellular carcinoma, with fibrolamellar and trabecular variants demonstrating the most favorable prognoses. These subtypes also show distinct patterns of tumor spread, underscoring the clinical value of histologic classification. Across all subtypes, age remains a strong and independent predictor of mortality, reinforcing its importance in risk stratification and individualized patient management.

E-POSTER ABSTRACTS

1376 - GP73 A novel non invasive biomarker for diagnostic and prognostic of HEV ALF elderly patients

Luyu Wang ¹, Changyi Ji ¹, Mengmeng Gu ², Jian Wu ²
Bengbu Medical University, School Of Laboratory
Medicine, Bengbu-China ¹ Suzhou Municipal Hospital,
Medical Laboratory Center, Suzhou-China ²

Background / Hypothesis: Hepatitis E virus (HEV) is a significant cause of acute liver failure (ALF), with a very poor prognosis in elderly patients. Against the background of an accelerating aging population and a rising incidence of HEV in China, there is an urgent need for novel biomarkers for early risk stratification and prognostic assessment. This study aims to evaluate the prognostic value of golgi protein 73 (GP73) in elderly patients with HEV-related acute liver failure (HEV-ALF).

Materials and Methods: A total of 123 subjects were enrolled, including 40 elderly patients with acute hepatitis E (AHE), 40 with HEV-ALF, and 43 healthy elderly controls. Serum GP73 levels were measured by ELISA and analyzed for their correlation with clinical indicators. To assess the diagnostic and prognostic value of GP73, receiver operating characteristic (ROC) curves, orthogonal partial least squares-discriminant analysis (OPLS-DA), and decision curve analysis (DCA) were employed to evaluate its efficacy in diagnosing HEV-ALF and predicting 30-day mortality.

Results: Serum GP73 levels were significantly elevated in elderly patients with HEV infection compared to healthy elderly controls (135.02 vs. 22.73 ng/mL, $p < 0.001$). Furthermore, GP73 was markedly higher in the HEV-ALF group than in the AHE group (208.94 vs. 76.69 ng/mL, $p < 0.001$). For diagnosing HEV-ALF in elderly patients, GP73 achieved an AUC of 0.881 (95% CI: 0.81–0.951), with a cutoff value of 138.30 ng/mL, yielding a sensitivity of 77.5% and specificity of 82.5%. Decision curve analysis (DCA) further demonstrated the clinical utility of GP73, showing stable net benefit across a range of threshold probabilities. Correlation analysis revealed that serum GP73 levels were positively associated with key indicators of liver injury and failure, including ALT, AST, TBIL, and INR ($p < 0.05$), highlighting its relevance to disease severity. During the 30-day follow-up, non-survivors exhibited significantly higher GP73 levels than survivors (274.87

± 58.76 vs. 190.52 ± 66.26 ng/mL, $p = 0.006$). GP73 also showed strong predictive performance for mortality, with an AUC of 0.848, sensitivity of 83.3%, and specificity of 85.3%. DCA confirmed its high decision-making value in predicting 30-day mortality.

Conclusions: GP73 is a potential diagnostic and prognostic biomarker of HEV-ALF elderly patients, and its high level suggests poor prognosis, which provides a new basis for early intervention.

1379 - Synergistic effects of type 2 diabetes and alcohol consumption on all cause and liver related mortality among patients with steatotic liver disease

Ruoqi Zhou ¹, Huilan Tu ¹, Fanpu Ji ², Rongtao Lai ³, Jie Wang ¹, Weijun Su ¹, Jingjing Tao ¹, Haotian Zhang ¹, Ming-hua Zheng ⁴, Vincent Wai-sun Wong ⁵, Yu Shi ¹, Xinrong Zhang ⁶

The First Affiliated Hospital, Zhejiang University School Of Medicine, State Key Laboratory For Diagnosis And Treatment Of Infectious Diseases, National Clinical Research Center For Infectious Diseases, Hangzhou-China ¹ The Second Affiliated Hospital Of Xi'an Jiaotong University, Department Of Hepatology, Xi'an-China ² Ruijin Hospital, Shanghai Jiao Tong University School Of Medicine, Department Of Infectious Diseases, Shanghai-China ³ The First Affiliated Hospital Of Wenzhou Medical University, MaflD Research Center, Department Of Hepatology, Wenzhou-China ⁴ The Chinese University Of Hong Kong, Hong Kong, Department Of Medicine And Therapeutics, Hong Kong-China ⁵ School Of Public Health, Sun Yat-sen University, Guangdong Provincial Key Laboratory Of Food, Nutrition And Health, And Department Of Epidemiology, Guangzhou-China ⁶

Background / Hypothesis:

Type 2 diabetes (T2D) and alcohol consumption have been acknowledged as major risk factors for adverse clinical outcomes in individuals with steatotic liver disease (SLD). However, data about the synergistic effects of T2D and alcohol on all-cause and liver-related mortality in SLD remains scarce.

Materials and Methods:

E-POSTER ABSTRACTS

Leveraging data from the UK Biobank, we included individuals with liver steatosis diagnosed by a fatty liver index ≥ 60 . Six groups stratified by T2D state and alcohol consumption were further defined: no T2D+no/mild alcohol (no/mild alcohol intake: female: <140 g/week, male: <210 g/week), no T2D+metabolic and alcohol-associated steatotic liver disease (MetALD; with moderate alcohol intake: female: $140\sim 350$ g/week, male: $210\sim 420$ g/week), no T2D+alcohol-associated steatotic liver disease (ALD; with severe alcohol intake: female ≥ 350 g/week, male ≥ 420 g/week), T2D+no/mild alcohol, T2D+MetALD, T2D+ALD. The risks of all-cause and liver-related mortality across these groups were compared by Cox proportional hazards regression, and the population attributable fraction (PAF) and relative excess risk due to interaction (RERI) were calculated to exam the interplay between these two factors.

Results:

24,309 all-cause deaths and 1,009 liver-related deaths were recorded for 175,713 participants with SLD from the UK Biobank. The coexistence of T2D and elevated alcohol intake, particularly in case of severe alcohol consumption, was associated with substantially worse outcomes, including a $1.23\sim 1.64$ fold increased risk of all-cause mortality and $1.58\sim 7.32$ fold risk of liver-related mortality compared with no T2D+no/mild alcohol (Table 1). While combination of T2D and alcohol use accounted for a modest PAF of 6.78% for all-cause mortality, they contributed to 40.52% of liver-related mortality. Significant RERI was exclusively observed for liver-related mortality but not all-cause mortality.

Conclusions:

Co-exposure to T2D and alcohol intake substantially increases the risk of all-cause and especially liver-related mortality in patients with SLD. Their interplay confers significant disease burden, underscoring the importance of abstinence and glycemic control in the management of SLD.

Keyword(s) :

1381 - From Crisis to Control Acute HCV Triggered Acute on Chronic Liver Failure With HRS Successfully Stabilized With Early Sofosbuvir-Velpatasvir and Hemoperfusion A Case Report

Nathaniel Camangon¹, Adrian Bugayong¹, Heherson Adriano¹

Veterans Memorial Medical Center, Internal Medicine - Section Of Gastroenterology, Quezon City-Philippines ¹

Background / Hypothesis:

Acute-on-Chronic Liver Failure (ACLF) remains a highly fatal syndrome with limited therapeutic options. In Hepatitis C virus (HCV)-related ACLF, direct-acting antiviral (DAA) therapy is conventionally delayed until clinical stabilization, fearing complications from hemodynamic instability and renal impairment. Given that ongoing viral replication drives the systemic inflammation characteristic of ACLF, we hypothesized that early initiation of Sofosbuvir-Velpatasvir (DAA) could accelerate clinical and biochemical recovery by rapidly mitigating the inflammatory burden.

Materials and Methods:

We report the case of a patient presenting with life-threatening HCV-related ACLF Grade 3 (MELD-Na 33) complicated by Hepatorenal Syndrome Type 1 (HRS Type 1), multi-organ failure, and immediate hemodialysis dependence. Sofosbuvir-Velpatasvir was initiated early. The patient received aggressive, multidisciplinary, and supportive care, including terlipressin, albumin, and a series of hemoperfusion (HP) sessions. We monitored the patient's serial laboratory parameters, including creatinine, total bilirubin, AST/ALT, and MELD-Na score, correlating trends with the timing of DAA and supportive interventions.

Results:

Following DAA initiation and intensive support, the patient achieved a rapid and sustained recovery. Key parameters demonstrated dramatic improvement: Creatinine dropped from a peak of approximately 427 micromoles per liter ($\mu\text{mol/L}$) to approximately 52 $\mu\text{mol/L}$ by Day 60, allowing successful weaning from hemodialysis. AST/ALT quickly returned to normal levels (from 1370 U/L and 523 U/L to almost normal by Day 23). The patient was successfully weaned off pressor support and survived the hospital course. The clinical outcome challenges the traditional paradigm of delaying DAAs, showing that early viral suppression, combined with aggressive multi-organ support (including HP), is feasible and associated with rapid organ recovery even in the setting of severe ACLF and HRS-1.

Conclusions:

This case demonstrates the potential role of early Sofosbuvir-Velpatasvir initiation as a supportive strategy in ACLF patients with hepatitis C, including

E-POSTER ABSTRACTS

those requiring hemodialysis. Early viral suppression may contribute to improved liver function and overall stabilization, although definitive evidence remains lacking. Given the paucity of data and absence of guideline recommendations, controlled studies are urgently needed to clarify the timing and safety of DAA initiation during ACLF and to determine whether early antiviral therapy should be incorporated into future management algorithms.

1382 - SARS CoV 2 Spike Protein Promotes HBV Replication via Autophagy and Enhances Inflammatory Responses in Chronic Hepatitis B Patients with Liver Dysfunction and Metabolic Disorders

Yufen Jiang¹, Xingzhong Miao¹, Honglin Shi², Linle Xu¹, Yu Chen¹, Hongbo Shi¹

Beijing Youan Hospital, Capital Medical University, Beijing Key Laboratory Research On Liver Regeneration And Artificial Liver Transformation, Fourth Department Of Liver Disease, Beijing-China¹ Beijing Youan Hospital, Capital Medical University, Beijing Institute Of Hepatology, Beijing-China²

Background / Hypothesis: Autophagy plays a critical role in viral infection and immune regulation, and the SARS-CoV-2 spike (S) protein may influence the pathogenesis of chronic hepatitis B (CHB) by modulating autophagy and immune responses. This study aims to investigate the effects of the S protein on HBV replication and immune function in CHB patients, elucidate the underlying mechanisms, and provide theoretical support for the safety and application of COVID-19 vaccines in CHB patients.

Materials and Methods: This study systematically investigated the effects of the SARS-CoV-2 spike (S) protein on HBV replication and immune function in CHB patients using both in vitro cell experiments and clinical sample analyses. In vitro, HepG2.2.15 cells were engineered to express the S protein, and HBV replication and autophagy-related changes were assessed. Autophagy inhibitors were applied to further validate the underlying mechanism. In addition, peripheral blood mononuclear cells (PBMCs) isolated

from CHB patients were co-cultured with the S protein, and immune cell activation and inflammatory responses were analyzed.

Results: Expression of the S protein significantly promoted HBV replication in HepG2.2.15 cells. Treatment with autophagy inhibitors suppressed HBV replication, indicating a key role of autophagy in S protein-induced enhancement of HBV replication. In clinical samples, S protein stimulation enhanced the inflammatory responses of T cells and monocytes in PBMCs from CHB patients, particularly in those with liver dysfunction and lipid metabolic disorders.

Conclusions: Our findings demonstrate that the SARS-CoV-2 S protein promotes HBV replication through autophagy activation and enhances immune-inflammatory responses in CHB patients. Autophagy inhibitors can reverse the S protein-induced promotion of HBV replication, suggesting autophagy as a potential therapeutic target. Clinical data further indicate that the immune-activating effects of the S protein are more pronounced in CHB patients with liver dysfunction and metabolic disturbances. Targeting the S protein–autophagy interaction may offer new strategies to improve the clinical management of HBV patients with COVID-19 and reduce disease burden.

1383 - Prognostic Impact of Cardiometabolic Kidney Dysfunction on Patients with Metabolic dysfunction-associated steatotic liver disease (MASLD)

Daniel Yi Nin Tung¹, Jing Kai Tioh², Mark Dhinesh Muthiah¹

National University Hospital, Gastroenterology And Hepatology, Singapore-Singapore¹ 2yong Loo Lin School Of Medicine, National University Of Singapore, Gastroenterology And Hepatology, Singapore-Singapore²

Background / Hypothesis: Metabolic dysfunction-associated steatotic liver disease (MASLD) frequently coexists with cardiometabolic and renal abnormalities. The prognostic impact of advanced cardiometabolic-kidney

E-POSTER ABSTRACTS

dysfunction (CKM Stage 3) among individuals with MASLD remains unclear. This study evaluated whether CKM Stage 3 is associated with increased mortality in a nationally representative U.S. cohort.

Materials and Methods:

We analyzed adults from NHANES 1999–2018 who met MASLD criteria and linked them to National Death Index mortality data. Participants were stratified into two groups: No CKM Stage 3 and CKM Stage 3. Survey-weighted analyses compared demographic, metabolic, hepatic, and renal biomarkers. Cox proportional hazards models estimated associations with all-cause and cause-specific mortality.

Results:

CKM 3 was present in 5% in the general population. This group demonstrated significantly worse metabolic and inflammatory profiles, including higher fasting glucose, insulin, triglycerides, and HOMA-IR, along with lower HDL cholesterol. Mortality risk was substantially elevated in MASLD participants with CKM Stage 3. Compared with those without CKM Stage 3, the CKM Stage 3 group had markedly higher risks of all-cause mortality (HR 2.77, 95% CI 1.82–4.21, $p < 0.001$), borderline non significant cardiovascular mortality (HR: 1.56, 95% CI 0.86 to 2.82, $p = 0.140$) but not in oncological related mortality.

Conclusions:

CKM Stage 3 more than doubles the mortality risk among U.S. adults with MASLD. These findings underscore the critical interplay between liver, cardiometabolic, and renal dysfunction and support incorporating CKM staging into MASLD risk stratification and clinical management.

1386 - Real World Clinical Experience with Long Term Albumin Therapy in Advanced Liver Disease A Case Based Perspective from Asia

Anand V. Kulkarni ¹, Cosmas Rinaldi A. Lesmana ², Kemal Fariz Kalista ², Rakhi Maiwall ³, Rosmawati Mohamed ⁴, Soek Siam Tan ⁵, Bibek Gyanwali ⁶
Asian Institute Of Gastroenterology, Department Of Hepatology, Hyderabad-India ¹ Department Of Internal Medicine, Dr. Cipto Mangunkusumo National General Hospital, Medical Faculty Universitas Indonesia,

Hepatobiliary Division, Jakarta-Indonesia ² Institute Of Liver & Biliary Sciences, Department Of Hepatology, New Delhi-India ³ Hospital Canselor Tuanku Muhriz, Universiti Kebangsaan Malaysia, Faculty Of Medicine, Kuala Lumpur-Malaysia ⁴ Sunway Medical Centre, Hepatology Department, Selangor-Malaysia ⁵ Grifols Asia Pacific Pte Ltd, Medical Affairs, Singapore-Singapore ⁶

Background:

Long-term albumin therapy (LTA) is recognized as a potential disease-modifying strategy in patients with advanced liver disease. Recent randomized trials and real-world observational studies suggest that LTA may improve patient survival and reduce incidence of liver-related complications. However, real-world clinical practice around LTA in Asia remains heterogeneous, reflecting disparities in patient characteristics, healthcare infrastructure, and access to treatment.

Objectives: This case series evaluated the clinical rationale, therapeutic strategies and longitudinal outcomes of LTA in advanced liver disease across five tertiary centers in Asia.

Methods:

Eight cases were contributed by hepatologists from Indonesia, India and Malaysia, including patients with decompensated cirrhosis or hepatocellular carcinoma (HCC) with metastasis not suitable for liver transplantation who received LTA for ≥ 3 months together with etiological treatment for the liver disease. Demographics and clinical data were collected including liver and renal function, ascites resolution, paracentesis frequency, serum albumin levels and quality-of-life indicators. Each case was analyzed to assess therapeutic rationale, safety, and observed outcomes.

Results:

Patients presented with diverse etiologies for decompensated cirrhosis and HCC (HBV, MASLD, polycystic liver disease), complications (refractory ascites, variceal bleeding, renal dysfunction) and baseline albumin levels (< 30 g/L). LTA dosing regimens varied from fixed doses (60 g/week loading followed 20-40 g/week maintenance) to individualized titration based on clinical response and serum albumin levels. Notably, one patient with HBV received 25 g/month and still experienced clinical benefit. LTA increased serum albumin levels, reduced paracentesis frequency and improved renal and liver function in all seven cases. One patient with MASLD achieved complete

E-POSTER ABSTRACTS

ascites resolution and discontinued diuretics, while another with polycystic liver disease continued to require biweekly paracentesis and diuretics despite LTA, highlighting variability in LTA response. Ascites control was eased by LTA in one patient with HCC and variceal bleeding, and in three patients with HBV. Quality of life indicators was assessed in two patients with metastatic HCC showed improvements in their quality-of-life with LTA. Safety profile was favourable, with one patient experiencing two episodes of pulmonary edema, treated with diuretics.

Conclusions:

Through individual patient trajectories, this Asian case series provided real-world insights into selection criteria, dosing strategies, and clinical benefits that extend beyond conventional indications supporting the potential role of LTA in improving clinical outcomes in patients with advanced liver disease. While variability in response and treatment regimens limited generalizability of the results, the findings were aligned with clinical trial data and underscore the need of treatment individualization, standardized protocols and further prospective studies in Asian populations.

1388 - External Validation of a Preoperative Microvascular Invasion Risk Prediction Model Using Gadoxetate Enhanced MRI for Predicting Early Recurrence After Surgical Resection in Patients With Single Hepatocellular Carcinoma

Sunyoung Lee¹

Severance Hospital, Yonsei University College Of Medicine, Radiology, Seoul-South Korea¹

Background / Hypothesis:

Microvascular invasion (MVI) in hepatocellular carcinoma (HCC) is a major risk factor for early recurrence (<2 years) after curative treatment. A preoperative prediction model incorporating tumor markers and gadoxetate-enhanced MRI features has been proposed for estimating MVI risk in patients with single HCC. This study aimed to externally validate the association between the predicted MVI risk and early recurrence after surgical resection.

Materials and Methods:

This study prospectively enrolled at-risk patients with surgically resected single HCC who underwent preoperative gadoxetate-enhanced MRI between July

2019 and June 2023. A previously developed MVI risk prediction model—based on tumor markers (alpha-fetoprotein and protein induced by vitamin K absence-II) and MRI features (peritumoral arterial phase hyperenhancement and peritumoral hepatobiliary phase hypointensity)—was applied to categorize patients into low- and high-risk groups. Early recurrence rates were compared using Kaplan–Meier curves with the log-rank test.

Results:

A total of 102 patients (median age, 61.0 years; 83 men) were analyzed. Based on the model, 75 patients were classified as low-risk and 27 as high-risk for MVI. Pathologically confirmed MVI was present in 17.3% (13/75) of the low-risk group and 92.6% (25/27) of the high-risk group ($P < 0.001$). Early recurrence rates within 2 years were significantly lower in the low-risk group than in the high-risk group (12.0% vs 55.6%, $P < 0.001$).

Conclusions:

The preoperative MVI risk prediction model demonstrated reliable external validity. High predicted MVI risk was strongly associated with pathological MVI and significantly higher early recurrence after resection. This model may help guide preoperative risk assessment.

1390 - A study on clinical factors influencing the recurrence of hepatitis B surface antigen following clearance after long term nucleoside analogue therapy in patients with hepatitis B virus infection

Jinni Huang¹, Jianning Jiang¹, Bobin Hu¹, Hang Wang¹, Yanfei Feng¹

The First Affiliated Hospital Of Guangxi Medical University, Department Of Infectious Diseases, Nanning-China¹

Background / Hypothesis:

In the era of pursuing clinical cure, while some HBV-infected patients achieve HBsAg clearance following effective antiviral therapy, a small proportion still experience reversion to positivity after seroconversion. However, current research findings on HBsAg reappearance have yet to reach a consensus. This study aims to investigate factors associated with the

E-POSTER ABSTRACTS

recurrence of hepatitis B surface antigen (HBsAg) after clearance in patients with hepatitis B virus (HBV) infection undergoing long-term nucleos(t)ide analogue (NUC) therapy, with a view to reducing the risk of HBsAg recrudescence.

Materials and Methods:

This single-centre, retrospective case-control study followed patients from the longitudinal cohort of HBV-infected individuals at the First Affiliated Hospital of Guangxi Medical University between January 2002 and October 2025. A total of 139 patients were enrolled and divided into an NUC monotherapy group and a NUC plus interferon (IFN) combination therapy group. Cox regression models and Kaplan-Meier analyses were employed to assess the association between clinical factors and HBsAg reversion.

Results:

Among 4219 patients with HBV infection treated with NUCs, the overall HBsAg seroconversion rate was 3.65%. The HBsAg seroconversion rate in the NUC plus IFN group was significantly higher than in the NUC monotherapy group ($P < 0.001$). Negative factors for HBsAg reactivation included first-line NUC regimens, NUC treatment duration exceeding 9 years, NUC consolidation therapy lasting over 1 year post-HBsAg clearance, and post-HBsAg clearance HBsAb levels not below 30 IU/mL. For the NUC plus interferon group, extended consolidation therapy (NUC > 1 year or IFN > 6 months) significantly reduced reactivation risk.

Conclusions:

For patients treated with NUC, first-line NUC regimens, extended treatment duration, and thorough consolidation therapy following seroconversion are critical factors in preventing HBsAg reappearance after clearance. Patients receiving NUC combined with IFN exhibit higher HBsAg seroconversion rates than those treated with NUC alone. However, inadequate duration of IFN or NUC consolidation therapy post-seroconversion may still result in a relatively high rate of HBsAg recurrence.

**1391 - Integrated Multi omics Liquid Biopsy
Advancing Early Detection and Precision
Management of HCC**

Xinhao Gao¹, Jitao Wang², Dengxiang Liu³, Juan Liu⁴,
Hezhao Wang¹, Shihao Guo¹, Huiyang Fan¹
Xingtai People's Hospital, Hepatobiliary Surgery,
Xingtai-China¹ Tsinghua University, Hepatobiliary
Surgery, Beijing-China² Xingtai People's Hospital, ,
Xingtai-China³ Tsinghua University, , Beijing-China⁴

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide, often diagnosed at late stages due to the limited sensitivity and specificity of current surveillance methods such as ultrasound and alpha-fetoprotein (AFP) testing. Liquid biopsy, which non-invasively analyzes circulating biomarkers, offers a promising alternative. However, single-omics approaches often lack the robustness required for early detection. Multi-omics integration presents a transformative strategy to enhance diagnostic accuracy and enable precision oncology in HCC.

Materials and Methods:

This review synthesizes recent advances in multi-omics liquid biopsy for HCC, incorporating genomic (e.g., TERT, TP53 mutations), epigenomic (e.g., RASSF1A methylation), proteomic/glycomic (e.g., AFP-L3, GP73, exosomal glycans), fragmentomic (cfDNA fragmentation patterns), and cellular biomarkers (CTCs, EVs). Cross-omics integration strategies—such as cSMART, HIFI, and ASDAm-H1—were evaluated alongside emerging technologies including nanopore sequencing, SERS-based single-exosome analysis, and machine learning models (e.g., XAI, GNNs, Bayesian Networks).

Results:

The integration of multi-omics biomarkers has demonstrated transformative diagnostic performance for early HCC. Cross-omics models consistently outperformed single-modality approaches: combined genomic-epigenomic assays achieved sensitivities of 80–90% for early-stage detection, while the fragmentomic-epigenomic HIFI model distinguished HCC from cirrhosis with exceptional accuracy (AUC 0.996, sensitivity 95.42%, specificity 97.83%). Integrated protein-epigenetic panels, such as the ASDAm-H1 index, reached an AUC of 0.96, and longitudinal application of multi-parametric scores like GALAD significantly improved sensitivity to 69.2% for early HCC compared to single measurements (53.8%). Fragmentomics-based models enabled early screening with sensitivities exceeding 96%, and metabolomic

E-POSTER ABSTRACTS

panels detected preclinical HCC up to one year before clinical diagnosis with 80% sensitivity. Beyond detection, multi-omics liquid biopsy proved vital for precision management: ctDNA mutation profiling enabled dynamic monitoring of targeted therapy response, PD-L1⁺ CTCs and cfDNA copy number variations predicted outcomes to immune checkpoint inhibitors, and machine learning-driven deconvolution of single-exosome SERS fingerprints or cfDNA methylation data provided unprecedented molecular resolution. These approaches not only identified AFP-negative HCC cases but also facilitated early recurrence prediction and molecular subtyping, effectively transitioning liquid biopsy from a passive detection tool to an active component in the dynamic, personalized management of HCC.

Conclusions:

Multi-omics liquid biopsy represents a paradigm shift in HCC management, enabling high-accuracy early detection and dynamic monitoring of disease progression and treatment response. Despite challenges in data integration, standardization, and clinical validation, future directions—including explainable AI, single-cell multi-omics, and closed-loop precision oncology systems—hold great promise. With continued interdisciplinary collaboration and standardization efforts, multi-omics liquid biopsy is poised to become the cornerstone of next-generation HCC care.

1392 - Feasibility of achieving a tumor and drug free state through conversion therapy followed by curative hepatectomy for patients with initially unresectable hepatocellular carcinoma

Jian-hong Zhong¹, Da-long Yang¹, Liang Ma¹, Yong-rong Liang², Ze Su³, Zhi-cheng Li⁴
Guangxi Medical University Cancer Hospital, Department Of Hepatobiliary Surgery, Nanning-China¹
First People's Hospital Of Qinzhou, Department Of Hepatobiliary And Pancreatic Surgery, Nanning-China²
First People's Hospital Of Nanning, Department Of Hepatobiliary Pancreatic Surgery, Nanning-China³
First Clinical Affiliated Hospital Of Guangxi University Of Chinese Medicine, Department Of General Of Surgery, Nanning-China⁴

Background / Hypothesis:

Whether initially unresectable hepatocellular carcinoma (HCC) patients who receive curative resection after conversion therapy can maintain long-term tumor-free survival in a drug-free state after postoperative drug withdrawal is unclear. This study aimed to compare the effectiveness of adjuvant PD-1 inhibitors versus a drug-free state in these patients.

Materials and Methods:

Data were retrospectively analyzed for patients with initially unresectable HCC who underwent curative hepatectomy after conversion therapy at 12 medical centers in China between January 2019 and June 2023. Tumor-free survival and overall survival were compared between patients who received PD-1 inhibitors and patients in a drug-free state after hepatectomy.

Results:

Relative to the 323 patients in a drug-free state, the 90 who received PD-1 inhibitors showed comparable tumor-free survival (HR 0.77, 95%CI 0.51–1.17) and overall survival (HR 0.59, 95%CI 0.33–1.04). Similar results were obtained for subsets of patients matched to each other through propensity scoring, for the subset of 112 patients who achieved pathological complete response after resection, and for the entire cohort in 12-month landmark survival analysis. An adjuvant PD-1 inhibitor regime lasting at least 6 months led to similar survival as shorter regimes, whether in terms of tumor-free survival (HR 0.89, 95% CI 0.31–2.35) or overall survival (HR 0.92, 95% CI 0.20–4.32). No treatment-related deaths occurred in the entire cohort.

Conclusions: Adjuvant PD-1 inhibitors or in combination with tyrosine kinase inhibitors may not provide survival benefit over a drug-free state to patients with initially unresectable HCC who undergo curative hepatectomy after conversion therapy.

Keyword(s) : hepatocellular carcinoma, conversion therapy, PD-1 inhibitor, adjuvant therapy

1394 - Clinical landscape Mutation mapping Quality of life and Treatment outcomes in Adolescent and Adult Wilsons disease patients in a South Indian cohort.

Rajat Prabhakar Pande¹, Aswin Krishna¹, Vivek Ashokan¹, Joeimon JI¹, Premkumar K¹, Premkumar K¹
Madras Medical College & Rajiv Gandhi Government

E-POSTER ABSTRACTS

General Hospital, Hepatology, Chennai-India ¹

Background / Hypothesis:

Wilson's Disease has a perplexing and an unparalleled clinical course presenting as a diagnostic and therapeutic challenge. Inherited in an autosomal recessive manner, copper deposits usually affect liver, brain, eyes, bones amongst other organ systems, having a diverse spectrum and impact on quality of life, morbidity and mortality

Materials and Methods:

This is an ambispective; single centre study done from January 2020 to October 2025 incorporating patients above 13 years of age. The patients were further divided into three groups based on their age. Group A (13-18 years), Group B (18-25 years), Group C (> 25 years)

Quality of life was assessed by SF 36 questionnaire. Genetic analysis was done by Next Generation Sequencing. Patients were followed for changes in MELD and CTP scores, and monitoring side effects of D penicillamine therapy and disease progression

Results:

The study involved 82 cases over 13 years of age encompassing 39 females and 43 males.

Clinical Landscape:

Patients were further divided into Decompensated cirrhosis, Compensated cirrhosis, Acute liver Failure/ACLF, Neuro hepatic Wilsons, and Asymptomatic. 58.3% patients had history of consanguinity. Atypical associations included retinitis pigmentosa (since birth, n=1) sick sinus syndrome requiring pacemaker (n=1) pituitary hypoplasia (n=1) and synovial osteochondromatosis (n=1). 6 patients had successful pregnancies, 2 had recurrent abortions and 2 patients had primary amenorrhoea.

Mutation Mapping:

45.12% of patients underwent genetic analysis. Mutations were divided into Missense variants, Stop Gained variants, Frameshift variants, Synonymous variants amongst others. Most of the patients had homozygous mutations followed by heterozygous mutations. One patient had two heterozygous mutations suggesting biallelic inheritance. The most common variants included chr13:g.52511412C>T followed by chr13:g.52548789del.

Quality of life:

60.9 % patients attempted the SF36 questionnaire to analyse the quality of life. 53.2% experienced better health than prior, 26.8% revealed being worn out

Additional information revealed 54% had completed formal education and 62.8% of patients were employed, while 2 of them experienced bullying at their workplace.

Treatment outcomes:

Out of patients receiving D penicillamine therapy, 4 patients developed worsening of neurological symptoms leading to stopping the drug. One patient developed Steven-Johnson Syndrome. After one year of therapy 14.6% patients had decrease in MELD score. Overall, 4 patients underwent liver transplantation (LDLT=3; DDLT=1) and 7 patients succumbed to the disease

Conclusion:

There is insufficient data on Wilson's disease and its behaviour in adolescence and early adulthood. This paper explores the multifaceted issues and unique challenges in these formative years, seldom addressed in prior studies.

Keyword(s) : Wilson Disease, Mutation mapping, Quality of Life

1395 - Four Year Management of Unresectable Hepatocellular Carcinoma Sustained Tumor Control and Cumulative Multi Organ Toxicities

Fang Chen ¹, Yuerong Zhang ¹

University Town Hospital Of Chongqing Medical University, Department Of Gastroenterology, Chongqing-China ¹

Background: Patients with unresectable Hepatocellular Carcinoma (HCC) undergoing long-term interventional therapy combined with systemic antitumor treatment may achieve effective tumor control, yet are at risk of developing therapy-related multi-organ injury during the course of treatment.

Methods: A 59-year-old male was hospitalized four years ago due to epigastric pain. Workup revealed mildly elevated ALT and AST, positive HBsAg, HBV-DNA 1.86×10^5 copies/ml, and AFP 308.10 ng/ml. Contrast-enhanced abdominal CT demonstrated a large right hepatic lobe mass measuring 121 mm × 83 mm, with suspected invasion of the right portal vein and right hepatic vein. The clinical diagnosis was HCC, BCLC stage C. The patient subsequently began long-term treatment involving interventional therapy combined with systemic antitumor therapy: Entecavir 0.5 mg po qd, Lenvatinib 8 mg po qd, Tislelizumab 200 mg ivgtt q3w, along with three sessions of interventional therapy, one session of radiofrequency ablation, one session of Yttrium-90 radioembolization,

E-POSTER ABSTRACTS

among other treatments.

Results: After four years of antitumor therapy, the patient's HBV-DNA became undetectable, and AFP decreased to 19.96 ng/ml. Follow-up contrast-enhanced abdominal CT showed no increase in the size of the primary tumor and no evidence of intra- or extrahepatic metastasis. However, during this 4-year treatment period, the patient sequentially developed damage to multiple organs and systems, including cardiovascular, gastrointestinal, skin/mucosa, renal, and endocrine systems. Over 3 years ago, the patient developed hypertension, managed long-term with oral antihypertensive agents with adequate control. Also over 3 years ago, recurrent diarrhea began. Endoscopy revealed telangiectasia in the jejunum and colon. 16S gut microbiota testing indicated dysbiosis. Symptoms improved with treatment involving Bifidobacterium and Glutamine. Nine months ago, skin lesions developed, diagnosed by dermatology as bullous pemphigoid, which improved with Methylprednisolone treatment. Over 2 years ago, renal dysfunction was identified. A renal biopsy performed by nephrology 7 months ago indicated IgA Nephropathy - Grade III, with Lenvatinib-induced renal damage not excluded. The condition improved with Methylprednisolone and other therapies. Two months ago, elevated blood glucose, abnormal thyroid function, and low cortisol rhythm were detected and are currently under monitoring.

Conclusions: Interventional therapy combined with systemic antitumor treatment can effectively control the progression of unresectable HCC. However, therapy-related organ injuries occurring during treatment may impede the sequential continuation of antitumor therapy, potentially leading to reduced patient life expectancy. Proactive and effective management of adverse events is crucial to mitigate their severity, achieving an optimal balance between tumor control and organ protection.

1397 - Ammonia Seeking Zinc Micromotors for Active Ammonia Scavenging in Hepatic Encephalopathy

Hua-xiang Yang¹, Chao Gao², Bin Chen², Xiao-cong Liu¹, Wu Wen¹

West China School Of Medicine, Sichuan University, Sichuan University Affiliated Chengdu Second People's Hospital, Department Of Gastroenterology And Hepatology, Chengdu-China¹ Sun Yat-sen University, School Of Materials Science And Engineering,

Guangzhou-China²

Background / Hypothesis:

Hepatic fibrosis, characterized by progressive hepatocyte injury, leads to the systemic accumulation of blood ammonia. This hyperammonemia not only aggravates underlying liver pathology but also crosses the blood-brain barrier, precipitating the neuropsychiatric complications of hepatic encephalopathy. Consequently, the development of targeted therapeutic platforms for the specific clearance of ammonia represents a significant and meaningful pursuit in managing this disease cascade.

Materials and Methods:

This work presents the design and fabrication of a biocompatible zinc (Zn)-based micromotor as a novel platform for active ammonia chemotaxis. The micromotor's propulsion is driven by a water-splitting reaction, generating motive force in an aqueous biological environment. Simultaneously, the dissolution of Zn creates a self-generated Zn^{2+} ion gradient. We demonstrate that this system exhibits robust directional movement towards a source of ammonia ($\text{NH}_3 \cdot \text{H}_2\text{O}$). This chemotactic behavior is governed by a coordination reaction between Zn^{2+} and ammonia molecules, leading to the formation of complex ions such as $\text{Zn}(\text{NH}_3)_1^+$ and $\text{Zn}(\text{NH}_3)_2^+$.

Results:

The coordination-based chemotaxis mechanism proved to be a generalizable strategy for guiding micromotor movement. In an in vivo model, these micromotors displayed a biomimetic collective behavior, enabling them to navigate precisely within the biological milieu. This resulted in a significant reduction of intrahepatic ammonia levels, thereby contributing to the reshaping of the pathological microenvironment. The entire operational mechanism functions in a green and zero-waste manner, enhancing its biocompatibility and facilitating its integration into the domain of sophisticated biological regulation.

Conclusions:

We have successfully established an environment-adaptive micromotor platform that effectively targets and mitigates hyperammonemia at its source. This technology holds considerable promise for the targeted treatment of hepatic fibrosis and associated hepatic encephalopathy. The underlying principles of this strategy, leveraging specific chemical reactions for targeted therapy, are expected to provide valuable

E-POSTER ABSTRACTS

inspiration for future advancements in personalized and precision medicine.

1398 - A Study to assess the relationship of Frailty and Myosteatosis in Cirrhotic patients

Joemon M George¹, Robert P Panakkal², Anoob John K A², Sojan George K², Rajany Antony², P S Kripal²
Rajagiri Hospital, Medical Gastroenterology, Ernakulam-India¹ Amala Hospital, Medical Gastroenterology, Thrissur-India²

Background / Hypothesis:

Frailty and myosteatosis are emerging as critical, yet underrecognized, predictors of poor outcomes in cirrhosis. Although sarcopenia has been extensively studied, the relationship between muscle fat infiltration (myosteatosis) and clinically measurable frailty remains insufficiently defined, especially using objective MRI-based metrics. Identifying high-risk phenotypes is essential as cirrhotic patients increasingly present with metabolic comorbidities such as diabetes, hypertension, and MASLD.

Aim: To evaluate the prevalence of frailty among cirrhotic patients with MRI-detected myosteatosis and to define a muscle PDFF cut-off predictive of frailty. Secondary goals were to identify independent and shared risk factors for frailty and myosteatosis

Materials and Methods:

In this hospital-based observational analytical study, 100 adult cirrhotic patients underwent comprehensive evaluation. Frailty was assessed using the Liver Frailty Index (LFI); MRI-derived proton density fat fraction (PDFF) at L1–L3 quantified myosteatosis. Demographic variables, comorbidities, Child-Pugh class, MELD-Na, and laboratory parameters were analyzed using chi-square tests, ANOVA, and ROC curves.

Results:: Frailty was strikingly common: 33% were frail and 55% pre-frail, highlighting profound functional impairment even in a mixed inpatient cohort. Muscle fat fraction averaged $15.97 \pm 7.51\%$. ROC analysis identified PDFF $\geq 15.44\%$ as a clinically meaningful threshold predicting frailty (AUC=0.748; 75.8% specificity, 61.8% sensitivity).

Age >60 years increased frailty risk 4.7-fold. Diabetes

($p=0.0001$) and hypertension ($p=0.047$) were strong determinants of both frailty and myosteatosis. NASH/MASLD emerged as the dominant etiology (54%) and conferred significantly higher vulnerability to both conditions compared with alcohol-related disease. Frailty severity correlated with Child-Pugh class ($p=0.0001$) and PT/INR ($p=0.017$), whereas myosteatosis was highest in Child-Pugh C ($p=0.007$). MELD did not correlate with myosteatosis, suggesting muscle quality deteriorates independently of conventional liver severity scores.

Conclusions:

Frailty and myosteatosis are highly prevalent, metabolically driven, and synergistic risk states in cirrhosis. A muscle PDFF cutoff of 15.44% provides an objective, MRI-based biomarker to identify patients at greatest functional decline. These findings underscore the urgent need to integrate routine muscle-quality assessment into cirrhosis evaluation—especially in MASLD and metabolic phenotype patients. Early targeted interventions addressing muscle fat infiltration may significantly alter the clinical trajectory and improve transplant readiness.

1400 - The Silent Risk of Steroid Therapy A Case of HBV Reactivation

Gülnur Kul¹, Asli Haykir Solay¹, Ediz Tütüncü¹
Ankara Etlik City Hospital, Infectious Diseases And Clinical Microbiology, Ankara-Türkiye¹

Background / Hypothesis:

Hepatitis B virus (HBV) is a chronic viral infection that causes significant morbidity and mortality worldwide. Immunosuppressive or immunomodulatory agents—particularly corticosteroids—pose a risk for HBV reactivation. In HBsAg-positive individuals, this may result in accelerated viral replication and clinical deterioration, potentially progressing to fulminant hepatitis. Despite this risk, short-term steroid therapy is often considered low risk, leading to the omission of antiviral prophylaxis. Here, we present a case of HBV reactivation following short-term systemic corticosteroid use.

Case Summary

A 50-year-old male with known chronic hepatitis B infection was under observation without antiviral therapy. His viral serology revealed HBsAg positivity, HBeAg negativity, anti-HBe positivity, and HBV DNA of

E-POSTER ABSTRACTS

6,810 IU/ml. At the three-month follow-up, HBV DNA had increased to 21,500 IU/ml—indicating a ~1 log rise. Upon detailed history-taking, it was discovered that the patient had been taking dexamethasone 4 mg/day for granulomatous mastitis over the past two months. This dose is equivalent to >20 mg of prednisolone. Given the patient's HBsAg-positive status, the therapy represented a high reactivation risk. The clinical picture was consistent with HBV reactivation, and antiviral treatment was initiated.

Discussion

In HBsAg-positive individuals, immunosuppressive treatment—especially moderate to high-dose systemic corticosteroids—is a well-known risk factor for HBV reactivation. Steroids facilitate reactivation by both directly enhancing viral replication and suppressing host immune response. In this case, only two months of dexamethasone 4 mg/day (equivalent to >20 mg prednisolone) led to a ~1 log increase in HBV DNA, indicating reactivation. This underscores that short-term corticosteroid therapy at such doses is not safe in HBsAg-positive patients. The lack of antiviral prophylaxis prior to steroid initiation represents a significant clinical oversight. Although such cases are rarely reported, this case emphasizes the need for HBV reactivation risk assessment and consideration of antiviral prophylaxis, regardless of steroid dose or duration.

United States ⁸ Gilead Sciences, Inc., Medical Affairs, Foster City-United States ⁹ Chang Gung Memorial Hospital, , Linkou-Taiwan ¹⁰ I-shou University, , Kaohsiung-Taiwan ¹¹

Background / Hypothesis: Therapeutic vaccines, such as nonreplicating arenaviral vectors GS-2829 and GS-6779, are a promising approach to achieve durable immune response and functional cure for chronic hepatitis B (CHB) infection. GS-2829 and GS-6779 were engineered to express hepatitis B surface antigen (HBsAg) and core antigen (HBcAg), and highly conserved polymerase reverse transcriptase and ribonuclease H domains. We evaluated the safety, tolerability, immunogenicity, and antiviral efficacy of GS-2829 and GS-6779 in virally suppressed patients with CHB.

Materials and Methods: In this multicenter, randomized (4:1), blinded, placebo-controlled Phase 1b study, alternating intramuscular administrations of GS-2829 or GS-6779 every 4 weeks (ie, 1 cycle = GS-2829 at week 0; GS-6779 at week 4) were evaluated: cohort 5, 2 cycles of low doses (2 × low); cohort 6, 2 cycles of high doses (2 × high); cohort 7, 3 cycles of high doses (3 × high). Safety and tolerability were monitored via treatment-emergent adverse events (AEs), serious AEs, and laboratory abnormalities. Viral efficacy included HBsAg, hepatitis B e antigen (HBeAg), and hepatitis B core-related antigen (HBcrAg). Immunogenicity was evaluated by interferon-gamma ELISpot analysis of hepatitis B virus (HBV)-specific T cells.

Results: Thirty patients (n = 10 per cohort) were enrolled; median age was 51 years, 63% were male, 100% were Asian, 7% had prior interferon use, and genotype B was most common (43%). At baseline, median (minimum, maximum) HBsAg levels for patients in the 2 × low, 2 × high, and 3 × high cohorts who received the vaccine were 1579 (1, 3737), 863 (1, 3725), and 401 (25, 2260) IU/mL, respectively; 0/8, 7/8 (88%), and 4/8 (50%) patients were HBeAg positive. Among 11 HBeAg-positive patients at baseline who received the vaccine, 5 (45%) achieved HBeAg loss. Quantitative declines in HBeAg and HBcrAg were observed in additional HBeAg-positive patients. In 25% (4/16) of patients in high-dose cohorts, HBsAg declined by ~0.5 log₁₀ IU/mL with mild (Grade ≤1) alanine aminotransferase increases. Patients on the

E-POSTER ABSTRACTS

vaccine showed induced HBV-specific T-cell responses—mainly against HBcAg and polymerase—and 94% of patients in high-dose cohorts had ≥ 3 -fold increases from baseline in T cells for ≥ 1 HBV antigen. All AEs were Grade ≤ 2 and nonserious; none led to discontinuation of study drugs.

Conclusions: Alternating doses of GS-2829 and GS-6779 were safe and well tolerated in virally suppressed patients with CHB. These safety, virology, and immunogenicity data support further investigation of GS-2829 and GS-6779 as CHB treatment.

1403 - Developing Blood based Lipid Biomarker for Hepatocellular Carcinoma Risk Prediction in Non cirrhotic MAFLD Patients

Fatema Safri ¹, Russell Pickford ², Brian Gloss ³, Jacob George ¹, Liang Qiao ¹

Westmead Institute For Medical Research, University Of Sydney, Storr Liver Centre, Sydney-Australia ¹
University Of New South Wales, Biomedical Mass Spectrometry Facility, Nsw-Australia ²
Westmead Institute For Medical Research, Westmead Bioinformatics Facility, Nsw-Australia ³

Background / Hypothesis:

The global rise in obesity and type 2 diabetes has positioned metabolic-associated fatty liver disease (MAFLD) as a major risk factor for hepatocellular carcinoma (HCC). While MAFLD contributes to nearly half of all HCC cases, approximately 12% occur in the absence of other liver diseases. Although advanced fibrosis and cirrhosis traditionally guide HCC surveillance, emerging evidence shows that nearly 40% of MAFLD-related HCC arises without cirrhosis, often at early stages and outside routine screening pathways. This highlights a need for early-stage risk prediction tools. Liver plays a central role in synthesising, processing and sorting fats throughout the body. Thus, it is noteworthy to explore the lipid reprogramming in MAFLD and its associated HCC.

This study uses a multi-omic approach to (a) investigate the lipid profiles of non-cirrhotic MAFLD-HCC (ncMAFLD-HCC) and cirrhotic MAFLD-HCC (cMAFLD-HCC) to understand the lipid reprogramming in HCC development, and (b) identify early detection/risk prediction biomarkers for ncMAFLD-

HCC.

Materials and Methods:

Liver biopsies and plasma samples from 221 individuals (140 MAFLD, 66 cMAFLD-HCC, and 15 ncMAFLD-HCC patients) were used in the study. Plasma lipid profiles were performed on 209 samples and 22 liver biopsies. RNA and ATAC sequencing were performed on 18 and 9 liver biopsies respectively. Lipids were extracted and analysed using liquid chromatography-tandem mass spectrometry (LC-MS/MS). Principal component analysis, multivariate statistics, and pathway enrichment analysis were performed using Metaboanalyst v6.0 and R studio.

Results:

Exploratory analysis of lipid profiles demonstrated clear separation among MAFLD, ncMAFLD-HCC and cMAFLD-HCC in both plasma and liver tissue samples. More than 100 lipid species, belonging to diacylglycerols, sphingomyelins, triglycerides, dihydroceramides, and linoleic acid derivatives, were differentially expressed in ncMAFLD-HCC as compared to the MAFLD and cMAFLD-HCC cohort. Logistic regression model with 10-fold cross-validation using a panel of five lipid species achieved 91% and 80% sensitivity and 90% and 93% specificity for panel 1 and panel 2, respectively.

Enrichment analysis linked these lipids to glycerolipid metabolism, G-protein signaling, MAPK signaling, and EGFR tyrosine kinase inhibitor resistance. Additionally, 54 lipid-metabolism-related genes were dysregulated in ncMAFLD-HCC, with enrichment in sphingolipid and glycerophospholipid pathways in liver tissue.

Conclusions:

ncMAFLD-HCC exhibits a distinct lipidomic signature, reflecting profound metabolic dysregulation. These findings are under validation using a bigger cohort and offer a foundation for developing lipid-based biomarkers for HCC risk prediction in non-cirrhotic MAFLD patients. Furthermore, enrichment analysis provide insight into HCC pathogenesis in ncMAFLD-HCC and these pathways are currently studied for their potential for therapeutic targets.

1404 - A Model for Prediction Hepatic Nodules Development to Hepatocellular Carcinoma in Patients with HBV Related Cirrhosis on Antiviral Therapy

Yaxin Li¹, Yuwei Wang¹, Yueyang Yu¹, Ying Han¹, Huiguo Ding¹

Beijing You'an Hospital Affiliated To Capital Medical University, Department Of Gastroenterology And Hepatology, Beijing-China¹

Background / Hypothesis:

Patients with hepatitis B virus (HBV)-related cirrhosis receiving nucleos(t)ide analogues (NAs) antiviral therapy remain at substantial risk of hepatocellular carcinoma (HCC). However, the surveillance programs for early HCC from hepatic nodules development in patients with HBV-related cirrhosis on antiviral therapy were still not well established. We aimed to develop and validate a nomogram incorporating ultrasound-detected hepatic nodules and routine clinical variables for HCC risk prediction in this population.

Materials and Methods:

The retrospective-prospective real-world cohort included 1,209 treatment-naïve patients with HBV-related cirrhosis who received NAs antiviral therapy for more than 1 year. Patients were randomly assigned to derivation (n = 846) and validation cohorts (n = 363) in a 7:3 ratio. A nomogram model for predicting hepatic nodules development to HCC was developed using multivariable Cox regression models. The predictive performance was assessed using time-dependent receiver operating characteristic (ROC) curve analysis and decision curve analysis. Patients were further stratified into three risk groups based on the total risk scores calculated from the nomogram, and the cumulative incidence of HCC was evaluated using the Kaplan-Meier method. The nomogram model's performance was validated and compared with aMAP, mPAGE-B and REAL-B. Additionally, we conducted a subgroup analysis to evaluate the model's performance in predicting early-stage HCC (Barcelona Clinic Liver Cancer 0-A stage).

Results:

Overall, 323 patients (26.7%) developed HCC during a median follow-up of 7 years, among whom 64.3% diagnosed at early stage. Age, hypertension, decompensated cirrhosis, hepatic nodules and duration of antiviral therapy were independent predictors of HCC, and these five variables were used to develop the prediction model. The nomogram achieved time-dependent AUCs of 0.729-0.762 in the

derivation cohort and 0.742-0.756 in the validation cohort for predicting 1-, 3-, and 5-year HCC risk, significantly outperforming existing models (derivation cohort: aMAP: 0.555-0.598, REAL-B: 0.588-0.636, mPAGE-B: 0.589-0.605; validation cohort: aMAP: 0.588-0.646, REAL-B: 0.601-0.630, mPAGE-B: 0.625-0.665). Furthermore, the nomogram stratified patients into three risk groups with significantly different HCC and early-stage HCC incidences. The 3-year cumulative HCC incidences in the low-, medium-, and high-risk subgroups were 5.2%, 15.2%, and 36.3%, respectively, in the derivation cohort. And the 3-year cumulative incidences of early-stage HCC were 5.0%, 11.8%, and 22.9% across risk groups.

Conclusions:

This nomogram incorporating hepatic nodules demonstrated good discrimination and calibration for HCC risk prediction in patients with HBV-related cirrhosis receiving antiviral therapy, enabling individualized surveillance strategies.

1405 - Impact of Smoking on the Longitudinal Progression of Liver Fibrosis

Hyuk Kim¹, Jeong-ju Yoo¹, Sang Gyune Kim¹, Young Seok Kim¹

Soonchunhyang University Hospital Bucheon, Internal Medicine, Bucheon-si-South Korea¹

Background / Hypothesis:

The adverse effects of smoking on liver-related outcomes have been suggested, yet evidence regarding its influence on fibrosis progression is limited. No prior study has thoroughly investigated the temporal relationship between smoking exposure and changes in liver fibrosis indices. We hypothesized that smoking accelerates the progression of liver fibrosis, reflected by longitudinal changes in FIB-4 scores.

Materials and Methods:

We analyzed 46,270 adults who underwent at least two health screening examinations at tertiary hospital. Smoking status was categorized as non-smoker, current smoker, or ex-smoker. Among ever-smokers, subjects were further grouped by cumulative exposure: low (<8 pack-years), intermediate (8–20 pack-years), and heavy (>20 pack-years). Fibrosis progression was assessed using repeated FIB-4 measurements. Linear mixed models (LMMs) were used to evaluate the

E-POSTER ABSTRACTS

temporal association between smoking status and FIB-4 change, adjusting for sex and weekly alcohol intake.

Results:

After adjustment for confounders, mean FIB-4 scores were significantly higher in current smokers ($\beta \pm \text{SE}$) and ex-smokers ($\beta \pm \text{SE}$) compared with non-smokers (mean $\pm \text{SE}$). In the linear mixed model, both current smoker ($\beta = 0.04565$, $\text{SE} = 0.00844$, $p < 0.0001$) and ex-smoker ($\beta = 0.07067$, $\text{SE} = 0.01976$, $p < 0.0001$) showed a significant increase in FIB-4 compared with non-smoker (mean = 1.1660, $\text{SE} 0.0143$, $p < 0.0001$). Pairwise comparisons showed higher FIB-4 progression in both current and former smokers relative to non-smokers, with no significant difference between current and former smokers.

Among ever-smokers, intermediate ($\beta = 0.02362$, $\text{SE} = 0.01604$, $p = 0.1410$) and heavy smoking ($\beta = 0.0008$, $\text{SE} = 0.00003$, $p = 0.9440$) groups showed slightly higher FIB-4 values than the low smoking group (mean = 1.2930, $\text{SE} = 0.01567$, $p < 0.0001$).

Conclusions:

Smoking is independently associated with accelerated progression of liver fibrosis. Both current and former smokers exhibit greater worsening of FIB-4 scores compared with non-smokers, and fibrosis progression occurs regardless of cumulative smoking exposure.

Keyword(s) : smoking, liver fibrosis, FIB-4, longitudinal analysis, pack-years

1406 - Assessing the Efficacy of donor derived cell free DNA (ddcfDNA) Measurement in Liver Transplant Recipients for Rejection Diagnosis and Therapeutic Response Evaluation A case report

So Kyung Yoon¹, Okjoo Lee¹, Jieun Kwon¹

Soonchunhyang University Seoul Hospital, Department Of Surgery, Seoul-South Korea¹

Background / Hypothesis:

Despite advancements in immunosuppressive therapies, rejection remains a significant challenge for post-liver transplantation. Current diagnostic methods for rejection, such as liver biopsy, are invasive and may not capture rejection episodes in a timely manner. The emergence of circulating biomarkers, particularly donor-derived cell-free DNA (ddcfDNA), presents a promising non-invasive approach for rejection diagnosis and therapeutic monitoring. This case report explores the feasibility and potential benefits of ddcfDNA measurement into clinical practice for liver transplant recipients.

Materials and Methods:

A 45-year-old male patient, about 200 days after deceased-donor liver transplantation for alcoholic liver cirrhosis, visited our hospital for regular follow-up. His liver function has been well maintained during the post-transplant follow-up, but on this day, his total bilirubin level was elevated to 3.02 mg/dL aspartate transaminase (AST) was 469 U/L alanine transaminase (ALT) was 779 U/L and he complained of itching sensation. The tacrolimus level was 11.3 ng/mL, however, the patient reported that he had skipped his immunosuppressant medication while traveling the week before.

Results:

The patient was hospitalized with suspected acute rejection, and a liver biopsy was performed to confirm diagnosis and the first serum ddcfDNA sample was collected. We checked the absolute number of ddcfDNA copies per mL of plasma and fraction of ddcfDNA (ddcfDNA%) and the result was 39.1%. The patient was diagnosed with T-cell mediated rejection, steroid pulse therapy was initiated with an intravenous methylprednisolone dose of 500 mg/day administered for 3 days and then tapered by half every day to 60 mg/day. After that, patient discharged with oral methylprednisolone initiated at 32 mg/day, tapered to 4–8 mg/day within 1–2 weeks. On discharge day, the total bilirubin level was 1.69 mg/dL, AST was 51 U/L, ALT was 164 U/L, and the patient was discharged without any symptoms. And the second serum ddcfDNA sample was collected at patient discharge day, the result was 9.01%, a decrease from the time of admission.

Conclusions:

ddcfDNA serves as a sensitive biomarker for detecting graft injuries in liver transplant recipients. Further large-scale research, which should ideally include protocol biopsies, will be needed to establish the practical value of ddcfDNA measurements in the management of liver transplant recipients.

Keyword(s) : Donor-derived cell-free DNA (ddcfDNA), Graft injury assessment, T-cell mediated rejection, Non-invasive biomarker

1407 - Osteoclast like giant cell tumor of the intrahepatic bile duct a rare neoplasm with a stable

E-POSTER ABSTRACTS

clinical course A case report

So Kyung Yoon¹, Okjoo Lee², Jieun Kwon¹

Soonchunhyang University Seoul Hospital, Department Of Surgery, Seoul-South Korea¹ Soonchunhyang University Bucheon Hospital, Department Of Surgery, Seoul-South Korea²

Background / Hypothesis:

Osteoclast-like giant cell tumors most commonly arise in the bone and are rarely identified within the gastrointestinal tract. Among these locations, the liver is an exceptionally uncommon site. We report a rare case of an osteoclast-like giant cell tumor originating from the intrahepatic bile duct in a 70-year-old woman.

Materials and Methods:

A bile duct mass was incidentally detected during a routine health examination in a 70-year-old woman. Further evaluation with magnetic resonance imaging and positron emission tomography was performed to characterize the lesion and assess operability. The patient subsequently underwent formal left hepatectomy with regional lymph node dissection. Histopathological and immunohistochemical studies were conducted to establish the definitive diagnosis.

Results:

Magnetic resonance imaging demonstrated segmental enhancing wall thickening with intraductal protruding components involving the hilar left bile duct, resulting in separation of the second-order branches and obstructive cholangiohepatitis in the left hepatic lobe. PET imaging showed a hypermetabolic hilar lesion suggestive of cholangiocarcinoma and mildly hypermetabolic lymph nodes in the common hepatic and celiac areas. Surgical resection was completed without evidence of adjacent organ invasion, and pathological examination confirmed an osteoclast-like giant cell tumor. At one-year follow-up, the patient remains disease-free with no evidence of recurrence.

Conclusions:

This report describes the first known case of an osteoclast-like giant cell tumor originating in the intrahepatic bile duct. The case adds to the limited literature on this rare entity and suggests that tumors in this location may demonstrate relatively indolent biological behavior.

1409 - Alcohol Associated Liver Cancer Burden Among Young Adults Comparing China With Global Trends From GBD 2021

Yaxin Li¹, Yuwei Wang¹, Ying Han¹, Huiguo Ding¹
Beijing You'an Hospital Affiliated To Capital Medical University, Department Of Gastroenterology And Hepatology, Beijing-China¹

Background / Hypothesis:

To assess temporal trends in alcohol-associated liver cancer burden among young adults (15-49 years) in China during 1990-2021 and compare with global patterns to provide evidence-based recommendations for prevention strategies.

Materials and Methods:

Using the Global Burden of Disease 2021 database, we analyzed age-standardized incidence rates (ASIR), age-standardized mortality rates (ASMR), and age-standardized disability-adjusted life years (DALY) rates for alcohol-associated liver cancer among young adults in China from 1990 to 2021. Temporal trends were evaluated using estimated annual percentage change (EAPC) with 95% confidence intervals, and findings were compared with global estimates.

Results:

In 2021, young adults in China showed lower rates than global levels across all metrics (ASIR: 0.9 vs. 1.1, ASMR: 0.9 vs. 1.1, and DALY: 22.0 vs. 26.4 per 100,000). Over 1990-2021, China demonstrated increasing trends in both ASIR (EAPC=0.62%, 95% CI: 0.42%-0.81%) and ASMR (EAPC=0.16%, 95% CI: 0.00%-0.32%) for alcohol-associated liver cancer among young adults, while the age-standardized DALY rate declined (EAPC=-0.18%, 95% CI: -0.34% to -0.01%). Conversely, global trends showed increases across all metrics: ASIR (EAPC=0.55%, 95% CI: 0.48%-0.62%), ASMR (EAPC=0.31%, 95% CI: 0.25%-0.37%), and age-standardized DALY rates (EAPC=0.12%, 95% CI: 0.06%-0.18%). Notably, young males accounted for the predominant disease burden both in China and globally, exhibiting consistently higher ASIR, ASMR, and age-standardized DALY rates than females.

Conclusions:

Although the burden of alcohol-associated liver cancer among young adults in China remains lower than global levels, the increasing trends warrant heightened public health attention. Targeted interventions for

E-POSTER ABSTRACTS

young males are urgently needed to mitigate the rising burden of alcohol-associated liver cancer.

Keyword(s) : Alcohol, Liver cancer, Incidence, Mortality, Disability-adjusted life years

1411 - Impact of gut microbiota on the aggravation of NAFLD development in high fat diet mice with circadian rhythm disruption

Mengxia Sun¹, Jia Dong¹, Mingli Su¹, Huiwei Liu², Liangshun Zhang², Jiacheng Cai¹, Hua Ye²

Ningbo University, Health Science Center, Ningbo-China¹ The Affiliated Lihuli Hospital Of Ningbo University, Gastroenterology, Ningbo-China²

Background / Hypothesis: Non-alcoholic fatty liver disease (NAFLD) is closely linked to gut dysbiosis, and circadian rhythm disruption (CRD) can exacerbate this imbalance. However, the interplay between NAFLD, CRD, and gut microbiota remains unclear. This study investigates the impact of gut microbiota on NAFLD progression in high-fat diet (HFD)-induced mice with CRD.

Materials and Methods: Male C57BL/6J mice were divided into three groups: normal diet with normal light-dark cycle (ND-LD), HFD with normal light-dark cycle (HFD-LD), and HFD with disrupted light-dark cycle (HFD-CRD). Mice were monitored for food intake, activity, and body weight. After 14 weeks, samples were collected from euthanized mice. The remaining HFD-LD mice were divided into two subgroups: fecal microbiota donor and normal light-dark cycle-saline gavage (LD-NS). The remaining HFD-CRD mice were divided into two subgroups: disrupted light-dark cycle-normal saline gavage group (CRD-NS) and disrupted light-dark cycle-fecal microbiota transplantation group (CRD-FMT). After a second 14 weeks, samples were collected from euthanized mice. Serum biomarkers, liver pathology, and gut microbiota (16S rRNA sequencing) were analyzed.

Results: HFD induced NAFLD, while CRD exacerbated metabolic dysfunction, liver injury, and gut microbiota alterations. Over time, the impact of CRD on glucose metabolism and liver injury diminished. CRD further altered gut microbiota in NAFLD mice, reducing microbial diversity and increasing pro-inflammatory taxa. FMT from HFD-LD mice partially restored gut microbiota composition, improved lipid metabolism, and reduced liver inflammation.

Conclusions: CRD worsens NAFLD by inducing gut dysbiosis, while FMT from HFD-LD mice mitigates these effects, indicating that gut microbiota plays a regulatory role in the exacerbation of NAFLD induced

by CRD in HFD-fed mice.

Keyword(s) : Non-alcoholic fatty liver disease; Circadian rhythm disruption; Gut microbiota; Fecal microbiota transplantation; 16S rRNA sequencing; High-fat diet

1412 - Lactobacillus acidophilus Modulates the Gut-Liver Axis and Ameliorates MASLD and Type 2 Diabetes-Related Metabolic Dysregulation

Hee Jin Park¹, Jung A Eom¹, Min Ju Kim¹, Satya Priya Sharma¹, Ki Kwang Oh¹, Sung-min Won¹, Hyun Joon Park¹, Sang Jun Yoon¹, In Gyu Park¹, Mi Ran Choi¹, Young Lim Ham², Ki Tae Suk¹

Hallym University, Institute For Liver And Digestive Diseases, Chuncheon-South Korea¹ Daewon University, Department Of Nursing, Jecheon-South Korea²

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) and type 2 diabetes (T2D) are strongly influenced by gut-liver axis disturbances. Altered microbial communities exert a significant impact on disease progression, yet their mechanistic contribution remains incompletely defined. This study aimed to evaluate whether *Lactobacillus acidophilus* improves hepatic and metabolic abnormalities by modulating gut microbiota and associated metabolic pathways.

Materials and Methods:

Human stool samples were collected from healthy controls, MASLD, and MASH patients (HC, n=39; MASLD, n=35; MASH, n=43) and analyzed by 16S-based microbial taxonomic profiling (MTP) to assess microbial diversity and taxonomic composition. In parallel, a Western diet (WD)-induced MASLD mouse model and ob/ob diabetic mice were used to evaluate the metabolic effects of *L. acidophilus*. *L. acidophilus* was administered 2 times/week at a concentration of 1×10^9 CFU. metformin was used as a positive control to compare the metabolic effects of *L. acidophilus*. Hepatic histology, serum biochemical parameters, glucose metabolism, qPCR and microbiome profiling were performed across models.

Results:

Human microbiome profiling showed that gut microbial imbalance worsened with disease severity, and *Lactobacillus* abundance exhibited a progressive decreasing trend from HC (0.26%) to MASLD (0.23%) and MASH (0.12%).

In WD-fed mice, *L. acidophilus* supplementation reduced hepatic steatosis and inflammatory injury

E-POSTER ABSTRACTS

(NAS: NCD, 0; WD, 7.1; La, 5.2) and significantly lowered hepatic cholesterol levels ($p = 0.0486$). *L. acidophilus* restored intestinal barrier markers (Occludin and Claudin) and attenuated hepatic inflammation by lowering $Tnf\alpha$ and $Il1\beta$ expression. It also modulated hepatic lipid metabolism by down-regulating *Cd36* and *Srebp1c* while enhancing *Ppar α* expression. Additionally, *L. acidophilus* partially improved WD-induced dysbiosis, reflected by recovery of the Firmicutes/Bacteroidota ratio. In ob/ob diabetic mice, *L. acidophilus* improved glucose homeostasis, reducing OGTT AUC (Con, 45733; La, 36888; Met, 36510). *L. acidophilus* also enhanced hepatic AMPK activation and modulated key metabolic regulators, decreasing *SREBP1c* and *G6pc* expression while increasing *Lpin1* expression, thereby reducing both lipogenesis and gluconeogenesis.

Conclusions:

L. acidophilus improved hepatic steatosis, lipid dysregulation, and glucose homeostasis across multiple MASLD and T2D models. These findings suggest that *Lactobacillus acidophilus* exerts hepatoprotective and antidiabetic effects through AMPK activation and gut microbiota modulation, supporting its potential as a microbiome-based therapeutic candidate.

Keyword(s) : *Lactobacillus acidophilus*; MASLD; Type 2 diabetes; Gut–liver axis; Gut microbiota

1413 - Bile fungal diversity correlated with severity and is predictive of carcinoma in patients with CAGB

Sanju Yadav¹, Nupur Sharma¹, Manisha Yadav¹, Neha Sharma¹, Gaurav Tripathi¹, Sushmita Pandey¹, Jaswinder Singh Maras¹
Institute Of Liver And Biliary Sciences, Molecular And Cellular Medicine, New Delhi-India¹

Background / Hypothesis: Gallbladder cancer (CAGB) has poor prognosis. While the bile microbiome and lipidome are associated with CAGB development, the contribution of fungal microbiota is unexplored. Our study aims to investigate the contribution of fungal microbiome and identify top fungal peptides to potentially stratify CAGB patients.

Materials and Methods: Bile samples were collected from patients undergoing cholecystectomy for GS disease ($n=10$), patients undergoing surgery for CAGB ($n=16$) and healthy liver donors ($n=16$) were subjected

to fungal peptide-based diversity analysis and metabolomics. Results were cross-validated on the plasma samples, correlated with clinical parameters, and subjected to machine learning analysis.

Results: Fungal peptide-based diversity analysis identified 6 Phylum and 24 Fungal Species differentially regulated in the bile samples of the study cohort. Fungal diversity (alpha and beta diversity) was significantly higher in CAGB as compared to GS or HC ($p<0.05$). 93 fungal peptides were upregulated and 63 were downregulated in CAGB ($p<0.05$, $FC>1.5$). Linear discriminant analysis significantly segregated CAGB patients with marked increase in *Aspergillus wentii* ($\log_2FC=12.21$), *Nosema bombycis* ($\log_2FC=11.25$), *Saccharomyces* ($\log_2FC=10.89$), *Saccharomyces cerevisiae* ($\log_2FC=10.68$) and *Schizosaccharomyces pombe* ($\log_2FC=10.38$; $p<0.05$). Fungal-metabolite correlation analysis ($r^2>5$, $p<0.05$) identified *Aspergillus wentii*, *Nosema bombycis*, and others were directly associated with lysine biosynthesis, taurine, and hypotaurine metabolism, fatty acid, and other in bile, and cysteine and methionine metabolism, ascorbate metabolism, purine metabolism and other in plasma. Probability of detection (POD) calculated using fungal peptides showed a diagnostic efficiency of 96% and segregated CAGB patients. The identified top 5 fungal peptides were validated using Single reaction monitoring analysis and predicted early mortality with $>90\%$ accuracy/sensitivity and specificity in Machine Learning model.

Conclusions: Bile fungal diversity correlates with CAGB development and identified fungal panel could be used for segregation and early diagnosis of CAGB patients.

Keyword(s) : CAGB- Gallbladder carcinoma, Fungal microbiome, metabolomics, Fungal peptides.

1420 - Machine learning model based on systemic metabolic factor for mortality prediction in acute hepatitis E virus infection development and validation from a dual center cohort

Haoshuang Fu¹, Gangde Zhao², Yanan Du¹, Qing Xie¹
Ruijin Hospital, Shanghai Jiao Tong University School Of Medicine, Department Of Infectious Diseases, Shanghai-China¹ Ruijin Hospital North, Shanghai Jiao Tong University School Of Medicine, Department Of Infectious Diseases, Shanghai-China²

Background / Hypothesis: Hepatitis E virus (HEV) infection remains a significant

E-POSTER ABSTRACTS

cause of acute liver failure with high short-term mortality. However, predictive models incorporating systemic metabolic features for mortality risk assessment in HEV patients are lacking. To address this gap, we aimed to incorporate systemic metabolic factors into a machine learning framework with the goal of enhancing the early and accurate prediction of mortality risk in hospitalized HEV patients.

Materials and Methods:

A total of 510 hospitalized HEV patients from two medical centers were retrospectively enrolled and divided into training, internal validation, and external validation cohorts. Metabolic parameters, including total cholesterol, high-density lipoprotein, low-density lipoprotein, and diabetes, were integrated via support vector machine to generate a Metabolism Score (Figure 1A). This score, combined with additional clinical variables, underwent least absolute shrinkage and selection operator regression for feature selection (Figure 1B). Five machine learning algorithms were subsequently developed to predict 28-day and 90-day mortality, and their predictive performance was compared across the three cohorts.

Results:

Ten predictors were identified, including Metabolism Score, infection status, WBC, creatinine, age, platelet count, albumin, TBIL, EGFR, INR, and GGT (Figure 1C). Among the five machine learning models, the logistic regression (LR) model achieved the best performance, with AUROC values of 0.87 (95% CI = 0.83-0.90), 0.98 (95% CI = 0.94-0.99), and 0.84 (95% CI = 0.69-0.94) for 28-day mortality (Figure 1D-I), and 0.86 (95% CI = 0.82-0.90), 0.88 (95% CI = 0.81-0.93), and 0.89 (95% CI = 0.75-0.97) for 90-day mortality in the training, validation, and external cohorts (Figure 1J-L, Figure 2A-C), respectively. Calibration curves showed excellent agreement between predicted and observed outcomes, and decision curve analysis demonstrated a greater net clinical benefit compared with treat-all or treat-none strategies. The LR model also outperformed the MELD score (Figure 2D-I) and was visualized as a nomogram to facilitate clinical use (Figure 2J).

Conclusions:

The LR model integrating systemic metabolic factors effectively predicts short-term mortality in HEV patients. This model provides an interpretable and clinically practical tool to support early risk stratification and personalized management, and may assist clinicians in timely identifying high-risk individuals.

failure, Machine learning, Clinical characteristic, Noninvasive, Predictive model, Prognosis.

1421 - Pharmabiotics *Phocaeicola dorei* ameliorates liver fibrosis by alleviating macrophage efferocytosis of neutrophils

Jung A Eom ¹, Satya Priya Sharma ¹, Ki Kwang Oh ¹, Sung-min Won ¹, Hyun Joon Park ¹, Sang Jun Yoon ¹, In Gyu Park ¹, Mi Ran Choi ¹, Hee Jin Park ¹, Min Ju Kim ¹, Young Lim Ham ², Ki Tae Suk ¹

Hallym University, Institute For Liver And Digestive Diseases, Chuncheon-South Korea ¹ Daewon University, Department Of Nursing, Jecheon-South Korea ²

Background / Hypothesis:

Liver fibrosis results from chronic inflammation, dysregulated immune responses, and persistent activation of hepatic stellate cells (HSCs). Increasing evidence shows that gut microbiota influence hepatic immunity and fibrogenesis. Among these microbes, *Phocaeicola dorei* has been observed to change dynamically during liver disease progression; however, its functional role in fibrosis remains unclear. We hypothesized that *P. dorei* attenuates liver fibrosis by suppressing neutrophil activation and limiting macrophage-mediated efferocytosis of apoptotic neutrophils, thereby reducing downstream HSC activation.

Materials and Methods:

Fecal metagenomic data from 90 individuals (normal, hepatitis, cirrhosis) were analyzed to examine microbial alterations and *P. dorei* abundance. Liver fibrosis was induced in C57BL/6 mice using a DDC diet, followed by oral gavage of *P. dorei* (10^9 CFU, twice weekly). Fibrosis severity, collagen deposition, immune-cell infiltration, and chemokine expression were assessed by histology, Sirius Red staining, immunofluorescence, and qPCR. HSCs were isolated for RNA sequencing to identify pathway changes modulated by *P. dorei*. In vitro assays using HL-60-derived neutrophils, THP-1 macrophages, and LX-2 cells were conducted to evaluate apoptotic body-driven activation and the effects of *P. dorei* supernatant on inflammatory and fibrogenic signaling.

Results:

P. dorei abundance exhibited stage-dependent alterations in human liver disease. In the DDC model, *P.*

E-POSTER ABSTRACTS

P. dorei supplementation significantly reduced fibrosis, hepatic neutrophil and macrophage infiltration, and expression of CC/CXC chemokines. RNA-seq revealed that *P. dorei* reversed DDC-induced activation of neutrophil degranulation, phagosome, and efferocytosis pathways in HSCs. Expression of key efferocytosis mediators such as Axl, Cd36, Mfge8, and Pros1 was suppressed. In vitro, apoptotic neutrophil bodies stimulated macrophage-HSC activation, increasing COL1A1, ACTA2, and TGF- β , whereas *P. dorei* supernatant markedly decreased these responses. *P. dorei* also shifted the gut microbial composition toward a more anti-inflammatory profile.

Conclusions:

P. dorei protects against liver fibrosis by suppressing neutrophil activation, reducing macrophage efferocytosis, and attenuating HSC activation. These findings highlight *P. dorei* as a promising next-generation pharmabiotic capable of modulating immune-microbiome interactions to limit fibrosis progression.

Keyword(s) : Liver fibrosis, Neutrophil degranulation, Macrophage efferocytosis

1424 - Comparing two intervention strategies to improve hepatitis B virus deoxyribonucleic acid testing rate among hepatitis B surface antigen positive hospitalized patients

Qinzhi Deng ¹, Sheng Luo ², Jieqiong Chen ², Nan Ye ², Qi Zhao ³

Ningbo No.2hospital, Ward 1, hepatology, Ningbo-China ¹ Wenzhou Medical University, Graduate School Of Wenzhou Medical University, Ningbo-China ² Ningbo Haichu Third Hospital, Internal Medicine Ward, Ningbo-China ³

Background / Hypothesis: Hepatitis B surface antigen (HBsAg) screening is fundamental for chronic hepatitis B management, while hepatitis B virus deoxyribonucleic acid (HBV-DNA) testing is crucial for determining the viral replication status and initiating antiviral therapy. However, the HBV-DNA testing rate among inpatients is generally low. This study aimed to analyze the HBsAg positivity rate and HBV-DNA testing among inpatients at Ningbo Second Hospital and to evaluate the effectiveness of two intervention measures—publishing departmental rankings on the hospital intranet and conducting on-site educational sessions in departments—in improving the HBV-DNA

testing rate.

Materials and Methods: 1. Retrospectively collect data from inpatients between August 2024 and November 2025 and calculate the monthly HBsAg positivity rate and HBV-DNA testing rate. 2. Starting from November 2024, departmental HBV-DNA testing rate rankings were published monthly on the hospital intranet. Changes in the testing rate over the subsequent 5 months (December 2024 to April 2025) were evaluated. 3. Starting from May 2025, on-site educational sessions emphasizing the clinical significance of HBV-DNA testing were conducted in the 10 departments with the lowest testing rates. Changes in the testing rate over the following 6 months (May to October 2025) were evaluated. A t-test was used to compare testing rates before and after the interventions, with a P-value < 0.05 considered statistically significant.

Results: 1. During the baseline period (August–November 2024), a total of 40,255 inpatients were included. The HBsAg positivity rate was 7.8% (3,139/40,255), and the mean HBV-DNA testing rate was 28.4%. 2. During the period of intranet ranking publication (December 2024–April 2025), a total of 48,176 inpatients were included. The HBsAg positivity rate was 7.3% (3,506/48,176), and the mean HBV-DNA testing rate was 28.4%, showing no significant change compared to the baseline (P = 0.94). 3. During the period of on-site educational sessions (May–October 2025), a total of 61,512 inpatients were included. The HBsAg positivity rate was 7.4% (4,531/61,512), and the HBV-DNA testing rate increased to 32.6%, showing a significant improvement compared to the previous period (P < 0.05).

Conclusions: Publishing testing rate rankings on the intranet alone did not effectively improve the HBV-DNA testing rate. However, targeted on-site educational sessions in departments significantly increased the HBV-DNA testing rate. Proactive, face-to-face medical education holds important practical value in enhancing HBV-DNA testing among inpatients.

Keyword(s) : HBV, HBsAg, HBV-DNA, Whole-Process Management of Hepatitis B

1425 - Fibroblast activation assessed by PRO C3 and PRO C6 is associated to accumulation of key bile acids A hallmark of fibrosis initiation and mortality in alcohol related liver disease

Andressa De Zawadzki ¹, Maja Thiele ², Stine Johansen ², Ida Falk Villumsen ², Peter Andersen ², Tommi Savitaival ³, Cristina Legido-quigley ³, Diana J Leeming ¹, Aleksander Krag ², Morten Karsdal ¹

E-POSTER ABSTRACTS

Nordic Bioscience, Hepatic And Pulmonary Research, Herlev-Denmark ¹ Odense University Hospital, Department Of Gastroenterology And Hepatology, Odense-Denmark ² Steno Diabetes Center Copenhagen, Systems Medicine, Herlev-Denmark ³

Background / Hypothesis: Alcohol-related liver disease (ALD) results from persistent liver damage due to excessive alcohol consumption, often progressing to fibrosis. Disrupted bile acid homeostasis is considered a key feature in liver fibrosis development in ALD. Studies in MASH and PSC patients have shown that antifibrotic therapy reduces both bile acid levels and the fibroblast activity biomarker PRO-C3, hinting at a link between bile acids (BA) and fibrogenesis, which remains unclear. This study investigates the potential role of bile acids in ALD-related fibrogenesis by analyzing associations between fibroblast activity biomarkers, bile acids, and clinical outcomes.

Materials and Methods: Serum levels of PRO-C3 (N-terminal pro-peptide of type III collagen) and PRO-C6 (endotrophin; type VI collagen formation) and plasma concentrations of bile acids obtained through UHPLC-MS/MS were assessed in a cross-sectional cohort of 450 patients with biopsy-proven ALD. Associations between circulating BA concentrations and fibrogenesis biomarkers were analyzed using Spearman correlation. The Wilcoxon test was applied to compare PRO-C3 and PRO-C6 levels in ALD patients stratified by low and high risk of outcomes over a median follow-up period of 5 years using Kaplan-Meier survival analysis obtain survival curves and hazard ratios for mortality (HRM) and decompensation (HRD).

Results: Fibrogenesis markers correlated with glycine conjugated BAs GCA (correlation coefficient of 0.67 for PRO-C3 and 0.45 for PRO-C6) and GUDCA (correlation coefficient of 0.53 for PRO-C3 and 0.34 for PRO-C6) and taurine conjugated bile acid TCA (correlation coefficient of 0.64 for PRO-C3 and 0.46 for PRO-C6) at baseline. GCA, GUDCA and TCA were elevated in ALD patients at risk of all-cause mortality and decompensation (GCA, cutoff of 684 ng/mL, $p < 0.001$ HRM = 3.5 and HRD = 7.6; GUDCA, cutoff of 575 ng/mL, $p < 0.001$, HRM = 2.8 and HRD = 4.1; TCA, cutoff of 720 ng/mL, $p < 0.001$, HRM = 2.6 and HRD = 3.7). Baseline levels of fibrogenesis markers were found to be significantly increased in the higher risk

groups stratified according to BA concentrations of GCA (PRO-C3, $p = 1.15 \times 10^{-28}$; PRO-C6, 8.9×10^{-14}) GUDCA (PRO-C3, $p = 2.67 \times 10^{-12}$; PRO-C6, 1.93×10^{-5}) and TCA (PRO-C3, $p = 2.87 \times 10^{-20}$; PRO-C6, 5.57×10^{-11}).

Conclusions: Increased circulating levels of toxic hydrophobic BA relate to activation of fibroblasts and to poor prognosis in ALD patients, suggesting that bile acids are linked to activation of fibrogenesis, and therefore induce the development of liver fibrosis in ALD.

Keyword(s) : bile acids, fibrogenesis, alcohol-related liver disease, collagens

1427 - Protein tyrosine phosphatase 1B promotes hepatic stellate cell activation via SRC signaling

Bootsakorn Boonkaew¹, Nuchanart Suntornnont¹, Chaiyaboot Ariyachet¹
Chulalongkorn University, Biochemistry, Bangkok-Thailand¹

Background / Hypothesis:

Liver fibrosis, a major cause of cirrhosis and liver cancer, affects millions globally with limited treatment options. It is a progressive pathological condition marked by excessive extracellular matrix (ECM) deposition that ultimately impairs hepatic function, driven by the activation of hepatic stellate cells (HSCs) into myofibroblasts. Understanding the molecular mechanisms of HSC activation is critical for developing effective therapies. Protein tyrosine phosphatase 1B (PTP1B), which is highly expressed in activated HSCs, has been implicated in collagen overproduction and fibrogenesis, expanding its established roles in metabolic disorders such as obesity and type 2 diabetes. We hypothesized that PTP1B promotes human HSC activation through regulation of pro-fibrotic signaling pathways.

Materials and Methods:

Primary human HSCs were subjected to gain- and loss-of-function experiments to evaluate the effects of PTP1B on HSC activation. Assays included proliferation, migration, and gene expression analyses. Mechanistic studies examined Src signaling, including the effect of the inhibitory tyrosine 530 residue. Pharmacological inhibition of Src and re-analysis of human fibrotic liver tissue datasets were performed to validate the functional and clinical relevance of the PTP1B-Src axis.

E-POSTER ABSTRACTS

Results:

PTP1B overexpression enhanced HSC activation, increasing cell proliferation, migration, and ECM-related gene expression, while PTP1B knockdown attenuated these effects. Mechanistically, PTP1B promoted Src activation by dephosphorylating its inhibitory Tyr530 residue, driving pro-fibrotic phenotypes. Src inhibition reversed the pro-fibrotic effects of PTP1B. Clinical dataset analyses revealed significant upregulation of both PTP1B and Src in fibrotic human liver tissues, with positive correlations to ECM gene expression.

Conclusions:

These findings identify the novel PTP1B-Src signaling axis that drives human HSC activation and hepatic fibrogenesis, highlighting PTP1B as a potential therapeutic target for liver fibrosis.

Keyword(s) : Liver fibrosis, Protein tyrosine phosphatase 1B (PTP1B), Hepatic stellate cells (HSCs), Extracellular matrix (ECM), Src, Dephosphorylation

1428 - Surgical Resection Versus Non Surgical Treatment for Hepatocellular Carcinoma with Portal Vein Tumor Thrombosis A Comprehensive Systematic Review and Meta Analysis

Sang-hoon Kim¹, Seok-hwan Kim², Dong-sik Kim³, Hae Won Lee⁴

Asan Medical Center, Liver Transplantation And Hepatobiliary Surgery, Seoul-South Korea ¹ Chungnam National University Hospital, Hepatobiliary And Pancreas Surgery, Daejeon-South Korea ² Korea University College Of Medicine, Surgery, Seoul-South Korea ³ Seoul National University Bundang Hospital, Surgery, Seoul-South Korea ⁴

Background / Hypothesis: The role of surgical resection (SR) as a primary treatment for hepatocellular carcinoma (HCC) with portal vein tumor thrombosis (PVTT) remains uncertain.

Materials and Methods: A comprehensive search of electronic databases from January 2000 to April 2024 identified studies comparing SR with transarterial chemoembolization (TACE), combined TACE and radiation therapy (TACE-RT), or sorafenib. Meta-analyses were conducted for comparison groups with at least three eligible studies. Hazard ratios (HRs) with 95 percent confidence intervals (CIs) for overall survival

(OS) were extracted or reconstructed from Kaplan-Meier curves.

Results: Twelve retrospective cohort studies involving 4,498 patients were included. SR demonstrated superior long-term OS compared with TACE in Vp1-2 (5-year OS: HR 0.53, 95% CI 0.35-0.79) and Vp3 (5-year OS: HR 0.68, 95% CI 0.61-0.75), with comparable outcomes in Vp4. SR and TACE-RT showed similar 1- and 3-year OS, although SR demonstrated a clear 5-year OS advantage in Vp1-3 PVTT (HR 0.48, 95% CI 0.31-0.74). Compared with sorafenib, SR provided superior OS in Vp1-2 (3-year OS: HR 0.26, 95% CI 0.18-0.38) and comparable OS in Vp3. Sensitivity analyses supported the robustness of these findings, and no substantial publication bias was detected.

Conclusions: Based on current evidence, SR is not inferior to non-surgical treatments including TACE, TACE-RT, and sorafenib in patients with HCC and PVTT and provides meaningful long-term survival benefits, particularly in those with segmental PVTT (Vp1-Vp2). Further comparative studies incorporating immunotherapy are needed in future research.

Keyword(s) : Hepatocellular carcinoma; tumor thrombosis; resection; transarterial chemoembolization; meta-analysis.

1429 - Meta analysis of efficacy and safety of CAR NK cell in the treatment of primary liver cancer

Guoyun Xuan¹

The Air Force Hospital Of Northern Theater Pla, Department Of Gastroenterology, Shenyang-China ¹

Background : According to the 2020 Global Cancer Statistics, there are 19.3 million new cancer cases and 10 million cancer deaths annually, highlighting the urgent need for effective cancer treatments. Traditional therapies, including surgery, radiotherapy, and chemotherapy, have limitations in treating hepatocellular carcinoma (HCC). While recent advancements in cancer biology and immunotherapy, particularly the emergence of CAR-NK cell therapy, demonstrate promising therapeutic potential, their efficacy in HCC treatment still faces significant challenges.

Materials and Methods: This study systematically searched the relevant studies in Pubmed, Embase, Cochrane and ClinicalTrial.gov databases up to March 2025, aiming to comprehensively evaluate the clinical efficacy and safety of CAR-NK cell therapy in hepatocellular carcinoma (HCC). The inclusion criteria

E-POSTER ABSTRACTS

were clinical trials that reported objective response rate (ORR).

Results:After screening, a total of 3 trials involving 49 patients were included. The results showed that NK cell therapy achieved an objective response rate of 72.3% in HCC (usually combined with local treatment), with good safety performance, where fatigue was the most common adverse event.

Conclusions:CAR-NK cell therapy offers a novel therapeutic approach for hepatocellular carcinoma (HCC). Given its promising initial results in HCC treatment, future research should focus on the following aspects. First, larger-scale multicenter clinical trials are required to validate the generalizability and reliability of these findings. Second, deeper exploration of CAR-NK cell therapy mechanisms is essential, including their behavior in the tumor microenvironment and impact on immune evasion. Additionally, research should address strategies to enhance the in vivo proliferation and persistence of CAR-NK cells, as well as reduce treatment-related adverse effects.

Keyword(s) : Natural killer cells; Hepatocellular carcinoma; Chimeric antigen receptor; Meta-analysis

1430 - Fibrosis non invasive test panel (FIB NIT) A novel biomarker panel for investigating fibrosis dynamics through individual components of fibrogenesis (PRO C3) fibrolysis (CTX III) and clinical outcomes (PRO C6) in alcohol related liver disease

Andressa De Zawadzki ¹, Professor Department Of Gastroenterology And Hepatology ², Stine Johansen ², Ida Falk Villumsen ², Peter Andersen ², Ida Z Spedtsberg ², Rune Vestermark ³, Morten Karsdal ¹, Aleksander Krag ², Diana J Leeming ¹
Nordic Bioscience, Hepatic And Pulmonary Research, Herlev-Denmark ¹ Odense University Hospital, Department Of Gastroenterology And Hepatology, Odense-Denmark ² Nordic Bioscience, Business Development, Herlev-Denmark ³

Background / Hypothesis: Persistent and excessive alcohol intake induces damage to the liver, impairing its ability to properly regenerate, potentially leading to alcohol-related liver disease (ALD). Non-invasive tests (NITs) quantifying the dynamics of the extracellular matrix (ECM) remodeling and disease activity may be important for patient prognosis. We aimed to investigate the above-mentioned utility of the serologically assessed FIBrosis Non-Invasive Test panel (FIB-NIT) consisting of three single markers that can

describe fibrogenesis (PRO-C3), patient outcomes PRO-C6) and fibrolysis (CTX-III). All, previously shown to be modulated by interventions in MASH clinical trials.

Materials and Methods: Serum biomarkers of fibrogenesis nordicPRO-C3TM (N-terminal pro-peptide of type III collagen) and for patient outcome nordicPRO-C6TM (endotrophin; type VI collagen formation) as well as fibrosis resolution nordicCTX-IIIITM (MMP degraded fragment of cross-linked type III collagen) were measured in a cross-sectional cohort of 450 biopsy-proven F0-F4 ALD patients. The biomarkers were investigated as single markers to understand disease mechanisms in relation to disease severity and prognosis of outcomes (mortality, liver related events and non-liver related outcomes) over a median 5-yr follow-up.

Results: ALD patients with advanced fibrosis (F3-F4) and cirrhosis exhibited increased fibrogenesis as observed from higher serum PRO-C3 and PRO-C6 ($p < 0.001$) as well as higher fibrolysis as shown by higher serum levels of CTX-III ($p < 0.001$) in comparison to patients with mild-moderate fibrosis (F0-2). Kaplan-Meier curves showed that all three biomarkers provided good prognostic value to stratify ALD patients at risk of all-cause mortality and decompensation (PRO-C3 cutoff of 12.6, hazard ratio for mortality (HRM) of 4.1 and decompensation (HRD) of 10.6; CTX-III cutoff of 15.6; HRM of 2.2 and HRD of 2.6; PRO-C6 cutoff of 11.2; HRM of 3.4 and HRD of 4.8.

Conclusions: The "FIB-NIT" biomarker panel may be utilized for evaluating fibrosis remodeling and risk of patient outcomes in ALD. This panel may offer insights into the underlying mechanisms of fibrosis progression and help understanding the mode of action of novel therapies in ALD as well as other chronic liver diseases.

Keyword(s) : fibrogenesis, fibrosis resolution, clinical outcomes, alcohol-related liver disease, collagens, extracellular matrix remodeling

1432 - Longitudinal Changes in Skeletal Muscle Index Among Patients With Cirrhosis A Mixed Effects Analysis in an Observational Cohort

E-POSTER ABSTRACTS

Qian Wang¹, Ming Kong², Yu Chen²

Beijing You'an Hospital Affiliated To Capital Medical University, Beijing Key Laboratory Of Liver Regeneration And Artificial Liver Transformation Research, Beijing 100069, China, Beijing-China¹
Beijing You'an Hospital Affiliated To Capital Medical University, Fourth Department Of Liver Disease (difficult & Complicated Liver Diseases And Artificial Liver Center), Beijing-China²

Background / Hypothesis: Sarcopenia is a common and severe complication of liver cirrhosis and is closely associated with adverse clinical outcomes. However, precise quantitative data describing the longitudinal rate of change in skeletal muscle index (SMI) based on abdominal CT imaging—and its associations with sex and age—remain limited in cirrhotic populations.

Materials and Methods: This retrospective study included 115 adult patients with cirrhosis (77 men and 38 women) from Beijing You'an Hospital, Capital Medical University. All patients underwent at least two abdominal CT examinations at intervals of 12 ± 3 months. Skeletal muscle area at the L3 vertebral level was measured and used to calculate SMI. A linear mixed-effects model was applied to estimate the longitudinal rate of SMI change over time.

Results: Cirrhotic patients exhibited a significant progressive decline in SMI, with an estimated annual decrease of -1.001 units/year (95% CI: -1.317 to -0.683, $P < 0.001$). Subgroup analyses showed no significant differences in the rate of SMI decline by sex (interaction $P = 0.812$) or age group (≥ 60 vs. < 60 years, interaction $P = 0.736$), indicating that the progression of sarcopenia is a pervasive process affecting patients with cirrhosis irrespective of sex or age.

Conclusions: This study quantitatively demonstrates a progressive decline in SMI during longitudinal follow-up in patients with cirrhosis, with a rate substantially exceeding the physiological age-related decline observed in healthy individuals. These findings underscore that sarcopenia represents a universal and consistent complication throughout the course of cirrhosis. Accordingly, routine longitudinal monitoring of SMI and early targeted intervention are

recommended for all patients with cirrhosis to improve long-term outcomes.

1433 - Functional changes following hepatocyte transplantation in mice with liver injury

Yuki Tamaki¹, Eri Nanizawa¹, Shun Otsuka¹, Naoyuki Hatayama¹, Munekazu Naito¹
Aichi Medical University, Department Of Anatomy, Nagakute-Japan¹

Background / Hypothesis: Percutaneous ethanol injection (PEI) is a widely used local therapy for hepatocellular carcinoma due to its minimal invasiveness and strong local tumor control. However, the diffusion of injected ethanol is difficult to control, and oxidative stress and necrosis have been reported to occur in normal hepatocytes surrounding the tumor, which may lead to hepatic dysfunction and poor prognosis. Preventing such injury to normal hepatocytes is for enhancing the safety of PEI. This study aimed to evaluate whether hepatocyte transplantation can suppress PEI induced liver damage in a normal mouse model.

Materials and Methods: C57BL/6 mice were divided into three groups: non-treated control (Control), PEI + PBS (Sham group), and PEI + hepatocyte transplantation (Treatment group). The PEI models were injected 20 μ L of 100% ethanol into the left hepatic lobe, and mice injected either PBS or primary hepatocytes isolated from GFP-transgenic C57BL/6 donor mice via intrasplenic, in the sham and treatment groups, respectively. Serum ALT was measured at 3, 6, 24, and 48 hours and at sacrifice. Mice were sacrificed at 1 and 4 weeks after treatment, and liver tissues were analyzed histologically by H&E staining for morphological assessment and GFP immunohistochemical staining for localization of transplanted cells and genetically by qRT-PCR of inflammation and fibrosis related genes.

Results: Serum ALT levels transiently increased in the treatment group compared with the sham group during the early phase after PEI, but the difference diminished over time until 48 hours. At 1 week, necrotic areas were smaller in the treatment group than in the sham group, indicating reduced hepatic injury. GFP-positive hepatocytes were detected in the liver at both 1 and 4

E-POSTER ABSTRACTS

weeks after transplantation, though no proliferation was observed between 1 and 4 weeks. qRT-PCR revealed that inflammatory cytokines and fibrosis markers tended to be lower in the treatment group compared to the sham group. In particular, Tgfb and Pai1 were significantly elevated in the sham group compared to the control group, whereas no significant differences were observed between the treatment and control groups. These findings suggest that hepatocyte transplantation may suppress hepatic inflammation and fibrotic responses following PEI.

Conclusions:

In a normal mouse model, hepatocyte transplantation reduced hepatic inflammation and fibrosis after PEI. Hepatocyte transplantation may help preserve normal liver tissue and contribute to improving the safety of PEI therapy.

Keyword(s) : hepatocyte transplantation, PEI, liver injury, liver regeneration

1434 - Awareness and Treatment Status of Patients with Chronic Hepatitis B Results from a Single Center Patient Survey in Hunan province China

Jun Chen¹, Xiao Zhong¹, Zebing Huang¹, Yan Huang¹
Xiangya Hospital Central South University, Infectious Diseases Department, Changsha-China¹

Background / Hypothesis: Chronic hepatitis B (CHB) remains a major public health challenge in China, with significant variations in treatment uptake and disease awareness. This single-center survey aimed to characterize real-world patient profiles, treatment awareness, and barriers to antiviral therapy.

Materials and Methods: A paper-based questionnaire was administered to CHB outpatients under the guidance of trained nurses, covering demographics, diagnosis and treatment history, HBV-related disease burden, and treatment decision factors.

Results: Among 145 respondents, 62.76% (91/145) were male and 82.76% (120/145) were aged 31–60 years; 52.41% (76/145) had a disease duration ≥ 10 years. Overall, 83.45% (121/145) were receiving antiviral therapy, predominantly with tenofovir alafenamide fumarate (TAF) or (entecavir) ETV (66.67%). Of the 24 untreated patients, main reasons for non-treatment included reluctance toward long-term medication (33.33%, 8/24), perception of no symptoms and thus no need for therapy (25.00%, 6/24), and no physician recommendation (25.00%, 6/24).

Although 79.31% (115/145) recognized HBV could lead to cirrhosis or cancer, 14.48% (21/145) mistakenly believed HBV is transmissible via shared utensils. Gender differences were observed: males more often followed physicians' advice (80.22% vs. 64.81%, $p < 0.05$), while females more frequently considered drug efficacy (31.48% vs. 23.08%), cost (16.67% vs. 6.59%), and treatment discontinuation (14.81% vs. 7.69%). Treated patients showed better awareness of transmission and treatment benefits. 85.7% of treated patients recognized the importance of timely treatment in preventing severe complications, compared with 54.5% of untreated patients. Digital channels were widely used for health information, with 40.69% of participants (59/145) selecting hospital official WeChat accounts or apps and 58.62% (85/145) utilizing at least one digital platform.

Conclusions: HBV awareness and treatment rates have improved among Chinese CHB patients, with TAF and ETV being the most common regimens. However, misconceptions about transmission and reluctance toward long-term therapy persist. Digital health platforms show potential in addressing knowledge gaps and supporting adherence.

Keyword(s) : Awareness and treatment; Chronic Hepatitis B; Single Center; Patient Survey

1435 - Individualized nutrition support improves outcomes in hepatitis B virus related acute on chronic liver failure patients at nutritional risk a randomized controlled trial

Zhipeng Li¹, Yeqiong Zhang¹, Liang Peng¹
Third Affiliated Hospital Of Sun-yat Sen University, The Infectious Disease Department, Guangzhou-China¹

Background / Hypothesis:

Patients with acute-on-chronic liver failure (ACLF) are at high nutritional risk, which adversely affects prognosis, yet robust evidence for nutritional interventions is scarce. This study evaluated the safety and efficacy of individualized nutritional support for hepatitis B virus-related ACLF (HBV-ACLF).

Materials and Methods:

In this single-center, open-label randomized controlled trial, HBV-ACLF patients meeting COSSH criteria with NRS-2002 ≥ 3 were randomized 1:1 to individualized nutritional support (energy target $1.2 \times \text{REE}$; protein 1.2 g/kg/day) or control (standard dietary advice). Assessments were performed at baseline, day 30, and day 90. Primary endpoints were 30- and 90-day transplant-free mortality. Secondary endpoints

E-POSTER ABSTRACTS

included safety, the incidence of adverse outcomes (ascites, gastrointestinal bleeding, infection, hepatic encephalopathy, hepatorenal syndrome, rehospitalization, and ICU admission), liver severity scores (MELD, COSSH-ACLF IIs), anthropometry (mid-arm circumference), muscle function (handgrip strength, gait speed, and SPPB), and quality of life (EQ-5D).

Results:

Between December 2023 and March 2025, 572 patients with HBV-ACLF were screened, 80 were randomized, and 78 (39 in the control group and 39 in the intervention group) were analyzed in the modified intention-to-treat population. Baseline characteristics were generally comparable between groups. Individualized nutrition significantly reduced transplant-free mortality at day 30 (2.6% vs. 20.5%, $p = 0.033$) and day 90 (17.9% vs. 38.5%, $p = 0.044$) compared to controls (Tab. 1). Adverse outcome rates were also significantly lower in the intervention group (day 30: 25.6% vs 56.4%, $p = 0.006$; day 90: 33.3% vs 74.4%, $p < 0.001$), with no excess in serious events, gastrointestinal reactions, complications, or hyperglycemia. The intervention group achieved greater improvements in MELD and COSSH-ACLF II scores, anthropometric indexes, muscle function, adverse clinical outcomes, and EQ-5D scores at follow-up (Fig. 1).

Conclusions:

In HBV-ACLF patients at nutritional risk, individualized target-driven nutritional support is safe, lowers 30- and 90-day transplant-free mortality, reduces adverse clinical outcomes, and improves hepatic function, muscle performance, and quality of life. These findings provide prospective, randomized evidence supporting early, goal-driven, and function-oriented nutrition treatments with dynamic assessments as a practical strategy in ACLF care.

1437 - Efficacy of Sequential or Combined Tenofovir Alafenamide in Entecavir Treated CHB Patients with Low Level Viremia and Its Impact on Lipid Levels

Yijing Zhang¹, Yueqiu Gao², Man Li³, Jie Shen⁴, Liying Huang²

Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Pharmacy
Department/department Of Hepatology, Shanghai-China¹ Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine,

Department Of Hepatology, Shanghai-China²

Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Shanghai Key Laboratory Of Traditional Chinese Clinical Medicine, Shanghai-China³ Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Pharmacy Department, Shanghai-China⁴

Background / Hypothesis:

To compare the efficacy of sequential tenofovir alafenamide (TAF) versus entecavir (ETV) plus TAF in ETV-treated chronic hepatitis B (CHB) patients with low-level viremia (LLV), and their effects on virological response, liver/kidney function, and lipid levels.

Materials and Methods:

A total of 217 CHB patients with LLV after ETV treatment (May 2020 - August 2023) were divided into the TAF group (sequential TAF, $n=180$) and the Combination group (ETV+TAF, $n=37$). After 1:1 propensity score matching (PSM), 37 patients were included in each group. SPSS 26.0 was used to compare HBV DNA undetectable rate, HBeAg seroconversion rate, liver/kidney function indices [LSM, PLT, AST, ALT, Cr], lipid levels [TC, TG, HDL-C, LDL-C], and adverse events.

Results:

After 48 weeks of treatment, the HBV DNA and HBeAg undetectable rates in the Combination group were 86.49% and 59.46%, respectively, higher than 59.46% and 35.14% in the TAF group ($\chi^2=6.852$, 4.391; $P=0.009$, 0.036). Post-treatment, LSM (7.01 ± 1.50 kPa), AST (18.02 ± 2.28 u/L) and ALT (19.85 ± 3.86 u/L) in the Combination group were lower than those in the TAF group (7.90 ± 1.68 kPa, 21.12 ± 2.85 u/L, 22.00 ± 3.90 u/L), with significant differences ($t=2.404$, 5.166, 2.383; $P=0.019$, 0.000, 0.020). PLT ($218.35 \pm 42.60 \times 10^9$) and Cr (70.92 ± 6.54 $\mu\text{mol/L}$) in the Combination group were higher than those in the TAF group ($192.82 \pm 44.13 \times 10^9$, 67.60 ± 6.13 $\mu\text{mol/L}$), with significant differences ($t=2.532$, 2.253; $P=0.014$, 0.027). Post-treatment, TC levels in the TAF group (5.60 ± 0.89 mmol/L) and Combination group (5.45 ± 0.80 mmol/L) were slightly higher than their pre-treatment levels [(5.18 ± 0.85) mmol/L, (5.02 ± 0.83) mmol/L] ($t=2.076$, 2.269; $P=0.041$, 0.026).

Conclusions:

Combined TAF therapy improves virological response, liver function, and fibrosis compared to sequential TAF in ETV-treated LLV patients, whereas sequential TAF has less impact on renal function. Both regimens may

E-POSTER ABSTRACTS

mildly elevate TC levels.

Background / Hypothesis: Seladelpar is a first-in-class delpar (selective peroxisome proliferator-activated receptor [PPAR]-delta agonist) indicated for the treatment of primary biliary cholangitis in combination with ursodeoxycholic acid (UDCA) in patients with an inadequate response to UDCA or as monotherapy in patients unable to tolerate UDCA. RESPONSE was a Phase 3, randomised, placebo-controlled clinical trial of seladelpar in patients with inadequate response/intolerance to UDCA. Patients completing RESPONSE were eligible to roll over into ASSURE (NCT03301506), an ongoing, open-label, long-term, Phase 3 safety trial. Here, we describe data from month 18 (month 6 of ASSURE) in patients with or without prior use of fibrates or obeticholic acid (OCA) who rolled over from RESPONSE into ASSURE.

Materials and Methods: Patients received 10 mg seladelpar orally daily or placebo in RESPONSE; patients received open-label 10 mg seladelpar in ASSURE. Fibrates and OCA were prohibited during the study period and a 6-week washout was required prior to entry in RESPONSE. Data were described for patients in ASSURE with or without prior use of fibrates/OCA

and based on whether they received seladelpar (continuous seladelpar patients) or placebo (crossover patients) in RESPONSE. Efficacy included the percentage of patients achieving a composite biochemical response (CBR; alkaline phosphatase [ALP] < 1.67 × upper limit of normal [ULN], ALP decrease ≥ 15%, and total bilirubin ≤ ULN). Safety assessments included adverse events (AEs) and laboratory parameters.

Results: Among patients who continued into ASSURE from RESPONSE (158), 16 continuous seladelpar and 11 crossover patients reported prior use of fibrates/OCA (total, n=27; 17%); 88 continuous seladelpar and 43 crossover patients reported no prior use of fibrates/OCA (total, n=131; 83%). At month 18, among continuous seladelpar patients, 9/15 (60%) patients with prior fibrate/OCA use achieved a CBR vs 54/87 (62%) patients without prior fibrate/OCA use. Among crossover patients, 7/11 (64%) patients with prior fibrate/OCA use vs 32/41 (78%) patients without prior fibrate/OCA use achieved a CBR at month 6 of ASSURE. From ASSURE initiation to month 6, incidence of AEs was similar across continuous seladelpar and crossover patients, regardless of prior OCA/fibrate use; no treatment-related serious AEs were reported.

Conclusions: In this interim analysis of continuous seladelpar and crossover patients from ASSURE, patients who reported prior use of fibrates/OCA achieved a similar sustained biochemical response with seladelpar compared with patients who reported no prior use. Seladelpar appeared safe and well tolerated in this subgroup.

Background / Hypothesis: Liver fibrosis is one of the key determinants of prognosis and treatment decisions in chronic hepatitis B (CHB). This study aimed to characterise liver-stiffness-based fibrosis stages in CHB patients in Georgia and evaluate their associations with viral, clinical, and demographic factors, thereby supporting clinical decision-making.

Materials and Methods: A cross-sectional study was conducted among 163 adults with CHB who underwent liver stiffness measurement (LSM) by transient elastography (TE). Variables included HBV DNA, HBeAg, ALT, AST, platelet count, BMI, presence of benign vs malignant liver lesions on abdominal ultrasound (US), antiviral treatment status, age and sex. Fibrosis stages were classified using LSM cut-offs: <7 kPa (F0–F1) and ≥7 kPa (≥F2). Cirrhosis was defined as liver stiffness >12.5 kPa (F4). For association analyses, stiffness was grouped into low <7 kPa (F0–F1) vs high ≥7 kPa (≥F2). Comparisons between low and high stiffness groups used independent-samples t-tests and chi-square tests. Pearson correlations assessed associations between continuous LSM and ALT, AST, platelet count, BMI, and HBV DNA; odds ratios (OR) with 95% confidence intervals (CI) were calculated.

Results: Of 163 patients (58.9% male; 24.1% aged ≥50 years), 69.9% had F0–F1 fibrosis and 30.1% had ≥F2, including 8.0% with F4. HBeAg negativity predominated (88.3%), and HBV DNA categories showed no significant group differences. Abdominal US identified benign liver lesions in 26.4% and hepatocellular carcinoma (HCC) in 1.8%. Patients with high stiffness (≥7 kPa) had higher ALT (64.5 vs 33.6 U/L, $p=0.004$), higher AST (43.4 vs 25.3 U/L, $p<0.001$), and lower platelet counts (210.8 vs $238.0 \times 10^9/L$, $p=0.013$). Age ≥50 years was strongly associated with high stiffness (51.3% vs 22.8%; OR=2.25, 95% CI 1.44–3.52; $p=0.001$). No significant associations were observed with sex, BMI, HBV DNA, HBeAg or ultrasound lesion type. Continuous LSM correlated with

AST ($r=0.439$, $p<0.001$), ALT ($r=0.225$, $p=0.004$), and inversely with platelets ($r=-0.378$, $p<0.001$). Treated patients more often had liver stiffness ≥7 kPa, higher fibrosis stages, HBeAg positivity, and ultrasound-detected HCC.

Conclusions: Higher liver stiffness in CHB patients was associated with older age, elevated transaminases, and lower platelet counts. No significant associations were observed with sex, BMI, HBV DNA, HBeAg or ultrasound lesion type. These findings may help identify patients at greater risk of fibrosis and support more targeted CHB management.

1440 - Prevalence and predictors of hepatitis B virus infection among sellers and workers at West Africa's largest market Kejetia Ghana a cross sectional study

Clinton Owusu Boateng ¹, Michael Agyemang Obeng ¹, De-graft Kwaku Ofori Boateng ², Abdul Latif Koney Shardow ¹, Daniel Kobina Okwan ³, Pius Takyi ¹, Godfred Yawson Scott ⁴

Kwame Nkrumah University Of Science And Technology, Kumasi Centre For Collaborative Research In Tropical Medicine, Kumasi-Ghana ¹ Elbe Kliniken Stade-buxtehude, Stade, Department Of Pathology, Stade-Germany ² Kwame Nkrumah University Of Science And Technology, Department Of Anatomy, Kumasi-Ghana ³ Kwame Nkrumah University Of Science And Technology, Department Of Medical Diagnostics, Kumasi-Ghana ⁴

Background / Hypothesis: Hepatitis B virus (HBV) infection remains a major public health challenge in sub-Saharan Africa, including Ghana, despite the infant vaccination programs. Limited data exist on HBV prevalence and predictors in informal sector populations, who may face unique occupational and behavioural exposures. This study assessed the prevalence and predictors of HBV infection among sellers and workers at Kejetia Market, Ghana's largest commercial hub.

Materials and Methods: A cross-sectional study was conducted among 489 adult market workers from December 4, 2024, to January 25, 2025. Participants

E-POSTER ABSTRACTS

were selected through stratified random sampling across occupational groups. Data on sociodemographic, occupational, and behavioural factors were collected using structured questionnaires. On-site testing for hepatitis B surface antigen (HBsAg) was performed using the Hightop One Step Rapid Test kit. Bivariate and multivariate logistic regression analyses were used to identify independent predictors of HBV infection. $P < 0.05$ was considered statistically significant.

Results: The overall prevalence of HBV infection was 7.36% (36/489), consistent with intermediate-to-high endemicity. Multivariate analysis identified three independent predictors of HBV infection. Female gender (aOR = 0.455, 95% CI: 0.221–0.937; $p = 0.033$) and absence of tattoos (aOR = 0.283, 95% CI: 0.110–0.730; $p = 0.009$) were associated with lower risk of HBV infection, while unvaccinated individuals had 3.37-fold increased odds of getting the infection (95% CI: 1.395–8.142; $p = 0.007$). HBV prevalence declined progressively with increasing vaccine doses, from 9.2% in unvaccinated individuals to 2.3% among those who had completed three or more doses.

Conclusions: HBV infection is common among Kejetia market workers, with prevalence exceeding both continental and global estimates. Gender, tattooing, and vaccination status were significant predictors of infection. Strengthening adult vaccination programs, promoting safe tattooing practices, and implementing male-focused screening and prevention interventions are critical to reducing HBV burden and achieving Ghana's contribution to the WHO goal of eliminating HBV by 2030.

Background / Hypothesis: Seladelpar is a first-in-class delpar (peroxisome proliferator-activated receptor [PPAR]-delta agonist) indicated for the treatment of primary biliary cholangitis (PBC) combined with ursodeoxycholic acid (UDCA) in adults with an inadequate response to UDCA, or as monotherapy in patients intolerant to UDCA. While seladelpar's efficacy in improving cholestatic markers is well established, its impact on liver stiffness measurements (LSMs), which typically worsen over time in PBC, remains underexplored. We report longitudinal LSM data in patients treated with seladelpar for up to 36 months (M) in an interim analysis of the ongoing, open-label Phase 3 ASSURE study (NCT03301506).

Materials and Methods: Patients enrolled in ASSURE from the placebo-controlled Phase 3 RESPONSE trial (NCT04620733) or earlier legacy seladelpar studies. LSM assessed by vibration-controlled transient elastography (FibroScan) was collected as an exploratory endpoint with local reads. This analysis included on-treatment LSM from patients with ≥ 1 post-baseline measurement, excluding values with a

E-POSTER ABSTRACTS

confirmed IQR/LSM ratio >30%. Baseline was defined at the time of seladelpar initiation. Patients were stratified by baseline LSM categories: <10.7, ≥10.7 and <16.9, and ≥16.9 kPa. LSM changes were assessed at 12M, 24M, and 36M, with category shifts assessed at 36M. Due to the non-normal distribution of LSM values, medians were reported. Data cutoff: Jan 31, 2025.

Results: A total of 311 patients were included in the analysis. LSM values at 36M were available in 114 patients. The overall median (IQR) LSM at baseline was 7.5 (5.9, 11.1) kPa. The median change in LSM was -0.2 (-1.7, 1.8) kPa, with a percent change of -2.9% (-22.8%, 25.9%). In patients with baseline LSM of <10.7 kPa, ≥10.7 and <16.9 kPa, or ≥16.9 kPa, median changes in LSM to 36M were +0.1 (-1.3, 1.8) kPa, -0.9 (-3.6, 4.8) kPa, and -5.2 (-10.6, 2.4) kPa, respectively. Similarly, median percent changes from baseline were +2.0% (-18.3, 26.1), -7.4% (-29.5, 38.7), and -29.7% (-51.5, 12.7). For category shifts, most patients (97/114 [85%]) were stable or improved at 36M. Patients whose LSM worsened by 30% or more from baseline were younger ($P < 0.05$), with otherwise comparable characteristics.

Conclusions: In this interim analysis, most patients maintained or improved their LSM category over 36M of seladelpar treatment. In the group at the highest risk for progression (≥16.9 kPa), there was a trend towards improvement with seladelpar.

1442 - Combination Therapy Using DPCAS Mode and DPMAS Mode of Artificial Liver Support System for Severe Liver Injury with Sepsis A Case Report

Wenjuan Shi ¹, Hong Wan ¹, Peng Luo ¹, Xuefang Yang ¹, Yue Kong ²

Lanzhou Second People's Hospital, Department Of Hepatology, Lanzhou City-China ¹ Gansu University Of Chinese Medicine, Department Of Integrated Traditional Chinese And Western Medicine Clinical Medicine, Gansu University Of Chinese Medicine, Lanzhou City-China ²

Background / Hypothesis: Sepsis is characterized by

acute onset and rapid progression, which easily leads to multiple organ failure. The clinical treatment of severe liver injury complicated with sepsis is extremely challenging. The efficacy of the combined DPCAS and DPMAS artificial liver modes in such severe cases lacks verification by single-case studies, and this study aims to explore the clinical efficacy of this combined therapeutic strategy.

Materials and Methods: A 56-year-old female patient with severe liver injury complicated with sepsis (SOFA score of 8 at admission) admitted to our hospital in March 2025 was selected as the research subject. She was given meropenem 1 g intravenously (once every 8 hours) and methylprednisolone 40 mg intravenously (once daily) for anti-infection and anti-inflammatory treatment, and 2 sessions of combined DPCAS-DPMAS artificial liver therapy were performed simultaneously. The patient's clinical data, laboratory test indicators (procalcitonin, C-reactive protein, liver function indexes) and imaging examination results were collected for retrospective analysis.

Results: After treatment, the patient's procalcitonin decreased from 48.8 ng/mL to 0.074 ng/mL, and the levels of C-reactive protein and interleukin-6 returned to normal; liver function indexes such as alanine aminotransferase (909 U/L) and total bilirubin (152.3 μmol/L) all decreased to the normal range. The patient's symptoms such as fever and jaundice completely resolved, the imaging manifestations of pulmonary inflammation improved significantly, she was successfully discharged on the 12th day of admission, and her condition was stable with no abnormal indicators during the 6-week follow-up.

Conclusions: Combined DPCAS and DPMAS artificial liver therapy can effectively alleviate the systemic inflammatory response mediated by sepsis and improve impaired liver function, which is a safe and effective clinical scheme for the treatment of severe liver injury complicated with sepsis.

Keyword(s) : DPCAS; DPMAS; Artificial liver support system; Severe liver injury; Sepsis

E-POSTER ABSTRACTS

1443 - Seladelpar is associated with sustained reductions in cholestatic markers and a consistent safety profile in patients with primary biliary cholangitis up to 48 months in the ongoing open label ASSURE study

Daniel Pratt ¹, Eric J. Lawitz ², Christopher L. Bowlus ³, Akin Kose ⁴, Kyung Min Kwon ⁴, Sarah Proehl ⁴, Xin Qi ⁴, Robert P. Kustra ⁴, Alejandra M. Villamil ⁵
Massachusetts General Hospital, Autoimmune And Cholestatic Liver Center, Boston-United States ¹ Texas Liver Institute, University Of Texas Health San Antonio, , San Antonio-United States ² Division Of Gastroenterology And Hepatology, University Of California Davis School Of Medicine, , Sacramento-United States ³ Gilead Sciences, Inc., Medical Affairs, Istanbul-Türkiye ⁴ The Liver Autoimmunity Unit, Hospital Italiano De Buenos Aires, , Buenos Aires-Argentina ⁵

Background / Hypothesis: Seladelpar is a first-in-class delpar (selective PPAR-delta agonist) indicated for the treatment of primary biliary cholangitis (PBC) in combination with ursodeoxycholic acid (UDCA) in adults with an inadequate response to UDCA, or as monotherapy in patients intolerant to UDCA. Here, we report the latest interim, long-term biochemical efficacy/safety data in a pooled population of patients treated with seladelpar in ASSURE.

Materials and Methods: ASSURE (NCT03301506) is an ongoing, open-label, long-term, Phase 3 trial of seladelpar in patients with PBC rolling over from the placebo-controlled, Phase 3 RESPONSE trial (NCT04620733) or with prior participation in legacy seladelpar trials. The Phase 2 and 3 parent studies for ASSURE required an inadequate response or intolerance to UDCA. Data cutoff: 1/31/2025. Patients were pooled starting with their initiation of seladelpar (at entry into RESPONSE for those randomized to seladelpar; at entry into ASSURE for all others). Patients received blinded, daily oral seladelpar 10 mg in RESPONSE and open-label, daily oral seladelpar 10 mg in ASSURE. Efficacy endpoints included composite biochemical response (CBR; alkaline phosphatase [ALP] $<1.67 \times$ the upper limit of normal [ULN], ALP decrease $\geq 15\%$ from baseline, and total bilirubin $\leq$ ULN), ALP normalization, ALP percent change from baseline, and other laboratory parameters summarized through 36 months (M). Safety was assessed by exposure-adjusted adverse events (AEs) per 100 patient-years of exposure through 48M.

Results: Among 337 patients treated with open-label seladelpar 10 mg, 258 were treated for ≥ 2 years and 117 were treated for ≥ 3 years, with 122 patients reaching their 36M visit by the data cutoff. Most patients achieved a CBR: 69% (225/325) at 12M, 70% (181/258) at 24M, and 67% (82/122) at 36M. ALP normalized in 35% of patients (114/325) at 12M, 37% (96/258) at 24M, and 34% (41/122) at 36M. Treatment with seladelpar resulted in sustained reductions in ALP, with mean percent changes from baseline of -43% at 12M, -43% at 24M, and -40% at 36M. Sustained reductions were also observed in alanine aminotransferase and gamma-glutamyl transferase through 36M. Seladelpar was well tolerated, with overall AEs reported in 83.2 patients per 100 patient-years in year 1 and 62.3 in year 4.

Conclusions: Seladelpar led to sustained reductions in biochemical markers of cholestasis with up to 36M of open-label treatment. Seladelpar also appeared to be safe and well tolerated; no new safety signals were identified with up to 48M of follow-up.

Keyword(s) : primary biliary cholangitis, seladelpar

1444 - Sustained and clinically meaningful improvements in moderate to severe pruritus patients with primary biliary cholangitis treated with seladelpar results from the ASSURE study up to 30 months

Gideon M. Hirschfield ¹, Andreas E. Kremer ², Cynthia Levy ³, Kris V. Kowdley ⁴, Hany Elbeshbeshy ⁵, Jeong Heo ⁶, Akin Kose ⁷, Kyung Min Kwon ⁷, Jie Liu ⁷, Caroline Burk ⁷, Daria B. Crittenden ⁷, Marlyn J. Mayo ⁸

E-POSTER ABSTRACTS

Texas Southwestern, , Dallas-United States ⁸

Background / Hypothesis: Pruritus affects up to 80% of patients with primary biliary cholangitis (PBC) and significantly impairs quality of life. Seladelpar (SEL), a first-in-class delpar (selective peroxisome proliferator-activated receptor [PPAR]-delta agonist), is approved for second-line treatment of PBC and has shown efficacy in improving cholestasis and pruritus in the pivotal, placebo (PBO)-controlled RESPONSE study (NCT04620733). We report long-term pruritus outcomes from the RESPONSE study and interim results from its ongoing open-label extension study, ASSURE (NCT03301506), with confirmatory psychometric validation of the pruritus numeric rating scale (NRS).

Materials and Methods: In RESPONSE, pruritus NRS was collected daily for 6 months (M), then weekly for one week each month through 12M. Upon rollover to ASSURE, NRS was collected daily for 6M and then at scheduled clinic visits. Other measures included the 5-D Itch and PBC-40. Patients with moderate to severe pruritus (NRS ≥ 4) at baseline (MSPN) were analyzed based on randomization to SEL 10 mg or PBO in RESPONSE and reported as continuous or crossover SEL 10 mg groups in ASSURE. Regression analysis and Bland-Altman plots assessed agreement between single-visit and weekly averaged NRS scores. Robust psychometric validation of NRS included reliability, convergent validity, and meaningful within-patient change analyses. Change from baseline in NRS, 5-D Itch, and PBC-40 Itch domain scores were assessed in ASSURE with a data cut off of Jan 31, 2025.

Results: Overall, there were 49 SEL and 23 PBO MSPN patients at baseline in RESPONSE. Among them, 33 SEL and 17 PBO patients rolled over to ASSURE, and 27 and 16 patients reached 30M. Daily NRS was strongly correlated with weekly NRS (r [95% CI], 0.93 [0.90, 0.95]). Validation of the NRS demonstrated it was valid and reliable. Reduction in pruritus with SEL in RESPONSE was maintained in ASSURE up to 30M, with clinically meaningful NRS improvement observed in $\geq 50\%$ of patients upon SEL initiation for crossover patients in ASSURE from 15M through 30M. Mean (SE) 5-D Itch total and PBC-40 Itch domain scores were reduced from baseline in continuous SEL (-4.6 [0.7]; -3.3 [0.7]) and crossover SEL (-5.8 [1.1]; -4.3 [1.0])

patients.

Conclusions: SEL led to sustained, clinically meaningful improvement in pruritus among MSPN patients in RESPONSE and with up to 30 months of treatment. Additionally, repeated psychometric validation confirmed the reliability and validity of the NRS as an outcome measure of pruritus in PBC.

Keyword(s) : primary biliary cholangitis, pruritus, seladelpar

1445 - Sirtuin 3 ameliorates acute on chronic liver failure via the glutathione peroxidase 4 mixed lineage kinase domain like protein mediated ferroptosis necroptosis interplay

Yuhong Liu¹, Hong Li¹

Guizhou Provincial People's Hospital, Department Of Infectious Diseases, Guiyang-China ¹

Background / Hypothesis:

Acute-on-chronic liver failure (ACLF) is a clinical syndrome defined by liver failure on preexisting chronic liver disease and is often associated with widespread hepatocyte death involving ferroptosis and necroptosis with high short-term mortality. Ferroptosis and necroptosis are two recently identified forms of non-apoptotic cell death, the role of ferroptosis and necroptosis in ACLF is not fully elucidated, evaluating the mode of cell death in ACLF will provide new insights for developing therapeutic strategies targeting cell death.

Materials and Methods:

Liver samples from six patients with acute-on-chronic liver failure (ACLF) were used. Bioinformatics analysis and establish the ACLF mouse model by combining chronic injury (chronic carbon tetrachloride [CCl₄] injection), acute hepatic insult (injection of a double dose CCl₄), and bacterial infection (intraperitoneal injection of *Klebsiella pneumoniae* [K.P.]), mice were also intraperitoneally pretreated with sirtuin 3 (SIRT3), mixed lineage kinase domain-like protein (MLKL), or glutathione peroxidase 4 (GPX4) inducers and inhibitors. Histological changes in liver tissue were monitored by hematoxylin and eosin staining. Mitochondrial morphology in murine hepatocytes was examined by transmission electron microscopy. Alanine aminotransferase (ALT) and aspartate aminotransferase

E-POSTER ABSTRACTS

(AST), glutathione, and iron levels were measured using commercial kits. Ferroptosis- and necroptosis-related protein and mRNA expression was detected by western blot and quantitative real-time polymerase chain reaction. SIRT3, GPX4, and MLKL were assessed by immunofluorescence analysis.

Results:

Bioinformatic analysis suggested potential crosstalk between ferroptosis and necroptosis in ACLF, possibly mediated by SIRT3. SIRT3, solute carrier family 7a member 11 (SLC7A11), and GPX4 protein expression was decreased and p53, acyl-CoA synthetase long-chain family member 4 (ACSL4), receptor interacting protein kinase (RIPK) 1, RIPK3, and MLKL levels were elevated in human ACLF liver tissue. In the ferroptosis and necroptosis inhibitor-treated groups demonstrated reduced serum transaminases (ALT, AST), diminished inflammatory mediators, decreased iron accumulation, attenuated hepatocellular injury, elevated GPX4 protein/fluorescence expression, and suppressed MLKL protein/fluorescence. In vitro co-immunoprecipitation confirmed a protein-protein interaction between GPX4 and MLKL. GPX4 overexpression lowered ALT, AST levels and substantially reduced MLKL expression, whereas GPX4 inactivation exacerbated necroptosis. Moreover, SIRT3 agonism alleviated ACLF-related liver injury and iron overload compared with results in the model group, concomitant with GPX4 upregulation and downregulation of p53, RIPK1, RIPK3, and MLKL. SIRT3 knockdown exacerbated both ferroptosis and necroptosis while aggravating hepatic damage in CCl₄/LPS-induced in vivo and in vitro models.

Conclusions:

SIRT3 activation attenuates CCl₄/K.P.-induced ferroptosis and necroptosis by inhibiting the GPX4/MLKL signaling pathway in ACLF.

Keyword(s) : sirtuin 3, ferroptosis, necroptosis, glutathione peroxidase 4/mixed lineage kinase domain-like protein, acute-on-chronic liver failure.

1446 - Metabolic dysfunction associated steatotic liver disease in patients with diabetes mellitus is linked with the severity of metabolic disorders.

Alexey Goncharov ¹, Armida Sasunova ¹, Vladimir Pilipenko ¹, Vasily Isakov ¹

Federal Center For Nutrition And Biotechnology,
Department Of Gastroenterology, Hepatology And Diet

Therapy, Moscow-Russia ¹

Introduction: MASLD is a metabolically determined disease. Studying the characteristics of various clinical variants of MASLD is important for developing approaches to treatment and prevention. The aim of the study was to identify clinical features in patients with DM with MASLD [MASLD(+)] compared to a control group with DM and without MASLD [MASLD(-)].

Materials and methods: A database of patients (n=5708) formed from 2021 to 2025 was analyzed. For the analysis, a cohort of patients with DM (n = 852) was selected; it included two subgroups: patients with MASLD (n = 686) and those without MASLD (n = 166). Pairs (n=91) of groups MASLD(+) and MASLD(-) were matched for sex, age, BMI, and cardiometabolic risk factors (hypertension, dyslipidemia). Vibration-controlled transient elastography with assessment of the controlled attenuation parameter (CAP) was used for determining the degree of steatosis and stage of liver fibrosis. Blood biochemical parameters characterizing lipid and carbohydrate metabolism were evaluated. The comparison of parameters was performed using the Wilcoxon criterion for continuous parameters and the χ^2 criterion for categorical parameters. The study was funded by a subsidy for the implementation of a state assignment (FGMF-2025-0003) of Federal Research Center of Nutrition and Biotechnology.

Results: The MASLD(+) and MASLD(-) groups did not differ by age (65.0 [58.5–70.0] vs. 64.0 [59.5–69.0] years; p=1.0), BMI (31.5 [29.8–35.8] vs. 31.3 [29.4–34.9] kg/m²; p=0.1), and percentage of women (79.1 vs. 79.1%; p=1.0). In the MASLD(+) group, compared with the MASLD(-) group, there was a larger waist circumference (101.0 [97.0 - 106.8] vs. 97.0 [90.0 - 102.0] cm; p=0.01), waist-to-hip ratio (0.94 [0.90–0.97] vs. 0.87 [0.84–0.94]; p=0.01), LDL (3.2 [2.2 - 3.9] vs. 2.5 [2.0 - 3.7] mmol/L; p=0.02), ALT (25.6 [18.0 - 40.6] vs. 19.6 [15.7 - 24.5] U/L; p<0.0001), total cholesterol (5.1 [4.0 - 5.9] vs. 4.2 [3.5 - 5.2] mmol/L; p=0.01). The two groups matched in fasting glucose (6.3 [5.4 - 7.2] vs. 5.9 [5.3 - 6.9] mmol/L; p=0.4), HbA1C (6.5 [6.0 - 7.3] vs. 6.2 [5.9 - 6.8]%; p=0.1), HOMA-IR (3.1 [2.2 - 4.0] vs. 2.5 [1.6 - 3.5]; p=0.3). In the MASLD(+) group, the MDRD GFR was lower (64.6 [46.9 - 77.0] vs. 71.0 [51.2 - 85.3] mL/min/1.73 m²; p=0.005) and the prevalence of F2-F4 liver fibrosis was higher (33,0 vs. 13,2%; p=0,002). Conclusion: patients with diabetes mellitus and MASLD have more pronounced metabolic disorders compared to the group with diabetes mellitus and without MASLD.

1448 - Insights from 10 years of Hepatitis C testing in Vancouver's inner city

Christina Wiesmann ¹, Shana Yi ², David Truong ², Brian Conway ¹

Simon Fraser University, Faculty Of Health Sciences, Burnaby-Canada ¹ Vancouver Infectious Diseases Centre, N/a, Vancouver-Canada ²

Background / Hypothesis:

Vancouver, Canada's inner-city, or downtown east side (DTES), is known for high rates of poverty, drug use, and Hepatitis C (HCV) infection, with up to 40% of individuals having HCV exposure. The Vancouver Infectious Diseases (VIDC) has been providing accessible point-of-care HCV testing and treatment to individuals living in this neighborhood for more than 10 years.

Materials and Methods:

VIDC provides regular point-of-care antibody testing in various inner-city locations including community centers, shelters, parks, and single room occupancy buildings. Data regarding HCV antibody and viremic status, as well as a range of other demographic and social variables is collected. We used odds ratios to determine characteristics significantly associated with HCV exposure from 2015 until September of 2025 when this analysis was completed.

Results:

A range of characteristics were found to be significantly associated with individuals with HCV exposure (presence of HCV antibodies). The most strongly associated characteristic was having a history of injection drug use. Smoking, poorer health status, being unemployed, having no post-secondary education, and having HIV were also significantly associated with having been exposed to HCV.

We did a separate analysis (students' t-test) in which we determined if the average age of individuals exposed to HCV was different from those not exposed to HCV in 2015, 2020, and 2025. We found no difference in 2015 or 2020, but saw that in 2025, individuals testing positive for HCV exposure were

significantly older than individuals with no exposure (48.6 YO vs. 44.5 YO; $p = 3.16E-07$).

Conclusions:

We identified many factors associated with HCV exposure, all of which are largely consistent with variables previously identified by other research groups. The observation that individuals without HCV exposure were significantly younger in 2025 may indicate that sustained treatment of HCV in this population is reducing the risk of HCV acquisition by individuals who have been using drugs for a shorter period of time. Follow-up analyses will investigate this finding further.

Keyword(s) : HCV, PWID, inner-city, demographics

1449 - Efficacy of low dose versus standard dose terlipressin in patients with variceal hemorrhage systematic review and meta analysis of randomized controlled trials.

Marybel Garcia-rodriguez ¹, Luis Antonio Manzo-francisco ¹, Norberto Carlos Chavez-tapia ¹
Medica Sur Clinic And Foundation, Gastroenterology, Mexico City-Mexico ¹

Background: Variceal hemorrhage remains the leading cause of cirrhotic mortality. Current guidelines recommend the use of terlipressin at a dose of 2 mg every 4 to 6 hours for 48 hours, followed by 1 mg every 4 to 6 hours for up to a maximum of 5 days, the minimum effective dose is undefined. Emerging evidence suggests lower doses may offer comparable efficacy to standard protocols, challenging current consensus due to limited data. The aim of this study is to compare the effects of lower doses of terlipressin versus standard doses in the treatment of acute variceal hemorrhage in adults with liver cirrhosis through a systematic review and meta-analysis of randomized clinical trials.

Materials and Methods: We searched Embase, PubMed and Cochrane database from inception to June 26, 2024 to identify randomized controlled trials comparing various doses of terlipressin with standard doses in individuals with cirrhosis for acute esophageal variceal bleeding. We defined standard dosing as a total dose >12 mg. The primary outcome was bleeding control. Secondary outcomes were early rebleeding and mortality. Risk of bias was assessed using the RoB 2 tool. Odds ratios (OR) and 95% confidence intervals

E-POSTER ABSTRACTS

were calculated, and heterogeneity was determined using I^2 . Registration number: CRD42024546649.

Results: Seven randomized clinical trials were included, with a total of 817 patients: 428 in the low-dose group and 389 in the standard-dose group. Three studies had a low risk of bias and four studies had a high risk of bias. No differences were observed in bleeding control (2 studies; OR 23.07; 95% CI: 0.00–960,436.71; $I^2 = 96.7\%$). Regarding the secondary outcome of early rebleeding, no differences were found between the low-dose and standard-dose groups (5 studies; OR 0.77; 95% CI: 0.34–1.74; $I^2 = 20.2\%$).

Conclusions: In this systematic review and meta-analysis, no differences were observed between low-dose and standard-dose terlipressin in the management of variceal bleeding in patients with cirrhosis.

1450 - The Impact of Hepatic Steatosis on Viral Load and Liver Fibrosis in Patients with Chronic Hepatitis B

Shi Yin ¹, Guanghui Ren ¹, Guiqun Huang ¹, Ying Zhu ¹
The First Affiliated Hospital Of Dalian Medical University, Department Of Infectious Disease, Liver Disease Center Of Integrated Traditional Chinese And Western Medicine, Dalian-China ¹

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) and chronic hepatitis B (CHB) are prevalent chronic liver conditions. This study aimed to investigate the effects of hepatic steatosis on HBV viral load and fibrosis progression in CHB patients, and to identify risk factors for liver fibrosis.

Materials and Methods: A total of 887 CHB patients were divided into CHB-only (n=560) and CHB+MASLD (n=327) groups. The CHB+MASLD group was further stratified into mild (S1), moderate (S2), and severe (S3) steatosis subgroups based on Controlled Attenuation Parameter (CAP) values. The effects of hepatic steatosis on viral load and fibrosis were analyzed. Binary logistic regression was used to identify risk factors for liver fibrosis in CHB.

Results: The mean CAP values in the CHB-only and CHB+MASLD groups were 199.65 ± 42.60 and 264.76 ± 41.13 dB/m, respectively ($p < 0.01$). Compared to the CHB-only group, the CHB+MASLD group had lower serum pgRNA levels (1.88 vs. 2.27; $p = 0.005$) and

lower HBeAg-positive patients (24.3% vs. 30.7%, $p = 0.044$). In HBeAg-negative patients, serum HBsAg levels were lower in CHB+MASLD group (2.73 vs. 2.90, $p = 0.031$), and in HBeAg-positive patients, serum pgRNA levels were also lower (2.66 vs. 4.55, $p = 0.015$). CAP was negatively correlated with pgRNA ($r = -0.117$, $p < 0.01$). Liver fibrosis indices APRI (0.26 vs. 0.30, $p = 0.001$) and FIB-4 (1.05 vs. 1.36, $p < 0.001$) were lower in the CHB+MASLD group than in the CHB-only group. Subgroup analysis revealed that the S1 subgroup of CHB+MASLD had a higher proportion of patients without fibrosis (82.7% vs. 72.1%) and lower proportions with early fibrosis (8.3% vs. 14.8%), advanced fibrosis (5.8% vs. 7.8%), and cirrhosis (3.2% vs. 5.3%) compared to CHB-only group. The distribution of fibrosis stages in S2 subgroup of CHB+MASLD group and CHB-only group was similar (no fibrosis: 71.1% vs. 72.1%; early fibrosis: 15.5% vs. 14.8%; advanced fibrosis: 7.2% vs. 7.8%; cirrhosis: 6.2% vs. 5.3%). However, the S3 subgroup of CHB+MASLD had higher proportions of early fibrosis (16.1% vs. 14.8%), advanced fibrosis (10.3% vs. 7.8%), and cirrhosis (10.3% vs. 5.3%) than CHB-only group. Logistic regression showed that CAP, age, gender, HBV DNA, pgRNA, AST and GGT were independent influencing factors for liver fibrosis. Patients with severe steatosis (S3) had a 5.1-fold higher risk of fibrosis compared to those without steatosis (OR=5.05, 95%CI: 2.48–10.29, $p < 0.001$).

Conclusions: Patients with CHB and MASLD comorbidity exhibit lower hepatitis B viral loads. Mild to moderate steatosis does not accelerate fibrosis progression, whereas severe steatosis does. Hepatic steatosis is an independent risk factor for liver fibrosis in CHB patients.

1451 - Diagnostic challenge in a young male patient presenting with feeling of upper abdominal lump and recent onset of black terry stool

Ponkaj Naha ¹

300 Bedded Hospital, Khanpur, Narayanganj, Department Of Medicine, Narayanganj-Bangladesh ¹

Background / Hypothesis:

Non cirrhosis portal hypertension (NCPH) is poorly understood disease. Most of the patient is initially incorrectly labeled as having liver cirrhosis presenting as haematemesis or melaena. This patient came to outpatient department (OPD) with complaints of lump in abdomen and melaena. After evaluation he

E-POSTER ABSTRACTS

had no etiology of liver cirrhosis in serological investigation and liver biopsy. So we chose to write this case report.

Materials and Methods:

A 19-year-old boy came to out-patient department (OPD) of Hepatology department for evaluation of lump in upper abdomen. The patient complaining 3months history of gradually increasing upper abdominal lump mainly left upper abdomen associated with some abdominal discomfort, fatigue and black terry stool for 3 days. Abdominal lump was not associated with vomiting, abdominal pain, fever, altered bowel habit, weight loss. On query, he had no H/O fever, coughs and jaundice. For evaluation of patient we admitted this patient into hospital and underwent several investigations. His physical examination revealed mild anemia and splenomegaly, otherwise unremarkable in all systemic examinations. After getting esophageal varices we had done endoscopic esophageal ligation (EVL) and searched etiology of liver cirrhosis. As we found no etiology, then we planned for liver biopsy.

Results:

Based on splenomegaly, esophageal varices with normal LFT and liver biopsy report we reached to diagnosis of NCPH to this patient. Investigation reports revealed-

10.08.2022 - 1. CBC: Hb: 9.6gm/dl, WBC: 5500/cumm, Platelets: 115000/cumm; 2. LFT: Bilirubin: 2.8mg/dl, SGPT: 16.8U/L, SGOT: 14U/L, Albumin: 4.3gm/dl, PT: 12sec; 3. USG of W/A: Splenomegaly, mild ascites.

12.08.2022 - 1. Endoscopy of UGIT: Oesophageal varices; 2. HBsAg, Anti-HCV & Anti-Hbc (T): Negative; 3. Hb electrophoresis: Normal.

15.08.2022 - Ceruloplasmin: 32mg/dl; Ferritin: 72ng/ml; 24 hours urinary copper: 7.53ugm; ANA, Anti-LKM & ASMA: Negative.

30.08.2022 - Liver biopsy: Mild steatosis (HAI-2/18, Knodell score: 3/22)

Conclusions:NCPH is rare and diagnosed by exclusion of other cause of liver cirrhosis. Treatment focus on

complication of portal hypertension. But NCPH has better prognosis than cirrhosis of liver.

Keyword(s) : Upper abdominal lump; Non cirrhosis portal hypertension; Splenomegaly; Esophageal varices; Liver biopsy

1452 - Evaluation of Urinary Hepatitis E virus Antigen Colloidal Gold Immunochromatographic Assay in Clinical Diagnosis of Hepatitis E virus Infection

Conglin Zhao ¹, Shuai Tao ², Qiang Li ¹, Chong Chen ³, Liang Chen ¹

Shanghai Public Health Clinical Center, Fudan University, Department Of Liver Disease, Shanghai-China ¹ Shanghai Public Health Clinical Center, Fudan University, Scientific Research Center, Shanghai-China ² Shanghai Public Health Clinical Center, Fudan University, Department Of Infectious Diseases, Shanghai- ³

Background / Hypothesis:Hepatitis E virus (HEV) is a significant public health concern worldwide. Current diagnostic methods for HEV infection have limitations in terms of accessibility and timeliness. To assess the diagnostic performance of the Wantai urinary HEV antigen (Ag) colloidal gold immunochromatographic assay (GICA) in HEV infection.

Materials and Methods:This prospective study enrolled 150 patients with suspected acute hepatitis E and 50 healthy controls. Paired urine, fecal, and serum samples were collected during initial clinical evaluation. Serum and fecal HEV RNA levels were quantified via reverse transcription-quantitative polymerase chain reaction (RT-qPCR), with genotyping performed by nested RT-PCR. Serum anti-HEV IgM/IgG levels were measured by Enzyme-Linked Immunosorbent Assay (ELISA), and urinary HEV antigen was detected using GICA. Diagnostic accuracy metrics were calculated against the reference standard of HEV RNA detection.

Results:HEV RNA was detected in 58% (87/150) of suspected cases. All successfully genotyped cases (69%, 60/87) were HEV genotype 4. All healthy controls tested negative for HEV RNA and urinary HEV Ag. The urinary HEV Ag GICA showed 98.9% sensitivity and 87.6% specificity, with high concordance with RT-qPCR (Kappa=0.85). Longitudinal follow-up revealed viral clearance and liver function normalization in most patients within 3-4 weeks post-symptom onset. 85.7% of patients achieved urinary HEV Ag negative conversion within 6-7 weeks, while anti-HEV IgM

E-POSTER ABSTRACTS

remained positive in all patients at follow-up conclusion.

Conclusions: Urinary HEV Ag GICA demonstrates high diagnostic reliability for acute HEV infection, offering a practical non-invasive option for resource-limited settings.

Keyword(s) : Hepatitis E virus; Antigen; Colloidal gold immunochromatographic assay; Diagnosis

1453 - The Impact of a Hospital Wide Alert and Referral Program on the Management of Hepatitis B Virus (HBV) Infection in Non Specialist Departments A Before and After Study

Yijing Cai¹, Lvqi Luo¹, Haibo Jia², Chao Cai¹, Mingqin Lu¹

The First Affiliated Hospital Of Wenzhou Medical University, Department Of Infectious Diseases, Wenzhou-China¹ The First Affiliated Hospital Of Wenzhou Medical University, Department Of Information, Wenzhou-China²

Background / Hypothesis:

A significant proportion of patients with Hepatitis B virus (HBV) infection are initially identified in non-specialist departments. Successful linkage to specialist care is critical for initiating appropriate management. we implemented a hospital-wide "HBV Elimination Program" with an automated SMS (short message system) alert for HBsAg-positive patients and evaluated its impact in non- specialist departments.

Materials and Methods:

A before-and-after study was conducted in a large tertiary hospital. The intervention, initiated in January 21st, 2025, involved sending SMS alerts to all outpatients and inpatients testing positive for HBsAg, advising them to attend a specialist consultation. The primary outcome—including HBV DNA testing rates in HBsAg-positive patients, referral rates, and antiviral treatment rates—were compared between the pre-intervention (February to July 2024) and post-intervention (February to July 2025) periods.

Results:

A substantial proportion (51.9%) of viremic HBV patients were initially identified in non- specialist departments. Following the intervention, the volume of HBsAg tests, HBV DNA tests, and specialist visits in 2025 increased to 168,916, 28430 and 121,913, from 155,882, 22876 and 104,817 in 2024, respectively. The HBsAg positivity rate remained stable (9.1% in 2024 vs. 9.4% in 2025). Critically, the HBV DNA testing rate among HBsAg-positive patients in non- specialist departments improved significantly from 60.7% to

64.7%. Furthermore, the referral rate from non-specialist to specialist departments surged from 27.8% to 35.7% ($P < 0.001$). Most importantly, the antiviral treatment rate for eligible viremic patients in non-specialist departments dramatically increased from 50.7% to 64.9% ($P < 0.001$).

Conclusions:

This study demonstrates that a simple hospital-wide alert system can effectively strengthen the HBV care cascade. This intervention significantly improved rates of HBV DNA testing, specialist referral, and ultimately, antiviral treatment initiation. This model presents a highly effective strategy for closing the gap in HBV management and advancing towards elimination goals.

Keyword(s) : HBV, alert system, referral, elimination.

1454 - Impact of Autoimmune Phenomena on the Clinical Presentation and Prognosis of Wilson's Disease A Retrospective Cohort Study

Hui Jiang¹, Shan Tang¹, Chen Liang², Hui Liu³, Haitian Yu¹, Siqi Zhang¹, Meihan Li¹, Yue Wang¹, Wei Hou¹, Sujun Zheng¹

Beijing Youan Hospital, Capital Medical University, First Department Of Liver Disease, Beijing-China¹ Beijing Jishuitan Hospital, Capital Medical University, Department Of Gastroenterology, Beijing-China² Beijing Youan Hospital, Capital Medical University, Department Of Pathology, Beijing-China³

Background / Hypothesis:

Wilson's disease (WD) patients often display autoantibody positivity and/or elevated serum immunoglobulins, collectively termed autoimmune phenomena (AP). The clinical relevance of AP in WD, particularly regarding disease severity and prognosis, remains unclear.

Materials and Methods:

We retrospectively enrolled treatment-naïve WD patients (Leipzig score ≥ 4) and classified them as WD with AP (AP-WD) or WD without AP (NAP-WD) based on autoantibody positivity (titer $\geq 1:100$) and/or IgG above the upper limit of normal. Baseline laboratory data, clinical complications, and liver histopathology were compared. Patients received standard anti-copper therapy and were followed longitudinally to evaluate the impact of AP on liver-related outcomes.

Results:

Eighty-six treatment-naïve WD patients were included (48 AP-WD, 38 NAP-WD). At baseline, AP-WD patients exhibited more severe laboratory and clinical features, including lower platelet counts, reduced albumin, prolonged international normalized ratio, higher APRI,

E-POSTER ABSTRACTS

MELD/PELD, and Child-Pugh scores, and greater prevalence of ascites (all $P < 0.05$). Histopathological analysis demonstrated increased plasma cell infiltration and heightened portal inflammatory activity in the AP-WD group ($P < 0.05$). Longitudinal follow-up revealed that the presence of AP was independently associated with an increased risk of adverse liver-related events, including liver failure, transplantation, or death.

Conclusions:

AP is common in WD and correlate with more severe hepatic dysfunction and poorer long-term outcomes. Screening for autoantibodies and IgG levels in newly diagnosed WD patients may provide important prognostic insight and facilitate early risk stratification, guiding tailored monitoring and management strategies.

1455 - Cardiovascular Outcomes of GLP 1 Receptor Agonists vs SGLT2 Inhibitors in Metabolic Associated Steatotic Liver Disease and Type 2 Diabetes A Real World Comparative Effectiveness Study

Po-yu Huang¹, Chun-chi Yang¹, Jheng-yan Wu², Ya-yun Cheng³, Hsuan-yuan Chang¹, Su-hung Wang¹, I-che Feng¹, Hsing-tao Kuo¹, Wei-ting Chang⁴, Ming-lung Yu⁵

Chi Mei Medical Center, Division Of Hepatogastroenterology, Department Of Internal Medicine, Tainan-Taiwan¹ Chi Mei Medical Center, Department Of Nutrition, Tainan-Taiwan² National Sun Yat-sen University, School Of Medicine And Doctoral Program Of Clinical And Experimental Medicine, Kaohsiung-Taiwan³ Chi Mei Medical Center, Division Of Cardiology, Department Of Internal Medicine, Tainan-Taiwan⁴ Kaohsiung Medical University Hospital, Kaohsiung Medical University, Hepatobiliary Division, Department Of Internal Medicine, Center Of Hepatitis Research, College Of Medicine And Center For Liquid Biopsy And Cohort, Kaohsiung-Taiwan⁵

Background / Hypothesis:

Patients with metabolic dysfunction-associated steatotic liver disease (MASLD) and type 2 diabetes (T2D) face elevated cardiovascular risk. While both glucagon-like peptide-1 receptor agonists (GLP-1 RAs) and sodium-glucose cotransporter-2 inhibitors (SGLT2is) reduce cardiovascular events, it remains unclear whether GLP-1 RAs confer greater protection than SGLT2is in this specific population. We aimed to compare the cardiovascular outcomes between these

two therapies in patients with MASLD and T2D.

Materials and Methods:

We conducted a retrospective cohort study using the TriNetX global health research network. Adults with T2D and MASLD initiating GLP-1 RA or SGLT2i therapy between 2017 and 2025 were identified. We performed 1:1 propensity score matching to balance demographics, comorbidities, and medications. The primary outcome was major adverse cardiovascular and cerebrovascular events (MACCE), defined as a composite of acute myocardial infarction, ischemic cerebrovascular events, and heart failure exacerbation. Cox proportional-hazards models were used to estimate hazard ratios (HRs).

Results:

After matching, 52,094 patients were analyzed (mean age 58.5 years). Over a median follow-up of 3.0 years, GLP-1 RA therapy was associated with a significantly lower risk of MACCE compared with SGLT2is (HR 0.86; 95% CI 0.80–0.92; $p < 0.001$). Secondary outcomes also favored GLP-1 RAs, including MACE (HR 0.83), heart failure exacerbation (HR 0.80), myocardial infarction (HR 0.68), stroke/TIA (HR 0.82), and all-cause mortality (HR 0.57) (all $p < 0.001$). Results were robust across landmark analyses and E-value estimation.

Conclusions:

In patients with MASLD and T2D, GLP-1 RA therapy was associated with a significantly lower risk of cardiovascular events compared with SGLT2is. These findings support prioritizing GLP-1 RAs in cardiometabolic risk management for this high-risk population.

Keyword(s) : MASLD; Type 2 diabetes; GLP-1 receptor agonists; SGLT2 inhibitors; Cardiovascular outcomes

1457 - Predictors for re hospitalization in liver cirrhosis the first longitudinal cohort study in the Republic of Moldova

Adela Turcanu¹, Ecaterina Cebanu¹, Eugen Tcaciuc¹, Daniela Buruiana¹

Nicolae Testemitanu State University Of Medicine And Pharmacy, Gastroenterology, Chisinau-Moldova¹

Background / Hypothesis:

Hospital readmissions for cirrhosis are considered an indicator of the quality of healthcare. Strategies

E-POSTER ABSTRACTS

applied to reduce hospital readmission rates for liver disease have not resulted in a significant decrease in the frequency of rehospitalization among patients with delta viral liver cirrhosis. The few studies involving European cohorts have identified different predictors. Aim: To evaluate rehospitalization as a pragmatic marker of insufficient monitoring in delta viral cirrhosis and to validate the predictors of readmission in the Moldovan cohort.

Materials and Methods:

We prospectively studied 131 patients with delta viral liver cirrhosis, discharged from a tertiary hospital and undergoing surveillance for a duration of ≥ 12 months. Data on demographic, laboratory, and disease-related risk factors were compiled. Twelve-month decompensation was defined as any of ascites, hepatic encephalopathy, or variceal hemorrhage. We used multivariate logistic regression to determine predictors of readmission.

Results:

Mean age of the study population (131 patients with viral delta cirrhosis) was 54.84 ± 9.54 years; 51.5% male. Over a 12-month period, 82% of patients presented at least one episode of decompensation, and 52% required (re)hospitalization. The results showed that male gender was associated with an approximately eightfold higher risk of decompensation compared to female gender (OR = 8.05; 95% CI: 2.01–213.66), portal thrombosis was a major determinant of decompensation (OR = 14.54; 95% CI: 1.03–552.00), and thrombocytopenia was associated with an approximately tenfold higher risk (OR = 10.41; 95% CI: 1.88–232.53). Analysis of the performance of the logistic model, assessed by the ROC curve, revealed a high discrimination capacity (AUC = 0.899), which confirms the value of the selected predictors in estimating the risk of decompensation.

Conclusions:

Rehospitalization is a pragmatic indicator of insufficient monitoring in delta viral cirrhosis. Our study is the first to validate some predictors of hospital readmission in viral delta liver cirrhosis. The results obtained provide useful information to design specific interventions in patients with liver cirrhosis and will help to mitigate readmissions.

Keyword(s) : rehospitalization, decompensation, liver cirrhosis

1458 - DIAGNOSTIC ACCURACY OF PIVKA II IN DETECTING HEPATOCELLULAR CARCINOMA AMONG AFP NORMAL PATIENTS A SYSTEMATIC REVIEW AND META ANALYSIS

John Derek Clutario¹, Madaline Eternity Labio², Oscar Cabahug¹

Makati Medical Center, Gastroenterology, Makati-Philippines¹ Makati Medical Center, Hepatology, Makati-Philippines²

Hepatocellular carcinoma (HCC), which constitutes the majority of primary liver cancers, remains a major public health challenge and ranks among the top causes of cancer-related mortality globally and in the Philippines. Early detection continues to be constrained by the largely silent nature of early-stage disease. Current surveillance relying on ultrasonography with or without alpha-fetoprotein (AFP) offers limited diagnostic precision, with AFP demonstrating only moderate sensitivity and missing up to half of HCC cases. A substantial subset of patients—particularly those with smaller or early-stage tumors—present with normal AFP levels, creating a critical diagnostic blind spot. These limitations heighten the call for more reliable biomarkers capable of strengthening the performance of existing screening frameworks.

Protein Induced by Vitamin K Absence-II (PIVKA-II) has emerged as a high-performance biomarker demonstrating superior diagnostic metrics compared with AFP, especially in AFP-normal individuals who account for 30–50% of HCC presentations. With reported sensitivity and specificity approaching 75% and 92%, respectively, PIVKA-II offers a promising avenue for closing gaps inherent in AFP-based surveillance.

This meta-analysis sought to evaluate the diagnostic accuracy of PIVKA-II relative to AFP in detecting HCC specifically among AFP-normal patients, with emphasis on sensitivity, specificity, and area under the curve (AUC), including for early-stage disease. Four peer-reviewed case-control studies published from 2016 to 2025 and comprising at least 146 AFP-normal patients were systematically identified through PubMed. Inclusion criteria focused on studies assessing diagnostic performance metrics for PIVKA-II. All studies underwent structured quality appraisal using the QUADAS-2 framework. Statistical synthesis was conducted using Meta-DiSc (v1.4), applying a random-effects model to account for interstudy heterogeneity.

Results demonstrated that PIVKA-II consistently

E-POSTER ABSTRACTS

outperformed AFP across diagnostic endpoints. For any-stage HCC, pooled sensitivity reached 80%, specificity 90%, and the AUC 0.9376, underscoring robust overall accuracy. In early-stage disease, PIVKA-II achieved a sensitivity of 79%, specificity of 82%, and an AUC of 0.888, confirming its strong performance even in the most diagnostically challenging subgroup.

Collectively, these findings reinforce PIVKA-II as a highly effective biomarker for detecting HCC among AFP-normal patients—an area where AFP alone falls short. Its integration into surveillance algorithms offers a strategic opportunity to enhance early detection, accelerate clinical decision-making, and improve long-term survival outcomes. Given its superior diagnostic profile, PIVKA-II warrants strong consideration for routine adoption in multimodal HCC screening and monitoring programs.

1460 - Dysregulated S100A8 A9–Monocyte Pathway in Cirrhosis Associated Immune Dysfunction and Its Reversal by Mesenchymal Stromal Cells

Lei Shi¹, Ziyang Zhang², Lei Dei³, Xuepei Lei⁴, Zerui Wang⁵, Mengqi Yuan¹, Yuefei Pan¹, Zeyi Zhang¹, Kaidi Zhu¹, Jiaqi Xiong¹, Zihao Chen¹, Song Mei⁶, Peng Zhang⁶, Fu-sheng Wang¹

The Fifth Medical Center Of Chinese PLA General Hospital, Senior Department Of Infectious Diseases, National Clinical Research Center For Infectious Diseases, Beijing-China¹ Peking University, 302 Clinical Medical School (the Fifth Medical Center Of Chinese PLA General Hospital), Beijing-China² Sichuan University, State Key Laboratory Of Biotherapy/collaborative Innovation Center For Biotherapy, West China Hospital, Chengdu-China³ Peking Union Medical College, Chinese Academy Of Medical Sciences And Comparative Medicine Center, Beijing-China⁴ The First Medical Center Of Chinese PLA General Hospital, Senior Department Of Gastroenterology, Beijing-China⁵ Capital Medical University, Rare Disease Center, Beijing Children's Hospital, National Center For Children's Health, Beijing-China⁶

Background / Hypothesis: Decompensated liver cirrhosis (DLC) is marked by cirrhosis-associated

immune dysfunction (CAID), characterized by concurrent systemic inflammation and immune deficiency. Monocytes are key drivers of CAID. The calcium-binding proteins S100A8/A9, highly expressed by activated monocytes, promote their recruitment and activation via TLR4 and RAGE, amplifying inflammatory cytokine and chemokine production. Mesenchymal stromal cells (MSCs) exhibit immunomodulatory properties, yet their specific effects on the S100A8/A9–monocyte axis in human CAID remain poorly defined. Materials and Methods: Using single-cell RNA sequencing and CyTOF data from a clinical cohort of MSC-treated DLC patients, we evaluated the effects of MSC infusion on monocyte immunophenotypes and S100A8/A9 expression. Circulating and liver tissue samples from DLC patients and healthy controls were analyzed alongside a CCl₄-induced cirrhotic mouse model. In vitro coculture experiments using patient-derived monocytes further examined MSC-mediated regulation of the S100A8/A9 pathway through RT-qPCR, flow cytometry, and transcriptomic profiling. Results: DLC patients showed increased proportions, absolute counts, and activation of peripheral CD14⁺ monocytes compared with healthy controls. These monocytes exhibited marked overexpression of S100A8/A9 and increased hepatic infiltration of S100A8/A9⁺ monocyte–macrophages in fibrotic regions. Single-cell data revealed a pro-inflammatory S100A8/A9^{high} subset enriched in leukocyte activation and cytokine-secretion pathways, whereas the S100A8/A9^{low} subset was enriched in antigen presentation and interferon- γ responses. Following MSC infusion, peripheral monocyte proportions declined, accompanied by a transcriptomic shift toward a S100A8/A9^{low} state. In vitro, MSCs suppressed monocyte activation markers and reduced S100A8/A9 mRNA expression. In the CCl₄ model, MSC treatment reduced fibrosis and decreased hepatic infiltration of S100A8/A9⁺ monocyte–macrophages. Conclusions: DLC is associated with increased monocyte activation and elevated monocyte-derived S100A8/A9 in the circulation and liver. MSC therapy appears to attenuate these abnormalities by downregulating the S100A8/A9–monocyte axis, providing mechanistic insight into its therapeutic potential in CAID.

1462 - Effectiveness and safety of tenofovir alafenamide for chronic hepatitis B patients with

E-POSTER ABSTRACTS

decompensated cirrhosis a retrospective study in Qinghai province

Baohua Wu¹, Bolan Zhu¹, Juan Li¹, Xusheng Wu², Ping Huang²

Qinghai Provincial People's Hospital, Gastroenterology Department, Xining-China¹ Clinical Medical College Of Qinghai University, Gastroenterology Department, Xining-China²

Background/Hypothesis: An increasing amount of evidence has demonstrated the effectiveness and safety of tenofovir alafenamide fumarate (TAF) in patients with chronic hepatitis B (CHB) and decompensated cirrhosis. However, there is limited long-term data on the effectiveness and safety of TAF. This study aimed to investigate the long-term effectiveness and safety of TAF in CHB patients with decompensated cirrhosis.

Materials and Methods: This single-center, retrospective study enrolled a total of 63 CHB patients with decompensated cirrhosis who were treated with TAF 25mg daily. The follow-up period lasts for 96 weeks. The primary endpoint of this analysis is the proportion of patients with an undetectable HBV DNA level (less than 5 IU/ml) at week 96. Other endpoints included the changes in Child-Pugh (CTP) and Model for end-stage liver disease (MELD) scores, and changes in ascites and hepatic encephalopathy (HE) from baseline. The safety profile, including drug-related adverse events (AEs) or serious adverse events (SAEs), and clinical outcomes such as liver transplantation, hepatocellular carcinoma (HCC) or death were also analyzed, as was renal function.

Results: Sixty-three CHB patients with decompensated cirrhosis were enrolled between January 2023 and February 2025, and were included in the analysis. Of the participants, 79.37% (n=50) were male, with a mean age was 55.24±8.58 years. The median baseline values for HBV DNA and ALT at baseline were 3.45×10⁶ IU/mL and 26.00 U/L, respectively. The mean values for CTP and MELD were 9.19±1.88 and 11.32±3.36, respectively. All 63 patients completed the 96-week follow-up. After 96 weeks of TAF treatment, 92.06% (58/63) patients had undetectable HBV DNA. The mean ALT level remained stable, decreasing from 26.00 U/L at baseline to 22.00 U/L after 96 weeks. The CTP score maintained stable from 9.19 at baseline to 9.49 at week 96 (P>0.05), and the mean MELD score significantly declined from 11.32 at baseline to 6.98 at week 96 (P<0.01). 50.79% (32/63) of patients had mild to moderate ascites at baseline, and this proportion decreased to 42.86% (27/63) by week 96 (P>0.05). HE occurred in 23 patients at baseline and was significantly reduced to 11

patients at week 96 (P<0.01). No drug-related AEs or SAEs were detected during the follow-up period, neither did liver transplantation, HCC, or death. During the 96 weeks of treatment, renal function, as indicated by serum creatinine (Scr) and β 2 microglobulin (β 2-MG), kept stable during the treatment.

Conclusions: This study demonstrated the long-term effectiveness and safety of TAF therapy for CHB patients with decompensated cirrhosis.

Keyword(s) : tenofovir alafenamide fumarate, chronic hepatitis B and decompensated cirrhosis.

1464 - Liver Fibrosis and Cardiovascular Health Jointly Predict Mortality in NAFLD and MAFLD

Mulilan Tuohede¹, Jing Liang², Pengfei Sun³

The Third Central Clinical College Of Tianjin Medical University, Department Of Gastroenterology, Tianjin-China¹ Central Hospital, Tianjin University, Department Of Gastroenterology, Tianjin-China² Tianjin Medical University General Hospital, Department Of Cardiology, Tianjin-China³

Background / Hypothesis: The interaction between cardiovascular health (CVH) and liver fibrosis progression in patients with nonalcoholic fatty liver disease (NAFLD) remains insufficiently elucidated. This study aimed to investigate the joint predictive value of CVH scores and liver fibrosis assessment tools (NFS and FIB-4) for cardiac and all-cause mortality.

Materials and Methods: This cohort study utilized data from the US National Health and Nutrition Examination Survey (NHANES) 2005–2018, including 25,634 participants with NAFLD. Liver fibrosis scores (NFS and FIB-4) were stratified into low, intermediate, and high categories, while CVH was classified as ideal, intermediate, or poor according to the "Life's Essential 8" score. Weighted Cox proportional hazards models were applied to estimate hazard ratios (HRs), with interaction terms incorporated to evaluate the modifying effect of CVH. Study outcomes were all-cause mortality and cardiac mortality.

Results: Higher liver fibrosis scores (NFS and FIB-4) were consistently associated with increased mortality risk. During a median follow-up of 91 months, 2,185 deaths occurred, including 540 cardiovascular deaths. Elevated fibrosis scores showed graded associations with all-cause mortality, and favorable cardiovascular health (CVH) attenuated this risk, whereas poor CVH further amplified it. For cardiovascular mortality, both NFS and FIB-4 remained significant predictors, and the

E-POSTER ABSTRACTS

interaction between fibrosis scores and CVH was statistically significant ($P < 0.001$). Individuals with high fibrosis scores and poor CVH showed the highest cardiovascular mortality risk.

Conclusions: Liver fibrosis assessed by NFS and FIB-4 was independently associated with both all-cause and cardiovascular mortality. For all-cause mortality, higher NFS and FIB-4 levels showed a significant and graded increase in risk, with notable risk elevation at $\text{NFS} \geq 1$ and $\text{FIB-4} > 1.5$, and these associations were stronger in individuals with poor cardiovascular health. For cardiovascular mortality, NFS and FIB-4 were both significant predictors, with NFS showing early separation in survival and FIB-4 demonstrating risk divergence after approximately 40 months. In MAFLD, FIB-4 and NFS remained consistently associated with cardiovascular mortality, with higher predictive strength compared with non-MAFLD participants.

Keyword(s) : NAFLD; MAFLD; Liver Fibrosis; FIB-4; NFS; Cardiovascular Health; All-Cause Mortality; Cardiovascular Mortality

1465 - Impact of metabolic dysfunction-associated steatotic liver disease on young hepatocellular carcinoma patients following curative resection

National Yang Ming Chiao Tung University, Institute Of Clinical Medicine, School Of Medicine, Taipei-Taiwan³

Background / Hypothesis: The prognostic impact of metabolic dysfunction-associated steatotic liver disease (MASLD) in hepatocellular carcinoma (HCC) remains controversial, particularly among younger patients. We investigated the clinicopathological features and survival outcomes of young HCC patients with and without MASLD after curative resection.

Materials and Methods: We retrospectively analyzed 289 treatment-naïve HCC patients aged ≤ 60 years who underwent curative resection between 2016 and 2022. Patients were categorized as non-MASLD ($n=154$) or MASLD ($n=135$) based on non-tumor liver histology.

Overall survival (OS) was the primary endpoint; recurrence-free survival (RFS) was secondary. Survival analyses were performed using Kaplan-Meier and Cox proportional hazards models.

Results: Compared with the non-MASLD group, patients with MASLD had higher body mass index, more cardiometabolic risk factors, lower aspartate aminotransferase (AST) and alpha-fetoprotein levels, earlier tumor stage, and smaller tumor size. After a median follow-up of 59.2 months, 56 deaths were recorded, with a 5-year OS of 76.9% overall. MASLD patients had significantly better 5-year OS (84.2% vs. 70.1%, $p=0.018$) and RFS (51.3% vs. 37.0%, $p=0.010$). However, in multivariate Cox analysis, MASLD was not an independent predictor of OS or RFS. Larger tumor size ($> 5\text{cm}$) independently predicted poorer OS (hazard ratio 2.10, 95% confidence interval 1.14–3.86, $p=0.017$), while elevated AST, larger tumor size, and microvascular invasion were independent predictors of poorer RFS.

Conclusions: Young HCC patients with MASLD presented with more favorable tumor characteristics and showed superior unadjusted OS and RFS after curative resection. However, MASLD itself was not an independent prognostic factor after adjustment, with tumor burden remaining the key determinant of outcomes.

Keyword(s) : MASLD, young HCC

1467 - Clinical and instrumental profile of patients with Cryptogenic steatotic liver disease

Alexey Goncharov¹, Igor Maev², Vasily Isakov¹
Federal Center For Nutrition And Biotechnology, Department Of Gastroenterology, Hepatology And Diet Therapy, Moscow-Russia¹
A.i. Yevdokimov Moscow State University Of Medicine And Dentistry, Department Of Propedeutics Of Internal Diseases And Gastroenterology, Moscow-Russia²

Clinical and instrumental profile of patients with cryptogenic steatotic liver disease

Introduction: In 2023, a revised classification of disorders presenting with hepatic steatosis was introduced, establishing several new diagnostic categories, including cryptogenic steatotic liver disease (CSLD). **Objective:** to determine the prevalence of CSLD

E-POSTER ABSTRACTS

within the spectrum of steatosis-associated liver diseases and to characterize its clinical and instrumental features.

Materials and Methods. A retrospective analysis was conducted using a database of 4,673 patients who underwent evaluation for liver steatosis and fibrosis. Diagnostic criteria for CSLD and other liver diseases were applied in accordance with the recommendations of the European Association for the Study of the Liver. The degree of steatosis and the stage of fibrosis were assessed using vibration-controlled transient elastography with measurement of the controlled attenuation parameter. Body composition was evaluated by bioimpedance analysis. Laboratory assessments included indicators of lipid and carbohydrate metabolism. The study was funded by a subsidy for the implementation of a state assignment (FGMF-2025-0003) of Federal Research Center of Nutrition and Biotechnology.

Results: The prevalence of CSLD was 0.8% (n = 22) among patients with confirmed hepatic steatosis (n = 2,643). Compared with individuals with metabolic dysfunction-associated steatotic liver disease (MASLD), patients in the CSLD group exhibited significantly lower rates of grade 3 steatosis (S3: 27.3% vs. 67.6%; $p < 0.001$) and advanced fibrosis (F2–F4: 9.1% vs. 29.3%; $p = 0.02$). When compared with a control group without hepatic steatosis and fibrosis (n = 266), patients with CSLD had a higher body mass index (median [Q1–Q3]: 24.1 [22.1–24.5] kg/m² vs. 22.4 [20.7–23.7] kg/m²; $p = 0.008$), primarily due to greater fat mass (19.0 [16.6–26.7] kg vs. 16.4 [12.2–20.5] kg; $p = 0.03$). No significant differences were observed between the CSLD and control group without steatosis and fibrosis in age, sex distribution, lipid profile parameters, or carbohydrate metabolism.

Conclusion: CSLD is a rare condition. Patients with CSLD differ from the control group only in terms of fat mass, despite both groups exhibiting body mass index values within the normal range. Parameters of lipid and carbohydrate metabolism in the CSLD cohort do not differ significantly from those of practically healthy individuals.

1470 - Hepatitis E virus orchestrates mitochondrial fusion to drive viral replication through mechanistic coupling of pro viral autophagy and innate immune evasion

Xiaoman Liu ¹, Yiyun Jiang ², Chen Wang ¹, Jialei Li ¹

Yijin Wang ¹

Southern University Of Science And Technology, Pharmacology, Shenzhen-China ¹ The Fifth Medical Center, Chinese PLA General Hospital, Pathology And Hepatology, Beijing-China ²

Background / Hypothesis:

Hepatitis E virus (HEV) represents a major cause of acute hepatitis globally, posing a significant clinical threat to immunocompromised individuals and pregnant women. Mitochondrial dynamics—the balance of fission and fusion—are increasingly recognized as central regulators of antiviral responses. This study systematically investigates whether HEV reprograms mitochondrial architecture to facilitate its replication and immune evasion.

Materials and Methods:

We performed immunohistochemistry and immunofluorescence on liver biopsies from HEV-infected patients to evaluate mitochondrial ultrastructure. Acute and chronic HEV infection models were established in hepatoma cell lines. Mitochondrial morphology was assessed using electron microscopy and confocal imaging. Viral replication, autophagic flux, and transcriptomic profiles were analyzed through genetic knockdown, pharmacological inhibition, and RNA sequencing.

Results:

Analysis of human liver biopsies revealed significant mitochondrial aggregation in 65% of acute HEV patients, which correlated strongly with elevated serum aminotransferase levels and disease severity. HEV infection consistently induced pronounced mitochondrial fusion across all cell models, mediated by a biphasic regulatory program: acute infection preferentially upregulated the inner membrane fusion GTPase OPA1, while chronic infection selectively enhanced the outer membrane mediator MFN1. Genetic ablation of either OPA1 or MFN1 reversed mitochondrial elongation and significantly suppressed HEV replication in both acute and chronic models. Integrated transcriptomic analyses demonstrated that depletion of OPA1 or MFN1 disrupted core pathways involved in autophagy and innate immune signaling. Specifically, OPA1 knockdown during acute infection inhibited pro-viral autophagy and enhanced interferon-stimulated gene (ISG) expression, whereas MFN1 knockdown exerted parallel effects in chronic infection. Pharmacological inhibition of autophagy with 3-methyladenine (3MA) substantially attenuated autophagic flux and suppressed HEV replication.

E-POSTER ABSTRACTS

Furthermore, HEV infection induced G0/G1 cell cycle arrest, which facilitated mitochondrial fusion and enhanced viral replication. Clinically, HEV ORF2 protein levels positively correlated with OPA1 and MFN1 expression in patient liver tissues.

Conclusions:

Our study establishes mitochondrial fusion as a critical host pathway co-opted by HEV to promote viral replication through coordinated activation of pro-viral autophagy and suppression of innate immune responses. These findings reveal a novel viral strategy and highlight mitochondrial fusion machinery as a promising therapeutic target against hepatitis E.

Keyword(s) : HEV; anti-virus; mitochondrial dynamics

1474 - Deciphering the mechanistic underpinnings of hepatitis E severity a tale of T cell exhaustion and maladaptive cDC2 activation at single cell resolution

Jian Wu ¹, Xiaoman Liu ², Yijin Wang ²

The Affiliated Suzhou Hospital Of Nanjing Medical University, Suzhou Municipal Hospital, Gusu School, Nanjing Medical University, Department Of Clinical Laboratory, Suzhou-China ¹ Southern University Of Science And Technology, Department Of Pharmacology, Shenzhen-China ²

Background / Hypothesis:

Hepatitis E virus (HEV) infection is the most common cause of acute viral hepatitis worldwide. Although typically self-limiting in immunocompetent hosts, a subset of patients progresses to fulminant hepatitis, which carries substantial mortality. The immune mechanisms underlying severe HEV infection remain incompletely elucidated. Using single-cell RNA sequencing (scRNA-seq), we sought to delineate the peripheral immune landscape and identify transcriptional programs associated with immunopathology versus protective immunity in severe HEV infection.

Materials and Methods:

We performed scRNA-seq on 20 peripheral blood mononuclear cell samples, including acute hepatitis E (AHE) patients (n=8), HEV-induced acute liver failure (HEV-ALF) patients (n=8,) and healthy controls (HCs) (n=4). Integrated bioinformatic analysis comprise differential expression, pathway enrichment, trajectory inference, and cellular communication mapping to delineate immune heterogeneity and dynamic changes across disease severity.

Results:

Unsupervised clustering identified 23 distinct transcriptomic clusters, corresponding to six major immune lineages. Oxidative phosphorylation was consistently enriched across all immune subsets in HEV-infected patients compared to HCs. Compared to AHE, ALF group exhibited pronounced activation of inflammatory pathways, including NOD-like receptor, TNF, NF- κ B, and IL-17 signaling. Further stratification of T and NK cells revealed nine functionally distinct subsets. IL-17 signaling was uniquely enriched in naïve T cells from HEV-infected patients versus HCs, but became broadly activated across all NK/T cell subsets in ALF. CD8⁺ effector memory T cells (TEM) were expanded in both AHE and ALF. Strikingly, HLA-DR⁺CD38⁺CD8⁺ TEM cells were markedly increased in AHE compared to HCs and ALF. Furthermore, CD8⁺ TEM cells in ALF displayed significant downregulation of cytotoxic effector molecules (GZMA, GZMH, GNLY, PRF1) compared to AHE. Pseudotime trajectory analysis indicated that CD8+TEMRA-lineage cells accumulated terminally in AHE, whereas ALF was characterized by enrichment along a CD8+TEM-differentiated trajectory. Additionally, cDC2 frequencies were elevated in both AHE and ALF groups. Within cDC2, ALF group showed enhanced MHC-II pathway activity and upregulated expression of all eight HLA class II genes, accompanied by the highest module score for HLA-II among myeloid subsets.

Conclusions:

Our findings delineate a pathognomonic immune signature for HEV-induced acute liver failure, characterized by broad inflammatory activation coupled with a state of CD8⁺ TEM cell paralysis and maladaptive cDC2-driven antigen presentation. This specific combination of excessive inflammation and impaired effector function provides a mechanistic basis for disease severity, revealing novel therapeutic targets to restore immune homeostasis in severe hepatitis E.

1475 - Serum cystathionine γ lyase (CTH) as a novel noninvasive biomarker for occult nonalcoholic steatohepatitis

Bobin Hu ¹, Xiaoting Li ¹, Hang Wang ¹, Yanfei Feng ¹, Jinni Huang ¹, Qian Wang ¹, Rong Xie ¹, Minghua Su ¹, Jianing Jiang ¹

The First Affiliated Hospital Of Guangxi Medical

E-POSTER ABSTRACTS

University, Department Of Infectious Diseases,
Nanning-China ¹

Background / Hypothesis:In nonalcoholic fatty liver disease (NAFLD), approximately 15%-40% of patients with normal liver function tests actually have occult NASH, whose risks of liver inflammation and fibrosis are often underestimated. There is currently a clinical lack of accurate noninvasive biomarkers for assessing hepatic inflammatory status. We found that cystathionine γ -lyase (CTH) gene expression is specifically upregulated during hepatic inflammation and hypothesized that its protein product, released into the bloodstream, could serve as a specific biomarker reflecting the true severity of liver inflammation.

Materials and Methods:The study enrolled 60 patients with biopsy-confirmed occult NASH and normal liver function. Serum CTH protein concentration was measured using ELISA and correlated with histological inflammatory activity grades (G-scores, 1-4). Traditional inflammatory markers including IL-6, IL-10, and CRP were also detected for comparison. All enrolled patients underwent regular longitudinal follow-up. Serial FibroScan examinations, abdominal CT imaging evaluations, and FIB-4 score calculations were performed to dynamically monitor liver fibrosis progression.

Results:Correlation analysis revealed a significant positive correlation between serum CTH protein levels and the degree of histological liver inflammation (correlation coefficient $r = 0.78$, $P = 0.000$). The diagnostic performance of CTH surpassed that of traditional inflammatory markers such as IL-6, IL-10, and CRP. Longitudinal follow-up data over an average observation period of 24 months showed that 70% of patients with persistently high serum CTH levels exhibited definite liver fibrosis progression. In contrast, no significant deterioration in fibrosis was observed in patients maintaining lower CTH levels.

Conclusions:Serum CTH protein levels are closely associated with the severity of liver inflammation in patients with occult NASH and can effectively predict the risk of fibrosis progression. These findings suggest that serum CTH protein holds promise as a valuable noninvasive biomarker for assessing hepatic inflammatory status and predicting disease outcomes in occult NASH patients, offering a new direction for early identification of high-risk individuals and implementation of personalized interventions.

Background / Hypothesis:

Direct-acting antiviral (DAA) agents have been approved for hepatitis C virus (HCV) treatment, providing higher rates of sustained virologic response (SVR) and fewer side effects. However, some patients have experienced treatment failure with prior DAA-based regimens. Vosevi, a pan-genotypic fixed-dose combination of sofosbuvir/velpatasvir/voxilaprevir, is indicated for patients with chronic HCV infection who previously failed DAA therapy. The Taiwan Food and Drug Administration (TFDA) requested a post-

E-POSTER ABSTRACTS

authorization study (PAS) to evaluate the safety and efficacy of Vosevi in the Taiwanese population.

Materials and Methods:

This multicenter observational study enrolled DAA-experienced patients who received a 12-week course of Vosevi between September 2021 and August 2024. Data were obtained from the Taiwan Association for the Study of the Liver (TASL) HCV Registry (TACR) database. All adverse events (AEs) were collected to evaluate the safety profile of Vosevi, while SVR at 12 weeks post-treatment (SVR12) was used to assess efficacy.

Results:

A total of 116 patients were enrolled across 15 sites in Taiwan. In the safety analysis set, 52 patients experienced 119 AEs (incidence: 44.8%; 95% CI: 36.1–53.9), corresponding to 2.0 events per person-year (95% CI: 1.5–2.7). Most AEs (97.5%) were non-serious. The most common AEs were gastrointestinal disorders (n=33, 28.4%), infections and infestations (n=14, 12.1%), and nervous system disorders (n=12, 10.3%). Two patients (1.7%) experienced serious adverse events (SAEs), and one patient (0.9%) experienced an adverse drug reaction (ADR). No serious ADRs, deaths, hyperbilirubinemia, or drug-induced liver injury (DILI) were reported.

Among 107 patients who completed treatment and follow-up with available SVR12 data, the SVR12 rate was 98.1% (105/107) in the modified full analysis set (mFAS). The SVR12 rates were consistently high across all HCV genotypes and comorbidities, including 100% among patients with genotype 3 or 6, liver cirrhosis, HBV/HIV coinfection, and those who underwent liver transplantation.

Conclusions:

A 12-week regimen of Vosevi (SOF/VEL/VOX) was safe, well-tolerated, and highly effective in DAA-experienced Taiwanese patients with chronic HCV infection. No new safety concerns were identified in this post-authorization study.

1478 - Unveiling Pyruvate Metabolism A Prognostic and Immunotherapeutic Beacon in Hepatocellular Carcinoma

Ning Wang¹

Tianjin Third Central Hospital, Department Of Gastroenterology And Hepatology, Tianjin -China¹

Background / Hypothesis:Pyruvate metabolism is crucial in the development and advancement of many types of human cancers. This study sought to investigate the prognostic and immunotherapeutic predictive value of pyruvate metabolism-related genes in hepatocellular carcinoma (HCC).

Materials and Methods:According to The Cancer Genome Atlas (TCGA) database, a machine-learning prognostic risk model was developed using the least absolute shrinkage and selection operator (LASSO) algorithm, based on pyruvate metabolism-gene signatures. The model's predictive accuracy was additionally confirmed with an independent dataset from the International Cancer Genome Consortium (ICGC) database. Consensus clustering was utilized to categorize HCC patients into subgroups according to pyruvate metabolism-gene signatures, with subsequent analyses of differential gene expression, clinical outcomes, and immune characteristics.

Results:In this study, 69 genes related to pyruvate metabolism were identified, and 13 of these genes were screened to create a risk score model through the LASSO regression method. The model effectively categorized HCC cohorts from the TCGA database into high- and low-risk groups, with the high-risk group representing notably poorer prognosis. The model's prognostic accuracy was further confirmed in HCC cohorts from ICGC database. HCC patients were stratified to two subgroups, C1 and C2, according to gene signatures related to pyruvate metabolism. Comparative analysis identified 1,907 differentially expressed genes (DEGs), comprising 1,539 upregulated and 368 downregulated genes. Patients in the C2 subgroup showed enhanced clinical outcomes and a superior response to immunotherapy relative to the C1 subgroup.

Conclusions:This study uncovered that pyruvate metabolism-related gene signatures served as reliable predictors of prognosis and immunotherapy response in HCC patients.

Keyword(s) : Hepatocellular carcinoma, pyruvate metabolism, prognosis, tumor microenvironment, immunotherapy response

E-POSTER ABSTRACTS

1479 - Disulfidptosis in Acute Liver Failure Roles Molecular Mechanisms and Potential Clinical Applications

Qi Yang ¹, Xiaoxuan Liu ¹, Yu Yu ¹, Li Bai ¹

Beijing Youan Hospital, Capital Medical University,
Fourth Department Of Liver Disease, Beijing-China ¹

Background / Hypothesis:

Acute liver failure (ALF) is a critical clinical emergency, but its pathogenesis has not been fully elucidated. Cell-free therapeutic strategies based on exosomes have received increasing attention in ALF treatment. Disulfidptosis, a newly discovered cell death modality in 2023, has not been systematically studied in ALF. It is urgent to explore new mechanisms of ALF pathogenesis and develop new effective alternative therapeutic strategies.

Materials and Methods:

D-galactosamine/lipopolysaccharide (D-GalN/LPS) was used to induce BALB/c mice and Alpha mouse liver 12 (AML12) cells respectively to construct in vivo and in vitro ALF models. Subsequently, HYX1-derived exosomes (HYX1-Exos) were administered to treat the ALF models. By detecting glucose and cysteine content, NADPH levels, and using qPCR, Western blot and immunohistochemistry to detect disulfidptosis-related gene and protein expression, the occurrence of disulfidptosis in the in vivo and in vitro ALF models was confirmed and the therapeutic effect of HYX1-Exos was evaluated. Meanwhile, bioinformatics methods were used to screen hub genes closely related to disulfidptosis in ALF patients, and validation was performed in the ALF model group and HYX1-Exos treatment group. In addition, RNA sequencing was performed on HYX1-Exos to screen potential functional miRNAs, their therapeutic effects in the in vitro ALF model were verified by transfecting miRNA mimics, and their in vivo efficacy in the in vivo ALF model was evaluated by tail vein injection of miRNA agomir.

Results:

Multiple indicators showed that disulfidptosis plays an important role in the in vivo and in vitro ALF models. HYX1-Exos had significant protective effects on D-GalN/LPS-induced ALF models, and could effectively inhibit the occurrence of disulfidptosis in vitro and in vivo. Through bioinformatics and machine learning analysis, two key genes, SLC7A11 and IQGAP1, were screened out, and the important role of SLC7A11 and IQGAP1-mediated disulfidptosis in ALF pathogenesis was confirmed. Further studies showed that HYX1-Exos alleviated ALF injury by inhibiting SLC7A11 and IQGAP1-mediated disulfidptosis. miRNA screening

identified miR-4492 as the key miRNA in HYX1-Exos targeting disulfidptosis, which showed significant therapeutic effects in both the in vivo and in vitro ALF models and could effectively inhibit the expression of SLC7A11 and IQGAP1.

Conclusions:

This study revealed that disulfidptosis participates in the pathogenesis of ALF through molecular mechanisms mediated by SLC7A11 and IQGAP1. HYX1-Exos effectively alleviates ALF liver injury by targeting and inhibiting the expression of disulfidptosis-related genes through its carried miR-4492, providing new theoretical basis and potential therapeutic strategies for the clinical treatment of ALF.

Keyword(s) : Acute liver failure; Disulfidptosis; Exosomes; SLC7A11; IQGAP1

1480 - Baseline Screening and Epidemiological Characteristics of First Degree Relatives of HBV Related Hepatocellular Carcinoma Patients A Multicenter Prospective Study in Jiangsu China

Yunqi Ji ¹, Ying Wang ², Meijuan Wang ³, Yuan Ding ⁴, Liangyun Chen ⁵, Weifeng Zhao ¹

The First Affiliated Hospital Of Soochow University, Infectious Disease, Suzhou-China ¹ The First Affiliated Hospital Of Soochow University, Public Health, Suzhou-China ² Hai'an People's Hospital, Infectious Disease, Nantong-China ³ Zhangjiagang First People's Hospital, Infectious Disease, Zhangjiagang-China ⁴ Changshu Second People's Hospital, Infectious Disease, Changshu-China ⁵

Background / Hypothesis:

First-degree relatives of patients with HBV-related hepatocellular carcinoma (HCC) constitute a high-risk population for chronic hepatitis B virus (HBV) infection. However, real-world screening uptake and antiviral treatment status in this group remain insufficiently characterized. We hypothesize that a structured program integrating screening, diagnosis, treatment, and tailored health education among first-degree relatives of HBV-related HCC patients will increase HBV detection and antiviral treatment uptake, thereby reducing risk of disease progression. This study reports the baseline findings of an ongoing multicenter prospective investigation aiming to establish an integrated screening–diagnosis–treatment–education model to improve HBV management in this high-risk population.

E-POSTER ABSTRACTS

Materials and Methods:

This multicenter, prospective observational study was conducted across eight medical centers in Jiangsu Province, China. All first-degree relatives of index patients with HBV-related HCC were consecutively enrolled. Baseline assessments included demographic characteristics, HBV serostatus (HBsAg), antiviral treatment status, and family history of HCC. Descriptive statistics and 95% confidence intervals (CI) were calculated. Subgroup analyses were performed by relationship type and gender. The present abstract summarizes baseline data before implementation of the comprehensive intervention package

Results:

A total of 839 first-degree relatives from 221 HBV-related HCC index families were identified. Among them, 378 relatives were deceased or otherwise unreachable, leaving 461 living first-degree relatives eligible for contact. Of these, 411 individuals (89.2%) completed HBV serological testing. Among the tested individuals (411), a total of 161 relatives were HBsAg-positive, yielding an HBV prevalence of 39.2% (95% CI: 34.5%–44.1%), markedly higher than the general population.

Among the tested participants (411), 67 relatives (16.3%) were receiving antiviral therapy. Among HBV-positive individuals (161 relatives), the antiviral treatment uptake was 41.6% (67/161; 95% CI: 34.0%–49.6%).

Subgroup analysis demonstrated a striking pattern of familial clustering. 42.31% of parents (33/78) were HBsAg-positive. The siblings of index patients exhibited elevated HBV prevalence, with rates of 51.75% (59/114) in this group, significantly higher than the general population. 26.14% of children (69/264) were HBsAg-positive, further supporting the clustering of HBV within the family structure. Regarding gender, HBV prevalence was comparable between females (43.2%) and males (56.8%).

Conclusions: This multicenter baseline analysis demonstrates extremely high HBV prevalence and suboptimal antiviral treatment uptake among first-degree relatives of HBV-related HCC patients in Eastern China. The pronounced familial clustering—particularly among parents and siblings—highlights the necessity of targeted public health interventions. The ongoing study will evaluate whether a comprehensive outreach and follow-up program can improve HBV screening

and treatment rates and ultimately reduce long-term HCC risk in this high-risk population.

Keyword(s) : Hepatitis B, Hepatocellular Carcinoma, First-degree Relatives.

1483 - Epidemiological Survey of Liver Cirrhosis in Tianjin Ten Year Data

Aili Fan ¹, Qing Ye ²

Third Affiliated Clinical College Of Nankai University, Gastroenterology And Hepatology, Tianjin-China ¹

Tianjin Third Central Hospital, Gastroenterology And Hepatology, Tianjin-China ²

Background / Hypothesis:

In recent years, the epidemiological characteristics of liver cirrhosis worldwide have undergone subtle changes. This study analyzed the epidemiological profile of liver cirrhosis over a decade at the largest liver disease center in Tianjin, China.

Materials and Methods:

In this retrospective study, we analyzed LC cases admitted between December 2015 and May 2025. Data on demographics, etiologies, and complications were collected. Etiological changes were assessed annually and compared between two periods (2016–2019 vs. 2020–2024). Continuous variables are expressed as mean $\pm$ SD and categorical variables as percentages. The Student's t-test, χ^2 test, one-way ANOVA, or univariate logistic regression were used for analysis. A P-value <0.05 was considered statistically significant. Analyses were performed using R and GraphPad Prism.

Results:

A total of 20,150 patients were included (65.69% male, 34.31% female). The peak age at diagnosis was 55–59 years. Mean age was 58.1 ± 10.6 years for viral hepatitis-related LC and 65.2 ± 10.5 years for autoimmune LC. Etiology distribution was: viral hepatitis 43.65% (HBV 37.86%, HCV 5.59%, mixed 0.19%), alcohol-related 13.66%, autoimmune 10.92%, mixed 4.25%, and other 26.84%. Viral hepatitis, alcohol-related, and mixed etiology were more common in males (all $P < 0.001$), while autoimmune LC was more common in females ($P < 0.001$). From 2016–2019 to 2020–2024, viral hepatitis decreased from 47.78% to 39.26% ($P < 0.001$), with HBV decreasing from 41.10% to 34.31% ($P < 0.001$). Autoimmune, metabolic, and vascular etiologies increased (all $P < 0.05$), while alcohol-related LC remained stable. Common complications included ascites (28.98%), HCC (30.69%), and UGIB (26.41%). Males had higher rates of HCC (36.83% vs 18.93%) and portal vein tumor thrombosis (5.98% vs 2.29%, both $P < 0.001$). Using HBV as reference, ORs for

E-POSTER ABSTRACTS

complications were: ascites—alcohol 2.435, autoimmune 1.796; UGIB—HCV 1.318, alcohol 1.812, autoimmune 1.495, mixed 1.412; HCC—HCV 0.651, alcohol 0.133, autoimmune 0.055, metabolic 0.067, vascular 0.089, mixed 0.34; hepatic encephalopathy—alcohol 2.195, autoimmune 1.533.

Conclusions:

Viral hepatitis remains the leading cause of LC in Northern China, although its proportion has decreased significantly, particularly for HBV. Alcoholic LC carries the highest risk of ascites, UGIB, and hepatic encephalopathy. The etiological spectrum is evolving, with a stable burden of alcohol-related LC and a rising contribution from metabolic liver diseases.

Keyword(s) :

1485 - Integrated Multi omics Liquid Biopsy Advancing Early Detection and Precision Management of HCC

Xinhao Gao¹, Jitao Wang², Dengxiang Liu³, Juan Liu⁴, Hezhao Wang¹, Shihao Guo¹, Huiyang Fan¹
Xingtai People's Hospital, Hepatobiliary Surgery, Xingtai-China¹ Tsinghua University, Hepatobiliary Surgery, Beijing-China² Xingtai, Xingtai People, Xingtai-China³ Beijing, Tsinghua University, Beijing-China⁴

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide, often diagnosed at late stages due to the limited sensitivity and specificity of current surveillance methods such as ultrasound and alpha-fetoprotein (AFP) testing. Liquid biopsy, which non-invasively analyzes circulating biomarkers, offers a promising alternative. However, single-omics approaches often lack the robustness required for early detection. Multi-omics integration presents a transformative strategy to enhance diagnostic accuracy and enable precision oncology in HCC.

Materials and Methods:

This review synthesizes recent advances in multi-omics liquid biopsy for HCC, incorporating genomic (e.g., TERT, TP53 mutations), epigenomic (e.g., RASSF1A methylation), proteomic/glycomic (e.g., AFP-L3, GP73, exosomal glycans), fragmentomic (cfDNA fragmentation patterns), and cellular biomarkers (CTCs, EVs). Cross-omics integration strategies—such as cSMART, HIFI, and ASDAm-H1—were evaluated alongside emerging technologies including nanopore sequencing, SERS-based single-exosome analysis, and

machine learning models (e.g., XAI, GNNs, Bayesian Networks).

Results:

The integration of multi-omics biomarkers has demonstrated transformative diagnostic performance for early HCC. Cross-omics models consistently outperformed single-modality approaches: combined genomic-epigenomic assays achieved sensitivities of 80–90% for early-stage detection, while the fragmentomic-epigenomic HIFI model distinguished HCC from cirrhosis with exceptional accuracy (AUC 0.996, sensitivity 95.42%, specificity 97.83%). Integrated protein-epigenetic panels, such as the ASDAm-H1 index, reached an AUC of 0.96, and longitudinal application of multi-parametric scores like GALAD significantly improved sensitivity to 69.2% for early HCC compared to single measurements (53.8%). Fragmentomics-based models enabled early screening with sensitivities exceeding 96%, and metabolomic panels detected preclinical HCC up to one year before clinical diagnosis with 80% sensitivity. Beyond detection, multi-omics liquid biopsy proved vital for precision management: ctDNA mutation profiling enabled dynamic monitoring of targeted therapy response, PD-L1⁺ CTCs and cfDNA copy number variations predicted outcomes to immune checkpoint inhibitors, and machine learning-driven deconvolution of single-exosome SERS fingerprints or cfDNA methylation data provided unprecedented molecular resolution. These approaches not only identified AFP-negative HCC cases but also facilitated early recurrence prediction and molecular subtyping, effectively transitioning liquid biopsy from a passive detection tool to an active component in the dynamic, personalized management of HCC.

Conclusions:

Multi-omics liquid biopsy represents a paradigm shift in HCC management, enabling high-accuracy early detection and dynamic monitoring of disease progression and treatment response. Despite challenges in data integration, standardization, and clinical validation, future directions—including explainable AI, single-cell multi-omics, and closed-loop precision oncology systems—hold great promise. With continued interdisciplinary collaboration and standardization efforts, multi-omics liquid biopsy is poised to become the cornerstone of next-generation HCC care.

1487 - Sphingosine Attenuates Steatosis but Exacerbates Fibrosis Risk in Metabolic Associated Fatty Liver Disease (MAFLD) via Hepatic LDLR Modulation

Meng Li¹, Lujie Liu¹, Yujie Qin¹, Yanfeng Xiao¹
The Second Affiliated Hospital Of Xi'an Jiao Tong University-department Of Pediatrics, Department Of Pediatrics, Shanxi Xi'an-China¹

Background: Dysregulated sphingolipid metabolism contributes to the pathogenesis of glucose intolerance, hepatic fibrosis, and tumor metabolism. However, the role of sphingosine in metabolic-associated fatty liver disease (MAFLD) remains poorly defined.

Methods: After one week of acclimatization, 3-week-old C57/BL-6J mice were fed a high-fat choline-deficient (HCD) diet for 10 weeks, followed by 4 weeks of either continued HCD feeding or HCD with oral sphingosine supplementation. Hepatic steatosis, inflammatory injury, and fibrosis were assessed across normal diet, HCD, and HCD + sphingosine groups. Circulating lipid profiles were also evaluated.

Results: Oil Red O staining revealed a significant increase in the steatosis area in the HCD group (34.924%) compared to the choline-deficient (CD) group (9.062%, $P = 0.004$), which was attenuated by sphingosine supplementation (15.922%, $P = 0.026$). In contrast, Picrosirius red staining indicated a higher fibrosis proportion in the HCD + sphingosine group than in the HCD group (0.577 vs. 0.250, $P = 0.004$). Moreover, the HCD + sphingosine group exhibited elevated LDL-cholesterol and reduced HDL-cholesterol levels, along with decreased membrane localization of the LDL receptor compared to the HCD group.

Conclusions: Sphingosine ameliorates hepatic steatosis but promotes LDL-cholesterol elevation and fibrosis risk in HCD-fed mice, likely through internalization of hepatic LDLR.

Keyword(s) : MAFLD, Sphingosine, Liver fibrosis, LDLR.

1488 - Eicosapentaenoic Acid Prevents the Short term High fat Diet-Enhanced Severity of Concanavalin A-Induced Liver Injury

Eri Nanizawa¹, Yuki Katoh², Yuki Tamaki¹, Shun Otsuka¹, Naoyuki Hatayama¹, Tetsuya Ishikawa³, Shuichi Hirai², Munekazu Naito¹
Aichi Medical University, Anatomy, Nagakute-Japan¹
Nihon University School Of Medicine, Functional

Morphology, Itabashi-Japan² Nagoya University, Integrated Health Sciences, Nagoya-Japan³

Background / Hypothesis:

Metabolic dysfunction-associated steatohepatitis (MASH) represents the progressive, inflammatory stage of metabolic dysfunction-associated steatotic liver disease (MASLD) and is a major driver of cirrhosis and hepatocellular carcinoma. Although early intervention is critical, the molecular events that increase hepatic susceptibility during the initial phase of MASLD remain insufficiently understood. An imbalance in n-3 and n-6 polyunsaturated fatty acids (PUFAs), frequently observed in MASLD, is known to influence hepatic inflammatory responses. Using our short-term high-fat diet (HFD) model, we previously showed that only 4 days of HFD feeding markedly exacerbates concanavalin A (Con A)-induced immune-mediated liver injury, indicating heightened hepatic vulnerability before overt steatosis or metabolic abnormalities appear. To clarify the mechanisms driving this early inflammatory priming, we investigated rapid PUFAs alterations and related immune-inflammatory pathways during the earliest stage of HFD exposure.

Materials and Methods:

Male C57BL/6 mice were fed an HFD for 4 days. Liver and serum samples were collected daily (day 0–4) and analyzed for n-3 and n-6 PUFAs composition using gas chromatography–mass spectrometry. To evaluate preventive effects, mice received eicosapentaenoic acid (EPA, 100 mg/kg) during the short-term HFD period. Con A-induced liver injury was triggered by intravenous administration of Con A (10 mg/kg), and liver damage was assessed by serum transaminase levels and histopathology. Inflammatory and coagulation-related pathways were further examined to elucidate mechanisms underlying early hepatic vulnerability.

Results:

Short-term HFD intake resulted in rapid and dynamic alterations in PUFAs profiles. Notably, hepatic and serum EPA levels significantly decreased, whereas arachidonic acid (AA) levels increased, indicating a shift toward a more pro-inflammatory lipid milieu. Consistent with these biochemical changes, HFD-fed mice exhibited markedly aggravated Con A-induced liver injury. EPA supplementation effectively attenuated the exacerbation of liver injury and reduced inflammatory cytokine expression and hepatic fibrin deposition. These findings suggest that the early decline in EPA contributes to heightened hepatic susceptibility, and restoring EPA levels mitigates both inflammatory and pro-coagulant responses during

E-POSTER ABSTRACTS

acute immune-mediated liver injury.

Conclusions:

Early exposure to an HFD induces a rapid imbalance of n-3 and n-6 PUFAs, lowering anti-inflammatory EPA while increasing pro-inflammatory AA, thereby heightening susceptibility to immune-mediated liver damage. EPA supplementation during this early phase significantly alleviates liver injury through anti-inflammatory and anticoagulant mechanisms. These results indicate that early EPA intervention may serve as an effective strategy to prevent MASLD progression before clinical symptoms emerge.

1489 - Transcriptomic profiling of liver biopsy tissues reveals $\alpha\beta$ T Cell activation and differentiation are associated with Idiosyncratic drug induced liver injury

Zhi-xiang Du¹, Dong-dong Li¹, Chuan-miao Liu¹, Jing-jing Shen¹, Yong-feng Yang²

First Hospital Of Bengbui Medical University, Department Of Infectious Disease And Liver Disease, Bengbu-China¹ The Second Hospital Of Nanjing, Affiliated To Nanjing University Of Chinese Medicine, P. R. China, Department Of Infectious Disease And Liver Disease, Nanjing-China²

Background / Hypothesis:

Idiosyncratic drug-induced liver injury (iDILI) is a rare liver injury with diverse clinical and pathological manifestations. We know very little about the pathological and physiological processes of iDILI. The lack of specific biomarkers makes it challenging for hepatologists to distinguish iDILI from other types of liver diseases effectively.

Materials and Methods:

Bulk RNA-Seq was performed on liver biopsy tissue from 17 iDILI patients and 13 normal liver tissues. The DESeq2 package and the WGCNA package were used to identify differentially expressed genes (DEGs) and hub modules, respectively. Functional enrichment analysis was performed on the DEGs and co-regulated genes. The results of the above bioinformatics analyses were validated by immunohistochemistry (IHC) on liver tissue.

Results:

We identified 769 DEGs (490 up-regulated genes and 279 down-regulated genes) between iDILI and HC. Go analysis of up-regulated genes enriched in $\alpha\beta$ mononuclear cell differentiation. KEGG analysis showed that the up-regulated genes were mainly enriched in Th17 cell differentiation and Th1 and Th2 cell differentiation. Enrichment analysis of 420 co-regulation genes obtained from DEGs and hub modules were enriched in the regulation of alpha-beta T cell activation. IHC confirmed that the infiltration of alpha-beta T cells in the liver tissue of IDILI manifests in different pathological phenotypes, with varying levels of CD4+ and CD8A+ T cell infiltration. The differentiation and infiltration of $\alpha\beta$ T cells contribute to the differential diagnosis of a variety of liver diseases.

Conclusions: Our study indicates that transcriptomic profiling of liver biopsy tissues reveals a significant association between $\alpha\beta$ T cell activation and differentiation and the pathological processes of iDILI.

Keyword(s) : idiosyncratic drug-induced liver injury, liver biopsy tissues, transcriptomics, $\alpha\beta$ T Cell

1490 - South Asian metabolic phenotype and fibrosis discordance in lean and obese metabolic dysfunction-associated steatotic liver disease insights from a Sri Lankan tertiary cohort

Prabhath Dasanayaka¹, Janaka Subasinghe¹, Nandana Dinamithra¹, Hasitha Wijewantha¹

National Hospital Kandy, Gastroenterology And Hepatology, Kandy-Sri Lanka¹

Background / Hypothesis:

South Asians develop metabolic dysfunction-associated steatotic liver disease (MASLD) at lower body mass indices, yet the fibrosis-risk phenotype of lean MASLD remains poorly characterised. We hypothesised that the South Asian metabolic phenotype may confer disproportionately high fibrosis susceptibility in lean MASLD, resulting in fibrosis indices comparable to obese counterparts despite lower anthropometric burden

Materials and Methods:

A cross-sectional analysis was conducted at a major Sri Lankan hepatology centre between August and October 2025. Adults with ultrasonographic hepatic steatosis and at least one metabolic risk factor were

E-POSTER ABSTRACTS

included. Height entries provided in non-metric formats were corrected to centimetres prior to recalculation of body mass index (BMI). Patients were categorised as lean (BMI <25 kg/m²) or obese (≥25 kg/m²). Clinical risk factors, metabolic parameters and non-invasive fibrosis markers (fibrosis-4 [FIB-4] index and aspartate aminotransferase-to-platelet ratio index [APRI]) were compared using independent t-tests and chi-square tests

Results:

Forty patients were analysed; 13 (32.5%) had lean MASLD. Despite significantly lower BMI (23.5 ± 0.9 vs 29.5 ± 3.6 kg/m²; $p < 0.001$) and waist circumference (96.7 ± 11.2 vs 109.7 ± 22.5 cm; $p = 0.019$), lean and obese MASLD showed similar metabolic comorbidity burdens including diabetes (30.8% vs 29.6%; $p = 1.00$) and hypertension (23.1% vs 33.3%; $p = 0.77$). Fibrosis markers were comparable: FIB-4 (1.31 ± 1.04 vs 1.17 ± 0.53 ; $p = 0.66$), APRI (0.36 ± 0.22 vs 0.32 ± 0.13 ; $p = 0.54$), and high FIB-4 >1.3 prevalence (38.5% vs 33.3%; $p = 1.00$). These findings demonstrate a fibrosis burden disproportionate to anthropometric profile, supporting a visceral adiposity-driven mechanism in lean South Asians

Conclusions:

Lean MASLD was common and exhibited fibrosis risk comparable to obese MASLD, despite markedly lower BMI. This highlights limitations of anthropometry-based stratification and underscores the need for South Asia-specific MASLD screening pathways incorporating routine fibrosis assessment irrespective of BMI. Findings support urgent multicentre validation to recalibrate fibrosis thresholds for lean South Asian populations

Keyword(s) : Lean MASLD, fibrosis discordance, metabolic phenotype, South Asia, non-invasive fibrosis markers

1491 - Dynamic network collapse in decompensated hepatic cirrhosis

Yanpei Mai ¹, Suzhen Jiang ¹, Shuo Yang ², Zixing Wang ¹

Peking University, Peking University Hepatology Institute, Beijing-China ¹ Peking University Radiology

Department, Peking University People's Hospital, Beijing-China ²

Background: Alterations in intrahepatic communication networks – driven by fibrotic bridging, vascular shunting, and metabolic dysfunction – serve as latent biomarkers for impending cirrhotic decompensation. However, the dynamic hepatic connectomes and its role in signaling decompensation remain unexplored.

Materials and Methods: We enrolled hepatic cirrhotic patients (with/without HCC) (2022–2025) undergoing gadoxetic acid-enhanced upper abdominal MRI with ≥5 imaging phases (non-contrast, arterial early, arterial late, portal venous, equilibrium). Dynamic contrast-enhanced T1-weighted MRI using a GE Discovery 750 3.0T or Siemens Prisma 3.0T scanner with standardized axial acquisition (FOV = 38 cm), performed prior to and following intravenous injection of 0.1–0.2 mL/kg gadoxetic acid disodium (Bayer AG, Germany). Liver partitioned into 8 segments (I–VIII, Couinaud classification). Representative slices. Circular ROIs placed centrally in Segments I–VIII, avoiding vessels and lesions <5 mm. 837 radiomic features per segment were extracted via PyRadiomics (first-order, GLCM, GLDM, GLSZM, NGTDM, wavelet features). Sliding window (window size=3 phases) was applied to build topological networks. Inter-segmental connectivity quantified by Pearson correlation, with sparsity controlled at 0.2. Small-worldness (sigma, clustering, path length), modularity, hub distribution, nodal centrality (degree, strength, betweenness, closeness, eigenvector) were analyzed.

Results: Significant network reorganization was observed in decompensated compared to compensated livers within the arterial-portal venous-equilibrium window. This included an increase in modularity (indicating functional fragmentation: 0.066 vs. 0.038), sigma (reflecting heightened randomness: 1.514 vs. 1.434), and a decrease in average path length (suggesting impaired information transfer efficiency: 0.786 vs. 0.818); all $P < 0.05$. Segment V dominated the liver network in compensation (20% hub prevalence, consistent with its anatomical centrality). Decompensation triggered hub redistribution: Peripheral Segments II–V & VII–VIII: 12–15%; Marginal Segments I & VI: 8–10%. This indicate collapse of compensatory network. The betweenness centrality of Segment I (measure of its information-bridging role) predicted decompensation risk: 18.2%, 54.2%, and

E-POSTER ABSTRACTS

83.3% in low, medium and high risk stratus, respectively. High-risk groups showed significantly elevated HRs for onset of ascites, hepatic encephalopathy and variceal bleeding; all $P < 0.05$.

Conclusions: This study pioneers a network paradigm for cirrhosis prognostication, shifting from isolated segmental biomarkers to system-level monitoring. The arterial-portal-equilibrium phase offers a critical window for detecting connectome-driven decompensation signals, with Segment I centrality emerging as a clinically important predictor.

1492 - Evaluating the accuracy of the histological diagnosis in unexplained liver injury A retrospective study

Lingling Yang¹, Zhikun Wang², Linqian Wu², Ke Bai², Qing Li³, Liangtao Zeng³, Yipeng Wan¹, Hui Zhu¹, Lifang Chen¹, Zhili Wen¹

The Second Affiliated Hospital Of Nanchang University, Gastroenterology, Nanchang-China¹ Jiangxi Medical College, Gastroenterology, Nanchang-China² The Second Affiliated Hospital Of Nanchang University, Pathology, Nanchang-China³

Background / Hypothesis:

Liver biopsy is a valuable tool for diagnosing liver diseases with unknown etiology, but it sometimes fails to provide a clear diagnosis. This study aimed to identify the cause of unexplained liver injury and evaluate the accuracy of histological diagnosis.

Materials and Methods:

A retrospective analysis was conducted on the clinical and histological data of patients with chronic liver disease of unknown aetiology at the Second Affiliated Hospital of Nanchang University, China, who underwent liver biopsy between September 2019 and June 2024. Diagnoses were divided into admission diagnosis, histological diagnosis, and final clinical diagnosis groups.

Results:

A total of 104 patients were included, with 64 women (61.5%) and 40 men (38.5%), 96 (92.3%) of whom received a definitive diagnosis through liver biopsy.

The main diseases were autoimmune liver disease (AILD, 49 cases, 47.1%), non-alcoholic fatty liver disease (NAFLD, 26 cases, 25.0%), drug-induced liver injury (DILI, 22 cases, 21.2%), others (11 cases, 10.6%) and unknown etiology (8 cases, 6.9%). AILD was most common in women (40 cases, 55.6%), while NAFLD was most common in men (19 cases, 40.4%). Histological diagnosis showed higher sensitivity, specificity, positive predictive values (PPVs), and negative predictive values (NPVs) compared to admission diagnosis. Venn diagram analysis revealed that 57.7% of cases matched between admission and histological diagnosis, 60.6% matched between admission and final clinical diagnosis, and 92.3% matched between the histological and final clinical diagnosis.

Conclusions:

Histological diagnosis is effective in determining the cause of unexplained liver injury, and liver biopsy remains a crucial tool.

Keyword(s) : Histological diagnosis, liver biopsy, unexplained liver injury.

1495 - Electrolytes as predicting factor on outcome in patient with cirrhosis Study from low socioeconomic south east Asian population.

Muhammad Fahad Zakir¹, Shahid Majid¹

Indus Hospital And Health Network, Gastroenterology, Karachi-Pakistan¹

Background / Hypothesis:

Patient with cirrhosis have significant abnormalities in their fluid and electrolyte balance, this is mainly manifested by the development of ascites, oedema, neurological symptoms etc. The common disorders of fluid, electrolyte and acid-base metabolism observed in cirrhosis are hyponatremia, hypokalaemia, hyperkalaemia, low albumin and low anion gap, in addition to an excess accumulation of body fluids. out of this hyponatremia is the most prevalent single electrolyte abnormality. The development of hyponatremia in cirrhotic patients is regarded as a poor prognostic sign. in our daily clinical practice, we have observed cirrhotic patients with much less sodium level than patients in same stages of cirrhosis in west. We want to study different electrolytes imbalances in our population of cirrhosis and their impact on the mortality.

E-POSTER ABSTRACTS

Materials and Methods:

We conducted a descriptive study, which was carried out at The Indus Hospital and Health Network. Data was collected in prospective fashion from April 2023 till October 2025, comparing the different electrolyte imbalances present at the time of admission in hospital with outcome in terms of mortality in patients of cirrhosis. Our study population comprised of one hundred consecutive adult patients, with the diagnosis of cirrhosis. Diagnosis of cirrhosis was based on histology, blood chemistry ultrasonographic features along with classical signs of decompensated cirrhosis such as ascites or oesophageal varices. Patients fulfilling the inclusion criteria were enrolled in the study. Data regarding the aetiology, stage, complications and electrolyte status of the patients at the time of first admission were recorded and then these patients were followed up in next one year for outcome. Our outcome was mortality. In the end data was analysed comparing outcome with initial presentation.

Results:

HCV is the most common cause of cirrhosis (58%). Great majority of patients (90%) have ascites. Among the different biochemical laboratory parameters Child Pugh score, sodium, Creatinine, Total bilirubin, Albumin and Prothrombin time were found to be influencing mortality, and this relationship was statistically significant (P value are <0.001, 0.03, 0.02, 0.01, 0.004, and 0.001 respectively).

Conclusions:

Cirrhosis of liver is associated with different electrolyte abnormalities, most of which clearly influences mortality.

Keyword(s) : ACLD, Electrolyte Imbalance, Low SocioEconomic population, Cirrhosis, Hyponatremia

1496 - Systemic Immune Inflammation Index as a Predictive Biomarker for Non Response to Ursodeoxycholic Acid in Primary Biliary Cholangitis

源唐¹, 红涛雷², 艺博孔¹, 映雪张¹, 亚杨¹, 瑞金黄³, 晖敏张¹, 秋燕赵¹, 雪芹张¹
云南省曲靖中心医院, 消化医学中心, 云南省曲靖市-

China¹ 昆明医科大学, 公共卫生学院, 云南省昆明市-
China² 曲靖市第二人民医院, 消化内科, 云南省曲靖市-
China³

Background :

Although ursodeoxycholic acid (UDCA) is the first-line standard treatment for primary biliary cholangitis (PBC), a proportion of patients exhibit an inadequate response, leading to a risk of disease progression. Given the close involvement of inflammatory pathway activation in PBC pathogenesis, the value of the Systemic Immune-Inflammation Index (SII), a novel inflammatory marker, in predicting UDCA non-response remains to be elucidated.

Materials and Methods: To investigate the predictive value of baseline SII levels for UDCA treatment non-response in patients with PBC.

This retrospective cohort study included 238 PBC patients from Qujing First People's Hospital and Qujing Second People's Hospital who received standard-dose UDCA. The SII was calculated using baseline data as follows: $SII = \text{platelet count} \times \text{neutrophil count} / \text{lymphocyte count}$. Treatment response was defined according to the European Association for the Study of the Liver criteria, with good response indicated by an alkaline phosphatase (ALP) level below 1.67 times the upper limit of normal after 12 months of UDCA therapy; otherwise, patients were classified as non-responders. Logistic regression analysis was used to assess the association between SII and UDCA non-response. To verify the robustness of the findings, the following analyses were performed: subgroup analysis stratified by baseline cirrhosis, tertile trend analysis of SII, and a sensitivity analysis excluding patients with baseline chronic diseases.

Results: This study included 238 patients with a median age of 55.5 years (interquartile range: 45.0–65.0), of whom 192 (79.7%) were female. Sixty-eight patients (28.6%) were classified as UDCA non-responders. Univariate analysis revealed significant differences between the non-response and response groups in age, sex, proportion with cirrhosis, ALP level, absolute neutrophil count, absolute lymphocyte count, platelet count, and SII (all $P < 0.05$). Multivariate logistic regression analysis confirmed that after adjusting for potential confounders, elevated SII remained an independent risk factor for UDCA non-response (OR =

E-POSTER ABSTRACTS

1.07, 95% CI: 1.03–1.11). Furthermore, this association was consistent across various analyses: in the subgroup with baseline cirrhosis (OR = 1.28, 95% CI: 1.10–1.49), in the SII tertile trend analysis (OR = 5.03, 95% CI: 2.08–12.17), and in the sensitivity analysis excluding baseline chronic diseases (OR = 1.07, 95% CI: 1.02–1.11), thereby confirming the robustness of the results.

Conclusions: Baseline Systemic Immune-Inflammation Index (SII) serves as an independent risk marker for predicting UDCA treatment non-response in PBC patients. This indicator holds significant value for the early identification of high-risk individuals and for guiding clinical decision-making toward individualized treatment strategies.

Keyword(s) :

1498 - A Case of Idiopathic Caroli Syndrome Misdiagnosed as Cholangiocarcinoma

Lingling Yang¹, Zhikun Wang², Ke Bai², Hui Zhu², Lifang Chen¹, Liangtao Zeng³, Zhili Wen¹

The Second Affiliated Hospital Of Nanchang University, Gastroenterology, Nanchang-China¹ Jiangxi Medical College, Gastroenterology, Nanchang-China² The Second Affiliated Hospital Of Nanchang University, Pathology, Nanchang-China³

Background / Hypothesis: We aimed to report a case of Idiopathic Caroli Syndrome that was initially misdiagnosed as cholangiocarcinoma, highlighting the diagnostic challenges and emphasizing the importance of comprehensive evaluation including histopathology and genetic testing in such rare liver diseases.

Materials and Methods: The patient was suspected to have autoimmune liver disease or hereditary metabolic liver disease. Histological findings reveal : (1) Fibrous tissue proliferation in the portal areas with the formation of fibrous septa; (2) Marked bile duct proliferation, dilation, and tortuosity (ductal plate malformation) within and around the fibrous septa; (3) Hyperplasia of bile duct epithelial cells without atypia; (4) Absence of bile plug formation. The Genetic testing revealed two heterozygous variants in the PKHD1 gene: c.10630T>A and c.5600+2T>G . The gene encodes fibrillin/multichannel protein, which is associated with ciliopathies.

Results: Based on the above findings, the diagnosis of Caroli Syndrome can be confirmed. Caroli Syndrome is

a rare congenital disorder characterized by cystic dilatation of the intrahepatic bile ducts, congenital hepatic fibrosis, and portal hypertension. It results from ductal plate malformation and typically presents with recurrent cholangitis or portal hypertension-related complications. Diagnosis is primarily based on imaging findings showing characteristic cystic or beaded bile duct dilatations. However, when inflammation persists or a large cyst is present, the characteristic features of cystic bile duct dilatation may disappear. Through liver biopsy, we have ruled out the possibility of cholangiocarcinoma. However, the persistent elevation of liver function indicators and CA19-9 suggests that the patient's disease remains progressive, highlighting the refractory nature of this disease.

Conclusions: Chronic inflammatory manifestations of Caroli syndrome may mimic cholangiocarcinoma. A multidisciplinary approach incorporating imaging, histopathology, and genetic testing is essential for accurate diagnosis and can prevent unnecessary surgical intervention. This case underscores the value of genetic analysis in diagnosing rare congenital liver disorders.

Keyword(s) : Caroli Syndrome; cholangiocarcinoma; PKHD1 gene; autosomal recessive polycystic kidney disease; liver biopsy; genetic testing.

1499 - A case of drug induced autoimmune hepatitis with negative serum markers

Lingling Yang¹, Ke Bai², Hui Zhu¹, Lifang Chen¹, Liangtao Zeng³, Zhili Wen¹

The Second Affiliated Hospital Of Nanchang University, Gastroenterology, Nanchang-China¹ Jiangxi Medical College, Gastroenterology, Nanchang-China² The Second Affiliated Hospital Of Nanchang University, Pathology, Nanchang-China³

Background / Hypothesis: This study aims to report a case of drug-induced autoimmune hepatitis (AIH) with negative autoantibodies, and to provide clinical evidence and practical experience for the diagnosis and management of similar patients.

Materials and Methods: The clinical, laboratory, imaging, and histopathological data, along with the treatment outcome, of a patient with drug-induced autoimmune hepatitis negative for autoantibodies were systematically collected and analyzed, and a comprehensive review of the relevant literature was conducted to support the diagnosis and discussion.

E-POSTER ABSTRACTS

Results:Based on the above data, DILI was initially considered. The patient's liver function was still unstable after two hospitalizations, and the cause of liver injury was unknown. Since all patients were negative for autoantibodies, there was insufficient evidence for the diagnosis of AIH. After the third admission, ultrasound-guided liver biopsy was performed to determine the cause. The pathological results showed the characteristic histological manifestations of AIH (moderate to severe interface hepatitis, lymphocyte and plasma cell infiltration, and rosette), and finally the patient was diagnosed with drug-induced autoimmune hepatitis combined with medical history. After diagnosis, prednisone acetate was given for one month, and her liver function indices improved significantly.

Conclusions:This case reconfirms that drugs can induce autoimmune hepatitis that is negative for autoantibodies. Acute or chronic hepatitis in the context of drug exposure history, even if autoantibodies are negative, should be alert to the possibility of DILI-AIH overlap. Liver histopathological examination is the key to the diagnosis. Early recognition and initiation of immunosuppressive therapy (such as glucocorticoids) are usually effective. Clinicians need to broaden their thinking to avoid delays in the diagnosis and treatment of this type of AIH due to negative autoantibodies.

Keyword(s) : drug-induced autoimmune hepatitis; negative autoantibodies; liver biopsy

1500 - Endogenous Endophthalmitis Associated With Liver Abscess Caused By Klebsiella pneumoniae

Dinh Thang Nguyen¹, Tu Huong Lam², Tan Phat Ho¹, Duy Thong Vo³
Cho Ray Hospital, Gastroenterology, Ho Chi Minh City-Vietnam¹ University Of Medicine And Pharmacy At Ho Chi Minh City, Internal Medicine, Ho Chi Minh City-Vietnam² University Medical Center Ho Chi Minh City, Gastroenterology, Ho Chi Minh City-Vietnam³

Background / Hypothesis:

Endogenous endophthalmitis is a rare but serious complication of liver abscesses, particularly those caused by *Klebsiella pneumoniae*. In this case report, we describe a notable instance of a patient presenting with both a liver abscess and endogenous endophthalmitis concurrently, highlighting the clinical challenge and significance of this association.

Case Description:

Endogenous endophthalmitis is a rare but serious complication of liver abscesses, particularly those caused by *Klebsiella pneumoniae*. Given that the patient had no history of eye trauma or previous eye surgeries, a presumptive diagnosis of endogenous endophthalmitis (EE) in her right eye was made. The patient presented with EE accompanied by abdominal pain, suggesting a possible abdominal source of infection. Abdominal ultrasound and computed tomography scan showed a lesion in her liver, which was suspicious for an abscess. Examination of fluid from the liver abscess, as well as swab samples from the patient's right eye, confirmed the presence of *Klebsiella pneumoniae*. Despite early percutaneous drainage of the liver abscess, the condition of the patient's right eye did not improve, ultimately necessitating an evisceration. The patient was discharged two weeks after admission and experienced no further complications during a three-month follow-up period.

Conclusions:

This case report serves as a reminder that when encountering patients with endogenous endophthalmitis, physicians should consider the possibility of a liver abscess. Physicians should be aware not only of the potential for extrahepatic septic metastases but also of their associated complications. The immediate initiation of a comprehensive multidisciplinary treatment approach is necessary to prevent complications arising from liver abscesses, including endogenous endophthalmitis.

Keyword(s) : liver abscess, *Klebsiella pneumoniae*, Endogenous endophthalmitis

1501 - Are third generation cephalosporin still considered first choice for ascitic fluid infection in decompensated cirrhotic patients Study from largest tertiary care hospital Pakistan.

Shahid Majid¹, Muhammad Fahad Zakir¹
Indus Hospital And Health Network, Gastroenterology, Karachi-Pakistan¹

Background / Hypothesis:

Ascitic fluid infection (AFI) is a serious complication in patients with decompensated liver disease with a mortality approaching 30%. Third generation cephalosporins (TGC) have been effectively used for this infection. However, resistance to third generation

E-POSTER ABSTRACTS

cephalosporins has been increasing for other infections. It is therefore imperative to define the effectiveness of Third generation cephalosporins for ascitic fluid infection and factors responsible for the resistance.

Materials and Methods:

This cross-sectional study was conducted on consecutive subjects with ascitic fluid infection who received of injection ceftriaxone from March 2023 till October 2025 at The Indus Hospital and Health Network, Karachi. Ascitic fluid infection was diagnosed based on ascitic fluid Polymorphonuclear count (PMN) of 250 cells/mm³ and or positive ascitic fluid culture. All patients had a repeat diagnostic tap of ascitic fluid 48 hours after the index tap. Failure of reduction of PMN count in the latter tap and/or ascitic fluid bacteria resistant to third generation cephalosporins resistance were considered as nonresponders. Patients receiving any other antibiotic, prior documented resistance to Third generation cephalosporins resistance and patients with hepatoma were excluded.

Results:

Total of 223 patients with ascitic fluid infection received third generation cephalosporins resistance during the study period and were analysed. Out of them 123 (55.2%) were males. Hepatitis C was the commonest aetiology in 151 (67.7%), 185(80.8%) were in Child class C, 175(78%) responded to Third generation cephalosporins while 48(22%) were nonresponders. Ascitic fluid culture was positive in 51(22.9%) patients. The predominant organism found in ascitic fluid was E. coli in 27(53%) of the culture positive group. However, 147(85%) of cases amongst culture negative group responded as compared to 28(55%) of patients in culture positive group. On univariate analysis total bilirubin >6mg/dl, PT >2.2 seconds and positive Ascitic fluid culture (p value 0.04, 0.02 and <0.001 respectively) were associated with non-response to third generation cephalosporins. On multivariate analysis only ascitic fluid positivity was associated with no response to third generation cephalosporins.

Conclusions:

We found 22% resistance to third generation

cephalosporins resistance in Spontaneous bacterial peritonitis, Positive ascitic fluid culture is independently associated with nonresponse to third generation cephalosporins.

Keyword(s) : ACLD, Ascites, SBP, Cirrhosis, Ascitic Fluid Infection, TGC, AFI, Third generation cephalosporin, spontaneous bacterial peritonitis, HCV, Hepatitis C, NBNC CLD

1502 - Chronic hepatitis B with autoimmune hepatitis in a male patient

Lingling Yang¹, Huiping Xie², Lifang Chen¹, Hui Zhu¹, Liangtao Zeng³, Zhili Wen¹

The Second Affiliated Hospital Of Nanchang University, Gastroenterology, Nanchang-China¹ Jiangxi Medical College, Gastroenterology, Nanchang-China² The Second Affiliated Hospital Of Nanchang University, Pathology, Nanchang-China³

Background / Hypothesis: We aimed to present a case of chronic hepatitis B coexisting with autoimmune hepatitis (AIH) in a male patient so as to discuss its clinical manifestations, diagnostic approach, and treatment strategies, thereby providing insights for the clinical management of AIH.

Materials and Methods: Based on the above findings, a definitive diagnosis of "chronic hepatitis B with AIH" was established. However, since the patient did not exhibit typical clinical features of AIH overlapping with chronic hepatitis B, we further explored whether chronic hepatitis B could have acted as a trigger for AIH. Given the relative rarity of AIH in male patients and the necessity for close monitoring of HBV-DNA levels during immunosuppressive therapy, we paid particular attention to balancing the sequence and timing of antiviral and immunosuppressive treatments when formulating the therapeutic plan.

Results: The final diagnosis in this case was "chronic hepatitis B combined with AIH." It is noteworthy that viral infection is a recognized triggering factor for AIH; for instance, various non-specific autoantibodies can be detected in some patients with hepatitis C virus infection. Similarly, chronic hepatitis B can also present with autoantibody positivity and extrahepatic autoimmune phenomena, overlapping with features of AIH. Further research has revealed that viral antigen epitopes share determinant clusters with certain liver autoantigens, potentially inducing cross-reactive immune responses through "molecular mimicry", leading to autoimmune liver injury. This suggests that

E-POSTER ABSTRACTS

HBV infection or its chronic progression may have acted as an initiating factor for AIH in this patient. Following the initiation of entecavir antiviral therapy, we performed a liver biopsy and administered immunosuppressive treatment. Both the pathological findings and the treatment response confirmed the diagnosis of AIH. At the two-month follow-up, the patient's liver function had normalized, IgG levels had decreased, HBV-DNA had become undetectable, and a recent outpatient review showed that the ANA had turned negative.

Conclusions: This case suggests that chronic hepatitis B may serve as a predisposing factor for AIH. Immunosuppressive therapy can significantly influence HBV-DNA levels; therefore, close monitoring of hepatitis B status during treatment is essential. Careful consideration of the sequence and strategy between antiviral and immunosuppressive therapies is crucial for the diagnosis and clinical management of patients with chronic hepatitis B complicated by AIH.

1503 - Clinical Features and Prognostic Assessment of MAFLD Related Cirrhosis Pathological vs. Clinical Diagnosis

Ying Wang¹, Yuqing Zhao¹, Jinjin Liu¹, Ying Jian¹, You Deng¹, Xinyan Zhao¹, Hong You¹, Jingjie Zhao²

Beijing Friendship Hospital, Capital Medical University, Liver Research Center, Beijing-China¹ Capital Medical University, Clinical Center For Metabolic Associated Fatty Liver Disease, Beijing-China²

Background / Hypothesis:

In light of the "burn-out" phenomenon in metabolic dysfunction-associated fatty liver disease (MAFLD), an international expert panel has suggested that cirrhosis can be attributed to MAFLD even without typical histological findings, provided there is prior evidence of fatty liver (by histology or imaging) along with metabolic risk factors. This study aimed to compare the clinical characteristics and prognostic scores between patients diagnosed using conventional pathological criteria and those diagnosed clinically.

Materials and Methods:

We retrospectively analyzed 151 patients hospitalized with MAFLD-related cirrhosis at our center between 2022 and 2024. The pathological diagnosis group included patients with cirrhosis and histological evidence of steatosis or steatohepatitis. The clinical diagnosis group was defined according to the APASL

clinical practice guidelines for MAFLD. We compared demographic, metabolic, and laboratory data, as well as prognostic scores between the two groups.

Results:

Of the 151 patients, 38 (25.2%) were diagnosed pathologically and 113 (74.8%) clinically. Compared to the pathological group, the clinical diagnosis group was older (68 vs. 61 years), had longer hospital stays (9 vs. 7 days), and a higher rate of decompensation (73.5% vs. 23.7%, all $p < 0.05$). Laboratory results showed that the clinical group had lower albumin (33.28 vs. 37.13 g/L), triglycerides (1.07 vs. 1.21 mmol/L), total cholesterol (3.40 vs. 4.01 mmol/L), LDL-C (2.08 vs. 2.45 mmol/L), and HDL-C (0.92 vs. 1.17 mmol/L), along with worse coagulation (INR 1.24 vs. 1.20, all $p < 0.05$). This group also had higher serum creatinine (64.30 vs. 55.50 $\mu\text{mol/L}$) and uric acid (342.70 vs. 287.20 $\mu\text{mol/L}$, all $p < 0.05$). Child-Pugh scores, the proportion of Child-Pugh class C (4.42% vs. 0.00%, $p = 0.001$), and MELD scores were all significantly higher in the clinical diagnosis group.

Conclusions:

In our center, most MAFLD-related cirrhosis cases were diagnosed clinically. These patients had more advanced disease, worse liver function, and poorer prognostic scores than those diagnosed pathologically. These findings highlight the importance of early and active clinical diagnosis to allow timely intervention and improve patient outcomes.

Keyword(s): Cirrhosis; MAFLD; Pathological diagnosis; Clinical diagnosis; Clinical features

1505 - The Mechanistic Basis of ASH1L's Oncogenic Role in Hepatocellular Carcinoma

Jihyun An¹, Jin-sung Ju², Bora Oh², Ji-hye Oh³, Wonkyung Kim³, Chang-ock Sung³, Ju Hyun Shim²
Hanyang University, Gastroenterology, Guri-South Korea¹ Asan Medical Center, Gastroenterology, Seoul-South Korea² Asan Medical Center, Pathology, Seoul-South Korea³

Background / Hypothesis: Recent studies have suggested that ASH1L promotes tumor progression and contributes to an immunosuppressive microenvironment in hepatocellular carcinoma (HCC). However, the molecular mechanisms by which ASH1L regulates HCC development remain unclear. This study aimed to investigate the oncogenic role of ASH1L in HCC and to elucidate its function in tumor progression.

Materials and Methods: To investigate the oncogenic role of ASH1L in HCC, protein expression was

E-POSTER ABSTRACTS

examined by western blot to identify cell lines with different endogenous levels. ASH1L expression was silenced in Hep3B and SNU-739 cells using lentivirus-mediated shRNA, followed by puromycin selection for three days to obtain stable knockdown cell lines. The efficiency of ASH1L knockdown was verified using qPCR and western blot. The functional consequences of ASH1L suppression were assessed using viability, colony formation, invasion, and migration assays. In addition, RNA sequencing of ASH1L-silenced cells was conducted to identify ASH1L-regulated genes, followed by validation using qPCR. All experiments were conducted in triplicate, and statistical significance was analyzed using a two-tailed Student's t-test.

Results: ASH1L expression was relatively high in Hep3B and SNU-739 cells, compared to other HCC cell lines. ASH1L knockdown significantly reduced cell viability and colony formation in both HCC cell lines for 3 days post-transfection. In addition, the invasive and migratory capacity was markedly reduced in Hep3B and SNU-739 cells. RNA sequencing using the SNU-739 cell line confirmed that suppression of ASH1L expression led to decreased expression of genes associated with extracellular matrix organization. Consistently, qPCR validation confirmed the downregulation of these ASH1L-regulated genes, supporting the role of ASH1L in promoting extracellular matrix remodeling and tumor progression.

Conclusions: ASH1L promotes HCC progression by regulating cell proliferation, invasion, and migration, likely through transcriptional regulation of extracellular matrix-related genes. These suggest that ASH1L functions as an oncogenic factor in HCC and may be a potential therapeutic target.

1506 - Effect of Semaglutide Therapy on Hepatic Steatosis and Liver Stiffness in Patients with Nonalcoholic Fatty Liver Disease (NAFLD) A Quasi Experimental Study

Dr. Md. Tanveer Rahman Rashed¹, Dr. Md. Shahinul Alam², Dr. Md Saiful Islam Alin², Dr. Md. Sabbir Hossain³, Dr. Md. Farhad Hossain⁴
Rajshahi Medical College Hospital, Hepatology, Rajshahi-Bangladesh¹ Bangladesh Medical University, Hepatology, Dhaka-Bangladesh² Dhaka Medical College Hospital, Hepatology, Dhaka-Bangladesh³ Sir Salimullah Medical College Hospital, Hepatology, Dhaka-Bangladesh⁴

Background / Hypothesis:

Non alcoholic fatty liver disease (NAFLD) is a leading cause of chronic liver disease worldwide, with limited pharmacologic treatment options. Semaglutide, a glucagon-like peptide-1 receptor agonist, has shown metabolic benefits and potential effects on hepatic steatosis. This study aimed to compare the effects of Semaglutide therapy and standard medical treatment on hepatic steatosis and liver stiffness in NAFLD patients.

Materials and Methods:

This quasi-experimental study was conducted at the Department of Hepatology, Bangladesh Medical University (BMU), Dhaka, from September 2022 to February 2024. Seventy-four adult NAFLD patients (CAP >234 dB/m; LSM ≥ 7.8 kPa and ≤ 14 kPa) were enrolled. Participants were randomly allocated into a treatment group (n=33), receiving subcutaneous Semaglutide (0.25 mg for first 4 weeks then followed by 0.5mg for next 4 week then escalated to 1 mg weekly for total 24 weeks), and a control group (n=37), receiving standard medical care without pharmacotherapy. Both groups received lifestyle modification with dietary counselling properly. Primary outcomes were changes in CAP and LSM measured by Fibroscan, secondary outcomes included changes in BMI and liver enzymes (ALT, AST). Statistical analysis was performed using SPSS version 27.

Results:

At 24 weeks, the treatment group showed significant reductions in CAP (mean change: 40.91 ± 36.26 dB/m) and LSM (mean change: 2.51 ± 1.46 kPa) compared to the control group (CAP: 8.27 ± 30.99 dB/m; LSM: -0.44 ± 2.48 kPa; $p < 0.001$ for both). Improvements in BMI, ALT, AST, and LDL were also statistically significant in the Semaglutide group ($p < 0.05$). No significant differences were observed in glycemic parameters or other lipid profile components. Semaglutide was well tolerated, with mild gastrointestinal side effects and no severe adverse events reported.

Conclusions: Semaglutide therapy significantly

E-POSTER ABSTRACTS

improves hepatic steatosis and liver stiffness in NAFLD patients compared to standard medical care. These findings support Semaglutide as a promising therapeutic option for NAFLD, warranting validation in larger randomized controlled trials.

Keyword(s) : Nonalcoholic fatty liver disease (NAFLD); Semaglutide; Hepatic steatosis; Liver stiffness; Controlled attenuation parameter (CAP); FibroScan; Quasi-experimental study

1508 - Minimal Hepatic Encephalopathy in Portal Vein Thrombosis An Underrecognized but Common Complication

Kseniya Gulyaeva¹, Maria Nadinskaia¹, Evelina Trashkun², Diana Daduns², Maxim Privalov³, Vladimir Ivashkin¹
Sechenov First Moscow State Medical University (sechenov University), The Department Of Propaedeutics Of Internal Disease, Gastroenterology And Hepatology, Moscow-Russia¹ Sechenov First Moscow State Medical University (sechenov University), The Institute Of International Education (iie), Moscow-Russia² Sechenov First Moscow State Medical University (sechenov University), The Department Of Oncology, Radiotherapy And Reconstructive Surgery, Moscow-Russia³

Background / Hypothesis: Type B hepatic encephalopathy (HE) is the least studied of the three types and occurs in patients with portosystemic shunting and no underlying liver disease. Aim: To determine the frequency and risk factors of HE in patients with non-cirrhotic non-malignant portal vein thrombosis (PVT).

Materials and Methods: A cross-sectional study included 44 adult patients with non-cirrhotic, non-malignant PVT, of whom 17 (39%) had childhood-onset PVT. The mean duration of portal hypertension was 92 months. All participants had liver fibrosis stages ranging from F0 to F2, as assessed by transient elastography. Minimal HE (MHE) was identified using psychometric tests. Ammonia concentration was measured in capillary blood using a PocketChem BA PA-4140 analyzer (ARKRAY Factory, Inc., Japan). Multivariable logistic regression models were used to determine factors associated with the presence of HE. Results: No cases of overt HE were identified in the study cohort, while 9 (20.5%) patients were diagnosed with MHE. Hyperammonemia was detected in all patients with MHE, representing a prevalence 1.7 times higher than that observed in patients without MHE (p

$= 0.022$). The median ammonia concentration was significantly higher in the MHE group than in patients without HE (116 [90–132] $\mu\text{mol/L}$ vs. 74 [41–102] $\mu\text{mol/L}$; $p = 0.019$). Using a calculated ammonia cut-off value of 88 $\mu\text{mol/L}$, patients whose levels were above this threshold were 15.3 times more likely to have MHE (odds ratio: 15.3; 95% confidence interval: 1.7–137.4; $p = 0.015$). Compared with patients without MHE, those with MHE had a significantly higher prevalence of large (≥ 10 mm in diameter) spontaneous or surgically created portosystemic shunts ($p = 0.004$). They also had increased concentrations of indirect bilirubin ($p = 0.035$), urea ($p = 0.046$), as well as lower serum sodium levels ($p = 0.037$). Together with sonographic spleen length and the presence of gastric varices, these variables were incorporated into the best-fitting logistic regression models. The models demonstrated an overall accuracy of 88.6–90.5%, a sensitivity of 66.7%, a specificity of 94.3–97.0% and an area under the curve (AUC) of 0.96–0.97. The established cut-off values were 15.3 $\mu\text{mol/L}$ for indirect bilirubin, 4.2 mmol/L for urea, 140.8 mmol/L for sodium and 15.0 cm for splenic length.

Conclusions: One in five patients with non-cirrhotic non-malignant PVT was found to have MHE. Risk factors for its development include large portosystemic shunts, gastric varices, spleen length, hyperammonemia, elevated levels of indirect bilirubin, urea, and low sodium levels.

Keyword(s) : psychometric tests, risk factors, logistic regression model, portosystemic shunts, ammonia

1509 - When Pressure Matters More Than Parenchyma Gut Dysbiosis in Different Types of Portal Hypertension

Kseniya Gulyaeva¹, Maria Nadinskaia¹, Roman Maslennikov¹, Yulia Aleshina², Irina Goptar², Alexander Lukashev², Elena Poluektova³, Vladimir Ivashkin¹

Sechenov First Moscow State Medical University (sechenov University), The Department Of Propaedeutics Of Internal Disease, Gastroenterology And Hepatology, Moscow-Russia¹ Sechenov First Moscow State Medical University (sechenov University), Martsinovskiy Institute Of Medical Parasitology, Tropical And Vector Borne Diseases, Moscow-Russia² Sechenov First Moscow State Medical University (sechenov University), V.kh. Vasilenko Clinic Of Internal Disease Propaedeutics, Gastroenterology And Hepatology, Moscow-Russia³

Background: Although changes to the gut microbiota

E-POSTER ABSTRACTS

are usually associated with liver failure in cirrhosis, the exact role of portal hypertension (PH) in causing these changes is unclear. Aim: To determine the impact of different types of PH on gut microbiota composition.

Materials and Methods: A cross-sectional study enrolled 91 participants: 25 patients with non-cirrhotic, non-malignant portal vein thrombosis (PVT group), 29 patients with liver cirrhosis (LC group), 15 patients with combined cirrhosis and PVT (LC-PVT group), and 22 healthy controls. PVT was confirmed by contrast-enhanced computed tomography. According to transient elastography, liver fibrosis stages were F0-F2 in the PVT group and F4 in all cirrhotic patients. Morning stool samples were collected for 16S rRNA gene sequencing using the DNBSEQ-G50 platform (MGI).

Results: In comparisons with controls, the relative abundance of Proteobacteria and Bacilli was significantly increased in the PVT, LC, and LC-PVT groups ($p = 0.033, 0.052, 0.018$ and $p = 0.001, <0.001, <0.001$, respectively), whereas the abundance of Clostridia and Euryarchaeota was significantly decreased ($p = 0.001, <0.001, <0.001$ and $p = 0.045, 0.006, 0.001$, respectively). No statistically significant differences were observed among the PH groups in the abundance of Proteobacteria ($p = 0.590, 0.675$, and 0.980), Euryarchaeota ($p = 0.149, 0.152$, and 0.655), Bacilli ($p = 0.263, 0.069$, and 0.235), or Clostridia ($p = 0.590, 0.823$, and 0.862) for the comparisons PVT vs. LC, PVT vs. LC-PVT, and LC-PVT vs. LC, respectively. The abundance of bacteria from the phylum Actinobacteria was significantly increased only in the PVT group compared with controls ($p = 0.008$), while no significant differences were observed in the cirrhotic groups ($p = 0.816$ and $p = 0.255$). Furthermore, Actinobacteria abundance was higher in the PVT group than in both cirrhotic groups ($p = 0.010$ and $p < 0.001$). A significant reduction in the abundance of the family Porphyromonadaceae was observed in both PVT groups (cirrhotic and non-cirrhotic) compared with controls ($p = 0.003$ and $p < 0.001$), whereas no significant difference was detected in the LC group ($p = 0.089$).

Conclusions: The marked similarity in the alterations to the gut microbiota observed in different types of PH, which are characterized by an increased abundance of Proteobacteria and Bacilli, as well as a decreased abundance of Clostridia and Euryarchaeota, suggests that PH itself, rather than hepatic dysfunction, is a key driver of gut dysbiosis.

Keyword(s) : gut microbiota, portal vein thrombosis, liver cirrhosis, 16S rRNA, Proteobacteria, Clostridia

1510 - INTEGRATED BIOINFORMATIC ANALYSIS OF THE ROLE OF SLC35B2 IN HEPATOCELLULAR CARCINOMA

Wei Hou¹

Translational Medicine Research Center, School Of Clinical Medicine, Qilu Medical University, Zibo-China¹

Background / Hypothesis:

SLC35B2 is a Golgi-resident transporter of the sulfate donor 3'-phosphoadenosine 5'-phosphosulfate (PAPS), which has been shown to play a crucial role in promoting tumor growth in hepatocellular carcinoma (HCC). However, the precise mechanisms underlying SLC35B2 expression in HCC remain largely unknown. This study aims to elucidate the mechanisms of SLC35B2 expression in HCC through comprehensive bioinformatic analyses.

Materials and Methods:

SLC35B2 expression and its prognostic significance across various cancers were assessed using SangerBox. In HCC, associations with prognosis, immune infiltration, and mutations were analyzed via UALCAN, BoxKaplan-Meier Plotter, GEPIA, Human Protein Atlas, TIMER 2.0, and SangerBox. Co-expressed genes were identified using STRING, and miRNA-gene interactions were explored through the DIANA-MicroT Webserver.

Results:

SLC35B2 expression was significantly elevated in various cancers, including GBM, LGG, UCEC, BRCA, LUAD, ESCA, STES, KIRP, COAD, PRAD, STAD, HNSC, LUSC, LIHC, SKCM, BLCA, OV, PAAD, TGCT, UCS, LAML, and CHOL. In HCC, high SLC35B2 levels correlated with poorer survival and were associated with increased immune cell infiltration, specifically macrophages, monocytes, and CD4 T cells, as well as TP53 mutations. Mechanistic analysis revealed co-expressed genes, including EXT2, B3GAT3, EXTL3, B4GALT7, SLC35D2, SLC35D1, SULT4A1, SLC35D3, RPL15, and TPST2. Additionally, hsa-miR-29a-3p and hsa-miR-29c-3p were identified as potential regulators of SLC35B2 expression.

Conclusions:

Our findings highlight the oncogenic role of SLC35B2 and its prognostic significance across various cancers. In HCC, elevated SLC35B2 expression influences tumorigenesis, progression, and prognosis, suggesting its potential as a diagnostic biomarker and therapeutic target.

Keyword(s) : SLC35B2; HCC

E-POSTER ABSTRACTS

1511 - A PAN CANCER ANALYSIS OF THE ROLE OF OXCT1 IN HUMAN CANCERS

Wei Hou ¹

Translational Medicine Research Center, School Of Clinical Medicine, Qilu Medical University, Zibo-China ¹

Background / Hypothesis:

OXCT1 (3-oxoacid CoA-transferase 1), a rate-limiting enzyme in the process of ketolysis, plays a multifaceted role in hepatocellular carcinoma (HCC) by regulating ketone body metabolism and protein succinylation, thereby promoting tumor progression. However, the expression patterns and functional roles of OXCT1 in various cancers remain largely undefined. This study aims to conduct a pan-cancer analysis to investigate the role of OXCT1 across different human cancers.

Materials and Methods:

Data for this study were obtained from the Cancer Genome Atlas, the Gene Expression Omnibus, and the Clinical Proteomic Tumor Analysis Consortium databases. We employed the R programming language and various online tools to analyze and visualize OXCT1 expression across different cancer types, as well as its associations with tumor molecular subtypes, immune subtypes, diagnosis, prognosis, clinical characteristics, and the immune microenvironment.

Results:

Variation analysis revealed that OXCT1 was differentially expressed across numerous cancer types, including LGG, BRCA, ESCA, STES, KIRP, KIPAN, COAD, PRAD, STAD, LUSC, LIHC, THCA, READ, PAAD, TGCT, UCS, LAML, KICH, and CHOL. Clinical analysis demonstrated that OXCT1 expression significantly correlated with clinical stages or grades in several cancer types. Among different cancer subtypes in the TCGA dataset, high OXCT1 expression was associated with poor prognosis in LAML, LIHC, BLCA, and UVM. Furthermore, we explored the oncogenic role of OXCT1 by analyzing its association with immune infiltration, finding that in most cancer types, OXCT1 expression was positively correlated with the infiltration of macrophages and NK cells. Mechanistic analysis of OXCT1's molecular function indicated that OXCT2, AACS, BDH1, HMGCL1, ACAA2, HMGCL, BDH2, HMGCS2, ACAT1, and ACAT2 may play critical roles in its interactions.

Conclusions:

Our findings underscore the oncogenic role of OXCT1 and its prognostic significance across various cancers, reinforcing its functional activity in cancer types

exhibiting aberrant OXCT1 expression. These studies warrant further molecular assays to elucidate the potential role of OXCT1 in tumorigenesis and provide a foundation for developing novel therapeutic strategies.

Keyword(s) : OXCT1; HCC

1512 - COMPREHENSIVE ANALYSIS OF THE ROLE OF TUMOR ASSOCIATED ANTI LMNB1 AUTOANTIBODY IN HEPATOCELLULAR CARCINOMA

Wei Hou ¹

Translational Medicine Research Center, School Of Clinical Medicine, Qilu Medical University, Zibo-China ¹

Background / Hypothesis:

Tumor-associated autoantibodies (TAABs) are produced by cancer patients in response to tumor-associated antigens (TAAs) and have emerged as promising biomarkers for early cancer detection. Recent studies indicate that LMNB1 plays a significant role in the development of hepatocellular carcinoma (HCC). However, detailed information regarding the regulatory mechanisms of HCC progression and the clinically aggressive phenotypes associated with TAABs is lacking. This study conducts a comprehensive analysis to investigate the role of tumor-associated anti-LMNB1 autoantibody in HCC.

Materials and Methods:

Study cases were obtained from the GEO (GSE144269, GSE14520, GSE22058, GSE25097, GSE36376, GSE63898), ICGC, and TCGA_GTEEx databases. Proteomic data were downloaded from PDC000198, PXD008373, and PXD036048. We utilized the R package and the online tool hccTAAb to perform various analyses, including gene and protein expression, survival analysis, immune infiltration, similarity analysis, and differential DNA methylation analysis.

Results:

The expression of LMNB1 in cancer tissues showed a significant increase compared to normal tissues across the GEO, ICGC, and TCGA_GTEEx transcriptomics datasets. Additionally, proteomic data from PDC000198, PXD008373, and PXD036048 also demonstrated elevated LMNB1 expression in HCC cases compared to healthy controls. Survival analysis revealed that higher LMNB1 expression correlates with poorer prognosis. Cox regression analysis for the TCGA-LIHC dataset yielded a hazard ratio (HR) of 1.32 (95% CI: 1.14-1.52, P=0.00122), while the ICGC-LIRI

E-POSTER ABSTRACTS

dataset yielded an HR of 2.17 (95% CI: 1.48-3.17, $P=0.00092$). Immune infiltration analysis using ssGSEA revealed significant differences in immunological features between high- and low-expression groups, including aDCs, macrophages, and Th2 cells. Similarity analysis identified the top 5 genes (TOP2A, GINS1, TPX2, KIFC1, NCAPG) exhibiting positive correlations, while LDHD, HPD, SLC27A5, CFHR4, and HPR showed negative correlations.

Conclusions:

Our findings underscore the role of tumor-associated anti-LMNB1 autoantibody and its prognostic significance in HCC. These studies warrant further molecular assays to elucidate the potential role of LMNB1 in tumorigenesis and to provide a foundation for future research.

Keyword(s) : LMNB1; HCC

1513 - PAN CANCER ANALYSIS OF HACD FAMILY AND UNRAVELLING THE ONCOGENIC ROLE IN HEPATOCELLULAR CARCINOMA

Wei Hou¹

Translational Medicine Research Center, School Of Clinical Medicine, Qilu Medical University, Zibo-China¹

Background / Hypothesis:

The HACD (3-Hydroxyacyl-CoA Dehydratase) protein family has demonstrated crucial and diverse roles in various cancers. However, a comprehensive understanding of the distinct contributions of different HACD family members across tumor types remains largely unexplored. This study conducts a systematic analysis to investigate the role of the HACD family in a range of human cancers, with a particular emphasis on hepatocellular carcinoma (HCC).

Materials and Methods:

Study cases were obtained from the Cancer Genome Atlas database, the Gene Expression Omnibus database, and the Clinical Proteomic Tumor Analysis Consortium. We utilized the R package and various online tools to analyze and visualize HACD expression across different cancer types, as well as its associations with tumor molecular subtypes, immune subtypes, diagnosis, prognosis, clinical characteristics, methylation status, and the immune microenvironment. Co-expressed proteins and regulatory miRNAs were identified through mechanistic analysis.

Results:

Our study reveals significant genetic heterogeneity among HACD family members, along with distinct clinical characteristics. Notably, compared to normal samples, the expression of HACD1 is significantly reduced in tumor samples, while the expression of HACD2 and HACD3 is markedly increased, with HACD4 showing no significant change. High expression of HACD2 has been associated with poor survival outcomes in patients with HCC. Mechanistic analysis identified genes co-expressed with HACD2, including HACD3, HACD4, ELOVL4, FADS1, ELOVL2, SCD5, TECR, SCD, HSD17B12, and ELOVL6. Additionally, hsa-miR-376c-3p may play a critical role in the regulatory interaction with HACD2.

Conclusions:

In summary, the findings of this study provide valuable insights to guide therapeutic strategies aimed at harnessing the impact of HACD family genes in cancer treatment. Our research warrants further molecular assays to elucidate the potential role of HACD2 in tumorigenesis and its viability as a therapeutic target in HCC.

Keyword(s) : HACD; HCC

1514 - AN INTEGRATED ANALYSIS OF THE ROLE OF tsRNA Asp 5 0002 IN HUMAN TUMORS ACROSS MULTIPLE CANCER TYPES

Wei Hou¹

Translational Medicine Research Center, School Of Clinical Medicine, Qilu Medical University, Zibo-China¹

Background / Hypothesis:

tsRNA-derived small RNA (tsRNA) represents a novel class of regulatory small noncoding RNA that plays a significant role in physiological processes as well as in the development of malignant tumors. tsRNA-Asp-5-0002, a 5'-tRNA fragment (tRF) consisting of 18 nucleotides (TCCTCGTTAGTATAGTGG), has recently been identified as a potential biomarker for hepatocellular carcinoma. However, its expression patterns and biological effects across various cancer types remain largely unexplored. This study aims to conduct a pan-cancer analysis to elucidate the role of tsRNA-Asp-5-0002 in different human cancers.

Materials and Methods:

Data for this study were obtained from the Cancer Genome Atlas (TCGA) database. We employed the R programming language along with several online tools to analyze and visualize the expression levels of tsRNA-Asp-5-0002 across 32 different cancer types, as well as

E-POSTER ABSTRACTS

its association with patient prognosis.

Results:

Analysis using the tsRinCancer module of the tsRFun platform revealed that tsRNA-Asp-5-0002 was differentially expressed in multiple cancer types, including ACC, DLBC, LGG, MESO, OV, READ, SARC, SKCM, TGCT, UCS, and UVM. Univariate Cox regression analysis conducted through the tsRSurvival module indicated that tsRNA-Asp-5-0002 was significantly associated with prognosis in several cancer types: CESC (cervical squamous cell carcinoma and endocervical adenocarcinoma, $P=0.005177$), COAD (colon adenocarcinoma, $P=0.023525$), KIRC (kidney renal clear cell carcinoma, $P=0.029378$), LUSC (lung squamous cell carcinoma, $P=0.023236$), and THYM (thymoma, $P=0.037697$). Furthermore, we identified 16 potential target genes predicted by the bioinformatics database miRDB: C1orf131, KIF24, FYTDD1, ZNF470, BTBD19, SHOX2, PLEKHG1, GATAD2A, CD48, GID4, GORASP2, NOTCH1, ATXN7, CIT, POTEF, and FBLN1.

Conclusions:

Our findings underscore the oncogenic role of tsRNA-Asp-5-0002 and its prognostic significance across various cancers, particularly in CESC, COAD, KIRC, LUSC, and THYM. These results warrant further molecular assays to deepen our understanding of the potential role of tsRNA-Asp-5-0002 and its target genes in tumorigenesis, providing a foundation for the development of novel therapeutic strategies.

Keyword(s) : tsRNA-Asp-5-0002; HCC

1515 - Investigating the Hidden Link How Common Is MAFLD Among Cataract Patients

Safaa M Abdelhalim ¹, Wael Mohamed Abdelghany ¹, Mohamed Esmail Khalil Esmail ², Manar M Sayed ³, Amany Mahrous Mahmoud ⁴, Hatem Ahmed Hassan ⁵, Omar Abdelazim ⁴

Department Of Gastroenterology, Hepatology And Tropical Medicine, Faculty Of Medicine, Minia University, Minia, Egypt, Tropical Medicine, Minia-Egypt ¹ Department Of Ophthalmology, Faculty Of Medicine, Minia University, Minia, Egypt., Ophthalmology, Minia-Egypt ² Radiology Department, Faculty Of Medicine, Minia University, Minia, Egypt., Radiology, Minia-Egypt ³ Department Of Gastroenterology, Hepatology And Tropical Medicine, Faculty Of Medicine, Minia University, Minia, Egypt., Tropical Medicine, Minia-Egypt ⁴ Department Of Internal Medicine, Faculty Of Medicine, Minia

University, Minia, Egypt, Internal Medicine, Minia- ⁵

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) is now widely recognized as a multisystem disease. The liver-eye interplay is a developing research area exploring interconnected metabolic and inflammatory pathways. However, the potential association between MAFLD and cataract remains scarcely investigated. we aimed to evaluate the prevalence of MAFLD among patients with cataract and assess its association with clinical, anthropometric, and metabolic parameters.

Materials and Methods:

A cross-sectional study was conducted on 150 Egyptian patients with cataract. Participants were classified into MAFLD and non-MAFLD groups based on the established diagnostic criteria. Fatty liver indices and liver fibrosis scores were evaluated.

Results:

The prevalence of MAFLD among cataract patients was 79.3%. Nuclear cataract was the most prevalent type (64.7%) among MAFLD patients. Compared with non-MAFLD patients, those with MAFLD had significantly higher BMI, waist circumference, hip circumference, hypertension (53.8% vs 25.8%; $p = 0.005$), and HbA1c (6.41 ± 1.1 vs 6.12 ± 1.36 ; $p = 0.004$). HSI, FLI, and FIB-4 scores were all significantly higher in the MAFLD group ($p < 0.001$). Multivariate analysis identified hip circumference (OR = 1.188), HSI (OR = 1.531), and FIB-4 (OR = 2.249) as independent predictors of MAFLD in cataract patients.

Conclusions:

MAFLD is highly prevalent among cataract patients, particularly those with nuclear cataracts. Hepatic steatosis index, FIB-4 score, and hip circumference were significant predictors of MAFLD. These findings emphasize the need for routine liver evaluation in cataract patients to enable early detection of MAFLD and to guide strategies for reducing metabolic, systemic, and ocular complications.

Background:

Hepatic steatosis is a growing public health concern, closely linked to obesity, diabetes, and dyslipidemia. Its non-invasive assessment relies mainly on transient elastography (FibroScan) and magnetic resonance imaging (MRI). However, conventional MRI without specialized sequences such as Proton Density Fat Fraction (MRI-PDFF) may underestimate steatosis. Among a cohort of 170 patients with hepatic steatosis, only 12 underwent both FibroScan and MRI, allowing preliminary evaluation of concordance. This study also aims to raise awareness among clinicians regarding the non-equivalence of conventional MRI and FibroScan in routine practice, and to inform the development of locally-adapted diagnostic algorithms.

Materials and Methods:

This retrospective preliminary study included 12 patients selected from a total cohort of 170 confirmed hepatic steatosis cases. Demographic parameters (age, sex), clinical features (BMI, metabolic risk factors), laboratory findings (cytolysis, cholestasis, thyroid panel, metabolic markers), virological status (HBV/HCV), and results from FibroScan (fibrosis and steatosis stages) and MRI (qualitative assessment) were collected. Concordance between FibroScan and MRI was defined as the simultaneous presence or absence of steatosis, while discordance indicated conflicting findings. Descriptive statistics and qualitative analyses of discordant cases were performed.

Results:

The subgroup included 9 women (75%) and 3 men, with a mean age of 51.9 years and mean BMI of 32.7 kg/m². Metabolic risk factors were frequent, including diabetes, hypertension, and dyslipidemia. FibroScan identified severe steatosis (S3) in 66% of patients and significant fibrosis in 25%. Conventional MRI detected steatosis in 75% of patients, primarily in a descriptive manner without quantification.

Concordance between FibroScan and MRI was

observed in 8 patients (66%). Discordance occurred in 4 patients (33%): 3 patients had steatosis detected by FibroScan but not by MRI, and 1 patient had steatosis described by MRI but not confirmed by FibroScan. These discrepancies highlight the limitations of conventional MRI sequences for semi-quantitative assessment, particularly in moderate or heterogeneous steatosis.

Conclusion:

This preliminary study demonstrates significant discrepancies between conventional MRI and FibroScan in assessing hepatic steatosis, with a concordance rate of 66%. Conventional MRI is limited by sequence choice and operator dependency. MRI-PDFF, not yet available in Morocco, provides objective, reproducible quantification and is essential for precise monitoring of metabolic liver disease. These findings underscore the need for clinician awareness, the development of locally-adapted diagnostic algorithms, and further larger studies reflecting real-world practice to optimize non-invasive assessment and patient management.

Keyword(s) : Hepatic steatosis, Fibroscan, proton density fat fraction, Magnetic resonance imaging, Non invasive diagnostic methods

1519 - Real world outcomes of atezolizumab and bevacizumab according to clinical risk factors for unresectable hepatocellular carcinoma A multicenter CLCSG cohort study

Background / Hypothesis:

Atezolizumab plus bevacizumab (Ate/Bev) is the established first-line therapy for advanced hepatocellular carcinoma (HCC), but evidence in real-world high-risk populations remains limited. Real-world cohorts often include high-risk patients, leading to less favorable outcomes compared with IMbrave150. This study aimed to evaluate survival outcomes in high-risk patients to help guide the need for more intensive treatment approaches.

Materials and Methods:

We retrospectively analyzed 792 patients with advanced HCC who received Ate/Bev between 2022 and 2024 at multiple centers in South Korea. In this study, high risk group (n= 261, 32.9%) was defined such as main portal vein invasion (Vp4), tumor involvement $\geq$ 50% of the liver volume, infiltrative type or bile duct invasion.

Results:

In the entire cohort, the median PFS and OS were 6.97 months (95% CI, 6.24–7.69) and 14.39 months (95% CI, 13.01–15.78), respectively. In the high-risk group, the median PFS was 5.92 months (95% CI, 4.73–7.09) and the median OS was 10.7 months (95% CI, 9.7–11.8), whereas in the non-high-risk group the median PFS was 7.85 months (95% CI, 6.69–9.02) and the median OS was 18.0 months (95% CI, 16.3–19.6). Both PFS and OS differed significantly between the two groups (Both p-value < 0.001). High-risk status was not associated with differences in ORR (53.3% vs. 50.6%, p = 0.536) or DCR (75.1% vs. 71.6%, p = 0.292). Variceal bleeding was observed in 5.7% (n=45) of patients and tended to be slightly more frequent in the high-risk group (6.7% (n=24) vs. 4.9% (n=21)), while severe proteinuria ($\geq$ 3+) occurred in 8.8% (n=70) and appeared somewhat more common in the non-high-risk group (10.7% (n=44) vs. 7.2% (n=26)). Neither difference reached statistical

significance (bleeding p = 0.274; proteinuria p = 0.146). Most bleeding events occurred within the first year.

Conclusions:

Real-world experience provides substantial clinical data for Ate/Bev, but treatment responses remain relatively poor in high-risk patients.

1520 - Hole in the Wall A Rare Case of Lenvatinib Associated Peptic Ulcer Perforation in Hepatocellular Carcinoma

Zyrah Lou Samar ¹, Shelomith Lozada-tuico ¹, Floen Michael Enriquez ¹, Miguel Edgardo Forés ¹
Makati Medical Center, Department Of Medicine, Section Of Gastroenterology, Makati City-Philippines ¹

Introduction: Lenvatinib is a type I tyrosine kinase inhibitor with antiangiogenic activity, approved as first-line treatment for patients with advanced, unresectable hepatocellular carcinoma (HCC). Gastrointestinal (GI) adverse effects are most commonly observed within the first six months of treatment initiation. Among these, gastrointestinal perforation is a rare but life-threatening complication, occurring in approximately 1.3% of patients receiving lenvatinib.

Case Presentation: We report the case of a 54-year-old Asian male with unresectable HCC who presented to the emergency department with acute, severe abdominal pain after two months of lenvatinib therapy (8 mg daily). An esophagogastroduodenoscopy (EGD) performed prior to treatment initiation revealed no abnormalities. Physical examination showed diffuse abdominal tenderness with guarding. Laboratory results were notable for elevated serum creatinine, hyponatremia, and prolonged INR. A non-contrast CT scan of the abdomen revealed massive pneumoperitoneum with extraluminal air surrounding the stomach and diffuse thickening of the gastric fundus wall. Empiric antibiotic therapy with piperacillin-tazobactam was initiated for suspected peritonitis secondary to GI perforation. An emergent exploratory laparotomy revealed a 2x2 cm perforated peptic ulcer on the lesser curvature of the stomach. Modified Graham patch repair was performed, and biopsy specimens were negative for *Helicobacter pylori*. Histopathology showed chronic inflammation, hemorrhage, and ulceration. The patient recovered well

E-POSTER ABSTRACTS

postoperatively and was discharged in stable condition.

Conclusion: This case highlights the importance of clinician awareness regarding the potential for serious, albeit uncommon, gastrointestinal complications associated with lenvatinib therapy. Early recognition and timely surgical intervention are critical to improving patient outcomes and reducing the risk of morbidity and mortality.

Keyword(s) : "lenvatinib", "perforated peptic ulcer", "unresectable hepatocellular carcinoma"

1521 - Risk Factors for Liver Fibrosis Severity in Patients with Nonalcoholic Steatohepatitis A Study Based on Liver Pathology

Pengyu Pan¹, Chunyan Wang¹

Tianjin Medical University, Tianjin Second People Hospital, Tianjin-China¹

Background / Hypothesis:

In order to determine the independent risk factors associated with the severity of liver fibrosis in patients with nonalcoholic steatohepatitis (NASH), we conducted this study from the perspective of liver pathological results and biochemical indicators.

Materials and Methods:

A retrospective analysis was conducted on 122 patients diagnosed with NASH via liver biopsy at Tianjin Second People's Hospital between December 2014 and December 2024. Clinical, laboratory, and pathological data were collected. Patients were categorized into F1, F2, and F3 stages based on fibrosis scores. Univariate analysis was used to compare variables across fibrosis stages. Spearman correlation was employed to assess associations between variables and fibrosis severity. Ordinal logistic regression with backward stepwise selection was applied to identify independent risk actors, with odds ratios (ORs) and 95% confidence intervals (CIs) calculated.

Results:

The mean age of participants was 41.6 ± 14.2 years, with 66 males (54.1%). According to fibrosis staging, there were 21 cases in F1 stage, 86 in F2 stage, and 15 in F3 stage. Univariate analysis showed that the degree of hepatic steatosis and lobular inflammation, levels of aspartic transaminase (AST) and low-density lipoprotein (LDL), prevalence of diabetes increased with increasing severity of fibrosis; while serum albumin

(ALB) levels and estimated glomerular filtration rate (eGFR) decreased with increasing severity of fibrosis. These differences were statistically significant ($P < 0.05$). Spearman correlation analysis indicated that diabetes, lobular inflammation, hepatic steatosis, AST, and LDL were positively correlated with fibrosis stage ($p > 0$, $P < 0.05$); AST and ALT were positively correlated with lobular inflammation ($p > 0$, $P < 0.05$); AST was positively correlated with the degree of hepatic steatosis ($p > 0$, $P < 0.05$); and AST showed a marginal positive correlation with ballooning degeneration ($P = 0.068$). Ordinal logistic regression identified lobular inflammation (OR = 5.058, 95%CI: 2.153-11.693, $P < 0.001$), hepatic steatosis (OR = 2.768, 95%CI: 1.398-5.474, $P = 0.003$), diabetes (OR=3.815, 95%CI: 1.220-11.929, $P = 0.021$), and elevated LDL levels (OR=1.669, 95%CI: 1.067-2.609, $P = 0.025$) as independent risk factors associated with the severity of liver fibrosis in patients with NASH.

Conclusions:

Lobular inflammation, hepatic steatosis, diabetes, and elevated LDL levels are independent risk factors associated with the severity of liver fibrosis in patients with NASH.

1522 - Efficacy and safety of hepatic arterial infusion chemotherapy sequential therapy versus Atezolizumab Bevacizumab in infiltrative hepatocellular carcinoma with portal vein thrombosis A cohort study with Propensity score matching

Sung Bum Cho¹, Young Eun Seo¹, Chan Joong Bae², Min Ho Shin³, Yang Seok Koh⁴, Chan Park⁵, Jae-uk Jeong⁶, Jae Hyun Yoon², Ki-hyun Kim¹, Wan-sik Lee¹, Young-eun Joo¹, Eun Myung⁷
Chonnam National University Hwasun Hospital, Internal Medicine, 24-South Korea¹ Chonnam National University Hospital, Internal Medicine, Hwasun-South Korea² Chonnam National University Hwasun Hospital, Department Of Preventive Medicine, Hwasun-South Korea³ Chonnam National University Hwasun Hospital, Hepatobiliary And Pancreatic Surgery, Hwasun-⁴ Chonnam National University Hospital, Department Of Radiology, Gwangju-⁵ Chonnam National University Hwasun Hospital, Department Of Radiation Oncology, Hwasun-⁶ Chonnam National University Bitgoeul Hospital, Internal Medicine, Hwasun-⁷

E-POSTER ABSTRACTS

Background / Hypothesis:

Infiltrative hepatocellular carcinoma (HCC) is an aggressive and biologically distinct subtype that often carries a poor prognosis. Because of its molecular characteristics—such as immunosuppressive signaling and low immune infiltrates—these tumors derive limited benefit from immunotherapy, highlighting the need for alternative treatment strategies. This study evaluates a hepatic arterial infusion chemotherapy (HAIC)-based sequential approach compared with atezolizumab and bevacizumab (ate/bev) in patients with infiltrative HCC with portal vein thrombosis.

Materials and Methods:

This cohort study included patients with infiltrative HCC with portal vein thrombosis treated with atezolizumab–bevacizumab (n=214) or HAIC sequential therapy (n=38) as initial treatment. HAIC based sequential approach consisted of six HAIC cycles with 4 week intervals using cisplatin 25mg/m² and 5-fluorouracil 750mg/m² for 4 days followed by tailored subsequent therapies including target agents, ate/bev or local therapy. 2:1 Propensity score matching was applied to adjust for potential baseline imbalances.

Results:

After propensity score matching, the median PFS was 8.05 months (95% CI, 5.63–10.47) in the Atezolizumab–Bevacizumab (Ate/Bev) group and 11.31 months (95% CI, 4.15–18.46) in the HAIC plus sequential therapy group (log-rank p = 0.005). The median OS was 15.01 months (95% CI, 11.41–18.62) in the Ate/Bev group compared with 20.27 months (95% CI, 11.97–28.59) in the HAIC plus sequential therapy group (log-rank p < 0.001). The objective response rate (ORR) was significantly higher in the HAIC plus sequential group compared with the Ate/Bev group (68.3% vs. 28.6%, p < 0.001). The disease control rate (DCR) was 92.1% in the HAIC plus sequential group vs. 78.6% in the Ate/Bev group (p = 0.020). Among the 38 patients treated with HAIC-based sequential therapy, grade ≥3 adverse events occurred in 12 patients (31.6%) This rate was not statistically significantly different from 50 of 219 patients (22.8%) observed in the Ate/Bev group (p=0.241).

Conclusions:

HAIC-based sequential treatment can be effective and

safe management alternative to atezolizumab and bevacizumab especially in patients with good liver function and performance status for infiltrative HCC with portal vein thrombosis .

1523 - Anserine promotes Antibacterial Defense in Cirrhosis via the Mup11+ Hepatocyte CD44+ pDC Crosstalk and CCL5 CCR5 Axis Short title Anserine Promotes Antibacterial Defense via CCL5 pDC in Cirrhosis

Ruochan Chen ¹, Jie Li ¹

Central South University, Infectious Disease, Changsha-China ¹

Background / Hypothesis: Patients with liver cirrhosis exhibit heightened susceptibility to severe bacterial infections, yet the underlying immune defects remain poorly characterized. We investigated the dysfunctional intercellular crosstalk within the cirrhotic liver that impairs antibacterial defense.

Materials and Methods:Employing integrated multi-omics, we performed single-cell RNA sequencing (scRNA-seq) on livers from control, infected control, cirrhotic, and infected cirrhotic mice. Key cellular interactions were validated using flow cytometry, functional assays (ex vivo/in vivo), targeted metabolomics, adoptive cell transfer, specific antibody blockade, and cell co-culture.

Results:scRNA-seq revealed a significantly depleted CD44+ plasmacytoid dendritic cells (pDCs) subpopulation responsible for impaired antibacterial immunity in cirrhosis. Multicellular cluster modeling of ligand-receptor interactions revealed that Mup11+ hepatocytes play a key immunoregulatory role via interaction with CD44+ pDCs in response to bacterial infection. Mup11+ hepatocytes play a crucial role in the recruitment of CD44+ pDCs via the CCL5-CCR5 interaction. Furthermore, targeted metabolomics and animal experiments identified histamine metabolite anserine increased the percentage of Mup11+ hepatocytes and CD44+ pDCs to decrease the bacterial burden and mortality in cirrhosis with infection. Finally, clinical validation in a national, multicenter and prospective patient cohort revealed that, CCL5, CD44+ pDCs and anserine are significantly correlated with the incidence of infection and outcome in patients with cirrhosis.

Conclusions: Our study uncovers a novel metabolic-

E-POSTER ABSTRACTS

immune axis wherein anserine potentiates Mup11+ hepatocytes-CD44+ pDCs crosstalk via CCL5-CCR5 to enhance antibacterial defense in cirrhosis. This multi-omics-driven discovery, validated across models and human cohorts, identifies therapeutic targets for a high-risk cirrhotic population.

Keyword(s) : Cirrhosis; Bacterial infection; Plasmacytoid dendritic cells (pDCs); Anserine; CCL5-CCR5 axis.

1524 - Carbamazepine induced cholestatic hepatitis with rapid fibrosis progression and biopsy confirmed pure red cell aplasia in a young woman

Prabhath Dasanayaka¹, Janaka Subasinghe¹, Nandana Dinamithra¹, Hasitha Wijewantha¹

National Hospital Kandy, Gastroenterology And Hepatology, Kandy-Sri Lanka¹

Background / Hypothesis:

Carbamazepine can cause idiosyncratic hepatic and hematologic toxicity, but the combination of persistent cholestatic hepatitis with rapid progression to advanced fibrosis and concurrent pure red cell aplasia (PRCA) is exceptionally uncommon. This case highlights a rare pattern of multisystem toxicity following short-term therapeutic exposure

Materials and Methods:

A 26-year-old previously healthy woman was initiated on carbamazepine 100 mg twice daily for suspected trigeminal neuralgia. Within one week she developed jaundice, pruritus and dark urine. Evaluation included viral serology (hepatitis A, B, C, E; Epstein-Barr virus; cytomegalovirus), autoimmune markers, metabolic studies, abdominal ultrasonography, magnetic resonance cholangiopancreatography and liver biopsy.

A short empiric course of corticosteroids was administered early in the illness without significant biochemical response. The subsequent development of severe anaemia prompted haematologic evaluation including bone marrow trephine biopsy. Causality for drug-induced liver injury (DILI) was assessed using established clinical criteria

Results:

All viral, autoimmune and metabolic aetiologies were excluded. Imaging demonstrated normal biliary anatomy. Liver biopsy revealed preserved lobular architecture with marked canalicular cholestasis and minimal inflammation, consistent with cholestatic DILI. Despite drug withdrawal and supportive care, cholestasis persisted. Transient elastography suggested advanced fibrosis (F3), and follow-up computed tomography at six months showed radiological features of cirrhosis, indicating rapid fibrosis progression.

Three months after presentation she developed profound anaemia. Bone marrow trephine showed complete absence of erythroid precursors with preserved granulopoiesis and megakaryopoiesis, confirming pure red cell aplasia. No marrow fibrosis, infiltrative process or viral trigger was identified. Darbepoetin therapy resulted in gradual haemoglobin normalisation and resolution of transfusion dependence. Liver biochemistry improved but remained cholestatic.

The chronology, exclusion of alternative causes and concurrent hepatic and marrow involvement support carbamazepine-induced multisystem drug toxicity

Conclusions:

Short-term carbamazepine exposure precipitated persistent cholestatic hepatitis with rapid progression to advanced fibrosis and concurrent biopsy-confirmed pure red cell aplasia. This case emphasises the importance of early drug withdrawal and careful monitoring for multisystem involvement in suspected DILI. Erythropoiesis-stimulating therapy may aid recovery in secondary PRCA associated with drug-induced liver injury

Keyword(s) : Drug-induced liver injury, Cholestatic hepatitis, Pure red cell aplasia, Carbamazepine toxicity, Advanced fibrosis

1530 - Integrative lipidomic and transcriptomic analyses reveal glycosphingolipid remodeling in metabolic dysfunction associated fatty liver disease related advanced fibrosis

Xiao Han¹, Pingping Lai¹, Xiaofei Tong², Chenglin Sun¹, Yankun Gao¹, Mengyang Zhang¹, Xiaoning Wu¹, Shuyan Chen¹, Yameng Sun¹, Hong You¹

E-POSTER ABSTRACTS

Beijing Friendship Hospital, Capital Medical University,
Liver Research Center, Beijing-China ¹ Beijing
Friendship Hospital, Capital Medical University,
Research Ward, Beijing-China ²

Background / Hypothesis:

The prevalence of metabolic dysfunction-associated fatty liver disease (MAFLD)-related advanced fibrosis is increasing, yet effective therapeutic options remain limited. Lipid metabolic dysregulation plays a pivotal role in fibrosis progression. This study integrated lipidomic and transcriptomic analyses to elucidate lipid alterations and underlying mechanisms in MAFLD-related advanced fibrosis.

Materials and Methods:

Paired plasma lipidomic and liver transcriptomic analyses were conducted in 20 biopsy-proven MAFLD patients (40% with advanced fibrosis). Differential lipid species were determined by limma with multivariable adjustment, and differentially expressed genes (DEGs) were determined by DESeq2. Functional enrichment of DEGs was performed via Gene Ontology (GO) biological process terms. Public transcriptomic datasets from human MAFLD and murine liver fibrosis models (high-fat diet [HFD], carbon tetrachloride [CCl₄], and choline-deficient amino acid-defined high-fat diet [CDAA-HFD]) were analyzed for validation.

Results:

Lipidomic analysis quantified 604 lipid species across 33 classes. In patients with advanced fibrosis, substantial alterations in glycosphingolipids were observed, characterized by marked increases in lactosylceramides (LacCer) and significant reductions in monosialodihexosyl ganglioside (GM3). Furthermore, the patients' hepatic transcriptomic analysis revealed upregulation of glycosphingolipid metabolic genes (e.g., UGCG and B3GNT5), alongside downregulation of GM3 biosynthetic genes (e.g., NEU3, NEU4, and ST3GAL5). These alterations were consistently observed in public human and mouse fibrosis datasets.

Conclusions:

MAFLD-related advanced fibrosis exhibits distinct remodeling of glycosphingolipid metabolism, particularly involving LacCer and GM3 pathways. These findings highlight potential lipid metabolic targets for antifibrotic therapy and warrant further *in vivo* validation.

Keyword(s) : Metabolic dysfunction-associated fatty liver disease, Lipidomic, Transcriptomic, Glycosphingolipid metabolism.

1532 - A Rare Case Of Acute Liver Failure (ALF) Secondary To Clozapine Induced Autoimmune Hepatitis

Pei Zheng Lee¹, Wei Lyn Yang¹

Tan Tock Seng Hospital, Gastroenterology And Hepatology, Singapore-Singapore¹

Background:

A 53yo Chinese woman with longstanding treatment-resistant schizoaffective disorder on long-term Olanzapine 20mg ON was admitted in Jan 2025 for relapse of schizophrenia. Her Liver Function Tests (LFTs) then were normal.

She was initiated on Clozapine 25mg daily on February 27 with dose escalation of 25mg every 3 days, reaching a target of 300mg daily on March 30. Olanzapine was discontinued. While her psychiatric symptoms improved, she developed significant lethargy and drowsiness on April 2.

Her LFTs then showed significant derangement: Bil 76µmol/L, ALT2078 U/L, ALP348 U/L, GGT301U/L, and INR 2.13. A comprehensive screen for viral and metabolic liver diseases was negative. A diagnosis of possible acute liver failure was established, though the patient was deemed unsuitable for liver transplantation.

While standard autoimmune liver markers (ANA, anti-LKM1, ASMA, AMA) returned as negative, serum Immunoglobulin G (IgG) was markedly elevated at 32.5g/L. An urgent liver biopsy was performed on April 4. The patient was initiated on plasma-exchange for 3 days (April 5–7) and concurrently received IV N-acetylcysteine.

Liver biopsy histology demonstrated confluent midzonal and centrilobular necrosis with mixed inflammatory infiltrate of neutrophils, plasma cells, lymphocytes, histiocytes, and eosinophils, without evidence of fibrosis.

IV hydrocortisone 100mg q8-hourly was initiated on April 8 with improvement of her LFTs and mentation (refer to summarized chart). An attempt to wean her to oral prednisolone 50mg daily on April 15 led to rapid LFT worsening, necessitating immediate escalation of

E-POSTER ABSTRACTS

steroid therapy back to IV hydrocortisone 100mg q6-hourly the following day.

After 37 days of continued IV hydrocortisone, her LFTs gradually improved. She successfully transitioned to oral prednisolone 30mg daily on May 15. Azathioprine 25mg daily was introduced on May 13 and increased to 50mg daily from May 15 onward, while oral prednisolone dose was further weaned.

Her LFTs normalised by May 19 (bil 24 μ mol/L, ALT 35U/L, ALP 125U/L). Concurrently, her IgG levels reached normal limits within three weeks of initiating steroid therapy.

Conclusion:

We present a rare case of ALF secondary to clozapine-induced severe AIH. This condition proved challenging to manage, necessitating a protracted course of high-dose intravenous hydrocortisone. Despite cessation of Clozapine, tapering IV Hydrocortisone dose (100mg q8hrly) to Oral Prednisolone (50mg daily) after 7 days of administration resulted in a rapid, severe biochemical relapse, which further supports our diagnosis of AIH.

While a few cases of clozapine-induced hepatotoxicity have been reported, none have described AIH or detailed a successful treatment outcome with steroids and immunosuppressants, making this case the first reported globally.

Keyword(s) :

1534 - FABP4 Exacerbates Drug Induced Cholestatic Liver Injury via NLRP3 GSDMD Dependent Pyroptosis

Yuelin Xiao¹, Tianhui Zhou¹, Haoshuang Fu¹, Qing Xie¹

Ruijin Hospital, Shanghai Jiao Tong University School Of Medicine, Department Of Infectious Diseases, Shanghai-China¹

Background / Hypothesis:

Pyroptosis, a pro-inflammatory form of programmed cell death, plays a critical role in amplifying inflammation during drug-induced cholestatic (DIC) liver injury, yet its regulatory mechanisms remain unclear. Fatty acid-binding protein 4 (FABP4) has been implicated in mediating inflammatory responses. This

study aimed to investigate the impact of FABP4 on pyroptosis in DIC and elucidate the underlying molecular mechanisms.

Materials and Methods:

The study employed Fabp4 knockout (Fabp4^{-/-}) and wild-type mice subjected to α -naphthylisothiocyanate (ANIT)-induced cholestasis, with parallel cohorts receiving the NLRP3 inhibitor MCC950. Liver tissues underwent Western blot and immunohistochemistry analysis to quantify pyroptosis executors (NLRP3, GSDMD-N), complemented by transmission electron microscopy (TEM) for ultrastructural characterization of hepatocytes. Serum ALT/AST levels and hepatic bile acid metabolism were assessed as functional indicators. Mechanistic validation included Western blot and immunohistochemical analysis of cholestatic DILI (C-DILI) patient samples and in vitro experiments where primary hepatocytes were treated with taurocholic acid (TCA) and chenodeoxycholic acid (CDCA).

Results:

ANIT challenge triggered significant NLRP3 and GSDMD-N upregulation in wild-type mice, which was markedly attenuated in Fabp4^{-/-} counterparts (Figure A). Immunohistochemistry revealed synchronized NLRP3/GSDMD overexpression in C-DILI patient livers and ANIT-WT mice, while Fabp4^{-/-} models exhibited significant suppression (Figure B-D). TEM confirmed significantly reduced characteristic pyroptotic morphology (large plasma membrane pores, ballooning degeneration) in hepatocytes from Fabp4^{-/-} mice (Figure E). Primary hepatocytes exposed to TCA/CDCA showed dose-dependent NLRP3 induction (Figure F). Crucially, MCC950 treatment significantly improved ANIT-induced liver injury (Figure H-I) and inflammation, mimicking the protective phenotype of ANIT-treated Fabp4^{-/-} mice, although without altering bile acid metabolism (Figure G-L).

Conclusions:

This study demonstrates that FABP4 exacerbates DIC liver injury by promoting NLRP3/GSDMD-dependent pyroptosis, thereby amplifying the inflammatory cascade. Therapeutic targeting of this axis via FABP4 inhibition or MCC950 analogs presents a promising strategy for DIC management, with mechanistic evidence supporting clinical translation.

1535 - Multimodal In Hospital Alert Intervention Significantly Improves HBV DNA Testing and Antiviral Treatment Rates among HBsAg Positive Patients in Non Specialty Departments

Shaorui Hao¹, Jiangshan Lian¹, Jiong Yu¹, Yingfeng Lu¹, Yida Yang¹

The First Affiliated Hospital, Zhejiang University School Of Medicine, State Key Laboratory For Diagnosis And Treatment Of Infectious Diseases, Department Of Infectious Diseases, Hangzhou-China¹

Background / Hypothesis:

Expanding screening and treatment is a core strategy for achieving the World Health Organization's goal of eliminating viral hepatitis as a major public health threat by 2030. This study aimed to evaluate the impact of a comprehensive in-hospital intervention on enhancing the HBV-DNA testing rate and subsequent antiviral treatment initiation among patients with a first-time HBsAg-positive result identified in non-infectious disease departments.

Materials and Methods:

Beginning in January 2025, our hospital implemented a comprehensive intervention to improve hepatitis B screening and management. For physicians: a pop-up alert in the Hospital Information System prompts the ordering physician to consider further action whenever an HBsAg-positive result is reported, providing quick options to "Order HBV-DNA test" or "Request Infectious Disease Department Consult." Additionally, an automated SMS reminder is sent to the physician for follow-up. For patients: the laboratory report automatically includes a comment stating "HBsAg Positive - Recommend consultation at the Infectious Disease Clinic for further assessment and HBV-DNA testing," and an SMS reminder is sent to the patient advising a visit to the Infectious Disease Clinic. We conducted a retrospective analysis comparing data from the pre-intervention period (January to September 2024) and the post-intervention period (January to September 2025).

Results:

During the pre-intervention period (Jan-Sep 2024), 14,586 eligible HBsAg-positive patients were identified in non-specialty departments. Among them, 6,957

(47.70%) underwent HBV-DNA testing. Of the 1,887 patients with a positive HBV-DNA result, 1,384 (73.34%) started antiviral treatment. Following the intervention (Jan-Sep 2025), 17,647 eligible HBsAg-positive patients were identified. HBV-DNA testing was performed in 9,254 (52.44%) of these patients. Among the 2,292 patients with detectable HBV-DNA, 2,245 (97.95%) received antiviral treatment. The increases in both HBV-DNA testing rate and treatment rate were statistically significant, $p < 0.001$.

Conclusions:

A multimodal alert Intervention via the hospital information system, SMS and laboratory report targeting both physicians and patients, significantly improved HBV-DNA testing and antiviral treatment rates among first-time HBsAg-positive patients in non-specialist departments. This integrated intervention model represents an efficient and scalable in-hospital management strategy that can contribute to achieving the global goal of eliminating viral hepatitis as a public health threat.

Keyword(s) : Multimodal In-Hospital Alert Intervention, HBV-DNA Testing, Antiviral Treatment Rates, hepatitis B screening and management

1536 - Diagnosis and treatment of occult primary hepatocellular carcinoma presenting with ovarian metastasis as the initial manifestation a case report

Shuqiang Hao¹, Pu Liu², Chengdong Chang², Zhongwen Wu³, Xiaoxin Wu³

The First Affiliated Hospital, Zhejiang University School Of Medicine, Department Of Oncology, Hangzhou-China¹ The First Affiliated Hospital, Zhejiang University School Of Medicine, Department Of Pathology, Hangzhou-China² The First Affiliated Hospital, Zhejiang University School Of Medicine, State Key Laboratory For Diagnosis And Treatment Of Infectious Diseases, Hangzhou-China³

Background / Hypothesis:

Primary extrahepatic hepatocellular carcinoma is a tumor that occurs outside the liver and has a histological morphology consistent with HCC. It is an extremely rare clinical phenomenon. Hepatoid Carcinoma of the Ovary (HCO), which originates in the ovary, is even rarer and has very few literature reports.

Results:

This case report based on a clearly diagnosed case of HCO and its subsequent treatment. This study was a

E-POSTER ABSTRACTS

single-case in-depth analysis. The research subject was a 52-year-old female who was treated at the First Affiliated Hospital of Zhejiang University School of Medicine in January 2025. After surgical treatment, the patient was diagnosed with HCO through pathological and immunohistochemical analysis. In addition, after diagnosis, the patient received an immune-targeted combination therapy based on tislelizumab combined with lenvatinib and achieved remarkable therapeutic effects, reaching a stable disease (SD) prognosis. Liver function damage related to tumor treatment occurred during the treatment process and improved after treatment.

Conclusions:

HCO can adopt the immune-targeted combination therapy regimen of tislelizumab combined with lenvatinib, which has a good therapeutic effect on tumors. At the same time, liver function damage related to tumor treatment should also be dealt with in a timely manner.

1537 - Targeting the Cholangiocytes Vitamin D TXNIP Pathway to Attenuate Ductular Reaction and Liver Fibrosis

Hua-xiang Yang¹, Xin Gao², Long Wang³, De-wen Wang¹, Xiao-cong Liu¹, Wu Wen¹

West China School Of Medicine, Sichuan University, Sichuan University Affiliated Chengdu Second People's Hospital, Department Of Gastroenterology And Hepatology, Chengdu-China¹ Shanxi Provincial People's Hospital, Department Of Gastroenterology And Hepatology, Taiyuan-China² West China School Of Medicine, Sichuan University, Sichuan University Affiliated Chengdu Second People's Hospital, Department Of Traditional Chinese Medicine, Chengdu-China³

Background / Hypothesis:

While ductular reaction (DR) is a recognized pathological hallmark of progressive liver injury, no targeted pharmacological interventions exist to modulate this process. Epidemiological evidence indicates a high prevalence of vitamin D deficiency in chronic liver diseases, yet the molecular mechanisms underpinning its potential hepatoprotective functions are poorly defined.

Materials and Methods:

We first established a clinical correlation between

plasma vitamin D concentrations and DR severity in patients. The functional impact of vitamin D signaling was then mechanistically dissected in a 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC)-induced murine liver injury model. Mice were administered 1,25(OH)2D3, the bioactive vitamin D metabolite. A cholangiocyte-specific Txnip-knockout mouse model was generated to define the cell-autonomous role of this key vitamin D target gene. A combination of in vivo phenotyping, primary cell culture, and molecular analyses was employed to assess DR, inflammation, fibrosis, cellular proliferation/death, and paracrine signaling.

Results:

Clinical data indicated a significant inverse relationship between systemic vitamin D levels and DR magnitude. 1,25(OH)2D3 supplementation in female mice potently suppressed DDC-triggered DR, inflammatory infiltration, and fibrotic deposition. This protection was coupled with the transcriptional induction of TXNIP within the biliary compartment. Genetic ablation of Txnip specifically in cholangiocytes markedly exacerbated the injury phenotype, enhancing DR, inflammation, and fibrogenesis. At the cellular level, Txnip deficiency resulted in a pronounced pro-proliferative and anti-apoptotic phenotype in cholangiocytes. Furthermore, Txnip-null cholangiocytes exhibited enhanced secretion of TNF- α and TGF- β , which in a paracrine manner activated Kupffer cells and hepatic stellate cells, thereby driving inflammation and collagen production. Critically, the protective effects of 1,25(OH)2D3 were entirely abrogated in biliary-specific Txnip-knockout mice, establishing TXNIP as a necessary downstream effector. Conversely, TXNIP overexpression was sufficient to attenuate the DDC-induced pathological cascade.

Conclusions:

This study elucidates a previously uncharacterized mechanistic pathway wherein vitamin D signaling, via the transcriptional upregulation of TXNIP in cholangiocytes, acts as a critical brake on ductular reaction and its associated inflammatory and fibrotic sequelae. Our findings position the vitamin D/TXNIP axis as a fundamental regulator of biliary epithelial cell response and a promising target for molecular interventions in liver fibrosis.

Keyword(s) : Vitamin D, Ductular reaction, Liver fibrosis, Cholangiocytes

E-POSTER ABSTRACTS

1538 - Development and Validation of a RF LASSO Cox Derived Nomogram Incorporating Inflammatory Markers to Predict Long Term Survival in Early Stage Hepatocellular Carcinoma after Microwave Ablation

Wenying Qiao¹, Qi Wang¹, Xi Wang¹, Ronghua Jin¹
Beijing Ditan Hospital, Capital Medical University,
Beijing Ditan Hospital, Capital Medical University,
Beijing-China¹

Background / Hypothesis: This study aimed to identify factors influencing overall survival (OS) in patients with hepatocellular carcinoma (HCC) undergoing microwave ablation (MWA) and to develop and validate novel nomograms for predicting 3-, 5-, and 8-year OS.

Materials and Methods: Data from 440 patients who received MWA at Beijing Ditan Hospital were analyzed using LASSO regression, random forest (RF), and multivariable Cox regression to identify independent prognostic factors. A prognostic nomogram was constructed and validated. OS was assessed using Kaplan–Meier curves.

Results: The variables selected by both LASSO and RSF were incorporated into a multivariable Cox regression model, which identified tumor number, tumor size, monocyte-to-lymphocyte ratio (MLR), and diabetes as independent risk factors for OS. The predictive accuracy, reliability, and clinical utility of the model were further confirmed through time-dependent AUC analysis, calibration curves, and decision curve analysis (DCA). Furthermore, risk stratification based on the model effectively differentiated patients into distinct prognostic subgroups.

Conclusions: A nomogram based on LASSO–RF–Cox analysis was developed to predict OS in early-stage HCC patients after MWA. This model may help identify high-risk individuals and facilitate clinical decision-making, particularly in primary care settings due to its simple and readily available predictors.

Keyword(s) : Hepatocellular carcinoma; Microwave ablation; Nomogram; Overall survival

1539 - The FABP4 CD36 FXR Axis Regulates Bile Acid Homeostasis in Drug Induced Cholestasis

Yuelin Xiao¹, Tianhui Zhou¹, Haoshuang Fu¹, Qing Xie¹

Ruijin Hospital, Shanghai Jiao Tong University School Of Medicine, Department Of Infectious Diseases, Shanghai-China¹

Background / Hypothesis:

Bile acid (BA) dysregulation is the pathological cornerstone of drug-induced cholestasis (DIC), driven primarily by impaired farnesoid X receptor (FXR) signaling—the master regulator of BA synthesis (via CYP7A1, CYP8B1) and transport (via BSEP, MRP2). While FABP4 is established as an adipokine mediating metabolic inflammation, its direct role in disrupting hepatic BA homeostasis remains unexplored. Critically, clinical data link elevated FABP4 to cholestatic severity, yet whether it modulates FXR to exacerbate BA accumulation is unknown. This study aims to elucidate the molecular mechanism by which FABP4 regulates BA homeostasis in drug-induced cholestasis.

Materials and Methods:

Fabp4 gene knockout (Fabp4^{-/-}) mice and the FABP4 inhibitor BMS309403 were applied to an alpha-naphthylisothiocyanate (ANIT)-induced cholestasis model. Hepatic BA profiles were determined by UPLC-MS/MS. To uncover the underlying mechanisms, FABP4-interacting proteins were initially screened by co-immunoprecipitation combined with mass spectrometry (Co-IP/MS), and the resulting data were further analyzed using the STRING database to identify high-confidence interaction partners. Among these, CD36 emerged as a top candidate, and their direct association was corroborated by immunofluorescence co-localization assay. The functional contribution of the FABP4/CD36/FXR axis was ultimately validated in AML-12 cells, HuH7 cells, and primary mouse hepatocytes.

Results:

Genetic ablation of Fabp4 (Fabp4^{-/-}) or its pharmacological inhibition with BMS309403 significantly attenuated ANIT-induced intrahepatic bile acid accumulation and concurrently ameliorated compositional BA profile disturbances, as shown by an altered CA/CDCA ratio (Figure A-C). To explore the underlying mechanism, we first identified FABP4-interacting partners through co-immunoprecipitation

E-POSTER ABSTRACTS

combined with mass spectrometry (Co-IP/MS), and subsequent STRING database analysis prioritized the fatty acid transporter CD36 as a high-confidence interactor. Their physical association was further visually confirmed by immunofluorescence co-localization in hepatocytes, which appeared to be dependent on FABP4's lipid-binding capacity (Figure D-H). Functionally, FABP4 overexpression inhibited FXR, thereby attenuating its repressive effect on the target genes CYP7A1 and CYP8B1 and consequently promoting BA synthesis. Notably, this effect was substantially rescued by CD36 knockdown (I-L), collectively demonstrating that the FABP4-CD36 interaction serves to inhibit FXR activity and thereby regulate bile acid metabolism.

Conclusions:

This study identifies FABP4 as a key driver of BA dysregulation in DIC, disrupting BAs homeostasis through CD36 interaction to inhibit FXR signaling. Genetic (Fabp4^{-/-}) or pharmacological (BMS309403) inhibition of FABP4 restores FXR signaling, thereby modulating the expression of FXR target genes CYP7A1 and CYP8B1 to regulate bile acid metabolism. The FABP4/CD36/FXR axis represents a conserved therapeutic target, with FABP4 inhibition offering a promising strategy to reactivate FXR and mitigate cholestatic injury.

Keyword(s) : Drug-induced cholestasis, FABP4, FXR, Bile acid dysregulation

1540 - Pruritus and Its Impact on Quality of Life in Primary Biliary Cholangitis A Study of Patients on Long Term Ursodeoxycholic Acid Treatment

Yunzhuang Zhao ¹, Chao Sun ², Jun Li ³, Jing Liang ³
Nankai University, Tianjin, Gastroenterology, Tianjin-China ¹ The First Affiliated Hospital Of Xi'an Medical University, Gastroenterology, Xi-China ² The Third Central Hospital Affiliated To Nankai University/tianjin Third Central Hospital, Gastroenterology, Tianjin-China ³

Background:

Primary biliary cholangitis (PBC) is an autoimmune liver disease, and pruritus is one of the most common symptoms. The severity of pruritus significantly impacts patients' quality of life. However, existing studies indicated that the incidence and severity of pruritus in treated PBC patients were under-evaluated, and its relationship with health-related quality of life (HRQOL) remained unclear.

Objective:

To observe the prevalence and influencing factors of pruritus in PBC patients receiving first-line treatment, and to explore the interrelationship between pruritus and perceived quality of life.

Methods:

This study included patients diagnosed with primary biliary cholangitis who visited our hospital between 2022 and 2024. Patients receiving ursodeoxycholic acid (UDCA) as first-line therapy for over 12 months underwent questionnaire follow-up. Included patients completed the Itch Numerical Rating Scale (NRS), EQ-5D-3L, Hospital Anxiety and Depression Scale, and Fatigue Scale Version 4. Statistical analysis assessed the prevalence and severity of pruritus in PBC patients. Multiple linear regression analyzed correlations between pruritus and quality of life/psychological health, while multivariate regression models examined influencing factors for pruritus occurrence.

Results:

This study included 415 PBC patients who had used UDCA for over 12 months. The prevalence of pruritus symptoms in the study population was 39.5% (n=164), with moderate-to-severe pruritus accounting for 11.1% (NRS>4, n=46). Participants were divided into an pruritus group (n=164) and a non-pruritus group (n=251) based on the presence of pruritus (NRS≥1). The prevalence of cirrhosis was significantly higher in the pruritus group than in the non-pruritus group (56.7% vs 37.5%, P<0.001). Compared with the non-pruritus group, the pruritus group showed significantly increased anxiety levels (5[IQR: 5]vs0[IQR: 5], P < 0.001), depression scores were higher (7(IQR:6)vs0 (IQR:4), P<0.001), and fatigue scores were significantly lower (42 (IQR:11)vs48 (IQR: 6), P<0.001). Furthermore, itch severity showed a linear correlation with patients' EQ-5D index scores, with worse scores corresponding to more severe itching (R²=0.10, P<0.001). Multivariate regression analysis identified disease duration (OR=1.05; P<0.05), UDCA response (Paris I criteria OR=0.54; P<0.05), portal hypertension (OR=1.98; P<0.05), and dry eye/mouth symptoms (OR=4.17; P<0.001) were independent factors associated with pruritus occurrence.

Conclusion:

This study demonstrated a high prevalence of pruritus (39.5%) among PBC patients undergoing first-line therapy. Disease duration, portal hypertension, and dry eye/mouth symptoms were independent factors

E-POSTER ABSTRACTS

associated with pruritus, while favorable UDCA response served as a protective factor. Furthermore, pruritus significantly impacted patients' quality of life; more severe pruritus was associated with greater anxiety, depression and fatigue, highlighting its significant disease burden.

Keyword(s) : PBC Pruritus HRQOL

1541 - Development and Validation of a Nomogram for Predicting Postoperative Survival in Patients with Multifocal Hepatocellular Carcinoma

Wenyong Qiao¹, Qi Wang¹, Xi Wang¹, Ronghua Jin¹
Beijing Ditan Hospital, Capital Medical University,
Beijing Ditan Hospital, Capital Medical University,
Beijing-China¹

Background / Hypothesis: Hepatocellular carcinoma (HCC) is one of the malignant tumors with high incidence and mortality worldwide. It ranks fifth among all cancers and is the third leading cause of cancer-related deaths. Multifocal hepatocellular carcinoma (M-HCC), as a subtype of HCC, exhibits significant heterogeneity in its clinical manifestations and prognosis. Although M-HCC is often regarded as a simple prognostic factor in existing studies, research on its specific prognostic impact is relatively scarce, lacking systematic and in-depth analysis. Therefore, accurate assessment of the prognosis of M-HCC patients, especially in predicting postoperative survival rates, remains of great clinical significance. The objective of this study is to construct a more precise prognostic prediction model for M-HCC patients by integrating multi-dimensional information including clinical, imaging, and laboratory examinations. This aims to provide more targeted guidance for individualized treatment and ultimately improve the overall survival rate of patients.

Methods : We applied Lasso regression, cross-validated Lasso (CV-Lasso), and random forest analysis to identify key prognostic factors. A nomogram was developed by weighting significant factors to predict postoperative survival. Patients were stratified into low/high-risk groups, and survival analysis was performed using Kaplan-Meier curves.

Results: A total of 578 M-HCC patients were enrolled in the study and randomly divided into a training set and a validation set. Through Lasso, CV-Lasso, and random forest analyses, we identified seven factors that significantly affect the prognosis of M-HCC patients.

age, antiviral therapy, Child-Pugh score, liver cirrhosis, white blood cell count (WBC), platelet count (PLT), and thrombin time (TT). Subsequently, based on these seven factors, we constructed a nomogram model to predict the 3-year, 5-year, and 8-year survival rates of patients. The predictive ability of the model was verified by ROC curves, with an area under the curve (AUC) of 0.688 for 5-year survival prediction and 0.784 for 8-year survival prediction, indicating high predictive accuracy. Kaplan-Meier survival curves further showed that the survival time of patients in the low-risk group was significantly longer than that in the high-risk group ($p < 0.0001$), demonstrating the discriminative ability of the model.

Conclusions: Postoperative antiviral therapy significantly improves M-HCC survival by enhancing immunity and protecting liver function. Child-Pugh score, age, and cirrhosis are associated with poor prognosis. Integrating multi-dimensional data to construct a personalized prognostic model enables precise treatment strategies, improving long-term outcomes and overall survival.

Keyword(s) : Multifocal Hepatocellular Carcinoma; Nomogram; Overall survival

1543 - Endothelial RUNX1 Controls Acetaminophen Induced Liver Injury by Regulating LSEC Dysfunction and Pathological Angiocrine Signaling

Wei Cheng¹, Jiahao Yuan¹, Jingyu Zhang¹, Han Tang¹, Min Cong¹
Beijing Friendship Hospital, Capital Medical University,
Liver Research Center, Beijing-China¹

Background / Hypothesis:

Acetaminophen (APAP)-induced liver injury (AILI) is a common cause of drug-induced liver injury (DILI). Liver sinusoidal endothelial cells (LSECs) act as essential gatekeepers of hepatic homeostasis and are central regulators of disease pathogenesis. Although Runx-related transcription factor-1 (RUNX1) is a master modulator of hematopoiesis and inflammatory responses, its specific function in LSECs during AILI remains unclear. This study aimed to investigate the role of RUNX1 in LSEC function and to delineate the underlying mechanisms in AILI.

Materials and Methods:

E-POSTER ABSTRACTS

Primary LSECs were isolated from AILI mice by density gradient centrifugation and adherence-based purification, and then subjected to gene expression analysis by RNA sequencing, qPCR, and western blotting. The role and expression of RUNX1 were further validated in vitro. Endothelial-specific Runx1-deficient mice were established via AAV2/9 delivery, and AILI was induced by APAP administration. Liver injury was evaluated through histology, biochemical assays (ELISA), and immunostaining. To explore the mechanism, we performed RNA sequencing on LSECs from APAP-injured mice to identify key signaling and angiocrine pathways. The correlation between RUNX1 and DILI was assessed by interrogating publicly available scRNA-seq datasets. Finally, the therapeutic effect of the RUNX1 inhibitor (Ro24-7429) was evaluated in vivo in the AILI mouse model.

Results:

We successfully isolated and characterized high-purity primary LSECs. RNA sequencing revealed a significant upregulation of RUNX1 in LSECs from AILI mice, with peak expression at the early injury phase (6 hours post-APAP). Consistent with these findings, RUNX1 expression was increased both in vivo and in vitro under APAP stimulation. Co-immunostaining with CD31 confirmed that RUNX1 expression was predominantly localized to LSECs. Notably, endothelial Runx1-deficient mice exhibited attenuated LSEC dysfunction, along with ameliorated liver injury and inflammation. Mechanistic studies in human immortalized and mouse primary LSECs indicated that RUNX1 deficiency activated pathways regulating LSEC dysfunction. Furthermore, RNA sequencing analysis revealed that RUNX1 knockdown mitigated the production of pro-inflammatory factors via a paracrine signaling mechanism, thereby protecting against hepatocyte injury. Importantly, pharmacological inhibition of RUNX1 effectively alleviated APAP-induced liver injury.

Conclusions:

Endothelial Runx1 deficiency and its pharmacological inhibition attenuate APAP-induced LSEC dysfunction and liver injury by reducing hepatocyte damage via a paracrine mechanism. Therefore, therapeutic targeting of RUNX1 represents a potential strategy for treating DILI.

1544 - Alterations in gut microbiota and metabolism are correlated with the severity of PBC.

Qi Wang¹, Wenyong Qiao², Xinyue Ma³, Han Shi⁴, Yanmin Liu³, Minghui Li¹, Chunyang Huang³, Ronghua Jin²

Beijing Ditan Hospital, Center Of Liver Disease Division, Beijing-China¹ Beijing Ditan Hospital, National Center For Infectious Diseases, Beijing-China² Beijing Youan Hospital, Center Of Liver Disease Division, Beijing-China³ Beijing Youan Hospital, National Center For Infectious Diseases, Beijing-China⁴

Background / Hypothesis:

The study aims to explore the differences in metabolic profiles and gut microbiota between GP210 antibody-positive (GP210_pos) and GP210 antibody-negative (GP210_neg) patients with primary biliary cholangitis (PBC).

Materials and Methods:

This study employed untargeted metabolomics to analyze serum metabolite differences between 31 patients negative for GP210 antibodies and 13 patients positive for GP210 antibodies in PBC. Additionally, 16S rRNA sequencing was used to compare the gut microbiota composition between the two patient groups. We further explored the correlations between differential metabolites and differential bacterial genera using Sankey diagrams and correlation network graphs. Finally, ROC curve analysis was performed for each metabolite to assess its effectiveness in identifying and predicting GP210 antibody-positive PBC.

Results:

In GP210_pos patients, 11 differential bacterial genera were identified, with the relative abundances of 4 genera significantly increased and 7 genera significantly decreased, along with 9 differential metabolites. Among these, the increased genera *Gemmiger*, *Faecalibacterium*, *Haemophilus*, and *Megasphaera* showed significant negative correlations with 1-Peroxyferolide, Steroid O-sulfate, and significant positive correlations with 10,16-Dihydroxyhexadecanoic acid. Conversely, the decreased genera *Streptococcus* and *Salmonella* exhibited significant negative correlations with Synaptotaxis factor K1, Cotylenin F, and Cassaidine. Additionally, ROC curve analysis revealed that Chaksine had the highest AUC value of 0.74, indicating strong

E-POSTER ABSTRACTS

predictive capability.

Conclusions:

This study identified significant differences in both metabolite profiles and gut microbiota composition in GP210_pos PBC patients. Univariate ROC analysis results specifically highlighted Chaksine as having strong predictive capability (AUC = 0.74) in its predictive model.

Keyword(s) : Primary biliary cholangitis; GP210 antibody ; gut microbiota

1545 - Significant Burden of Liver Related Outcomes in DM MASLD despite Low Fatty Liver Index Results from Two Nationwide Cohort Studies

Hyein Han ¹, Moon Haeng Hur ², Hyunjae Shin ², Sungho Won ¹, Yun Bin Lee ², Eun Ju Cho ², Jeong-hoon Lee ², Su Jong Yu ², Jung-hwan Yoon ², Yoon Jun Kim ²

Seoul National University, Institute Of Health And Environment, Seoul-South Korea ¹ Seoul National University College Of Medicine, Department Of Internal Medicine And Liver Research Institute, Seoul-South Korea ²

Background / Hypothesis: Lean metabolic dysfunction-associated steatotic liver disease (MASLD), defined by hepatic steatosis with cardiometabolic risk factors in non-obese individuals, is relatively common in Asian populations, but may be overlooked when risk assessment relies solely on noninvasive steatosis markers such as the fatty liver index (FLI). We aimed to evaluate the burden of liver-related outcomes (LROs) in MASLD patients classified as having low steatosis likelihood by FLI.

Materials and Methods: A retrospective cohort study was conducted using the Korean National Health Insurance Service (NHIS) database. Patients with diabetes mellitus who underwent health screening examinations between 2009 and 2013 were included. MASLD was stratified according to FLI into control (FLI < 20), suboptimal (FLI 20–30), and definite (FLI > 30) groups, and LROs were evaluated using Fine–Gray competing risk models. In addition, we conducted parallel analyses in participants from the UK Biobank.

Results: Among 986,436 individuals in the NHIS database, 149,682 (15.2%) were classified as having suboptimal MASLD by FLI. The suboptimal MASLD group had a significantly increased risk of composite LRO (subdistribution hazard ratio [sHR] = 1.10, 95%

confidence interval [CI] = 1.06–1.15, $p < 0.001$) compared to the control group, specifically for hepatocellular carcinoma (sHR = 1.17, 95% CI = 1.09–1.26, $p < 0.001$), and liver-related death (sHR = 1.22, 95% CI = 1.12–1.34, $p < 0.001$). The elevated risk persisted in a cause-specific model and across subgroups. In the suboptimal MASLD group, higher AST and ALT were independently associated with increased risks of LRO (AST: sHR = 1.25, 95% CI = 1.22–1.27; ALT: sHR = 1.15, 95% CI = 1.13–1.17; both $p < 0.001$). However, among 391,220 individuals in the UKB database, the suboptimal MASLD group had a comparable risk of LROs to the control group (sHR = 1.06, 95% CI = 0.61–1.81, $p = 0.844$).

Conclusions: MASLD patients with borderline FLI still experienced a significant burden of LROs in the Korean NHIS cohort but not in the UK Biobank cohort. These findings highlight the limitations of steatosis markers for risk stratification and emphasize the need for more comprehensive assessment strategies, especially in populations with lean MASLD.

Keyword(s) : fatty liver; lean NAFLD; liver cancer; NHIS; UK Biobank.

1546 - Tranexamic acid on risks of rebleeding in acute variceal bleeding a retrospective cohort study on local data in Hong Kong

Aaron Tsz-wang Lo ¹, Grace Lai-hung Wong ¹, Yee-kit Tse ¹, Vincent Wai-sun Wong ¹

The Chinese University Of Hong Kong, Department Of Medicine And Therapeutics, Hong Kong-Hong Kong SAR, China ¹

Background / Hypothesis:

Variceal haemorrhage is considered one of the most severe complications of liver cirrhosis and portal hypertension. It is postulated that the severity of bleeding is aggravated by hyperfibrinolysis. Recent randomized controlled trial by Kumar et al. demonstrated that tranexamic acid reduces the risk of failure to prevent rebleeding in upper gastro-intestinal bleeding in patients with Child-Turcotte-Pugh class B or C. We analysed local data in Hong Kong on the impact of tranexamic acid on rebleeding rates and overall survival in variceal bleeding.

Materials and Methods:

We performed a retrospective cohort study on adult patients with history of acute gastrointestinal variceal bleeding between January 2000 and May 2020

E-POSTER ABSTRACTS

identified using a territory-wide database in Hong Kong. Patients with hepatocellular carcinoma, previous thrombotic events and dialysis-dependent end stage renal failure were excluded. The primary and secondary endpoints were 6-week rebleeding events with reference to Baveno V criteria and 6-week all-cause mortality respectively. Propensity score matching was applied to the study cohort before endpoint comparison.

Results:

A total of 5225 patients with 6331 variceal bleeding events were analysed. 374 events in patient receiving tranexamic acid within 1 day of presentation were compared to 374 events in propensity score matched control group. Clinical characteristics were comparable between groups. No significant inter-group difference was observed in rates rebleeding events by 6 weeks (20.1% in treatment group vs 17.1% in control, $p = 0.35$) and 6-week all-cause mortality (20.6% in treatment group vs 21.9% in control, $p = 0.64$).

Conclusions:

In conclusion, tranexamic acid was not shown to significantly improve both rebleeding risks and overall survival by 6 weeks in this local retrospective cohort. Further studies are required to examine the role and safety of tranexamic acid in patients with variceal bleeding.

1547 - Micro RNAs (-122 -34a and -99a) as Potential Predictive Biomarkers for MAFLD

Mohamed Abdel-samiee¹, Olfat Hendy²
National Liver Institute, Menoufia University,
Hepatology And Gastroenterology, Shebin El-kom-
Egypt¹ National Liver Institute, Menoufia University,
Clinical Pathology, Shebin El-kom-Egypt²

Background / Hypothesis:The development of non-invasive diagnostic tools to diagnose non alcoholic fatty liver remains essential for patient safety rather than invasive techniques. Mi-RNAs are present in almost all body fluids such as serum, plasma and urine. The increased use of circulating mi-RNAs in clinical practice is explained by their ability to accurately reflect the physiological/pathological state of the tissue they are derived from. This case control study was to address the value of circulating miRNAs as potential non invasive biomarker for the diagnosis of MAFLD

and monitoring of disease progression.

Materials and Methods:Routine clinical assessment, laboratory tests, anthropometric study and liver biopsy results reported for 210 patients with MAFLD (124 patients of simple steatosis (SS) and 86 of MASH). Apparently matched age and sex healthy individuals ($n=90$) were included as control group. Exclusion criteria were; presence of hepatitis viral markers (for B and C), autoimmune hepatitis, alcohol consumption, hepatocellular carcinoma, liver cirrhosis or portal hypertension, diabetes mellitus or ischemic heart disease. Serum sample were tested for mirco-RNAs (-122, -34a and -99a) by quantitative-PCR.

Results:By histopathology, 124 of MAFLD group were of SS and 86 patients were of MASH. Both mi-RNA-122 and -34a level were increased in MAFLD compared to healthy controls ($p<0.001$) and at a cut-off=1.261, mi-RNA-122 had 92%-sensitivity, 85%-specificity to differentiate between MAFLD from healthy controls. While mi-RNA-99a were significantly decreased in MAFLD patients with further decreased in disease severity, and at a cut-off=0.46, the miR-99a had 94%-sensitivity and 96%-specificity to discriminate between SS from MASH.

Conclusions:The integration of circulating mi-RNA panel achieved to diagnose MAFLD cases and to discriminate between SS and MASH. Large scale study is still needed to verify the other miRNAs profile and their role in MAFLD pathogenesis and targeting therapy.

Keyword(s) : MAFLD, MicroRNA, liver biopsy, MASH

1548 - The Potential Role of A Gut Hormone in MAFLD

Mohamed Abdel-samiee¹, Olfat Hendy², Mona Shafie², Heba Alam³, El-sayed Ibrahim¹

Shebin El-kom-Egypt³

Background / Hypothesis:Ghrelin is a gut hormone

E-POSTER ABSTRACTS

with various functions including energy metabolism and inflammation inhibition. Nuclear factor-kappa B (NF- κ B) participates in the initiation and the progression of inflammation, particularly, the cardiovascular and adipose tissue inflammation. To date the combined role of Ghrelin and NF- κ B in the pathogenesis of metabolic non-alcoholic fatty liver disease (MAFLD) is a matter of debate. We investigated whether acyl ghrelin level and NF- κ B could interplay a role in lipid metabolism and inflammatory injury in MAFLD.

Materials and Methods: Ninety three adult participants were included in the study, 28 patients had proved nonalcoholic steatohepatitis (NASH), and 40 patients had simple steatosis, as well 25 healthy subjects, matched for age, gender and Body mass index (BMI) to the patients were included in the study as a healthy control group. Full history and clinical examination, abdominal ultrasonography and liver biopsy were done when indicated. Liver function tests, lipid profile, blood sugar, insulin and C-peptide, fasting insulin, and plasma acyl ghrelin concentrations were measured. Nuclear NF- κ B microRNA expression was measured by quantitative real time polymerase chain reaction.

Results: Fasting insulin, insulin C-peptide, homeostatic model assessment insulin resistance (HOMA-IR), alanine amino-transferases (ALT) and gamma glutamyl transpeptidase (GGT) were significantly increased and high density lipoprotein cholesterol (HDL-C) was significantly decreased in MAFLD group compared to control group. In addition, a significant increase in ALT, GGT, fasting insulin, insulin C peptide and HOMA-IR were detected in the NASH group compared to group of simple steatosis. The plasma levels of acyl-ghrelin was significantly decreased in MAFLD groups compared to normal control group, the lowest level was detected in NASH group as compared to group of simple steatosis. The expression of NF- κ B microRNA was significantly increased in MAFLD groups compared to normal control group and its level was significantly increased in NASH compared to simple steatosis. The NF- κ B mRNA was positively correlated with BMI, HOMA-IR, ALT, fasting insulin, insulin C-peptide and liver histopathology and acyl-ghrelin was inversely correlated with BMI, HOMA-IR, ALT, fasting insulin,

insulin C peptide and liver histopathology. Both were significantly correlated with HDL-C.

Conclusions: Acyl ghrelin attenuated MAFLD-induced liver injury through down regulation of NF- κ B and they are associated with disease progression. Further large scale studies are recommended to consider ghrelin as promising drug for the prevention and treatment of MAFLD.

Keyword(s) : MAFLD; Acyl ghrelin, NF- κ B, Liver Biopsy

1549 - Retrospective Audit of Terlipressin Use in Hepatorenal Syndrome – Acute Kidney Injury (HRS AKI)

Rachel Teo¹, Mark Dhinesh Muthiah², Benjamin Kai Yi Nah³, Guan Huei Lee⁴, Margaret Li Peng Teng³
National University Hospital, Division Of Internal Medicine, Singapore-Singapore¹ National University Hospital, Yong Loo Lin School Of Medicine, National University Of Singapore, Division Of Gastroenterology And Hepatology, Department Of Medicine, National University Centre For Organ Transplantation, Singapore-Singapore² National University Hospital, Division Of Gastroenterology And Hepatology, Department Of Medicine, Singapore-Singapore³ National University Hospital, Division Of Gastroenterology And Hepatology, Department Of Medicine, National University Centre For Organ Transplantation, Singapore-Singapore⁴

Background / Hypothesis:

Terlipressin is a vasopressin analogue which induces splanchnic vasoconstriction, thereby reducing portal inflow and redistributing circulatory volume from the splanchnic to the systemic circulation, which ultimately improves renal perfusion. It is widely used for treating hepatorenal syndrome – acute kidney injury (HRS-AKI). However, emerging evidence suggests an increased risk of respiratory adverse events (AEs) associated with terlipressin treatment. This study aimed to evaluate the efficacy and safety of terlipressin in a real-world cohort of Asian patients with HRS-AKI.

Materials and Methods:

A retrospective cohort study comprising 51 patients aged ≥ 21 years with chronic liver disease who received terlipressin for HRS-AKI between January 1 2005 and June 30 2023 was conducted. Primary outcomes included treatment response (based on the 2015 criteria), incidence of AEs, and mortality. Multivariate

E-POSTER ABSTRACTS

logistic regression was employed to assess the associations between relevant covariates and outcomes.

Results:

Among the 51 patients, 15 (29.4%) achieved a complete response to treatment, 5 (9.8%) had a partial response, and 25 (49%) had no response. Reasons for non-response were initiation of renal replacement therapy (RRT) in 9 patients and absence of stage regression in 15 patients. 18 patients (35.3%) experienced AEs of any severity, with 12 (23.5%) having respiratory-related AEs. 41 patients (80.4%) died, while 3 patients (5.9%) underwent liver transplantation. Modality of terlipressin administration (bolus versus continuous) and number of days of albumin exposure prior to treatment were significantly associated with development of any AE. However, no covariates were found to be significantly associated with mortality.

Conclusions:

Terlipressin remains an effective treatment for HRS-AKI; however, its use is associated with a distinct AE profile, particularly respiratory complications. It should therefore be used selectively with careful monitoring, particularly in patients receiving bolus dosing or large volumes of albumin pre-treatment. These factors should be considered when evaluating the benefit-risk profile of terlipressin in clinical decision-making.

1550 - VCTE Radiomics for Non Invasive Assessment of Hepatic Fibrosis in Metabolic Dysfunction Associated Steatohepatitis

Shuying Song¹, Haoshuang Fu¹, Qing Xie¹
Ruijin Hospital, Shanghai Jiao Tong University School Of Medicine, Department Of Infectious Diseases, Shanghai-China¹

Background / Hypothesis:

Fibrotic metabolic dysfunction-associated steatohepatitis (MASH) is the leading cause of all-cause and liver-related mortality. Radiomics could predict disease progression. We developed a diagnostic model for identifying fibrotic MASH using radiomics analysis based on hepatic vibration-controlled transient elastography (VCTE).

Materials and Methods:

A total of 163 patients with biopsy-proven metabolic dysfunction-associated steatotic liver disease (MASLD)

were enrolled and divided into training (50%) and validation (50%) cohorts. The outcome was defined as Fibrotic MASH (NAS ≥ 4 and fibrosis stage ≥ 2). VCTE images were obtained and extracted 1209 radiomics feature, where 7 features were selected using Least absolute shrinkage and selection operator regression. R Score was established using support vector machines based on selected features. The diagnostic model was constructed using multiple logistic regression based on R Score and clinical data, which performance was compared with previous models (Agile 3+, Agile 4, FAST, FIB-4, FNI, NFS).

Results:

Fibrotic MASH patients presented elder ages, higher AST, and higher liver stiffness measurement (LSM) than Non-Fibrotic MASH patients ($P < 0.05$). The Radiomics Score (R Score), constructed via SVM using selected features, demonstrated significantly different distributions between Fibrotic MASH and Non-Fibrotic MASH patients in both training and validation cohorts (all $P < 0.01$). R Score [odds ratio (OR)=13171.60, 95%CI=93.08-1863829.74, $P < 0.01$], LSM (OR=1.19, 95%CI=1.05-1.36, $P=0.01$), age (OR=1.06, 95%CI=1.02-1.11, $P=0.01$), and AST (OR=1.02, 95%CI=1.00-1.04, $P=0.04$) were independent risk factors for Fibrotic MASH. These factors (AST, R Score, LSM, Age) were incorporated to construct diagnostic model for Fibrotic MASH, which was named ARLA model (Figure 1A). The ARLA yielded the best diagnostic performance for Fibrotic MASH in both the training (AUROC=0.86, 95%CI=0.78-0.94, Figure 1B) and validation (AUROC=0.87, 95%CI=0.78-0.95, Figure 1C) cohorts. The dual cut-off approach was implemented with a sensitivity ≥ 0.85 for ruling out and a specificity ≥ 0.85 for ruling in the disease. Therefore, the cut-off values of ARLA points were 59.3095 and 68.1445 for rule-out and rule-in, respectively, with characteristics detailed in Figure 1D-E. Accordingly, ARLA exhibited highest correct classified proportion of 69% and 70% in both cohorts (Figure 2A-B). The two-step approach based on FIB4 and ARLA exhibited smaller grey zone and higher correct classified proportion than traditional two-step approach based on FIB-4 and LSM (Figure 2C-D).

Conclusions:

The ARLA model based on VCTE radiomics and clinical characteristic yielded the best diagnostic performance for Fibrotic MASH than preexisting scores. It could be a noninvasive and cost-effectiveness tool for early identification of progressive MASH patients for clinical intervention.

1553 - Hepatic G3BP1 Acts as a Critical Role Integrating Autophagy and Lipogenesis to Suppress MASLD Progression

Hua-xiang Yang¹, Xin Gao², De-jun Kong³, Xiao-cong Liu¹, Wu Wen¹

West China School Of Medicine, Sichuan University, Sichuan University Affiliated Chengdu Second People's Hospital, Department Of Gastroenterology And Hepatology, Chengdu-China¹ Shanxi Provincial People's Hospital, Department Of Gastroenterology And Hepatology, Taiyuan-China² Beijing Friendship Hospital Affiliated To Capital Medical University, Department Of General Surgery, Beijing-China³

Background / Hypothesis:

The molecular mechanisms governing the progression of metabolic dysfunction-associated steatotic liver disease (MASLD) to steatohepatitis (MASH) remain incompletely defined. A comprehensive understanding of the regulatory proteins involved in hepatic lipid metabolism and stress response is critical for elucidating disease pathogenesis.

Materials and Methods:

We initially identified a significant reduction in GTPase-activating protein-binding protein 1 (G3BP1) expression in liver specimens from human MASLD/MASH patients. To define the cell-autonomous functions of G3BP1 in hepatocytes, we generated and characterized hepatocyte-specific G3BP1 knockout (G3BP1-HKO) mice under metabolic challenge. An integrated approach, utilizing histopathology, immunoblotting, co-immunoprecipitation, and luciferase reporter assays, was employed to dissect the phenotypic and molecular consequences of G3BP1 loss.

Results:

G3BP1 deficiency in hepatocytes markedly accelerated the development and severity of hepatic steatosis and inflammatory injury in mice. At the mechanistic level, we identified G3BP1 as a novel and essential regulator of autophagic flux. G3BP1 directly interacted with the SNARE proteins STX17 and VAMP8, and this interaction was necessary for efficient autophagosome-lysosome fusion. Independently, G3BP1 ablation enhanced hepatic de novo lipogenesis. We determined that this

pro-lipogenic effect was consequent to impaired nuclear translocation of the transcription factor TFE3, a known repressor of lipogenic genes. G3BP1 was required for the nuclear accumulation of TFE3, thereby establishing a direct molecular link between G3BP1 and the transcriptional control of lipid synthesis.

Conclusions:

This study unveils a dual-protective mechanism orchestrated by G3BP1 in the liver. G3BP1 safeguards against MASLD/MASH progression by concurrently promoting the completion of autophagy via SNARE complex facilitation and suppressing lipogenesis through enabling TFE3-mediated transcriptional repression. These findings position G3BP1 as a central node integrating proteostatic and metabolic pathways, offering profound insights into the fundamental biology of liver steatosis and highlighting a potential target for therapeutic intervention.

Keyword(s) : Autophagy, Lipogenesis, MASLD, G3BP1

1554 - Micro RNA Gene Polymorphisms in Egyptian Cirrhotics who developed Hepatocellular Carcinoma

Mohamed Abdel-samiee¹, Fatma Khalaf², Ashraf Eljaky¹, Nashwa Shebl¹, Mervat Abdelkerim¹, Warda Osman¹, Esam Zayd¹, Maha Alam³, Karema Diab³, Fatma Omar⁴, Eman Abdelsameea¹

National Liver Institute, Menoufia University, Hepatology And Gastroenterology, Shebin El-kom-Egypt¹ National Liver Institute, Menoufia University, Biochemistry, Shebin El-kom-Egypt² National Liver Institute, Menoufia University, Clinical Pathology, Shebin El-kom-Egypt³ National Liver Institute, Menoufia University, Microbiology, Shebin El-kom-Egypt⁴

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer worldwide. It is also the fifth cause of death due to cancer in the world. This is mainly due to the fact that HCC is usually being diagnosed at an advanced stage due to a difficult early diagnosis. To save life, new diagnostic and prognostic biomarkers for HCC are of paramount significance. The development and progression of hepatocellular carcinoma (HCC) is a multistage process involving the deregulation of genes that are crucial to cellular processes. Multiple risk factors are correlated with HCC. We determined the association between micro-RNA gene polymorphisms and development of HCC in Egyptian Patients.

E-POSTER ABSTRACTS

Materials and Methods:The current case-control study included 200 participants, they were recruited from the Outpatient Clinics and Inpatient Department, National Liver Institute-Menoufia University, Egypt, 90 of them were proved as HCC by clinical examination, laboratory and triphasic CT findings. As well as 110 of participants randomly selected from healthy subjects with matched age, sex, risk factors that may affect HCC development as (Diabetes Mellitus, Hypertension and/or smoking) were enrolled in the study as a control group. Cases with chronic hepatitis without HCC, autoimmune hepatitis and chronic inflammatory diseases are excluded by clinical and laboratory investigations. Tumor staging was done using BCLC staging system. Quantification and genotyping of Micro-RNA were performed.

Results:

Among the 200 patients, 2 groups were described: group I included 90 HCC patients with a male majority (72.2%) and 110 controls in group II. Three microRNA SNPs were assayed in both patients and controls. There was a significant association between rs10061133 miR-499b and the risk of HCC. The genotypes GG or G allele were associated significantly to an increased risk of HCC (GG: OR (95% CI)= 2.91 (1.23-4.22), $p = 0.013$; G allele: OR (95% CI)= 1.79 (1.12-2.15), $p = 0.026$) compared with the genotype of AA or AG or A allele

Conclusions:An association between the miRNA499 SNPs and the susceptibility to HCC, aiming to explore some roles and mechanisms of SNPs within miRNA in the occurrence and development of primary liver cancer. To the best of our knowledge, no previous studies elicited such finding. We hope that our efforts and findings will facilitate the use of miRNA SNPs in early detection of HCC and may be targeting for HCC therapy. Further prospective investigations with a large number of cases would allow us to evaluate miRNA-499 polymorphism in a variety of clinical settings to better understand its role in HCC.

1556 - Serum kallistatin level in comparison to other noninvasive panels for potential portal hypertension Evaluation in Egyptian cirrhotics

Mohamed Abdel-samee¹, Mohamed Abbasy¹,

Abdelaziz Farag², Ali Nada¹, Mona Elabd³
National Liver Institute, Menoufia University,
Hepatology And Gastroenterology, Shebin El-kom-
Egypt¹ Damietta, Hepatology And Gastroenterology,
Damietta-² National Liver Institute, Menoufia
University, Clinical Pathology, Shebin El-kom-Egypt³

Background / Hypothesis:

The development of esophageal varices is an important consequence of portal hypertension. In accordance with the Baveno VI consensus, noninvasive tools are recommended to stratify patients and to identify those who are at risk of high-risk esophageal varices (HREV), for whom endoscopic assessment is warranted. We investigated the diagnostic value of serum kallistatin levels, along with other biochemical panels, in the assessment of portal hypertension among Egyptian individuals with liver cirrhosis.

Materials and Methods:

This cross-sectional research evaluated 90 cirrhotic cases who were admitted to the National Liver Institute's Hepatology and Gastroenterology Department as well as the Endoscopy Unit at Menoufia University by measuring the serum KAL level and comparing it to other panels in order to grade esophageal varices according to the results of GI endoscopy.

Results:

The mean age of the 90 individuals who were enrolled in the study was 59.8 ± 9.8 years; 42.2% of them were female, and 57.8% were male. Patients with varices had a considerably decreased mean level of blood kallistatin. Additionally, it demonstrates a notable decrease in individuals with extensive varices. The presence of EV can be predicted by kallistatin with a sensitivity of 76.5% and a specificity of 98.6% at cut-off levels of 23.1 $\mu\text{g/ml}$.

Conclusions: Serum kallistatin may serve as a potential indicator for identifying esophageal varices, particularly the large and more life-threatening types.

1557 - AADN score Predicting Response to transarterial chemoembolization sintilimab and lenvatinib in patients with hepatocellular carcinoma

E-POSTER ABSTRACTS

Xue Zhang¹, Dongbo Chen¹, Hongsong Chen¹
Peking University People's Hospital, Peking University
Hepatology Institute, Beijing-China¹

Background / Hypothesis:

Although the triple therapy of transarterial chemoembolization (TACE) combined with immune checkpoint inhibitors and tyrosine kinase inhibitors is becoming an effective treatment for unresectable hepatocellular carcinoma (uHCC). However, there is still a lack of effective tools for predicting therapeutic effects at present.

Materials and Methods:

To develop a predictive tool for the prognosis of uHCC patients treated with TACE, sintilimab and lenvatinib. Based on multicenter data, this study constructed and validated an AADN score as variables to predict overall survival in patients treated with this combination therapy. This study included 188 uHCC cases (training cohort: n = 101, validation cohort: n = 87) from three different hospitals. who treated with TACE, sintilimab and lenvatinib.

Results:

In multivariate analysis, alpha-fetoprotein ≥ 100 ng/mL [hazard ratio (HR) = 2.579, P = 0.010], alkaline phosphatase > 120 U/L (HR 2.234, P = 0.021), direct bilirubin > 7.3 μ mol/L (HR = 2.931), P = 0.007) and neutrophil to lymphocyte ratio > 2.5 (HR = 3.127, P = 0.006) were identified as independent prognostic factors and were used to establish the AADN score. Kaplan-Meier survival curves and time-dependent receiver operating characteristic curves were used to assess the accuracy of the AADN score, with area under receiver operating characteristic curve values of 0.827 (training cohort, 95% confidence interval: 0.743-0.911) and 0.832 (validation cohort, 95% confidence interval: 0.742-0.923). According to the score, the patients were divided into low-risk, intermediate-risk and high-risk groups. Overall survival and progression-free survival were significantly different between groups.

Conclusions:

The AADN score can distinguish the prognostic risk of uHCC patients treated with TACE, sintilimab and lenvatinib, provides a basis for individualized treatment decision-making, and have clinical application prospect.

Keyword(s) : Hepatocellular carcinoma; Transarterial chemoembolization; Sintilimab; Lenvatinib; AADN score

1558 - Detection of Small Fiber Neuropathy Changes by Sudoscan in Hepatitis C Virus Infected Cirrhotics

Mohamed Abdel-samiee¹, El-sayed Tharwa¹
National Liver Institute, Menoufia University,
Hepatology And Gastroenterology, Shebin El-kom-
Egypt¹

Background / Hypothesis: Worldwide, 130-170 million people are infected with hepatitis C virus (HCV), which represents more than 3 % of the world's population. HCV infection is associated with several extrahepatic manifestations, some of which are neurological and mostly related to immune mechanisms. Hepatitis C Virus (HCV) infection can affect the neurological system and neuropathy is one of these manifestations. HCV infection is associated with diabetes mellitus (DM) type II and diabetic patients are at higher risk of acquiring HCV infection. Sweat function has been proposed to assess early autonomic neuropathy. Aim: this study aimed to evaluate small fiber neuropathy in asymptomatic HCV-related cirrhotic patients with or without diabetes mellitus through sweat function assessment by SUDOSCAN test.

Materials and Methods:

three groups were involved: 47 healthy controls, 48 HCV-related cirrhotic patients without DM (Group 1) and 49 HCV-related cirrhotic patients with DM type II (Group 2). All participants were subjected to liver panel tests, renal function tests, cell blood counts, HbA1c, abdominal ultrasound. Sweat function was assessed in all patients and controls by measuring hand and feet Electrochemical Skin Conductance (ESC, μ S) using Sudoscan

Results:

Peripheral neuropathy was detected in none of the controls, 39% of Group 1 patients and in 62% of Group 2 patients (p < 0.0001). The mean feet ESC (FESC) was 88.3 ± 6.8 μ S in controls, 67.2 ± 19.2 μ S in Group 1 and 57.9 ± 19.4 μ S in Group 2 (p < 0.0001). A significant correlation was observed between FESC and bilirubin, albumin, creatinine, international normalized ratio,

E-POSTER ABSTRACTS

transaminases and splenic size.

Conclusions: the mean FESC are decreased in HCV-related cirrhosis with or without DM when compared to the control group, suggesting small fiber autonomic neuropathy based on sweat function assessment. SUDOSCAN seems a valuable noninvasive method for early detection of small fiber neuropathy in asymptomatic HCV-related cirrhosis with or without DM. Long-term follow-up would be useful to evaluate the progression of neurological dysfunction in this population; and future studies are needed to confirm our results in a larger population of hepatic patients with or without cirrhosis of any etiologies, along with a clinical neurological examination.

Keyword(s) : HCV; Small Fiber; Neuropathy; Sudoscan

1561 - Cell type specific bidirectional modulation of Zfp36l2 by a Chinese herbal formula reverses T cell exhaustion to suppress hepatocellular carcinoma

Zimeng Shang¹, Xiaoli Liu¹, Huiwen Yan¹, Yuqing Xie¹, Zhe Zhang¹, Wanxin Shi¹, Yanyu Xu², Xinhua Song², Zhiyun Yang¹

Beijing Ditan Hospital, Capital Medical University, Center Of Integrative Medicine, Beijing-China¹ Capital Medical University, College Of Traditional Chinese Medicine, Beijing-China²

Background / Hypothesis:

A major limitation in cancer immunotherapy is the establishment of terminally exhausted CD8⁺ T cells within the tumor microenvironment. We investigated the mechanism of Yangyin Fuzheng Jiedu Formula (YFJD), a traditional Chinese medicine formula, and hypothesized that it counteracts T cell exhaustion through a novel, cell-type-specific mechanism.

Materials and Methods:

The therapeutic efficacy of YFJD was evaluated in multiple immunocompetent murine HCC models, including MYC/CTNNB1/sg-p53 and c-MYC/Mcl1 (hydrodynamic injection), as well as subcutaneous models (sgPten/c-Met and c-MYC-driven HCC5). A critical dependency test was performed by comparing YFJD efficacy in immunocompetent C57BL/6J mice versus CD8⁺ T cell-deficient Balb/c nude mice bearing HCC5 subcutaneous tumors. Mechanistic studies employed high-dimensional flow cytometry, single-cell RNA sequencing (scRNA-seq), in vivo CD8⁺ T cell depletion, and in vitro co-culture systems with siRNA-mediated gene silencing.

Results:

YFJD robustly inhibited tumor growth across all models

and extended survival. This efficacy was strictly dependent on CD8⁺ T cells, as it was abrogated in Balb/c nude mice and upon CD8⁺ T cell depletion in immunocompetent hosts. YFJD remodeled the tumor immune microenvironment, specifically reducing the frequency of PD-1⁺TIGIT⁺TIM-3⁺ terminally exhausted CD8⁺ T cells and enhancing T cell polyfunctionality. scRNA-seq revealed that YFJD bidirectionally regulated the RNA-binding protein Zfp36l2—upregulating it in terminally exhausted CD8⁺ T cells while downregulating it in tumor cells. Functional studies confirmed that Zfp36l2 knockdown in tumor cells abolished YFJD-enhanced, CD8⁺ T cell-mediated tumor killing.

Conclusions:

Our work unveils a novel mechanism of action for YFJD: it orchestrates a cell-type-specific bidirectional regulation of Zfp36l2. By simultaneously targeting this node in both CD8⁺ T cells and tumor cells, YFJD effectively reverses T cell exhaustion and promotes anti-tumor immunity, presenting a sophisticated therapeutic paradigm for HCC.

Keyword(s) : Hepatocellular carcinoma, CD8⁺ T cell exhaustion, Tumor microenvironment, Zfp36l2, Bidirectional regulation, Genetic mouse models

1562 - Evaluation of HBV RNA as a predictive biomarker to determine intrahepatic HBV activity among chronic hepatitis B virus infected patients

Md. Mostafizur Rahman¹, S M Rashed Ul Islam¹, Sheikh Mohammad Noor E Alam Dew², Dulal Chandra Das², Munira Jahan¹

Bangladesh Medical University, Department Of Virology, Dhaka-Bangladesh¹ Bangladesh Medical University, Department Of Hepatology, Dhaka-Bangladesh²

Background: Chronic hepatitis B virus (HBV) infection is a serious global public health concern that can lead to liver failure, cirrhosis, and subsequently hepatocellular carcinoma. HBV DNA has been used to assess the disease progression, but HBV DNA is rapidly undetectable after antiviral therapy while HBV RNA serves as an effective biomarker for monitoring the effectiveness of therapy and predicting disease prognosis. HBV RNA is a direct transcriptional product of hepatitis B virus (HBV) covalently closed circular DNA (cccDNA), playing a crucial role in amplifying and replicating the viral genome. This study was focused to determine the HBV RNA as an alternative marker for reflecting intrahepatic HBV activity and analyzing the correlation of plasma HBV RNA with HBV DNA and HBsAg.

E-POSTER ABSTRACTS

Materials and Methods: This descriptive cross-sectional study included 20 chronically infected, treatment-naïve patients and 20 patients treated with entecavir for over 48 weeks. Plasma and intrahepatic tissue were collected. HBV DNA and HBV RNA was extracted from the plasma samples and quantified by quantitative reverse transcription PCR (qRT-PCR). cccDNA were extracted by DNeasy Blood and Tissue kit (Qiagen, Netherlands) from the hepatic tissue subsequently was digested by Plasmid-Safe™ ATP-Dependent DNase (PSAD) (Epi-Centre Technologies Corp. Madison, WI, USA). The digested product was used to amplify cccDNA using specific primers by GoTaq qPCR master mix (Promega, Madison, USA). HBsAg levels were measured by chemiluminescence-based immunoassay (CLIA).

Results: HBV DNA and RNA were detected in all the treatment-naïve participants, while HBV RNA was detected in 25% of anti-viral treated patients, though having undetectable HBV DNA. The cccDNA was detected in 75% (15/20) and 70% (14/20) of treatment-naïve and treated patients respectively. HBV DNA and RNA levels were significantly higher in the treatment-naïve group compared to treated patients ($p < 0.001$). On the contrary, no significant difference was observed in HBsAg level between the groups ($p = 0.228$). HBeAg-positive patients showed significantly higher levels of HBsAg, HBV DNA, and RNA compared to HBeAg-negative patients. In addition, results demonstrated a strong positive correlation of HBV RNA with HBV DNA irrespective of anti-viral treatment, HBeAg seropositivity, and cccDNA detectability ($p < 0.001$). Nevertheless, with HBsAg level, no significant correlation was observed. Serum HBV RNA level can predict detected cccDNA with moderate accuracy (65%).

Conclusion: Serum HBV RNA is a promising biomarker for determining viral activity in both treatment-naïve and antiviral-treated chronic hepatitis B patients. Its assessment may improve therapy response monitoring and management, providing a viable alternative to invasive

Keyword(s) : Hepatitis B virus, HBV-DNA, HBV-RNA, cccDNA, quantitative HBsAg, Chronic Hepatitis B patients

1563 - Dynamics of Fibrosis Regression and Long term Liver related Events in Patients with Compensated Cirrhosis A 13 year Prospective

Cohort on Entecavir Therapy

Xinyu Liu¹, Mingyue Ma¹, Hui Ma¹, Bo Feng¹, Qian Jin¹, Danli Ma¹, Yandi Xie¹

Peking University People's Hospital, Peking University Hepatology Institute, Beijing-China¹

Background / Hypothesis: Chronic hepatitis B virus (HBV) infection is a leading cause of cirrhosis worldwide. Although nucleos(t)ide analogue (NA) therapy can slow the progression of HBV-related cirrhosis, the extent of achievable fibrosis regression and the long-term incidence of liver-related events (LREs) beyond ten years remain unclear. This study aimed to characterize 13-year dynamics of fibrosis reversal and LREs in a prospective cohort receiving NA therapy.

Materials and Methods: Fifty treatment-naïve patients with chronic hepatitis B and compensated cirrhosis were enrolled from 2012 to 2013 and received entecavir (ETV). Semi-annual assessments included laboratory tests, FibroScan, APRI, FIB-4, ALBI, Child-Pugh and MELD scores. LREs were defined as hepatic decompensation, hepatocellular carcinoma (HCC) or liver-related death. Cumulative incidences were estimated by Kaplan-Meier analysis, and predictors were identified via Cox regression models.

Results: After a median follow-up of 11.0 years (IQR 9.1–12.0), 12 patients developed LREs, including 9 cases of HCC. Kaplan-Meier analysis showed that cumulative LRE incidence rates of 0%, 11.0%, 22.6%, and 33.6% at 1, 5, 9, and 13 years, respectively. Corresponding HCC incidence rates of 0%, 8.8%, 13.5%, and 28.8%. Among 27 patients presented with significant liver fibrosis ($\text{FIB-4} \geq 3.25$) at baseline, cumulative fibrosis reversal rates were 25.9%, 46.5%, 75.2%, and 75.2% at 1, 4, 7, and 11 years, respectively. ALT was elevated in 24 patients at baseline, with a normalization rate of 91.7% (22/24) at year 1. Non-invasive indicators (LSM, APRI, Child-Pugh, ALBI), decreased significantly within the first year and remained stable throughout follow-up (1–11 years). Baseline characteristics did not predict clinical outcomes, however, multivariate analysis of on-treatment data at year 1 identified ALBI score as an independent predictor of subsequent LREs (HR 16.41, 95% CI 1.92–140.15, $P = 0.011$).

Conclusions: Long-term NA therapy leads to sustained

E-POSTER ABSTRACTS

fibrosis regression in over 75% of patients with compensated HBV-induced cirrhosis. Nonetheless, the risk of LREs persists, affecting nearly one-third of patients by year 13. The ALBI score at one year of treatment is a strong predictor of long-term outcomes, supporting its use for risk stratification and guiding enhanced surveillance in high-risk individuals.

Keyword(s) : Long-term outcomes, Prediction, Liver-related events, HBV-induced cirrhosis, Antiviral therapy

1566 - Enrichment of intratumoral *Cutibacterium acnes* in Advanced Hepatocellular Carcinoma and its promotive role in tumor progression

Huan Liu¹

The Second Affiliated Hospital Of Chongqing Medical University, Department Of Infectious Diseases, Institute For Viral Hepatitis, Chongqing-China¹

Background / Hypothesis:

The significance of tumor-resident intracellular microbiota is increasingly recognized. However, studies on the molecular mechanisms by which intratumoral bacteria promote hepatocellular carcinoma (HCC) development remain scarce. This study aimed to characterize the microbiota signature of HCC tissues and explore its role in HCC progression.

Materials and Methods:

First, we confirmed the presence of microbiota using staining, fluorescence in situ hybridization (FISH), and transmission electron microscopy (TEM). Additionally, some bacteria were cultured from fresh HCC tissues. Subsequently, 16S rRNA sequencing revealed a significant difference in beta diversity between early-stage and advanced-stage HCC.

Results:

Moreover, the abundance of *Cutibacterium acnes* (*C. acnes*) was higher in advanced-stage HCC tissues than in both early-stage HCC tissues and adjacent normal tissues. We further demonstrated that *C. acnes* significantly promotes the proliferation and migration of HCC cells. Consistently, subcutaneous tumor models confirmed that *C. acnes* accelerates HCC development.

Conclusions: Our findings suggest that eliminating *C. acnes* or inhibiting its downstream signaling pathways

may serve as a novel therapeutic strategy for HCC.

Keyword(s) :

1569 - Impact of Thrombophilia on the Extent of Portal Vein Thrombosis at Diagnosis

Ismail Qarch¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Selma Sabbah¹, Fatima Zahra Ajana¹, Maryeme Kadiri¹

Mohamed V University, Gastroenterology C Department, Rabat-Morocco¹

Background / Hypothesis:

Portal vein thrombosis (PVT) is the partial or complete obstruction of the portal vein and may extend to intrahepatic branches or the splanchnic venous axis, influencing risks such as portal hypertension and intestinal ischemia. Thrombophilic conditions—including natural anticoagulant deficiencies, antiphospholipid syndrome (APS), and myeloproliferative neoplasms (MPNs)—are known risk factors, but their impact on the extent of PVT is not well defined. Clarifying this relationship is essential to guide anticoagulation and surveillance. This study aimed to evaluate the relationship between major thrombophilic conditions and the anatomical extent of PVT at diagnosis in a Moroccan tertiary care cohort.

Materials and Methods:

We conducted a retrospective study including all patients with imaging-confirmed PVT (recent or chronic with cavernoma) managed at a university hospital between 2010 and 2025. Thrombosis was categorized as:

Localized: limited to the main portal trunk

Extended: involving intrahepatic portal branches, the spleno-mesenteric trunk, superior mesenteric vein, and/or splenic vein

Patient demographics, etiology, and extent of thrombosis were systematically collected. Etiologies were classified as natural anticoagulant deficiencies, APS, MPNs, idiopathic, and other causes (mainly inflammatory or infectious). The proportion of extended thrombosis was compared across etiological groups.

Results:

A total of 83 patients were included. The mean age was

E-POSTER ABSTRACTS

44.9 years (range 19–76), with a strong female predominance (77.1%; sex ratio M/F = 0.3). The most frequent underlying cause was natural anticoagulant deficiency (31.3%, n=26), followed by APS and MPNs (13.3% each, n=11), idiopathic forms (18.1%, n=15), and other causes (24.1%, n=20).

The prevalence of extended thrombosis varied markedly according to etiology:

APS: 72.7% (8/11)

MPNs: 63.6% (7/11)

Anticoagulant deficiencies: 46.2% (12/26)

Idiopathic forms: 20% (3/15)

These data highlight that patients with APS or MPNs are at substantially higher risk for extensive thrombotic involvement, whereas idiopathic cases tend to remain localized.

Conclusions:

In this cohort, thrombophilic conditions, particularly APS and MPNs, were strongly associated with extended PVT at diagnosis. These findings underline the need for systematic thrombophilia screening in all patients presenting with PVT to identify high-risk individuals. Early identification of patients predisposed to extensive thrombosis allows for timely initiation of appropriate anticoagulation, close imaging surveillance, and individualized management strategies. Recognition of the link between specific thrombophilic disorders and thrombus extension is critical for optimizing outcomes and preventing severe complications such as portal hypertension or intestinal ischemia. Future studies should evaluate prospective risk stratification algorithms and local adaptation of therapeutic strategies to improve patient prognosis in Moroccan and regional practice settings.

1570 - Gadoteric Acid-Enhanced MRI Parameters for Functional and Volumetric Assessment in Chronic Liver Disease Stratification

Fatih Işık¹, Muhammed Emre Işıktaş², Muhammed Halid Yener², Serdar Sipahioğlu³, Fatih Alper²
Erzurum Regional Training And Research Hospital, Radiology, Erzurum-Türkiye¹ Atatürk University, Radiology, Erzurum-Türkiye² Ankara Dışkapi Yıldırım Beyazıt Eğitim Ve Araştırma Hastanesi, Radiology, Ankara-Türkiye³

Background / Hypothesis:

Chronic liver disease (CLD) encompasses a progressive continuum from non-advanced to compensated and decompensated cirrhosis. Accurate staging is essential for prognostication, therapeutic decision-making, and transplant planning. Gadoteric acid-enhanced MRI offers quantitative functional biomarkers of hepatocellular uptake and biliary excretion, while splenic volumetry reflects portal hypertension severity. However, few studies have simultaneously assessed both functional MRI biomarkers and volumetric indicators across clinically defined CLD stages. We hypothesized that hepatocellular function-based indices—Hepatocellular Uptake Index (HUI), Liver-Spleen Index (LSI), Relative Liver Enhancement (RLE), and Contrast Uptake Index (CUI)—combined with spleen volume would demonstrate complementary, stage-dependent behavior, improving non-invasive stratification of CLD severity.

Materials and Methods:

This retrospective single-center study included 140 patients who underwent gadoteric acid-enhanced MRI between March 2020 and June 2025. Patients were categorized into three groups based on EASL 2021 criteria: non-advanced CLD (NA-CLD, n=18), compensated advanced CLD (CA-CLD, n=97), and decompensated advanced CLD (DA-CLD, n=25). Circular ROIs (2.0–5.0 cm²) were placed on segments VI and VIII of the liver, spleen, and paraspinal muscle on hepatobiliary phase (20-minute) and unenhanced images (Figure 1). RLE, CUI, HUI, and LSI were computed using established formulas. Liver and spleen volumes were calculated using validated ellipsoid models. Kruskal-Wallis, Spearman correlation, and Dunn-Bonferroni post-hoc analyses were applied.

Results:

HUI (p=0.006), LSI (p=0.013), RLE (p=0.033), and spleen volume (p<0.001) differed significantly across disease stages, while CUI (p=0.120) and liver volume (p=0.165) did not (Figure 2). HUI and LSI showed consistent decreases from NA-CLD to both CA-CLD and DA-CLD (p<0.05), indicating progressive hepatocellular impairment (Figure 4). RLE exhibited significant decline only between CA-CLD and DA-CLD (p=0.027). Spleen volume was significantly higher in both CA-CLD and DA-CLD compared to NA-CLD (p<0.001). Spearman analysis revealed significant negative correlations

E-POSTER ABSTRACTS

between disease stage and both HUI ($p=-0.250$, $p=0.003$) and LSI ($p=-0.228$, $p=0.007$), and a positive correlation for spleen volume ($p=0.240$, $p=0.005$) (Figure 5). Strong inter-parameter correlations were found between RLE and CUI ($p=0.821$), and between HUI and LSI ($p=0.756$) (Figure 3).

Conclusions:

HUI and LSI demonstrated the strongest stage-dependent declines and monotonic associations with disease severity, indicating high sensitivity to progressive hepatocellular dysfunction. Spleen volume provided complementary structural insight into portal hypertension. In contrast, liver volume alone was not discriminatory. These findings support a parallel interpretation model integrating functional GA-MRI indices with splenic volumetry (Figures 3–6) to enhance non-invasive staging of chronic liver disease and potentially inform future multiparametric MRI-based risk stratification frameworks.

1571 - Impact of Hepatitis B Virus Infection on Surgical Conversion and Survival in Unresectable Hepatocellular Carcinoma Treated With TACE Targeted Therapy and PD 1 Inhibitors

Yuhao Su¹, Yuxin Liang¹, Deyuan Zhong¹, Xiaolun Huang¹

Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School Of Medicine, University Of Electronic Science And Technology Of China, Liver Transplantation Center And Hbp Surgery, Chengdu-China¹

Background / Hypothesis: Hepatitis B virus (HBV) infection is a predominant etiological driver of hepatocellular carcinoma (HCC), yet its potential influence on the efficacy of conversion therapy in patients with unresectable HCC (uHCC) remains poorly defined. Triple therapy consisting of transarterial chemoembolization (TACE), targeted agents, and PD-1 inhibitors has demonstrated promising downstaging potential. However, whether the unique viral-immune microenvironment of HBV-related HCC confers differential therapeutic benefit has not been systematically investigated. We hypothesized that HBV infection may modulate tumor immunobiology and angiogenic signaling, thereby enhancing responsiveness to triple therapy.

Materials and Methods: This retrospective single-center cohort study included 190 consecutive uHCC patients treated with triple therapy between February 2022 and February 2025. Patients were stratified into HBV-positive ($n = 133$) and HBV-negative ($n = 57$) groups based on HBsAg status. Propensity score matching (PSM, 1:1, caliper 0.02) was performed to balance baseline characteristics. The primary endpoint was surgical conversion. Secondary endpoints included tumor response (mRECIST), overall survival (OS), progression-free survival (PFS), and treatment-related adverse events (AEs).

Results: After PSM, 32 matched pairs were included. HBV-positive patients achieved significantly higher surgical conversion rates both before PSM (25.6% vs. 12.3%, $P = 0.041$) and after PSM (20% vs. 10%, $P = 0.021$). Tumor response was also superior in the HBV-positive group, with higher ORR (36.7% vs. 20%, $P = 0.043$) and DCR (83.3% vs. 60%, $P = 0.045$). HBV-positive patients exhibited significantly prolonged OS and PFS. After matching, median OS was not reached in the HBV-positive cohort but was 20 months in HBV-negative patients ($P = 0.014$). Median PFS was 28.4 vs. 17.3 months, respectively ($P = 0.030$). Tumor diameter ≥ 7 cm was the only independent predictor of OS (HR 3.64, $P = 0.019$) and PFS (HR 12.66, $P = 0.002$). Grade 3–4 AEs were comparable between groups, and no treatment-related deaths occurred.

Conclusions: HBV-positive patients receiving TACE combined with targeted therapy and PD-1 inhibitors achieve superior surgical conversion, enhanced tumor response, and improved survival compared with HBV-negative patients. HBV infection status may serve as a clinically meaningful factor for selecting candidates to benefit from conversion therapy in uHCC.

Keyword(s) : unresectable HCC; HBV infection; conversion therapy; TACE; tyrosine kinase inhibitor; PD-1 inhibitor; survival outcomes

1572 - Comparison of Long term Efficacy and Renal Safety between Entecavir and Tenofovir Alafenamide Fumarate in Treatment naive Patients with Chronic Hepatitis B

Ao Chen¹, Wenjia Shang¹, Xue Shi¹, Yushan Dai¹,

E-POSTER ABSTRACTS

Xinyi Tai ¹, Weiquan Xu ¹, Peng Chen ², Jianwei Jia ¹,
Liying Guo ¹, Jing Miao ¹
Tianjin Second People 's Hospita, Department Of
Traditional Chinese Medicine, Tianjin-China ¹ Tianjin
Second People 's Hospita, Integration Of Traditional
Chinese Medicine And Western Medicine, Tianjin-China
²

Background / Hypothesis:

To analyze the long-term virological efficacy and renal safety of entecavir (ETV) and tenofovir alafenamide fumarate (TAF) as first-line antiviral therapies in patients with chronic hepatitis B (CHB).

Materials and Methods:

A retrospective analysis was performed on CHB patients who received ETV or TAF treatment and completed ≥ 192 weeks of follow-up. Propensity score matching (1:1) was used to balance baseline data (age, sex, liver/renal function), resulting in 45 patients in each group. The Kaplan–Meier method was used to compare the cumulative incidences of renal dysfunction, low-level viremia (LLV), HBV DNA suppression, and HBeAg/HBeAb seroconversion. Intergroup differences were analyzed by the Log-rank test, hazard ratios (HR) were estimated by the Cox proportional hazards model, and repeated measures ANOVA was used to evaluate the dynamic changes in quantitative HBsAg and estimated glomerular filtration rate (eGFR).

Results:

After propensity score matching, the two groups were well-balanced in baseline characteristics (age, gender, liver/renal function). With prolonged treatment, the cumulative incidence of renal dysfunction gradually increased in both groups, with parallel survival curves and no significant difference ($\chi^2=0.032$, $P=0.858$; TAF vs. ETV HR=1.083, 95% CI, 0.44–2.66). The cumulative incidence of LLV also increased over time, which was slightly higher in the TAF group but not statistically significant ($\chi^2=0.415$, $P=0.520$; HR=1.233, 95% CI, 0.610–2.494). For HBV DNA suppression, the cumulative rates increased similarly in both groups ($P>0.05$) with a median time of 48 weeks (HR=1.063, 95% CI, 0.693–1.631). No significant differences were observed in HBeAg/HBeAb seroconversion rates between the two groups; the median time to HBeAb seroconversion was 96 weeks in both groups, while the median time to HBeAg seroconversion was 48 weeks in the ETV group and 96 weeks in the TAF group (HR=0.85, 95% CI, 0.51–1.42). HBsAg levels declined significantly over time in both groups ($P=0.001$).

0.001) with no intergroup differences. Baseline eGFR was similar between the two groups (≈ 109 mL/min-1.73m²) and showed a mild linear decline ($F=22.420$, $P<0.001$), with no significant intergroup variations at different time points.

Conclusions:

During approximately 192 weeks of real-world follow-up, both ETV and TAF as first-line antiviral therapies achieved similar HBV DNA suppression rates and HBeAg/HBeAb seroconversion rates, with comparable effects on lowering HBsAg quantitation. There were no significant differences between the two regimens in terms of the cumulative incidence of renal dysfunction and dynamic changes in eGFR, indicating overall favorable renal safety.

1574 - Aeromonas Infections in Hepatic Hospital Source Specific Distribution and Antimicrobial Resistance Profiles Over Two Decades

Zhen Cai ¹, Suming Chen ², Ranxing Zhang ²
Eye Hospital, China Academy Of Chinese Medical Sciences, The Clinical Laboratory, Beijing-China ¹ Fifth Medical Center Of Chinese Pla General Hospital, The Clinical Laboratory, Beijing-China ²

Background / Hypothesis:

Aeromonas species represent a serious threat to patients with hepatic disease, who are particularly vulnerable to bacterial infections due to immunocompromised status. However, comprehensive data focusing on Aeromonas infections specifically in this population remain scarce. This study aimed to investigate the clinical distribution and antimicrobial resistance patterns of Aeromonas species isolated from patients in hepatic hospital.

Materials and Methods:

We conducted a retrospective study at a tertiary liver hospital of Beijing from 2000-2023. Clinical data and microbiological results were extracted from the laboratory information system. Species identification and antimicrobial susceptibility testing were performed following standard protocols. Data analysis was completed using WHONET 5.6 and SPSS 22.0.

Results:

E-POSTER ABSTRACTS

A total of 408 *Aeromonas* strains were identified between 2000 and 2023. Among 197 patients with clearly documented clinical data, 91.4% (180/197) had underlying liver diseases, including cirrhosis, hepatocellular carcinoma, biliary tract disorders, and HBV/HCV-related liver infections. The predominant species were *A. hydrophila* (36.52%), *A. veronii* bv *sobria* (30.88%), and *A. caviae* (27.45%). Bloodstream infections were the most common (46.6%), followed by ascites (28.1%), bile (8.8%), stool (7.1%), hydrothorax (6.0%), and sputum (3.4%). Notably, *A. hydrophila* was the predominant species in bloodstream infections (47.6%), significantly higher than in ascites, bile, stool, and hydrothorax. In ascites, *A. veronii* bv *sobria* (46.5%) was most frequent, while *A. caviae* dominated in bile (66.7%), stool (51.6%), and hydrothorax (44.0%). Bloodstream isolates exhibited lower resistance rates to most antibiotics compared to ascites isolates. Regarding species-specific AMR, *A. caviae* demonstrated higher resistance to ceftazidime (CAZ), cefepime (FEP), piperacillin/tazobactam (TZP), aztreonam (ATM), and levofloxacin (LVX) than *A. hydrophila* and *A. veronii* bv *sobria*. In contrast, *A. veronii* bv *sobria* showed the lowest resistance rates overall.

Conclusions: In patients with hepatic disease, *Aeromonas* species exhibit distinct clinical distributions and antimicrobial resistance patterns based on infection sources. Source-specific predominance was observed, with *A. hydrophila* in blood, *A. veronii* bv *sobria* in ascites, and *A. caviae* in biliary and abdominal sources. The higher resistance in non-bloodstream isolates and significant inter-species variation underscore the need for tailored antimicrobial strategies in this high-risk population.

Keyword(s) : *Aeromonas*, antimicrobial resistance, liver disease, clinical distribution

1575 - Metastatic Hepatic Pleomorphic Liposarcoma with Ruptured vascular mass A case report

Debby Grace Jardiolin¹, Angela Salvaña¹
Philippine General Hospital, Gastroenterology, Manila-Philippines¹

Background / Hypothesis:

Pleomorphic liposarcoma is a rare subtype of liposarcoma, accounting for less than 5% of all liposarcoma cases and representing one of the most aggressive forms of soft tissue sarcoma.¹ While liposarcomas primarily occur in the extremities and

retroperitoneum, hepatic involvement is exceedingly rare, with only a handful of cases reported in the literature.² The liver, being a vascular organ, presents a unique set of challenges when sarcomas metastasize or originate within it. These tumors are often diagnosed at advanced stages due to their asymptomatic nature in early phases and the nonspecificity of initial symptoms such as epigastric pain, anorexia, and nausea.

Materials and Methods:

This case report describes a 25-year-old male presenting with metastatic hepatic pleomorphic liposarcoma complicated by a ruptured vascular mass and systemic metastases. The patient initially experienced nonspecific symptoms, including epigastric pain, anorexia, and nausea, leading to delayed diagnosis. Imaging revealed a large, vascular hepatic mass with evidence of capsular rupture, while histopathology confirmed a high-grade pleomorphic liposarcoma.

Results:

The management of this case focused on controlling the complications arising from the advanced stage of pleomorphic liposarcoma of the liver, including tumor rupture, obstructive jaundice, and systemic metastases. The primary therapeutic intervention was transarterial embolization (TAE), performed in two separate sessions, to manage the vascular nature of the hepatic tumor and prevent further hemorrhage.

Conclusions: The case underscores the complexities of managing hepatic sarcomas, including the use of transarterial embolization to control vascular rupture and the challenges of addressing systemic metastases. While some studies have explored the role of embolization and surgical interventions in managing liver sarcomas, their effectiveness remains variable.⁷ This case contributes to the growing body of literature on pleomorphic liposarcoma, offering insights into its clinical course, radiological findings, and therapeutic challenges.

Keyword(s) : liposarcoma, liver, TACE

1577 - Long Term HBsAg Kinetics and Prognostic Significant in Patients with Compensated Cirrhosis A 13 year Prospective Cohort on Entecavir Therapy

Mingyue Ma¹, Xinyu Liu¹, Hui Ma¹, Bo Feng¹, Qian Jin

E-POSTER ABSTRACTS

¹, Danli Ma ¹, Yandi Xie ¹

Peking University People's Hospital, Peking University
Hepatology Institute, Beijing-China ¹

Background / Hypothesis: Hepatitis B surface antigen (HBsAg) levels in patients with chronic hepatitis B (CHB) reflect disease activity and are predictive of long-term outcomes. However, most existing studies are limited to approximately 5 years of follow-up and rely on a narrow set of serological markers, making it difficult to characterize the long-term kinetics of HBsAg and its prognostic significance during nucleos(t)ide analogue (NA) therapy. This study established a prospective cohort with up to 13 years of follow-up to evaluate the association between baseline HBsAg levels and clinical prognosis, and to delineate the long-term trajectory of HBsAg over time.

Materials and Methods: From 2012 to 2013, 50 treatment-naïve patients CHB patients with compensated cirrhosis receiving entecavir (ETV) treatment were enrolled and followed semi-annually. Serial data included HBsAg, HBeAg, multiple laboratory and imaging parameters, and records of long-term clinical events (LREs), defined as hepatic decompensation, hepatocellular carcinoma, or liver-related death. HBsAg kinetics were analyzed using a linear mixed-effects model, HBeAg changes with generalized estimating equations, and prognosis with the Kaplan–Meier analysis and Cox regression models.

Results: Over the 13-year period, HBsAg levels demonstrated a steady and continuous decline, with an average annual reduction of 24.4%, representing the most consistent and time-dependent serological markers. Among ? patients who were HBeAg-positive at baseline, HBeAg seroconversion rates were ?% and ?% at years 5 and 10, respectively. Virological response (VR, defined as HBV DNA < 10 IU/mL) was achieved in 67.3% (33/49) of patients at 6 months and 85.7% (42/49) at 1 year. Regarding clinical outcomes, patients with baseline HBsAg < 1000 IU/mL exhibited significantly higher LRE-free survival ($p = 0.013$), indicating that lower initial HBsAg levels are associated with improved long-term clinical stability.

Conclusions: This 13-year ultra-longitudinal study

systematically confirms two key characteristics of HBsAg during antiviral therapy: (1) HBsAg levels demonstrate a sustained decline over time, serving as the most stable kinetic marker of long-term treatment response; and (2) patients with lower baseline HBsAg levels experience better clinical outcomes and higher LRE-free survival. These findings provide an important foundation for individualized risk stratification and treatment efficacy evaluation in CHB patients with compensated cirrhosis.

Keyword(s): Hepatitis B, HBsAg Kinetics, Compensated Cirrhosis

1578 - Construction of a Predictive Model for Adverse Outcomes in Patients with Acute Decompensated Cirrhosis Based on PBMC Transcriptomic Analysis

Zelu Meng ¹, Jiyang Chen ¹, Ying Nie ¹, Yani Zhou ¹, Siqi Sun ¹, Yining Zhang ¹, Yu Shi ¹, Yida Yang ¹
The First Affiliated Hospital, Zhejiang University School Of Medicine, Zhejiang University School Of Medicine, Zhejiang-China ¹

Background / Hypothesis:

The PREDICT study described three subtypes of acute decompensated cirrhosis (AD) with different pathophysiology and prognosis: stable decompensated cirrhosis (SDC), unstable decompensated cirrhosis (UDC) and pre-acute-on-chronic liver failure (pre-ACLF). The mortality rates of patients with different subtypes vary. Among them, the one-year mortality rate of SDC patients is the lowest (about 10%), while that of UDC and pre-ACLF patients is as high as 36% and 67% respectively. Therefore, there is an urgent need to identify high-risk AD patients early and intervene for them in a timely manner.

Materials and Methods:

Based on the inclusion and exclusion criteria and the completeness of the 90-day follow-up outcome, a total of 163 AD patients were ultimately included and divided into the recovery group (no readmission due to decompensation during the 90-day follow-up period) and the non-recovery group (readmission due to decompensation or progression to ACLF or death during the 90-day follow-up period). Peripheral blood was collected within 24 hours of their first admission and transcriptomic analysis of PBMCs was subsequently performed between the two groups. The random forest and the Least Absolute Shrinkage and Selection Operator (LASSO) regression were adopted for feature gene screening and to construct the

E-POSTER ABSTRACTS

prediction model.

Results:

PBMC transcriptome sequencing analysis revealed 165 DEGs between the recovery group and the non-recovery group. Nine key genes (FOXC1, TPD52, NOS1AP, SPRY2, TIFAB, MANSC1, AP3B2, ROBO4, HLA-DQA1, TPST1) were screened out through random forest and LASSO regression. A prediction model with good accuracy (AUC=0.82), calibration and practicability was constructed, which was superior to the traditional MELD-Na (AUC=0.579) and CLIF-C AD (AUC=0.617) scores.

Conclusions:

The predictive model constructed using the 9 key DEGs screened by LASSO regression can effectively guide the risk stratification of AD patients, and this model can be used as an auxiliary tool for evaluating the prognosis of AD patients.

1579 - Comparative Outcomes of Subsequent Line Therapies Following First Line Atezolizumab Plus Bevacizumab for Advanced Hepatocellular Carcinoma in a High Volume Korean Center

Ye Rim Kim¹, Jiwon Yang¹, Dongman Yu¹, Yeongseok Hwang¹, Jihyun An², Han Chu Lee¹, Ju Hyun Shim¹
Asan Medical Center, Gastroenterology, Seoul-South Korea¹ Hanyang University, Gastroenterology, Seoul-South Korea²

Background: While first-line therapy for advanced hepatocellular carcinoma (HCC) is well established, optimal subsequent-line treatment after immunotherapy remains unclear and varies widely across centers. We analyzed the patterns and outcomes of second- to fourth-line systemic therapies following first-line atezolizumab plus bevacizumab in a high-volume tertiary center.

Methods: We analyzed data from 353 patients with advanced HCC who underwent subsequent treatment after failure of 3 or more cycles of first-line atezolizumab plus bevacizumab initiated between May 2022 and December 2023 at a high-volume tertiary center in Korea. Overall survival (OS) and progression-free survival (PFS) were evaluated using the Kaplan-Meier method, and differences between treatment groups were compared using the log-rank test.

Results: Tyrosine kinase inhibitors (TKIs) constituted the majority of subsequent-line systemic therapies. In the second-line setting, lenvatinib (n=174, 49.3%) and sorafenib (n=114, 32.3%) were most frequently used, with no use of immune checkpoint inhibitors (ICIs). Sorafenib was the leading therapy (n=85, 52.1%) in the third-line setting, followed by regorafenib (n=43, 26.4%), and ICIs (n=11, 6.7%). In the fourth-line setting, regorafenib was most commonly administered (n=40, 44.9%), followed by nivolumab (n=22, 24.7%) and cabozantinib (n=12, 13.5%). Among second-line therapies, lenvatinib showed longer median OS (9.5 vs 8.3 months; HR 1.17, 95% CI 0.87–1.58, p=0.30) and significantly longer median PFS (5.3 vs 2.8 months; HR 1.55, 95% CI 1.19–2.02, p=0.001) compared with sorafenib. In the third-line setting, TKIs (n=136) and ICIs (n=11) demonstrated similar outcomes, with comparable median OS (6.9 vs 4.0 months; HR 1.86, 95% CI 0.80–4.32, p=0.15) and median PFS (1.7 vs 1.8 months; HR 1.05, 95% CI 0.56–1.95, p=0.88). In the fourth-line setting, outcomes for TKIs (n=57) and ICIs (n=21) were likewise similar in median OS (5.6 vs 5.5 months; HR 1.00, 95% CI 0.54–1.85, p=0.99) and median PFS (1.9 vs 1.8 months; HR 0.85, 95% CI 0.51–1.41, p=0.53).

Conclusions: TKIs were the predominant subsequent-line therapies after first-line atezolizumab plus bevacizumab, with lenvatinib showing superior PFS compared with sorafenib in second-line setting. Beyond second line, TKIs and ICIs demonstrated similar survival outcomes. These real-world treatment patterns highlight the need for multi-center prospective studies to guide optimal post-immunotherapy sequencing.

Keyword(s) : Hepatocellular carcinoma, Immunotherapy, Subsequent-line therapy, Treatment sequencing, Real-world data

1582 - Proteomic Profiling and Clinical Correlation of Prognostic Proteins in Advanced Hepatocellular Carcinoma with Hyperbilirubinemia

Jianing Wang¹, Chuyue Xiong¹, Fanping Meng¹
Peking University, Health Science Center, Beijing-China¹

Background / Hypothesis:

This study focused on patients with advanced hepatocellular carcinoma (HCC), aiming to analyze differentially expressed proteins and their enriched pathways in the baseline serum of patients with hyperbilirubinemia compared to those with normal

E-POSTER ABSTRACTS

total bilirubin (TBil) levels, and to investigate the role of key regulatory proteins in HCC progression by integrating prognostic information.

Materials and Methods:

A total of 72 HCC patients receiving targeted immunotherapy were enrolled and stratified into a hyperbilirubinemia group (n=28) and a normal TBil group (n=44) based on TBil levels. Proteomics technology was employed to compare baseline differential proteins between the groups, followed by functional enrichment analysis and protein-protein interaction (PPI) network construction. Cox regression analysis was conducted in the hyperbilirubinemia group, and key proteins were validated through survival analysis.

Results:

Baseline differential protein analysis identified 35 upregulated proteins (including IL-17A) and 1 downregulated protein. KEGG pathway enrichment revealed that these proteins were primarily involved in the cytokine-cytokine receptor interaction pathway. The Cox regression model assessed the prognostic value of IL-17A, and survival analysis demonstrated a significantly shorter median overall survival in the high IL-17A expression group (HR=3.15, 95% CI: 1.17-8.46, P=0.023), indicating that IL-17A is an independent predictor of poor prognosis.

Conclusions: High IL-17A expression is significantly associated with poor prognosis in HCC patients with hyperbilirubinemia, serving as both a prognostic biomarker and a potential therapeutic target.

1583 - Effect Of Polyethylene Glycol Versus Lactulose on Hepatic Encephalopathy In Patients With Liver Cirrhosis A Randomized Clinical Trial (PEG HE Trial)

Om Parkash¹, Shahab Abid¹, Mahrukh Ali¹, [Abhishek Lal¹](#), Saeed Hamid¹
Aga Khan University, Medicine, Karachi-Pakistan¹

Background / Hypothesis:

Hepatic encephalopathy is a prevalent complication of liver cirrhosis being responsible for significant morbidity and mortality. Lactulose remains the gold standard treatment for liver cirrhosis; however, its use

is limited by refractory effectiveness and adverse effects. Polyethylene glycol is emerging to be a potential alternative therapy. This study aimed to compare effectiveness and safety of PEG and lactulose in patients hospitalized with HE.

Materials and Methods:

This randomized controlled trial, with parallel group was conducted at Aga Khan University, Karachi, Pakistan. Eligible patients were randomized to receive either PEG or lactulose. The primary outcome was resolution of HE with ≥ 1 -grade reduction in HESA score at 24, 48, and 72 hours. The secondary outcomes were the length of hospital stay, adverse events, readmissions, and three-months mortality.

Results:

A total of 55 patients were enrolled. Patients receiving PEG and lactulose achieved comparable effectiveness in resolution of HE in 72 hours (p-value = 0.7232). At 24 and 48 hours, both PEG and lactulose achieved similar HESA scores demonstrating comparable effectiveness in resolving HE, although not statistically significant (p-value = 0.2605, p-value = 0.5222). The lower bounds of the 95% confidence intervals for risk differences continuously stayed above the 10% threshold, indicating that PEG was non-inferior to lactulose at all timepoints. No adverse events were reported in both groups, with similar readmissions and three-month mortality.

Conclusions:

PEG was found to be effective in resolving HE with initial improvement in symptoms and safety profile. PEG presents to be a viable alternative to lactulose for HE management, although long-term studies with larger sample sizes are warranted.

1584 - Drug related hepatic steatosis associated with antineoplastic drugs A pharmacovigilance study from the FDA adverse event reporting system (FAERS)

[Yanjie Lin¹](#), Guiqiang Wang¹, Hong Zhao¹
Peking University First Hospital, Department Of Infectious Disease, Center For Liver Disease, Beijing-China¹

Background / Hypothesis:

E-POSTER ABSTRACTS

Since drug-induced hepatic steatosis is relatively rare but closely related to adjusting the treatment of the primary disease, preventing liver steatosis and its inflammation. This study investigated the risk factors of drug-induced hepatic steatosis by analyzing a large dataset from the FDA Adverse Event Reporting System (FAERS).

Materials and Methods:

The reporting odds ratios (ROR) and information component (IC) were used to evaluate the reports of hepatic steatosis from the first quarter of 2004 to the third quarter of 2024. Univariate, LASSO and multivariate regression analyses were used to explore the risk factor. Moreover, the time to onset of hepatic steatosis was also assessed.

Results:

Overall, 16,767 cases related to fatty liver disease were found in FAERS. In total, 117 drugs were found to be associated with hepatic steatosis, with antineoplastic drugs (28/117), antiviral drugs (18/117), psychotropic drugs (17/117), and immunomodulatory drugs (12/117) being the most common. Age under 41 years old, a heavier weight and 13 different drugs, including 3 antineoplastic drugs of interest, namely Methotrexate, Pegaspargase, and Tamoxifen, were risk factors for hepatic steatosis. The median time to onset was 123.50 days, while the onset of Pegaspargase was faster, with a median time of only 19 days ($P < 0.001$).

Conclusions:

With the increasing variety of drugs, it's necessary to focus on hepatic steatosis and steatohepatitis caused by drugs, and adjust the therapeutic drugs in a timely manner to reduce the incidence of liver fibrosis, liver cirrhosis and prevent the interruption of treatment for the primary disease.

Keyword(s) : drug-induced hepatic steatosis, antineoplastic drugs, pharmacovigilance, FAERS, adverse events

1585 - 20(s) ginsenoside Rg3 inhibits hepatocellular carcinoma via akkermansia driven regulation of intestinal microbiota and bile acid metabolism

Xuemei Zhang ¹, Hai Feng ¹, Zhuo Yu ¹

Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Department Of Liver Disease, Shanghai-China ¹

Background / Hypothesis:

Hepatocellular carcinoma (HCC) remains a leading cause of cancer-related mortality worldwide. The gut-liver axis is increasingly recognized as a critical regulator of HCC pathogenesis. We hypothesized that 20(S)-ginsenoside Rg3, a bioactive component of ginseng, exerts anti-HCC effects by promoting Akkermansia-driven modulation of intestinal microbiota and bile acid metabolic homeostasis, thereby enhancing natural killer (NK) cell function.

Materials and Methods:

HCC models were established via Hepa1-6 cell orthotopic inoculation in C57BL/6 mice, which were treated with 20(S)-ginsenoside Rg3 or PBS by gavage. Germ-free (GF) mice, fecal microbiota transplantation (FMT), and antibiotic depletion experiments validated gut microbiota dependence. 16S rRNA sequencing, targeted metabolomics, RNA sequencing, Western blotting, and flow cytometry were used to analyze microbiota composition, bile acid profiles, and NK cell function.

Results:

20(S)-ginsenoside Rg3 significantly reduced HCC tumor burden without altering mouse weight or directly affecting HCC cell viability. It localized primarily in the intestinal lumen, and its anti-HCC effects were abrogated in GF and antibiotic-treated mice but restored by FMT from Rg3-treated mice. Rg3 dose-dependently promoted Akkermansia growth, which synergistically enhanced anti-HCC efficacy. Moreover, Rg3 increased intestinal and serum ursodeoxycholic acid levels and activated the PI3K/AKT/mTOR pathway to enhance NK cell function.

Conclusions:

20(S)-ginsenoside Rg3 inhibits HCC through the gut microbiota-Akkermansia-bile acid axis, which activates the TGR5/PI3K/AKT pathway to enhance NK cell-mediated anti-tumor immunity. This study provides a promising therapeutic strategy for HCC.

1586 - Construction and validation of a nomogram for predicting survival in hepatocellular carcinoma patients with hyperbilirubinemia receiving targeted immunotherapy

Jianing Wang ¹, Chuyue Xiong ¹, Fanping Meng ¹

E-POSTER ABSTRACTS

Peking University, Health Science Center, Beijing-China

1

Background / Hypothesis:

To construct a nomogram prediction model for predicting the 3-, 6-, and 12-month survival rates of patients with hepatocellular carcinoma (HCC) accompanied by hyperbilirubinemia undergoing targeted immunotherapy and to evaluate its predictive efficacy.

Materials and Methods:

A retrospective analysis was conducted on 203 patients with HCC accompanied by hyperbilirubinemia who received targeted immunotherapy at The Fifth Medical Center of Chinese PLA General Hospital from June 2020 to September 2024. Overall survival (OS) was calculated based on post-discharge follow-up results, and clinical data were compared between the death and survival groups. Univariate and multivariate Cox regression analyses were used to identify significant variables. A nomogram prediction model for survival prognosis was constructed using R software. The predictive efficacy of the nomogram was comprehensively evaluated and validated by calculating the concordance index (C-index), area under the receiver operating characteristic (ROC) curve (AUC), calibration curves, decision curve analysis (DCA), and risk stratification analysis.

Results: Univariate regression analysis showed that baseline alpha-fetoprotein (AFP) level, baseline total bilirubin (TBil) level, TBil decline within one week, baseline aspartate aminotransferase (AST) level, and Child-Pugh classification were associated with patient survival time. Multivariate Cox regression analysis revealed that baseline AFP level and Child-Pugh classification were independent risk factors for survival time. Based on considerations of clinical utility and comprehensiveness of the predictive model, the study adopted a variable selection strategy grounded in clinical importance. Five variables were included in the final model: baseline AFP level, baseline TBil level, TBil decline within one week, baseline AST level, and Child-Pugh classification. The nomogram demonstrated a C-index of 0.725 (95% CI: 0.674–0.776). The AUC values for predicting 3-, 6-, and 12-month OS were 0.786, 0.786, and 0.821, respectively. Calibration curves and DCA indicated good consistency and strong clinical utility. Risk stratification based on the total model score showed significant differences in OS among low-,

medium-, and high-risk patients ($P < 0.0001$).

Conclusions: The nomogram prediction model, incorporating baseline AFP level, baseline TBil level, TBil decline within one week, baseline AST level, and Child-Pugh classification, has good predictive value for survival in patients with HCC accompanied by hyperbilirubinemia and can serve as a reference for prognostic assessment.

1590 - Decoding the Genetic Overlap A Pathway to Early Diagnosis of AKI in Cirrhotic Patients

Ning Wang¹

Tianjin Third Central Hospital, Department Of Gastroenterology And Hepatology, Tianjin-China¹

Background / Hypothesis: Acute kidney injury (AKI) is a common and serious complication in patients with cirrhosis, characterized by high morbidity and mortality. The causes of AKI in cirrhotic patients include renal hypoperfusion due to volume depletion, acute tubular necrosis, and hepatorenal syndrome. Clinically, renal injury in these patients is often overlooked, and the onset of hepatorenal syndrome typically indicates progression to an end-stage condition. Therefore, early identification and increased attention to acute kidney injury in cirrhotic patients are of great importance. This study aims to identify shared genetic signatures between cirrhosis and AKI, which may contribute to the early detection of renal impairment in this patient population.

Materials and Methods: Based on transcriptomic data analysis, common differentially expressed genes (DEGs) between cirrhosis and AKI were identified. Subsequent analyses included gene correlation analysis, functional enrichment analysis, and receiver operating characteristic (ROC) analysis of the candidate genes. Finally, the subgroup analysis of cirrhosis patient samples was performed based on the candidate genes.

Results: Compared with the control group, 115 DEGs were identified in cirrhosis patients, of which 98 genes were up-regulated and 17 genes were down-regulated. Meanwhile, 55 DEGs were obtained from AKI patients, including 32 up-regulated and 23 down-regulated

E-POSTER ABSTRACTS

genes. Ultimately, a total of 9 common DEGs between cirrhosis and AKI were identified (COLEC11, HAO2, ADAMTS1, RGS2, S100A8, CNDP1, NQO1, LCN2, AKR1B10). Functional analysis of these candidate genes indicated significant enrichment in metabolic pathways. ROC analysis demonstrated that the candidate genes exhibited high predictive performance in both cirrhosis and AKI cohorts, suggesting their potential as shared diagnostic biomarkers for cirrhosis and AKI. In addition, two distinct subgroups (C1 and C2) were identified in cirrhosis patients. Comparing the two subgroups, 215 DEGs were acquired, including 174 up-regulated and 41 down-regulated genes.

Conclusions: This study successfully identified the shared gene signatures between liver cirrhosis and AKI, which contributed to the early identification of AKI in cirrhotic patients.

1591 - Circulating Hypermethylated RASSF1A as a Possible Marker of Hepatocellular Carcinoma in Chronic HCV patients

Mohamed Abdel-samee¹, Mona Hassona², Nevine F. Shafik³, Suzanne Estaphan⁴, Sarah Ismail⁵, Mary Naguib², Eman Abdelsameea¹

National Liver Institute, Menoufia University, Hepatology And Gastroenterology, Shebin El-kom-Egypt¹ National Liver Institute, Menoufia University, Clinical Pathology, Shebin El-kom-Egypt² National Cancer Institute, Menoufia University, Clinical Pathology, Cairo-Egypt³ Faculty Of Medicine, Physiology, Cairo-Egypt⁴ Faculty Of Medicine, Clinical Pathology, Cairo-Egypt⁵

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is a global health problem and the fourth leading cause of cancer-related deaths worldwide. The carcinogenic role of methylation, a critical epigenetic modification, is well known in HCC. Thus, in this study, we aimed to assess the role of plasma level of methylated RASSF1A in post hepatitis C virus (HCV) cirrhotic patients as a non-invasive diagnostic marker for HCC.

Materials and Methods:

The levels of methylated RASSF1A were determined in plasma of 120 participants who were classified to three groups (40 participants each); HCC patients on top of

chronic HCV infection, post hepatitis C cirrhotic patients without HCC in addition to healthy matched age and sex control group. Methylation-sensitive restriction enzyme digestion and real-time quantitative polymerase chain reaction method was employed to measure the expression level of RASSF1A.

Results:

Patients with HCC exhibited significantly higher levels of circulating hypermethylated RASSF1A than post hepatitis C patients and control groups. In addition, a statistically significant correlation between RASSF1A and the different clinico-pathological parameters was observed. The receiver operating characteristic curves plotted showed that plasma RASSF1A helped in significant differentiation between HCC and cirrhotic patients.

Conclusions:

Circulating hypermethylated RASSF1A could be a non-invasive diagnostic marker for discriminating HCC among post HCV cirrhotic patients and characterizing their progression.

Keyword(s) : circulating DNA; hypermethylation; RASSF1A; liquid biopsy; hepatocellular carcinoma

1593 - Geniposide alleviates ALD by reducing CXCR2+neutrophil infiltration through inhibiting FKBP5 CXCL1 signaling pathway

Junhua Feng¹, Yiwen Hou¹, Longshan Ji¹, Yueqiu Gao¹, Man Li¹

Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Shanghai Key Laboratory Of Traditional Chinese Clinical Medicine, Shanghai-China¹

Background / Hypothesis: Alcohol-associated liver disease (ALD) is a major cause of liver transplantation and death worldwide, contributing significantly to liver cirrhosis and hepatocellular carcinoma, with limited effective treatment options. Geniposide (GEN) is one of the important active ingredients from Zhizi Dahuang Decoction (ZZDHD), a classic traditional Chinese medicine formula for the treatment of ALD. This study aimed to investigate the effects of GEN treating ALD, and to explore its underlying mechanisms in ALD.

Materials and Methods: NIAAA model was built to evaluate effects of GEN treating ALD. Anti-Ly6G antibody was used to deplete neutrophils in NIAAA

E-POSTER ABSTRACTS

model. Adeno-associated virus (AAV)-mediated overexpression model of CXCL1 was generated. Single-cell transcriptomics and transcriptome sequencing were conducted to screen the regulatory mechanism. Oil-Red O staining was employed to evaluate lipid deposition. A series of in vitro assays, including cell viability, transwell migration, tunnel were employed. Protein expression levels were analyzed by western blotting and immunofluorescence.

Results: ZSDHD administration and GEN reduced hepatic damage, lipid accumulation and oxidative stress in NIAAA model mice. ZSDHD and GEN reduced neutrophil infiltration in the liver. Analytic results from single-cell transcriptomics showed that CXCR2+neutrophils were recruited in livers of NIAAA model, and the expression levels of CXCL1 and FKBP5 in hepatic cells were increased in NIAAA model. Ethanol treatment promoted the secretion of CXCL1 in AML12 cells, facilitating neutrophil migration, which is partially restored by GEN administration. In addition, hepatocytic apoptosis was reduced by GEN. Overexpression of CXCL1 contributed to the migration of neutrophils and hepatocytic apoptosis, and eliminated the effective effects of GEN treating ALD. FKBP5 and the downstream signaling molecules were inhibited by GEN, which was correlated with CXCL1 expression.

Conclusions: GEN alleviated ALD by reducing hepatocytic apoptosis via inhibiting FKBP5/CXCL1 mediated CXCR2+neutrophil recruitment. These results highlight the potential of GEN as a novel therapeutic agent for the treatment of ALD.

Funding: This work was supported by the National Natural Science Foundation of China (No.82574840).

1594 - A machine learning model for predicting hepatocellular carcinoma in patients with MASLD

Han Ah Lee¹, Young Youn Cho¹, Hyung Joon Kim¹, Seung Up Kim², Jeong-hoon Lee²

Chung-ang University, Internal Medicine, Seoul-South Korea¹ Seoul National University, Internal Medicine And Liver Research Institute, Seoul-South Korea²

Background/Hypothesis: The risk of hepatocellular carcinoma (HCC) is significantly elevated in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). This study aimed to develop and

validate a machine learning model for predicting HCC in a large, multicenter MASLD cohort.

Materials and Methods: A total of 18,484 MASLD patients from six Korean hospitals (2001–2022) were included after data preprocessing. Patients from Severance Hospital were divided into a training cohort (n=3,721) and an internal validation cohort (n=4,370), while patients from the remaining institutions comprised the external validation cohort (n=10,393). To account for substantial differences in HCC incidence among hospitals, two additional external validation subsets were created: external set 2 excluding institutions with markedly high incidence, and external set 3 including only those institutions. Four machine learning algorithms—gradient boosting machine (GBM), random survival forest (RSF), deep neural network (DNN), and survival support vector machine (surv-SVM)—were developed using 12 variables selected from prior evidence and multivariable Cox regression results. Model performance was compared using the C-index, AUROC, AUPRC, sensitivity, specificity, and F1 score across all cohorts.

Results: During a median follow-up of 51.6 months, 357 HCC events occurred (incidence: 0.45 per 100 person-years). GBM demonstrated the strongest performance in the training cohort (C-index 0.95, AUROC 0.98, AUPRC 0.36), with well-balanced sensitivity (0.93) and specificity (0.97). Internal validation confirmed stable performance (C-index 0.90, AUROC 0.89, AUPRC 0.19), outperforming RSF and the Cox-based scoring model. External validation sets 1–3 consistently supported the robustness of GBM, with AUROCs ranging from 0.83 to 0.89, C-indices from 0.82 to 0.88, and AUPRCs from 0.19 to 0.25, indicating superior discrimination in imbalanced data. SHAP analysis identified liver cirrhosis, age, diabetes, LDL-cholesterol, and antihypertensive medication use as major contributors to increased HCC risk, while higher platelet count and albumin were associated with decreased risk.

Conclusions: This multicenter study developed and validated a GBM-based machine learning model using 12 readily available clinical variables for predicting HCC in MASLD patients. The model demonstrated consistently strong performance across internal and multiple external validation cohorts, exceeding that of traditional Cox-based approaches. Although external validation in non-Korean populations and prospective evaluation of clinical utility remain necessary, the GBM model provides a promising foundation for future individualized HCC surveillance strategies in MASLD.

1595 - Development and validation of a non invasive model for predicting advanced liver fibrosis in patients with metabolic dysfunction associated fatty liver disease and dysglycemia

Xuejie Zhang¹, Feixiang Xiong¹, Dandan Chen¹, Jialiang Chen¹, Yang Zhou¹, Tong Wu¹, Xiaoming Ji¹, Yuyong Jiang¹, Yixin Hou¹

Beijing Ditan Hospital, Capital Medical University, Center Of Integrative Medicine, Beijing-China¹

Background / Hypothesis:

The confluence of metabolic dysfunction-associated fatty liver disease (MAFLD) and dysglycemia delineates a high-risk subgroup characterized by a substantially increased likelihood of progressive liver fibrosis. This study aimed to develop and validate a novel, parsimonious non-invasive model for the accurate prediction of advanced fibrosis (stage F3–F4) in this at-risk population.

Materials and Methods:

A retrospective analysis was conducted in 606 consecutive adults with biopsy-proven MAFLD and dysglycemia from Beijing Ditan Hospital (2010–2025). The cohort was randomly split into training (n=424) and validation (n=182) cohorts. Variable selection was performed via multivariable logistic regression. Model performance was rigorously evaluated for discrimination (AUC), calibration, and clinical utility (DCA), including a head-to-head comparison with FIB-4 and APRI.

Results:

Three variables were identified as independent predictors of advanced fibrosis: body mass index (BMI) (adjusted odds ratio [aOR] 1.40 per 1 kg/m² increase, 95% CI 1.30–1.51; P < 0.001), alanine aminotransferase (ALT) (aOR 1.01 per 1 U/L increase, 95% CI 1.01–1.01; P < 0.001), and white blood cell count (WBC) (aOR 1.15 per 1 × 10⁹/L increase, 95% CI 1.01–1.31; P = 0.035).

The resulting model demonstrated exceptional discrimination, with an area under the curve (AUC) of 0.87 (95% CI 0.84–0.91) in the training cohort and 0.91 (95% CI 0.87–0.95) in the validation cohort. It significantly outperformed both FIB-4 and APRI across all performance metrics, exhibited excellent calibration, and provided superior net clinical benefit across a wide range of risk thresholds. The model demonstrated

robust generalizability across subgroups stratified by sex, BMI, and other metabolic factors, with consistently high AUCs (all >0.85).

Conclusions:

We developed a highly accurate and validated non-invasive model based on BMI, ALT, and WBC for predicting advanced fibrosis in patients with MAFLD and dysglycemia. Its simplicity and reliance on readily available parameters render it ideally suited for deployment in primary care and diabetology settings, where it could refine risk stratification and guide specialist referrals.

1597 - Glycyrrhizin Preparations in Liver Diseases A Systematic Review of Mechanisms and Therapeutic Potential

Tianyu Ma¹, Yao Xie¹, Minghui Li¹

Capital Medical University, Hepatic Department, Beijing-China¹

Glycyrrhizin preparations, derived from the traditional Chinese medicine licorice, are important hepatoprotective agents in modern liver disease treatment. Their main active components include 18 α - and 18 β -glycyrrhetic acid, with representative drugs such as diammonium glycyrrhizinate, compound glycyrrhizin, and magnesium isoglycyrrhizinate. This review systematically elaborates on the pharmacokinetic characteristics of glycyrrhizin preparations and their multi-target pharmacological mechanisms, including anti-inflammatory, membrane-stabilizing, antioxidant, anti-apoptotic, and immunomodulatory effects. It also comprehensively reviews clinical evidence and efficacy in various liver diseases, such as viral hepatitis, drug-induced liver injury, alcoholic liver disease, non-alcoholic fatty liver disease, and autoimmune liver disease. Additionally, the safety profile, particularly the management of pseudoaldosteronism and drug interactions, is discussed. Finally, future research directions are outlined to provide a theoretical basis and practical reference for rational clinical use.

Budd-Chiari Syndrome and Predictive Factors for Recanalization

Auteurs : Souili, borahma, chabib, lagdali, ajana, kadiri

Introduction:

Budd-Chiari syndrome (BCS) is a rare but severe vascular liver disorder caused by obstruction of the hepatic veins and/or inferior vena cava, leading to potentially life-threatening portal hypertension complications. Diagnosis relies primarily on imaging, and management follows a stepwise approach from medical therapy to interventional procedures. Some patients experience spontaneous recanalization with medical treatment alone. This study aimed to analyze the clinical, biological, and radiological characteristics of BCS patients in our department and identify factors predictive of recanalization.

Materials and Methods:

We conducted a retrospective, monocentric, descriptive, and analytical study at the Gastroenterology Department in ibn sina hospital, Rabat, including patients diagnosed with BCS between 1995 and 2025. Data were collected from medical records and analyzed using Jamovi software.

Results:

A total of 38 patients were included (mean age 32 years; F/M ratio 4.5:1). Hypertension was the most frequent comorbidity (18%). Hepatic risk factors were identified in 29% of patients. The most common presenting symptoms were abdominal distension (50%), asthenia (45%), jaundice (32%), and upper gastrointestinal bleeding (26%). On examination, ascites was present in 61%, collateral venous circulation in 66%, splenomegaly in 42%, and liver abnormalities in 53%. Imaging revealed hepatic vein obstruction in 84%, inferior vena cava obstruction in 34%, and chronic liver disease features in 63%. Liver tests showed cholestasis in 68%, cytolysis in 42%, and hepatocellular insufficiency in 42%.

Primary etiologies predominated: thrombophilia (29%), Behçet's disease (13%), myeloproliferative neoplasms (11%), and celiac disease (5%). Secondary causes included hepatocellular carcinoma and sarcoidosis (each 2.6%). Complications included ascites (71%),

upper gastrointestinal bleeding (32%), and hepatic encephalopathy (5%). All patients received etiological treatment and anticoagulation when indicated. Recanalization occurred in 29% of cases. Univariate analysis identified two predictive factors: diagnostic delay <6 months ($p = 0.021$) and anticoagulation combined with treatment of the underlying cause ($p = 0.037$).

Conclusion:

Early diagnosis and prompt management of BCS significantly increase the likelihood of spontaneous recanalization. Patients diagnosed within six months of symptom onset and receiving anticoagulation alongside targeted therapy for the underlying cause demonstrate the best outcomes.

1600 - Liver Fibrosis Activity on MRI (cT1) Predicts Incident Neurological Events Independent of Brain MRI Metrics in the UK Biobank

Wen Hui Lim¹, Darren Tan¹, Cheng Han Ng¹, Daniel Huang¹, Eunice Tan¹, Mark Muthiah¹

Yong Loo Lin School Of Medicine, National University Of Singapore, Division Of Gastroenterology And Hepatology, Department Of Medicine, National University Hospital, Singapore-Singapore¹

Background / Hypothesis:

Chronic liver disease is increasingly recognised as a systemic inflammatory state with multisystem effects. Hepatic fibro-inflammation promotes cytokine release, metabolic dysfunction, endothelial injury, and immune activation—processes that mirror mechanisms driving cerebral small-vessel disease, neuroinflammation, and neurodegeneration.¹⁻³ These shared pathways suggest a potential liver-brain axis, but the contribution of hepatic fibro-inflammatory activity to neurological outcomes is not well defined. Corrected T1 (cT1), a quantitative MRI biomarker of liver fibro-inflammation, enables non-invasive assessment of this biology. We examined whether cT1 predicts incident neurological events independent of brain MRI burden.

Materials and Methods:

We analysed 29,344 UK Biobank participants with liver MRI (cT1, Proton Density Fat Fraction [PDFF]) and brain MRI (white matter hyperintensity [WMH] volume).

E-POSTER ABSTRACTS

Neurological events were defined using hospital records coded by ICD-10, including cerebrovascular disease, dementia, and late-life depression. cT1 was categorised as <800 ms, 800–875 ms, and ≥875 ms. High WMH burden was defined as WMH volume above the age-adjusted 80th percentile. Outcomes included (1) neurological events and (2) neurological-related hospitalisation. Prevalent events that occurred prior to the date of imaging were excluded. Cox models were adjusted for age, sex, diabetes, hypertension, dyslipidaemia, smoking, alcohol, education level, and Townsend deprivation index.

Results:

530 incident neurological events occurred during follow-up. Higher cT1 independently predicted neurological events (per 100 ms: HR 1.36, 95% CI 1.14–1.62, $p < 0.001$) and was significant for the ≥875 ms group (HR 2.32, 95% CI 1.14–4.72, $p = 0.021$). WMH >80th percentile (age-adjusted) was also associated with neurological events (HR 1.39, 95% CI 1.10–1.75, $p = 0.006$). Combining cT1 ≥800 ms with WMH >80th percentile produced the highest risk (HR 2.13, 95% CI 1.15–3.96, $p = 0.017$). Liver fat content as measured by PDFF was not associated with increased risk of neurological events.

Conclusions:

Higher liver fibro-inflammatory activity measured by cT1 is independently associated with neurological outcomes, and risk is amplified when combined with high age-adjusted WMH burden. Liver MRI biomarkers identify individuals at heightened risk of brain disease, highlighting a potential liver–brain axis in ageing.

Keyword(s) : liver-brain axis, cT1, PDFF, WMH

1604 - Liver MRI Biomarkers of Fibro inflammation and Steatosis Predict Long term Liver Outcomes and Mortality in the General Population

Darren Tan¹, Wen Hui Lim¹, Cheng Han Ng¹, Eunice Tan¹, Mark Muthiah¹, Daniel Huang¹
Yong Loo Lin School Of Medicine, National University Of Singapore, Division Of Gastroenterology And Hepatology, Department Of Medicine, National University Hospital, Singapore-Singapore¹

Background / Hypothesis:

Liver fibro-inflammation and steatosis contribute to multisystem metabolic dysfunction through chronic

inflammatory signalling, immune activation, and hepatokine-mediated metabolic crosstalk. These pathways may predispose to adverse systemic outcomes, including progressive liver disease and mortality. 1-3 Quantitative liver MRI biomarkers—corrected T1 (cT1), reflecting fibro-inflammation, and proton density fat fraction (PDFF), reflecting steatosis—enable non-invasive assessment of hepatic pathobiology. We examined whether cT1 and PDFF predict incident liver outcomes in a large population cohort.

Materials and Methods:

Participants from the UK Biobank with complete liver MRI (cT1 and PDFF) were included. cT1 was categorised as <800 ms, 800–<875 ms, and ≥875 ms; PDFF as <5%, 5–<10%, and ≥10%. Outcomes included (i) liver events (ICD-10 codes representing chronic liver disease, cirrhosis, portal hypertension, hepatic decompensation, hepatocellular carcinoma, and liver-related procedures), (ii) liver-related hospitalisation, and (iii) all-cause mortality. Prevalent liver events occurring on or before the imaging date were excluded. Cox proportional hazards models adjusted for age, sex, diabetes, hypertension, dyslipidaemia, smoking, and alcohol exposure.

Results:

Among 33,565 individuals (median age 65 years), 1,509 (4.5%) had cT1 800–<875 ms and 263 (0.8%) had cT1 ≥875 ms. Higher cT1 strongly predicted liver events (per 100 ms HR 2.17 [1.75–2.69], $p < 0.001$; cT1 800–<875 ms HR 3.01 [2.04–4.44], $p < 0.001$; cT1 ≥875 ms HR 5.27 [2.81–9.85], $p < 0.001$) (Table 1). PDFF also independently predicted liver events (per 1% HR 1.08 [1.06–1.10], $p < 0.001$; PDFF ≥10% HR 3.15 [2.20–4.50], $p < 0.001$). cT1 ≥875 ms was associated with significantly increased risk of all-cause mortality (HR 2.09 [1.10–3.97], $p = 0.025$).

Conclusions:

cT1 and PDFF are robust, independent predictors of incident liver events in the general population, with cT1 also associated with mortality. Liver MRI biomarkers may enable early risk stratification and preventive intervention.

1605 - Clinical Characteristics and Epidemiological Features of Hepatitis E Virus Infection Among

E-POSTER ABSTRACTS

People Living with HIV in Shanghai China

Conglin Zhao¹, Shuai Tao², Qiang Li¹, Chong Chen³,
Liang Chen¹

Shanghai Public Health Clinical Center, Fudan University, Department Of Liver Disease, Shanghai-China¹ Shanghai Public Health Clinical Center, Fudan University, Scientific Research Center, Shanghai-China² Shanghai Public Health Clinical Center, Fudan University, Department Of Infectious Diseases, Shanghai-China³

Background / Hypothesis:

Hepatitis E virus (HEV) poses a significant public health concern, particularly among immunocompromised populations. This study aimed to investigate HEV seroprevalence, clinical characteristics, and associated risk factors in people living with HIV (PLWH) in Shanghai, China.

Materials and Methods:

In this retrospective cohort study, 670 adult PLWH(> 18 years) underwent anti-HEV testing at Shanghai Public Health Clinical Center (2018-2024). These included epidemiological characteristics such as age, gender, ethnicity, and marital status. Hepatic profiles were also collected, comprising albumin (ALB), alanine aminotransferase (ALT), aspartate aminotransferase (AST), and total bilirubin (TBIL). HIV-specific markers were documented, including CD4 count, antiretroviral therapy (ART) regimen, and WHO clinical stage. Serum anti-HEV IgM and IgG antibodies were detected using Enzyme-Linked Immunosorbent Assay (ELISA) kits. The CD4 count was quantified in peripheral blood specimens from PLWH using flow cytometric analysis.

Results:

A retrospective analysis was conducted on serum IgG and IgM antibodies specific to HEV in 670 PLWH and 464 HIV-negative controls. The overall anti-HEV seropositivity rate among PLWH was 30.15% (202/670, 95% CI 26.68–33.62), with an IgG positivity rate of 30.00% (201/670, 95% CI 26.53–33.47). IgM positivity was observed in 1.19% (8/670, 95% CI 0.59–2.39), and dual IgM/IgG positivity in 1.04% (7/670, 95% CI 0.50–2.16). The seropositivity rate of anti-HEV IgG in the HIV-negative control group was 17.67% (82/464, 95% confidence interval: 14.20–21.14), with no IgM positivity, which was significantly lower than that in PLWH ($\chi^2 = 22.84$, $P < 0.001$). Univariate and multivariate analyses identified advanced World Health Organization (WHO) HIV stage (III/IV) as an independent risk factor for HEV co-infection ($P < 0.05$). Notably, no significant associations were observed with

age, gender, CD4 count, or liver function parameters.

Conclusions:

In summary, this study demonstrates that PLWH in Shanghai exhibit an increased risk of HEV infection, with advanced HIV disease stage (WHO III/IV) identified as a key associated factor. This underscores the necessity of incorporating targeted HEV screening awareness and prevention strategies into HIV care programs, particularly for patients with advanced disease. These findings provide a foundation for future research and potential refinements in clinical practice aiming to enhance care and prognosis for affected individuals.

1606 - Marked HBsAb elevation in anti HBc positive cancer patients receiving PD 1 inhibitors two case reports and literature review

Chaoqian Huang¹, Chao Cai¹, Mingqin Lu¹

The First Affiliated Hospital Of Wenzhou Medical University, Department Of Infectious Disease And Hepatology, Wenzhou-China¹

Background / Hypothesis:

PD-1 inhibitors have achieved major advances in cancer treatment and are increasingly studied for their immunological effects in chronic HBV infection. Chronic HBV remains a global health burden, and current therapies rarely achieve complete viral clearance. Persistent antigen exposure leads to sustained PD-1 overexpression and impaired immune control, making PD-1/PD-L1 blockade a potential therapeutic strategy. While previous studies have focused on changes in HBV DNA and HBsAg during PD-1 therapy, little is known about its influence on HBsAb production. This report describes two anti-HBc-positive cancer patients who developed elevated HBsAb after PD-1 inhibitor treatment, along with associated liver enzyme abnormalities.

Materials and Methods:

We retrospectively evaluated two male cancer patients with isolated anti-HBc positivity and negative HBsAg who received PD-1 inhibitors (pembrolizumab or sintilimab). Both developed immune-related liver injury after receiving PD-1 inhibitors, with significant elevations in ALT, AST, bilirubin, ALP, and GGT. Clinical manifestations, liver biochemical markers, HBV serology, and HBV DNA were collected before and after PD-1 inhibitor therapy.

E-POSTER ABSTRACTS

Results:

Each patient demonstrated a pronounced increase in HBsAb titers, rising from <2.00 and 4.91 mIU/mL at baseline to 303.65 mIU/mL and 405.06 mIU/mL, respectively. Throughout the clinical course and follow-up, HBsAg and HBV DNA remained negative. Liver function progressively improved after immunosuppressive therapy and IVIG administration. No virological rebound or new-onset HBV markers were detected during follow-up.

Conclusions:

PD-1 inhibition was associated with significant HBsAb elevation in two anti-HBc-positive cancer patients. This finding suggests that PD-1 blockade may partially restore exhausted HBV-specific B cells and T cells, reactivating immune memory and enhancing antiviral humoral responses. This immunologic effect provides early clinical observations regarding the impact of checkpoint inhibitors on HBV-related immune responses. The accompanying immune-related hepatic injury highlights the importance of careful monitoring. Larger studies are needed to clarify the clinical significance of this serologic change.

Keyword(s) : PD-1 inhibitor treatment, Hepatitis B virus, HBsAb increase, anti-HBc-positive patients

1610 - STING Aggravates Liver Fibrosis in Chronic hepatitis B concurrent with Metabolic Dysfunction Associated Steatotic Liver Disease by Modulating Gut Microbiota and Inducing Macrophage Derived Lysozyme Expression

Binghui Yu ¹, Suping Hai ¹, Wenhui Wu ¹, Qiang Gao ¹, Xitang Li ¹, Feiyang Xu ¹, Xizhe Zheng ¹, Junjian Hu ¹, Qin Ning ¹, Xiaojing Wang ¹

State Key Laboratory For Diagnosis And Treatment Of Severe Zoonotic Infectious Disease, Huazhong University Of Science And Technology, Department And Institute Of Infectious Disease, Tongji Hospital, Wuhan-China ¹

Background / Hypothesis:

The coexistence of Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) in individuals with Chronic Hepatitis B (CHB) has been increasing annually. In the early stage of MASLD, high-fat diet-induced impairment of the intestinal epithelial barrier may activate the cyclic GMP-AMP synthase (cGAS)-stimulator of interferon genes (STING) pathway. Interactions along the gut-liver axis are likely to contribute to adverse outcomes in this comorbidity.

We hypothesize that STING activation during the early stage of the concurrent presence of CHB and MASLD exacerbates liver disease progression by altering the gut microenvironment.

Materials and Methods:

A mouse model of CHB concurrent with MASLD was established by hydrodynamic injection of pAAV/HBV1.2 combined with feeding a high-fat diet (HFD). The study utilized STING knockout mice (Sting^{-/-}), alongside their littermate controls. In vitro, THP-1 cells were administered a STING agonist, whereas LX-2 cells were subjected to lysozyme stimulation and appropriate controls were established for all treatments. The evaluation of STING and lysozyme-associated markers was conducted using Western blotting, immunofluorescence and enzyme-linked immunosorbent assay (ELISA).

Results:

At 8 weeks, CHB concurrent with MASLD mice exhibited moderate hepatosteatosis and lobular inflammatory infiltration compared to those in the CHB group. Compared to mice with CHB or MASLD alone, the comorbidity group exhibited more severe gut barrier disruption and altered microbiota composition. Specifically, the comorbid mice showed increased abundances of *Blautia*, *Erysipelatoclostridium*, and *Pseudomonas*, and decreased abundances of *Alloprevotella* and *Lachnospiraceae_UCG_001* relative to the CHB group. STING expression and activation were elevated in intestinal tissue. STING knockout restored gut barrier integrity and microbiota balance. Fecal microbiota transplantation from Sting^{-/-} mice alleviated steatosis and reduced ALT, AST, and free fatty acid levels. STING was highly enriched in intestinal macrophages, and its activation promoted lysozyme expression. Elevated serum lysozyme and increased CD64/lysozyme co-localization were observed in the comorbidity model. In vitro, lysozyme stimulated LX-2 activation, upregulating collagen I and fibronectin.

Conclusions:

Our study demonstrates that intestinal macrophage STING activation modulates gut microbiota and promotes liver fibrosis via lysozyme-induced hepatic stellate cell activation in the early stage of the concurrent CHB and MASLD model. Consequently, lysozyme may represent a potential therapeutic target for mitigating fibrosis in CHB patients concurrent with MASLD.

1611 - Irreversible Electroporation (NanoKnife) in the Management of Refractory Recurrent Hepatocellular Carcinoma A Systematic Review of Diagnostic and Therapeutic Advances

Mengjiao Xu¹, Shiyu Wang², Yaqin Zhang¹, Ziyu Zhang¹, Xinxin Li¹, Wen Deng¹, Weihua Cao¹, Xin Wei¹, Zixuan Gao¹, Linmei Yao¹, Shuojie Wang¹, Yao Xie¹, Minghui Li¹

Hbv Infection, Clinical Cure And Immunology Joint Laboratory For Clinical Medicine Capital Medical University, Department Of Hepatology Division 2, Beijing-China¹ Hbv Infection, Clinical Cure And Immunology Joint Laboratory, Capital Medical University, Department Of Hepatology Division 2, Beijing-China²

Background / Hypothesis:

This review focuses on recent advances and provides a comprehensive overview of the multifaceted research progress of nanoknife technology in the treatment of refractory recurrent hepatocellular carcinoma. Firstly, the pathological mechanisms of refractory recurrent hepatocellular carcinoma, including the risk factors for different types of recurrence, are described. Then, the relevant principles of nanoknife technology, such as the molecular basis of irreversible electroporation mechanism and the development history of this technology, are introduced. Subsequently, its current status in minimally invasive diagnosis and treatment, comparison with other therapeutic strategies, and evaluation of efficacy are discussed from the perspective of clinical application.

Materials and Methods:

We define recurrent refractory hepatocellular carcinoma as the presence of multiple recurrent liver lesions post-surgery (≥ 3 lesions), involvement of major hepatic vessels by recurrent lesions (e.g. invasion of hepatic veins or portal veins, or formation of intravascular tumour thrombi), extrahepatic spread and distant metastases (e.g. lung, bone or brain metastases), multiple intraperitoneal lymph node metastases, invasion of adjacent liver tissues or organs, and peritoneal seeding metastasis. By retrieving and screening relevant medical reports from PubMed (<https://pubmed.ncbi.nlm.nih.gov>) over the past decade, regardless of content, we provide this paper with theoretical and practical support based on the data therein.

Results:

It also covers technological advances and innovations, epidemiological studies, controversies and challenges, and looks forward to potential future breakthroughs in the treatment of this disease, the direction of research on the mechanism of irreversible electroporation, and the prospects for personalized treatment applications, aiming to provide a comprehensive reference for further research and application of nanoknife technology in the treatment of refractory recurrent liver cancer.

Conclusions:

In summary, nanoknife as an innovative non-thermal ablation technology has demonstrated broad application prospects in the diagnosis and treatment of refractory recurrent liver cancer. Its advantages in treating tumors located in complex anatomical positions, along with enhanced efficacy when combined with immunotherapy, gene therapy, and personalized treatment, make it a promising therapeutic option. Future researches should continue to explore these combined strategies to enhance the clinical efficacy of nanoknife technology, and, further large-scale clinical studies remain necessary to verify its long-term efficacy and safety, as well as to optimize clinical application strategies for liver cancer patients.

Keyword(s) : irreversible electroporation, nanoknife, minimally invasive diagnostic and therapeutic techniques, hepatocellular carcinoma, tumor microenvironment

1612 - Kuan Sin Yin potentiates PD1 blockade in hepatocellular carcinoma by enhancing B cell derived Granzyme B mediated apoptosis

Shuoshuo Ma¹, Xiaolun Huang¹

Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School Of Medicine, University Of Electronic Science And Technology Of China, Department Of Liver Transplantation Center And Hepato-biliary-pancreatic (hbp) Surgery, Chengdu-China¹

Background / Hypothesis: The Chinese herbal formula Kuan-Sin-Yin (KSY) has unexplored potential in hepatocellular carcinoma (HCC) therapy. Given its lack of direct anti-proliferative effect on HCC cells in vitro, we hypothesized that KSY exerts its anti-tumor activity by modulating the tumor immune microenvironment, particularly in combination with immune checkpoint inhibitors.

E-POSTER ABSTRACTS

Materials and Methods:HCC cell viability was assessed using the CCK-8 assay. An immune cell-HCC organoid co-culture system and a subcutaneous HCC model in C57BL/6 mice were established to evaluate the anti-tumor efficacy of KSY alone and in combination with an anti-PD1 antibody. Tumor-infiltrating immune cells were analyzed by flow cytometry. UPLC-HRMS was employed to characterize KSY components, and a multi-database analysis (SwissTargetPrediction, TCGA, Genecards, OMIM) was conducted to identify potential targets. GO and KEGG pathway enrichment analyses were performed. Underlying mechanisms were validated using TUNEL staining, Western blotting, immunofluorescence, and neutralizing antibody experiments.

Results:Medium/high doses of KSY significantly inhibited HCC growth in both the immune-co-culture organoid model and in vivo, and synergistically enhanced the efficacy of anti-PD1 therapy. Flow cytometry revealed that KSY promoted the infiltration of various immune cells, including macrophages, B cells, NK cells, and CD8+ T cells, into tumors. Integrated target gene sets were significantly enriched in apoptosis and the PI3K-AKT signaling pathway. Consistently, TUNEL staining and Western blot confirmed that KSY induced tumor cell apoptosis. While KSY broadly modulated the immune landscape, its combination with anti-PD1 specifically and further enhanced B cell infiltration. The supernatant from KSY-primed B cells induced apoptosis and suppressed AKT phosphorylation in HCC cells. This pro-apoptotic effect was specifically abolished by a Granzyme B neutralizing antibody, but not by antibodies against TNF- α or TRAIL. Immunofluorescence further demonstrated increased B cell infiltration accompanied by elevated Granzyme B levels in tumors from the combination therapy group.

Conclusions:This study demonstrates that KSY augments the anti-tumor efficacy of PD1 blockade in HCC by remodeling the tumor immune microenvironment. A key mechanism involves the activation of B cells, which secrete Granzyme B to induce tumor cell apoptosis via inhibition of the PI3K-AKT pathway. These findings provide a compelling rationale for developing KSY as an adjunctive therapy to immune checkpoint blockade in HCC.

1613 - History of Abdominal Surgery and of Treatment for Esophagogastric Varices Are Risk Factors for Portal Vein Thrombosis in Patients with Cirrhosis

Chao Ma¹, Menyao He¹, Yuyu Li¹, Qian Li¹, Yihong Chen¹, Hailun Yang¹, Zhonghui Ning², Qiang Xu², Sayilaxi Jieensinuer², Ailifeire Abulajiang², Xiaozhong Wang², Feng Guo²

Xinjiang Medical University, School Of The Fourth Clinical Medical, Urumqi-China¹ Traditional Chinese Medicine Hospital, Xinjiang Medical University,, Department Of Hepatology, Urumqi-China²

Background / Hypothesis:To analyze the factors influencing the development of portal vein thrombosis in patients with cirrhosis.

Materials and Methods:A retrospective study was conducted to collect clinical data of 319 hospitalized patients with cirrhosis admitted to Xinjiang Uygur Autonomous Region Hospital of Traditional Chinese Medicine from January 2021 to December 2024. Demographic information, serological indicators, abdominal ultrasound, portal vein ultrasound, and other relevant clinical data were collected for all patients. CTP scores were calculated for each patient. Patients were then divided into two groups: the portal vein thrombosis group and the non-portal vein thrombosis group. Multivariate logistic regression analysis was further performed to identify factors influencing the development of PVT in patients with cirrhosis.

Results:A total of 61 patients (19.1%) had liver cirrhosis complicated with portal vein thrombosis. Stratified by CTP score: 8 cases (7.3%) were in CTP class A, 36 cases (25.7%) in CTP class B, and 17 cases (24.2%) in CTP class C; the distribution of etiologies (chronic hepatitis B, autoimmune liver disease, and other causes) showed statistically significant differences ($P < 0.05$). Between the two groups, significant differences were observed in spleen thickness, splenic length, portal vein flow velocity, history of abdominal surgery, history of esophagogastric variceal treatment (including endoscopic ligation and sclerotherapy), and severe gastric varices (all $P < 0.05$). For serological parameters, hemoglobin levels, albumin levels, and international normalized ratio (INR) differed significantly between the two groups (all $P < 0.05$). Multivariate logistic regression analysis identified three independent risk factors for PVT in patients with liver cirrhosis: History of

E-POSTER ABSTRACTS

abdominal surgery (OR=11.986, 95% CI: 1.088-132.010, $P<0.001$), History of esophagogastric variceal treatment (OR=4.229, 95% CI: 2.085-8.577, $P<0.001$), Spleen thickness (OR=1.048, 95% CI: 1.011-1.086, $P=0.011$) were independent risk factors for portal vein thrombosis in patients with cirrhosis.

Conclusions:History of abdominal surgery, history of esophagogastric variceal treatment, and spleen thickness are risk factors for portal vein thrombosis in patients with liver cirrhosis.

Keyword(s) :

1614 - Autoimmune hemolytic anemia complicated by portal vein thrombosis in a pediatric liver transplant recipient

Zehra Ikbal Karabal¹, Tonguç Utku Yılmaz²

Acibadem University Faculty Of Medicine, Medicine Faculty, Istanbul-Türkiye¹ Acibadem University Faculty Of Medicine, Transplantation And General Surgery, Istanbul-Türkiye²

Background / Hypothesis:Autoimmune hemolytic anemia (AIHA) is a rare but serious complication following pediatric liver transplantation, with reported incidence of 1-3%. Immune dysregulation under chronic immunosuppression is the proposed mechanism. Thrombotic complications associated with post-transplant AIHA, including portal vein thrombosis (PVT), are infrequently reported but represent life-threatening events requiring urgent intervention. This report presents a case demonstrating this severe complication and its successful management.

Materials and Methods:Among 165 pediatric liver transplant recipients at Acibadem Atakent Hospital (2016-2025), three developed AIHA post-transplant (incidence 1.8%). This case report presents the index case complicated by portal vein thrombosis. Analysis included clinical course, immunosuppression protocols, laboratory parameters including hemolytic markers and coagulation studies, imaging findings, therapeutic interventions, and outcomes.

Results:A 10-month-old girl underwent living donor liver transplantation for biliary atresia. Post-operatively,

the patient was maintained on tacrolimus and mycophenolate mofetil following initial steroid taper. Five months post-transplant, she presented with fever and jaundice. Laboratory evaluation revealed severe hemolytic anemia (hemoglobin 7.5 g/dL, hematocrit 6.9%), marked elevation of lactate dehydrogenase (1751 IU/L), hyperbilirubinemia (total bilirubin 4.92 mg/dL), and thrombocytopenia (platelets $75 \times 10^3/\mu\text{L}$). Direct antiglobulin test was positive, confirming AIHA. Coagulation studies demonstrated significant abnormalities with low protein S activity (48.1%) and elevated D-dimer (3.78 mg/L), indicating hypercoagulable state. Doppler ultrasonography identified partial portal vein thrombosis, a rare and serious complication. Treatment consisted of high-dose methylprednisolone (4 mg/kg) and rituximab for AIHA management. Concurrent intravenous heparin anticoagulation was initiated for PVT. The thrombosis resolved completely within five days. Hemolytic parameters gradually normalized, with eventual negative direct antiglobulin test confirming AIHA remission.

Conclusions:Post-transplant AIHA can precipitate life-threatening thrombotic complications including portal vein thrombosis through mechanisms involving severe hemolysis, thrombocytopenia, and acquired hypercoagulability. This case demonstrates the critical importance of comprehensive evaluation including coagulation studies and vascular imaging in AIHA patients. Successful management requires aggressive multimodal therapy combining immunosuppression with prompt anticoagulation. Clinicians managing pediatric liver transplant recipients should maintain vigilance for AIHA and systematically assess for thrombotic complications in this vulnerable population.

1616 - SNX10 Promotes Lipid Accumulation in Hepatocytes by Inhibiting Autophagic Flux

Shiyan Chen¹, Jixin Sun², Kexin Song², Kefeng Li³, Yingjuan Zeng², Mingxing Huang¹

The Third People's Hospital Of Zhuhai, Zhuhai engineering technology research center of occupational And Mental Health, Zhuhai-China¹ The Fifth Affiliated Hospital, sunyat-sen University, Endocrinology Department, Zhuhai-China² Macao Polytechnic University, Centre For Artificial Intelligence

E-POSTER ABSTRACTS

Driven Drug Discovery, Faculty Of Applied Sciences,
Macau Sar-China ³

Background / Hypothesis:

Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD) is a highly prevalent condition with limited therapeutic options. Autophagy, a cellular catabolic process that clears excess lipids, is a critical protective mechanism against hepatic steatosis. Sorting Nexin 10 (SNX10), a member of the endosome-associated SNX protein family, is implicated in regulating the autophagy-lysosome pathway. However, its specific role in the pathogenesis of MAFLD is unknown. This study aimed to elucidate the function of SNX10 in hepatic lipid metabolism and its underlying autophagic mechanism.

Materials and Methods:

An in vitro model of hepatic steatosis was established by treating human LO2 hepatocytes with free fatty acids (FFAs). Gain- and loss-of-function studies were performed using lentiviral-mediated overexpression and siRNA-mediated knockdown of SNX10, respectively. Lipid accumulation was quantified by Oil Red O staining. The expression of SNX10 and key autophagy-related genes (e.g., Atg5, Atg7) and proteins (e.g., LC3, SQSTM1/p62) was analyzed by qPCR and Western blotting. A protein-protein interaction network was generated using the STRING database to explore potential mechanistic links.

Results:

FFA treatment of LO2 cells induced a steatotic phenotype, characterized by increased lipid deposition and a corresponding upregulation of SNX10 at both the mRNA and protein levels. Lentiviral-mediated overexpression of SNX10 was sufficient to significantly increase intracellular lipid deposition. Mechanistically, SNX10 overexpression led to a marked accumulation of the autophagosome marker LC3-II, indicating an impairment of autophagic flux, without significantly altering levels of the autophagy substrate SQSTM1/p62. Conversely, siRNA-mediated knockdown of SNX10 significantly ameliorated lipid accumulation both at baseline and under FFA-induced stress. This protective effect was associated with restored autophagic activity, as evidenced by a significant upregulation of Atg5 expression and a reduction in LC3-II levels. STRING analysis further supported a functional interaction between SNX10 and the core autophagy machinery, including Atg5.

Conclusions:

Our findings demonstrate that SNX10 is a negative regulator of autophagy in hepatocytes. Elevated SNX10 expression, as observed in a cellular model of MAFLD,

promotes lipid droplet accumulation by inhibiting autophagic flux. This study identifies SNX10 as a novel contributor to hepatic steatosis and suggests that targeting SNX10 could be a potential therapeutic strategy to restore autophagy and alleviate lipid burden in MAFLD.

Background / Hypothesis:

This study aims to assess whether steroid-based regimen enhances the clearance of jaundice and improves native liver survival (NLS).

Materials and Methods:

We included all infants with biliary atresia (BA) undergoing Kasai portoenterostomy (KPE) at our centre. The algorithm-initiated prednisolone was initiated if stools remained acholic.

Results:

Of 127 infants, 70 formed the Steroid Group (SG) and 57 the Historical Cohort (HC). Jaundice clearance at 6 months was superior with steroids (61.4% vs 38.6%; OR 2.53, 95% CI 1.23-5.19, P=0.013). Kaplan-Meier analysis demonstrated improved 24-month NLS (log-rank P=0.044) in SG. Multivariate analysis identified younger age at KPE (aOR 1.021 per day, 95% CI 1.004-1.038, P=0.016), lower pre-operative bilirubin (aOR 1.163, 95% CI 1.024-1.320, P=0.020) and steroid use (aOR 2.13, 95% CI 1.001-4.53, P=0.050) as independent predictors of success.

Conclusions:

Moderate-dose prednisolone after KPE enhances early bile drainage and prolongs native-liver survival. Optimal benefit is achieved when surgery is performed

1618 - Optimizing Nucleos(t)ide Analogs Combined Peg IFN α Regimen for CHB with Low Level Viremia Efficacy and Predictors

Shiyu Wang¹, Yuanjiao Gao², Yaqin Zhang¹, Shuojie Wang¹, Ziyu Zhang¹, Xinxin Li², Weihua Cao¹, Wen Deng¹, Xin Wei¹, Linmei Yao¹, Zixuan Gao¹, Yao Xie¹, Minghui Li¹

Hbv Infection, Clinical Cure And Immunology Joint Laboratory For Clinical Medicine Capital Medical University, Department Of Hepatology Division 2, Beijing-China¹ Hbv Infection, Clinical Cure And Immunology Joint Laboratory, Capital Medical University, Department Of Hepatology Division 2, Beijing-China²

Background / Hypothesis:

The optimization of therapy in chronic hepatitis B with low-level viremia represents a current research hotspot. To compare the efficacy of nucleos(t)ide analogs (NAs) combined with pegylated interferon- α (Peg-IFN α) versus NAs alone in optimizing treatment for NAs-experienced chronic hepatitis B (CHB) patients with low-level viremia, and to analyze influencing factors.

Materials and Methods:

A prospective real-world multicenter study enrolled 362 CHB patients with low-level viremia at Beijing Ditan Hospital Liver Disease Center, Beijing YouAn Hospital and the Fifth Medical Center of the Chinese PLA General Hospital from January 2022 to December 2024. Patients were divided into two groups based on preference: the NAs group and the NAs+PEG-IFN group. Primary endpoints included complete virological response (CVR), HBsAg clearance rate, and HBeAg seroconversion rate at 48 weeks. Secondary endpoints were reductions in HBV DNA and HBsAg levels from baseline.

ResAt 48 weeks, the NAs+PEG-IFN group showed significantly higher CVR and HBsAg clearance rates compared to the NAs group (26.84% vs. 15.56%, $\chi^2=4.72$, $P=0.030$; 15.44% vs. 2.22%, $\chi^2=8.35$, $P=0.004$). HBeAg seroconversion was higher in the NAs+PEG-IFN group (69.177% vs. 55.56%), but the difference lacked statistical significance ($\chi^2=3.48$, $P=0.062$). The NAs+PEG-IFN group achieved greater HBsAg reduction ($-0.65 \log_{10}$ IU/mL vs. $-0.28 \log_{10}$ IU/mL, $Z=-2.45$, $P<0.05$) and HBV DNA reduction ($-0.70 \log_{10}$

IU/mL vs. $-0.53 \log_{10}$ IU/mL, $Z=-2.15$, $P<0.05$). Baseline low HBsAg and rapid HBsAg decline at 12 weeks were independent predictors of HBsAg clearance (OR=0.52 and OR=2.50, $P<0.05$). ults:

Conclusions:

Compared to NAs optimization, the NAs+PEG-IFN regimen significantly improved CVR and HBsAg clearance rates, and reduced HBsAg and HBV DNA levels in NAs-experienced CHB patients with low-level viremia.

1620 - Precision Treatment and Frontier Advances of Glycyrrhizin Preparations in Drug Induced Liver Injury

Dianya Qiu Qiu¹, Lu Zhang Zhang¹, Zixuan Gao Gao¹, Tianyu Ma Ma¹, Xin Wei Wei¹, Shiyu Wang Wang¹, Wen Deng Deng¹, Shuojie Wang Wang¹, Yao Xie Xie¹, Minghui Li Li¹

Beijing Ditan Hospital, Capital Medical University, Department Of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University, Beijing 100015, China, Beijing-China¹

Background / Hypothesis:Drug-induced liver injury (DILI) poses significant challenges in clinical practice. Glycyrrhizin preparations, derived from licorice (*Glycyrrhiza uralensis*), exhibit multi-target effects and are recommended as a core therapy in various guidelines. This study aims to summarize the evidence-based data, precision treatment strategies, and recent advances of glycyrrhizin preparations for DILI. The central hypothesis is that these preparations exert their therapeutic effects on DILI through multi-target mechanisms, including newly discovered pathways such as gut-liver axis modulation and epigenetic regulation.

Materials and Methods:We conducted a systematic review to comprehensively examine the pharmacological mechanisms, clinical evidence, and guideline recommendations for glycyrrhizin preparations. Furthermore, we specifically investigated precision use strategies based on DILI type, severity, and patient subgroups, and explored novel mechanisms of action, such as regulation of the gut-liver axis.

E-POSTER ABSTRACTS

Results:Glycyrrhizin preparations demonstrate proven efficacy in treating DILI and are widely endorsed by various guidelines. Their mechanisms of action involve multiple aspects, including the modulation of the gut-liver axis and epigenetic regulation. Management strategies for potential adverse reactions, such as pseudoaldosteronism, were also summarized.

Conclusions:Glycyrrhizin preparations represent a key therapeutic option for DILI. Further research is warranted to validate these novel mechanisms and to optimize their precise clinical application.

Keyword(s) : Glycyrrhizin preparations, Drug-induced liver injury(DILI), Precision treatment, Evidence-based medicine, Gut-liver axis

1621 - Establishment and assessment of a nomogram for predicting hepatic parasites disease

Yanuo Chen¹

Southeast University, Medical School, Nanjing-China¹

Background / Hypothesis:

Hepatic parasite disease (HPD) is a widely endemic helminthic disease. Diagnosis involves serum serologic testing for antibodies against hydatid antigens, preferably with imaging by ultrasound or computed tomography (CT) and magnetic resonance imaging (MRI). Although the sensitivity of ultrasound diagnosis reaches 89% and CT yields positive results in 93% of cases, some people still have an unclear imaging diagnosis. Pathology is also an important way of diagnosis. However, inappropriate needle aspiration or open biopsy could lead to spillage of the cyst contents and catastrophic dissemination of the parasites. Therefore, there is an urgent need for an efficient and non-invasive diagnostic method in the clinic. The aim of this study was to combine multiple clinical features into a nomogram for predicting the individual risk of hepatic parasites disease.

Materials and Methods:

216 patients with hepatic space-occupying disease were collected. Patient characteristics and 8 serum markers were subjected to univariate and multivariate analysis, the results of which were used to construct

the nomogram.

Results:

Eosinophil count, typical clinical symptoms, age, and alpha-fetoprotein were significantly significant between hepatic hemangioma and the other hepatic space-occupying diseases. The area under the receiver operating characteristic curve was 0.842 (95% CI: 0.770~0.915) for the training set, and the area under the receiver operating characteristic curve was 0.756 (95% CI: 0.613~0.889) for the validation set, which shows that the model has good discrimination. The use of the nomogram was better than that of a single marker. Furthermore, the nomogram showed better discriminative ability than the biomarker alone. Notably, the validation indicated high stability and reproducibility.

Conclusions:Use of the nomogram is superior to that of a serum marker alone and holds promise in clinical application.

Keyword(s) : Hepatic parasitic disease, Eosinophil count, Typical symptoms, Age, Alpha-fetoprotein, Nomogram

1622 - Impact of Tuberculosis Co-infection on All-Cause Mortality in Patients with Viral Hepatitis A Propensity Score-Matched Retrospective Study

Jianyun Wang¹, Tongxu Zeng¹, Shaoli Bai¹, Wenjuan Shi¹

The No.2 People's Hospital Of Lanzhou, Department Of Infectious Diseases, Lanzhou-China¹

Background / Hypothesis:

Viral hepatitis and tuberculosis (TB) frequently coexist and may interact to worsen clinical outcomes. We examined the association between TB co-infection and short-term and long-term all-cause mortality among patients with viral hepatitis using a large intensive-care cohort.

Materials and Methods:

Retrospective cohort study using the MIMIC-IV database. A total of 11,777 patients with viral hepatitis were identified (TB group = 1,228; Non-TB group = 10,549). Propensity score matching (PSM) at a 1:3 ratio yielded 4,253 patients (TB group = 1,193; Non-TB group = 3,060). Outcomes were all-cause mortality at 30, 90, 180 and 360 days. Survival was assessed by Kaplan-Meier analysis and adjusted using three Cox proportional hazards models.

E-POSTER ABSTRACTS

Results:

Before and after PSM, mortality was significantly higher in the TB group at 180 days and 360 days ($p < 0.01$), whereas no significant differences were observed at 30 or 90 days. Kaplan–Meier curves confirmed lower survival in the TB group at 180- and 360-day intervals ($p < 0.05$). After PSM, the adjusted hazard ratios (95% CI) for 360-days mortality in the TB group were 1.385 (1.190–1.612), 1.375 (1.181–1.600) and 1.579 (1.348–1.850) across Models I–III, respectively (all $p < 0.05$). For 180-day mortality, adjusted HRs were 1.323 (1.107–1.580), 1.313 (1.099–1.569) and 1.556 (1.292–1.857) in Models I–III (all $p < 0.05$). Subgroup analyses showed an overall increased mortality associated with TB co-infection (HR 1.38; 95% CI 1.19–1.61; $p < 0.001$), with significant interactions for chronic kidney disease (p for interaction = 0.002), COPD ($p < 0.001$), pneumonia ($p = 0.028$) and diabetes ($p = 0.015$), indicating effect modification by these comorbidities.

Conclusions: In this large matched cohort of patients with viral hepatitis, TB co-infection was associated with significantly increased long-term (180- and 360-day) all-cause mortality but not with short-term (30- or 90-day) mortality. The association was modified by several comorbid conditions, underscoring the need for targeted management and further investigation into mechanisms and therapeutic strategies for high-risk subgroups.

Keyword(s) : Viral hepatitis; Tuberculosis; Co-infection; Mortality; Propensity score matching

1623 - Molecular Association of Circadian Rhythm and Tryptophan Metabolism Pathway in the Pathogenesis of Chronic Hepatitis B

Chunfeng Mei¹, Shihao Zheng¹, Yongan Ye¹
Dongzhimen Hospital, Beijing University Of Chinese Medicine, Liver Diseases Academy Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis: Chronic Hepatitis B (CHB) remains a significant global health burden, yet the intricate molecular mechanisms driving its progression are not fully elucidated. This study aimed to investigate the underlying molecular connections between circadian rhythm signaling and metabolic pathways in the pathogenesis of CHB.

Materials and Methods: We retrieved transcriptome data from peripheral blood mononuclear cells (PBMCs) of CHB patients from the GEO public database. Differential Expression Genes (DEGs) were identified by integrating the data with established circadian rhythm

gene sets. Subsequently, a robust pipeline combining three machine learning algorithms—LASSO regression, Support Vector Machine (SVM), and XGBoost—was employed to confidently screen for core key genes associated with CHB. Gene Set Enrichment Analysis (GSEA) was performed to dissect the functional pathways enriched by these key genes. Furthermore, we utilized publicly available microbiome data from CHB patients to conduct functional enrichment analysis on differential gut microbiota, establishing a potential host-microbiota-metabolism axis.

Results: The machine learning screening strategy successfully identified four core genes—HTR7, TH, PPP1CB, and SMARCD3—strongly associated with CHB. GSEA results indicated that the expression of HTR7 was significantly enriched in pathways related to Hepatitis B, circadian rhythm regulation, and tryptophan metabolism. Analysis of the gut microbiota in CHB patients further revealed that differentially abundant bacteria, including *Pseudomonas*, *Clostridium*, and *Bacteroides*, were also highly enriched in the tryptophan metabolic pathway, specifically participating in the Kynurenine (Kyn) pathway.

Conclusions: This study provides evidence revealing a critical molecular link between circadian rhythm dysregulation and the tryptophan-kynurenine metabolic axis in CHB patients. The core genes HTR7, TH, PPP1CB, and SMARCD3 may function as host regulatory factors, driving CHB progression by modulating these pathways. These findings offer new insights into the potential pathophysiological mechanisms of CHB and highlight the potential of developing novel diagnostic biomarkers and therapeutic strategies targeting the circadian rhythm-metabolic axis.

Keyword(s) : Chronic Hepatitis B (CHB), Circadian Rhythm, Tryptophan Metabolism, Kynurenine Pathway, HTR7

1626 - Baseline Gut Microbiota Signatures Associated with Interferon Response and Functional Cure in Chronic Hepatitis B

Siqi Sun¹, Sisi Yang¹, Jiyang Chen¹, Zelu Meng¹, Yihe Yu¹, Jintao Ning¹, Hongyu Jia¹

The First Affiliated Hospital, Zhejiang University School Of Medicine, Infectious Diseases, Hangzhou-China¹

Background / Hypothesis: Chronic hepatitis B (CHB) remains a major public health challenge, with

E-POSTER ABSTRACTS

functional cure (hepatitis B surface antigen [HBsAg] loss) rarely achieved by current therapies. The gut–liver axis has been implicated in antiviral immunity, but it remains unclear whether baseline gut microbiota composition influences interferon (IFN) treatment response or functional cure outcomes. We aimed to identify baseline gut microbiota signatures associated with IFN response and HBsAg loss in CHB.

Materials and Methods: We enrolled adult CHB patients initiating pegylated IFN α -2b therapy (n=102), along with healthy controls (HC, n=28). Baseline stool samples underwent shotgun metagenomic sequencing. We first compared alpha- and beta-diversity between CHB and HC. Among IFN-treated patients, we then performed two subgroup analyses: (i) a virological response analysis comparing responders (R, n=42) and non-responders (NR, n=60); and (ii) a functional cure analysis comparing patients who achieved HBsAg loss (FC, n=12) and those who did not (non-FC, n=90). Differentially abundant genera were identified using Wilcoxon rank-sum tests and LEfSe. Additionally, trends were analyzed along a four-level “clinical remission axis” (NR $\rightarrow$ R without FC $\rightarrow$ FC $\rightarrow$ HC).

Results: Baseline overall diversity did not differ significantly between CHB and HC groups, although CHB showed a modest enrichment of certain bile acid-related and potentially pro-inflammatory genera (e.g., *Escherichia*). Similarly, within IFN-treated patients, alpha- and beta-diversity were comparable between responders and non-responders. However, several short-chain fatty acid (SCFA)-producing genera (e.g., *Roseburia*, *Lacrimispora*) were more abundant in R, whereas the dysbiosis-associated genus *Megamonas* was enriched in NR. In the functional cure analysis, FC patients had higher baseline abundances of SCFA-producing genera, while non-FC patients were enriched in genera associated with dysbiosis or inflammation. Along the clinical remission axis (NR $\rightarrow$ R without FC $\rightarrow$ FC $\rightarrow$ HC), SCFA-producing commensals increased stepwise in relative abundance, whereas potentially pathogenic or dysbiosis-related taxa (e.g., *Escherichia/Shigella*, *Megamonas*) progressively decreased.

Conclusions: Baseline gut microbiota diversity alone was not strongly associated with IFN response, but specific compositional and functional profiles correlated with treatment outcomes. An SCFA-rich, low-inflammatory microbiota — characterized by enrichment of *Roseburia*, *Lacrimispora* and related genera and depletion of *Megamonas* and other

opportunistic taxa — was linked to better IFN response, a higher likelihood of functional cure, and a microbiota profile resembling healthy controls. These findings highlight the gut microbiota as a potentially modifiable determinant of treatment outcomes in CHB and support microbiota-targeted strategies to improve IFN therapy outcomes.

1627 - Clinical and Serological Predictors of Virological Response to Nucleos(t)ide Analogue Therapy in Chronic Hepatitis B A 7 Year Cohort Study

Chaimaa Elmajoudi¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Selma Sebbah¹, Fatima Zahra Ajana¹, Meryem Kadiri¹
Chu Ibn Sina, Mohammed V University, Rabat, Morocco, Department Of Hepato-gastroenterology C, Chu Ibn Sina, Rabat-Morocco¹

Background / Hypothesis:

Chronic hepatitis B remains a major global health concern, associated with increased risk of progression to cirrhosis and hepatocellular carcinoma (HCC). Antiviral therapy with nucleos(t)ide analogues aims to suppress viral replication, prevent disease progression, and improve survival. Identifying factors that predict favorable virological response could help optimize patient management. This study aimed to evaluate clinical, virological, and biological characteristics associated with treatment response in patients with chronic hepatitis B receiving nucleos(t)ide analogue therapy.

Materials and Methods:

We conducted a retrospective, descriptive, and analytical study over a 7-year period (2018–2025), including all patients with chronic hepatitis B treated with nucleos(t)ide analogues. Patients under surveillance only or lost to follow-up were excluded. Collected data included demographic characteristics (age, sex), comorbidities (diabetes, hepatic steatosis, immunosuppression), viral coinfections (HCV, HDV), family history of cirrhosis or HCC, serological markers (HBsAg, anti-HBs, HBeAg, anti-HBe), baseline viral load, ALT levels, and fibrosis stage (F0–F2 vs. F3–F4). The primary outcome was sustained virological response (SVR), defined as viral load <2,000 IU/mL after treatment. Secondary outcome was complete virological response (CVR), defined as SVR with HBsAg

E-POSTER ABSTRACTS

loss. Statistical analyses included univariate analysis (Chi-square for qualitative variables, Mann–Whitney for quantitative variables) and multivariate logistic regression.

Results:

Eighty-one patients were included (45 men, 36 women; male-to-female ratio 1.25). Mean age was 47.5 years (range: 23–82). Comorbidities included diabetes in 12.3% (n=10), hepatic steatosis in 6.2% (n=5), HCV coinfection in 3.7% (n=3), HDV coinfection in 2.5% (n=2), and immunosuppression in 13.6% (n=11). Family history of cirrhosis or HCC was reported in 12.3% (n=10).

Treatment responses:

- SVR was achieved in 92.6% (n=75).
- CVR occurred in 7.4% (n=6).

Univariate analysis identified elevated ALT ($p=0.0029$), anti-HBe positivity ($p=0.0029$), HBeAg positivity ($p=0.0030$), and anti-HBs positivity ($p=0.0041$) as significantly associated with SVR. Age, diabetes, hepatic steatosis, fibrosis stage, and coinfections were not significantly associated with SVR. Analyses of CVR and serological response showed no statistically significant associations.

Multivariate analysis did not identify independent predictors of SVR, likely due to collinearity and the limited number of non-SVR events.

Conclusions:

Serological markers (anti-HBe, HBeAg, anti-HBs) and elevated ALT were associated with virological response, while metabolic and viral comorbidities had no impact. Complete virological response was rare. These findings support the value of baseline serological and biochemical markers in predicting antiviral response in chronic hepatitis B.

Keyword(s) : Chronic hepatitis B – Nucleos(t)ide analogues – Virological response – Predictive factors

1628 - A Prospective Study on a Group Mindfulness Based Intervention for Patients with Metabolic Dysfunction Associated Fatty Liver Disease Effects on Liver Steatosis and Psychological Symptoms

Qiangqian Wang¹, Peng Xiao¹, Taolong Zhou¹, Kefeng Li², Mingxing Huang¹

The Third People's Hospital Of Zhuhai, Hospital, Zhuhai-China¹ Macao Polytechnic University, University, Macao-China²

Background / Hypothesis:

The prevalence of Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD) is a growing global health concern. MAFLD is frequently comorbid with psychological distress; for instance, our previous research utilizing the UK Biobank cohort demonstrated a significant incidence of new-onset major depressive disorder among MAFLD patients. Mindfulness-Based Cognitive Therapy (MBCT), a structured group psychological intervention, is effective for treating depression and anxiety. However, its therapeutic potential in the MAFLD population, whose treatment has traditionally focused on pharmacologic and lifestyle interventions, remains unexplored. This study aimed to investigate the effects of a group MBCT intervention on liver steatosis and psychological symptoms in patients with MAFLD.

Materials and Methods:

This prospective, single-arm study recruited 34 patients diagnosed with MAFLD (Controlled Attenuation Parameter [CAP] > 238 dB/m, with comorbid obesity or dyslipidemia) from a hepatology outpatient clinic. Participants underwent an 8-week group MBCT program while continuing standard medical care. Liver steatosis (CAP value via transient elastography), depression (HAMD-17), anxiety (HAMA), sleep quality (PSQI), life satisfaction (SWLS), and mindfulness (MAAS) were assessed at baseline and post-intervention. Paired-sample t-tests were used to compare pre- and post-intervention outcomes. (Ethics Approval No: ZHSYKY2025042706; Clinical Trial Registration No: MR-44-25-077097).

Results:

At baseline, a high prevalence of psychological distress was observed, with 70.6% of participants reporting depressive symptoms and 64.7% reporting anxiety symptoms. Following the 8-week intervention, participants showed a statistically significant reduction in mean scores for depression (HAMD-17, $P = 0.048$) and anxiety (HAMA, $P = 0.014$). Positive, though not statistically significant, trends were observed for improvements in liver steatosis (mean CAP), Body Mass Index (BMI), sleep quality (PSQI), life satisfaction (SWLS), and mindfulness levels (MAAS) (all $P > 0.05$). Details are presented in Table 1 and Figure 1.

Conclusions:

E-POSTER ABSTRACTS

This study, the first of its kind in China, demonstrates that an 8-week group MBCT intervention can significantly alleviate depressive and anxiety symptoms in patients with MAFLD. While improvements in liver steatosis and other metabolic markers did not reach statistical significance, likely due to the small sample size and short study duration, the positive trends are encouraging. These findings provide a strong rationale and preliminary evidence for conducting larger, randomized controlled trials to validate the benefits of MBCT on both psychological and physiological outcomes in the MAFLD population. This research pioneers the integration of psychological care into the holistic management of MAFLD, suggesting a promising new adjunctive therapeutic avenue.

Keyword(s) : MAFLD MBCT

1630 - The effect of hepatic steatosis on the efficacy of immune based integrative treatment for viral HCC

Yanuo Chen¹

Southeast University, Medical School, Nanjing-China¹

Background / Hypothesis:

Studies have shown that immunotherapy combined with other therapies have positive clinical efficacy. However, there are also findings showing that HCC caused by NASH may not respond well to immunotherapy. Most HCC patients in Asian countries are caused by hepatitis virus infection, but with the improvement of life quality, more patients are also combined with varying degrees of hepatic steatosis. So it is significant to find out how patients with viral-HCC as well as liver steatosis respond to immunotherapy. Since immunotherapy alone is rarely used in the clinical treatment of advanced liver cancer, this study explored the effect of hepatic steatosis on the efficacy of immunotherapy-based comprehensive treatment for HCC caused by hepatitis virus, hoping to provide reference for individualized treatment of HCC.

Materials and Methods:

Clinical data, treatment strategies and follow-up data of 213 viral-HCC patients who were not suitable for direct surgical treatment from 2019.01 to 2023.12 in Nanjing Drum Tower Hospital were collected. Their efficacy was evaluated by mRECIST criteria. Patients were divided into four groups according to liver steatosis and whether they were treated with immunotherapy. The efficacy of each group was

compared. The independent risk factors affecting the efficacy were analyzed by univariate and multivariate Logistic regression. For follow-up data, Kaplan-Meier method was used to analyze the difference in survival rate. Cox regression analysis was performed to analyze the independent risk factors affecting the survival of patients.

Results:

1. For patients receiving immune combined therapy, the ORR(11.54%) and DCR(30.77%) in patients with hepatic steatosis were significantly lower than the ORR(41.18%) and DCR(69.93%) in patients without hepatic steatosis($P<0.05$). Hepatic steatosis, portal vein thrombosis and multiple tumors were independent risk factors for poor prognosis; 2. There was no significant difference between the efficacy of non-immune comprehensive treatment for liver steatosis patients and non-steatosis patients; 3. In patients with liver steatosis, the ORR(11.54%) and DCR(30.77%) in samples receiving immune combined therapy were significantly lower than the ORR(77.78%) and DCR(88.89%) in samples receiving non-immune therapy($P<0.05$), but Cox regression showed that the usage of immunotherapy was not an independent risk factor for patients' survival; 4. In patients without liver steatosis, there was no significant difference between the efficacy of immune combined therapy and non-immune combined therapy.

Conclusions: The efficacy of immune combined therapy in hepatic steatosis patients is worse than that in non-steatosis patients.

E-POSTER ABSTRACTS

Of Chinese Medicine, Department Of General Of Surgery, Nanning-China ² Jilin University, School Of Philosophy And Sociology, Jilin-China ³ First People's Hospital Of Nanning, Department Of Hepatobiliary And Pancreatic Surgery, Nanning-China ⁴ First People's Hospital Of Qinzhou, Department Of Hepatobiliary And Pancreatic Surgery, Qinzhou-China ⁵ Second Affiliated Hospital Of Guangxi Medical University, Department Of General Surgery, Liuzhou-China ⁶ People's Hospital Of Beiliu, Department Of Oncology, Yulin-China ⁷ People's Hospital Of Guangxi Zhuang Autonomous Region, Department Of Hepatobiliary, Pancreatic And Spleen Surgery, Nanning-China ⁸ Liuzhou Workers' Hospital, Department Of Oncology, Liuzhou-China ⁹ Affiliated Hospital Of Guilin Medical University, Department Of Hepatobiliary And Pancreatic Surgery, Guilin-China ¹⁰ Second Affiliated Hospital Of Guilin Medical University, Department Of Hepatobiliary And Pancreatic Surgery, Guilin-China ¹¹ Wuzhou People's Hospital, Department Of Hepatobiliary Surgery, Wuzhou-China ¹² Guangxi Medical University Cancer Hospital, Department Of Hepatobiliary Surgery, Nanning-China ¹³

Background / Hypothesis: Accurate identification of major pathological response (MPR) following conversion therapy is critical for determining the optimal surgical strategy and guiding the extent of resection in hepatocellular carcinoma (HCC). However, a non-invasive method for reliably predicting MPR remains unavailable. This study aims to develop ensemble learning models that integrated clinical and computed tomography (CT) radiomic features to predict MPR in HCC patients.

Materials and Methods: This retrospective study included 266 confirmed HCC patients from 11 Chinese centers who underwent conversion therapy followed by hepatectomy. The patients were randomly allocated into a training set (n = 186) and a validation set (n = 80). Patient demographics were analyzed to construct a clinical model. Radiomic features were extracted from preoperative contrast-enhanced CT images (venous phase) for each patient. Feature selection was performed using analysis of variance and the least absolute shrinkage and selection operator algorithm. A radiomics score was computed based on a radiomic signature formula. Subsequently, a combined clinical-radiomic model was developed. The model's performance was assessed using the receiver operating characteristic (ROC) curve, calibration curve, and decision curve analysis (DCA).

Results: A total of 1130 radiomic features were

extracted from the CT images of each patient, among which 7 features were selected based on their nonzero coefficients associated with MPR. Three clinically relevant factors—downstaging after conversion therapy, α -fetoprotein response, and Barcelona Clinic Liver Cancer stage—were significantly correlated with MPR. Among the evaluated algorithms, LightGBM achieved the best performance as assessed by five-fold cross-validation on the training set. After integrating the optimal algorithm with clinical factors, the combined radiomic model yielded areas under the ROC curve of 0.900 (95% CI: 0.855–0.938) for the training set and 0.791 (95% CI: 0.689–0.886) for the validation set. DCA further confirmed the clinical utility of the integrated model.

Conclusions: This study successfully developed an integrated clinical-CT radiomic model for predicting MPR, which may assist in guiding surgical decision-making for HCC patients after conversion therapy.

Keyword(s) : hepatocellular carcinoma, conversion therapy, major pathological response, radiomic

1632 - Predictive Value of INR and DBIL for Short Term Prognosis after the First Artificial Liver Support System Treatment in Patients with Acute on Chronic Liver Failure

Ma Haiwen Ma ¹, Wan Hong Wan ¹, Shi Wenjuan Shi ¹, Wei Li We ¹, Zhou Xiaoli Zhou ¹, Yang Xuefang Yang ¹, Yue Kong ²

The Second People's Hospital Of Lanzhou City, Department Of Infectious Diseases / Third Department Of Liver Diseases, Lanzhou City-China ¹ The First Affiliated Hospital Of Chengdu Medical College, Department Of Gastroenterology, Lanzhou-China ²

Background / Hypothesis:

Acute-on-Chronic Liver Failure (ACLF) carries a poor prognosis, and the Artificial Liver Support System (ALSS) is a critical therapeutic modality. However, early identification of individuals at high risk for poor clinical outcomes following their first ALSS treatment remains a significant clinical challenge. This study aimed to investigate the predictive value of International Normalized Ratio (INR) and Direct Bilirubin (DBIL) for 28-day prognosis in ACLF patients undergoing initial ALSS therapy.

Materials and Methods:

This retrospective study enrolled 150 ACLF patients meeting inclusion criteria who received ALSS treatment at Lanzhou Second People's Hospital, Gansu Province,

E-POSTER ABSTRACTS

China, between 2017 and 2025. Patients were stratified into a good prognosis group (n=99) and a poor prognosis group (n=51) based on their 28-day outcomes. Baseline characteristics and laboratory parameters were collected and compared between the groups. Univariate and multivariate logistic regression analyses were employed to identify independent prognostic risk factors. The predictive performance of INR and DBIL was evaluated using Receiver Operating Characteristic (ROC) curve analysis.

Results:

- 1、Baseline Characteristics: The poor prognosis group exhibited a significantly higher incidence of infection compared to the good prognosis group (49.0% vs. 31.3%, $P=0.034$). For other baseline comparisons where no significant differences were found (Age, Sex, Etiology, Cirrhosis, Ascites).
- 2、Laboratory Parameters: Levels of DBIL, INR, and Neutrophil-to-Lymphocyte Ratio (NLR) were significantly higher in the poor prognosis group, while Lymphocyte count (LYM) was significantly lower (all $P<0.05$).
- 3、Multivariate Analysis: Multivariate logistic regression analysis confirmed that both INR (OR = 4.318, 95% CI: 1.891-9.858, $P=0.001$) and DBIL (OR = 1.005, 95% CI: 1.001-1.010, $P=0.016$) were independent risk factors for poor 28-day prognosis.
- 4、ROC Curve Analysis: ROC curve analysis demonstrated that the predictive performance of INR (AUC = 0.669, 95% CI: 0.577-0.761) was superior to that of DBIL (AUC = 0.604, 95% CI: 0.508-0.699). At its optimal cut-off value of 1.775, INR predicted poor prognosis with a sensitivity and specificity of 74.5% and 56.6%, respectively.

Conclusions:

INR and DBIL serve as independent risk factors predicting the 28-day prognosis following the first ALSS treatment in ACLF patients. Notably, INR exhibits superior predictive value. In clinical practice, monitoring pre-treatment INR levels, particularly focusing on the critical threshold of >1.775 , holds significant practical value for risk assessment and facilitating individualized treatment strategies.

Keyword(s) : Acute-on-Chronic Liver Failure; INR; DBIL; Prognosis

1633 - MVPS and Thrombophilic Abnormalities as Leading Causes of Non Tumoral Portal Vein Thrombosis Epidemiological and Evolutionary Insights from a Cohort of 83 Patients

Chaïmaa Elmajoudi¹, Mohamed Borahma¹, Fatima

Zahra Chabib¹, Nawal Lagdali¹, Selma Sebbah¹, Fatima Zahra Ajana¹, Meryem Kadiri¹
Chu Ibn Sina, Mohammed V University, Rabat, Morocco, Department Of Hepato-gastroenterology C, Chu Ibn Sina, Rabat-Morocco¹

Background / Hypothesis:

Non-tumoral portal vein thrombosis (PVT) results from diverse mechanisms, in which porto-sinusoidal vascular disorders (PSVD/MVPS) and thrombophilic abnormalities play central roles. Their relative contributions and natural course remain incompletely characterized. This study aimed to describe the etiological distribution of non-tumoral PVT in a cohort of 83 patients, with a focus on MVPS and thrombophilic forms, and to analyze their epidemiological, radiological, and evolutionary characteristics.

Materials and Methods:

We retrospectively included 83 patients with imaging-confirmed non-tumoral PVT. Collected data included age, sex, etiology (MVPS, thrombophilia, cirrhosis, idiopathic), type and extension of thrombosis, and clinical evolution. Descriptive analyses were performed, with global comparisons across etiological groups.

Results:

Among 83 patients, main etiologies were MVPS (33; 39.8%), thrombophilia (32; 38.6%), idiopathic (15; 18.1%), and cirrhosis (3; 3.6%). Median age was 45 years, and 77% were women. PVT was total in 78% and partial in 20%. Extension involved the portal vein alone in 49.4%, splanchnic veins in 42.2%, and portal branches in 8.4%. Epidemiological and thrombosis profiles were largely similar between etiologies, although MVPS patients were slightly younger and showed somewhat more splanchnic extension. Clinical course was generally favorable: stable thrombosis in ~70%, cavernoma in 6%, progressive extension in 10%, regression/recanalization in 5%, and disease-related death in 10%. Overall prognosis was comparable across etiologies, though MVPS tended toward more cavernomas and extensions, and mortality was slightly higher in the thrombophilia group.

Conclusions:

In this cohort, MVPS and thrombophilic abnormalities were the leading causes of non-tumoral PVT. While

E-POSTER ABSTRACTS

clinical and radiological profiles were broadly similar across groups, MVPS and thrombophilic forms tended to exhibit more extensive thrombosis and complications. These findings highlight the importance of a thorough and targeted etiological assessment to guide management and follow-up.

Keyword(s) :

1635 - Predictors of Incomplete Biochemical Response to Ursodeoxycholic Acid in Primary Biliary Cholangitis Insights from a Moroccan Cohort

Rajae Belhocine¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Salma Sebbah¹, Fatima Zohra Ajana¹, Maryeme Kadiri¹
University Hospital Center Ibn Sina, Mohammed V University, Department Of Hepato-gastroenterology, Medicine C, Rabat-Morocco¹

Background / Hypothesis:

Ursodeoxycholic acid (UDCA) remains the cornerstone therapy for primary biliary cholangitis (PBC), but a substantial proportion of patients fails to achieve adequate biochemical response, which is associated with worse long-term outcomes. Identifying early predictors of incomplete response is essential for timely therapeutic optimization. This study aimed to determine the prevalence and clinical predictors of UDCA non-response in a Moroccan cohort, after excluding potential confounding factors.

Materials and Methods:

This retrospective analytical study included 101 patients diagnosed with PBC between 2016 and 2025 at a tertiary Moroccan center. Diagnosis was based on the 2017 EASL criteria. All patients received UDCA at standard doses (13–15 mg/kg/day), and biochemical response was assessed at 12 months according to the Paris II criteria. Patients with active autoimmune or endocrine disorders that could bias biochemical evaluation were excluded. Clinical, biochemical, and histological data were systematically analyzed. Comparisons between responders and non-responders were performed using univariate analysis to identify predictors of incomplete UDCA response.

Results:

The mean age at diagnosis was 49.8 years (range 18–78), with marked female predominance (sex ratio M/F = 0.10). Incomplete biochemical response to UDCA was observed in 50.5% of patients. Advanced fibrosis (F3–

F4) was strongly correlated with non-response ($p < 0.001$). Severe cholestasis, reflected by alkaline phosphatase $\geq 2 \times$ ULN ($p = 0.043$) and gamma-glutamyl transferase (GGT) $\geq 5 \times$ ULN ($p = 0.005$), as well as the presence of clinical portal hypertension ($p = 0.027$), were also significantly associated with poorer therapeutic outcomes. Conversely, age, sex, pruritus, anti-mitochondrial antibody positivity, and associated autoimmune diseases showed no significant correlation with UDCA response.

Conclusions:

This study provides additional insight into determinants of biochemical response to UDCA in PBC. The high proportion of incomplete responders highlights the heterogeneous therapeutic profile of the disease and underscores the need for early evaluation of disease severity. Advanced fibrosis and marked cholestasis emerged as the strongest predictors of treatment failure, reinforcing the relevance of baseline risk stratification. These findings support the development of refined treatment algorithms integrating early identification of high-risk patients and timely therapeutic intensification to improve long-term outcomes.

Keyword(s) : Primary biliary cholangitis, ursodeoxycholic acid, incomplete response, advanced fibrosis, predictors

1636 - Metabolic Dysfunction–Associated Steatotic Liver Disease in Normal Weight Individuals Clinical Biological Fibrosis and Autoimmune Profiles in a Moroccan Cohort

Imane El Mouatamid¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Selma Sabbah¹, Fatima Zahra Ajana¹, Maryeme Kadiri¹
Mohamed V University Ibn Sina Hospital, Medecine C, Rabat-Morocco¹

Background / Hypothesis:

Metabolic dysfunction–associated steatotic liver disease (MASLD), formerly known as non-alcoholic fatty liver disease (NAFLD), is usually linked to overweight and obesity. However, a subset of patients develops hepatic steatosis despite having a normal body mass index (BMI). This phenotype may involve distinct pathophysiological mechanisms and can progress to severe liver disease despite the absence of obesity. The aim of this study was to describe the prevalence, clinical and biological features, elastographic findings, associated metabolic and

E-POSTER ABSTRACTS

autoimmune conditions, and evolutionary profile of MASLD in normal-weight individuals in our population, and to raise awareness of this phenotype to guide tailored diagnostic and surveillance strategies.

Materials and Methods:

This retrospective, descriptive study included 68 patients with hepatic steatosis and BMI between 18 and 25 kg/m², selected from a cohort of 170 patients followed in a hepatology and gastroenterology department. Demographic, clinical, laboratory, metabolic, elastography data, and associated autoimmune conditions were collected. Liver fibrosis was assessed by elastography when available.

Results:

The mean age was 47 years (range 23–62), with a male-to-female ratio of 0.79. Most patients were asymptomatic; hepatic steatosis was discovered incidentally in 77%, while 16% presented with biliary colic and 7% with atypical epigastric pain. Liver function tests showed cytotoxicity in 31%, cholestasis in 11%, both in 10%, and normal profiles in 48%. Metabolic assessment was performed in 81% of patients: diabetes was present in 38%, dyslipidemia in 14%, hypertension in 17%, while 25% had no detectable metabolic disorder. Elastography showed F0–F1 fibrosis in 67.6% and F2 in 7.35%; no advanced fibrosis (F3–F4) was observed.

Associated autoimmune and other conditions were frequent: celiac disease in 22%, Crohn's disease in 14%, ulcerative colitis in 1.4%, and hepatitis C infection in 10%.

Conclusions:

MASLD in normal-weight individuals represents a distinct phenotype from obesity-related hepatic steatosis. A substantial proportion of normal-BMI patients develop steatosis, likely linked to metabolic abnormalities such as insulin resistance, dyslipidemia, or gut microbiota alterations, with a notable frequency of associated autoimmune conditions. These findings support recognition of normal-weight MASLD as a specific clinical entity, warranting tailored diagnostic evaluation and surveillance that considers both metabolic and autoimmune risk factors. Further larger studies are needed to confirm these results and to develop locally-adapted diagnostic and management algorithms.

1637 - The impact of serum lipids metabolism on the prognosis of hepatitis B virus related acute on chronic liver failure

Jing Lai¹, Hong Deng¹, Zhebin Wu¹, Xiaoan Yang¹, Hong Shi¹

Third Affiliated Hospital, Sun Yat-sen University, Department Of Infectious Diseases, Guangzhou-China¹

Background / Hypothesis:

At present, the relationship between lipids metabolism and the prognosis of liver failure is a hot spot. The purpose of this study was to explore the relationship between serum lipids parameters and the prognosis of hepatitis B virus related acute-on-chronic liver failure (HBV-ACLF).

Materials and Methods:

For patients with HBV-ACLF, to compare dynamic changes of serum lipids parameters in dead group with that of the group of survived more than 12 weeks. The diagnostic criteria were in accord with American Association for the study of Liver Diseases practice guidance on acute-on-chronic liver failure and the management of critically ill patients with cirrhosis in 2023. Differences between groups were made by the t-test. And $P < 0.05$ is considered statistically significant. Differences between groups were made by the t-test. And $P < 0.05$ is considered statistically significant.

Results:

From January 1, 2020 to July 1, 2025, 71 patients with HBV-ACLF had enrolled in Third Affiliated Hospital of Sun Yat-sen University, including 30 cases died within 5 weeks and 41 patients hand survived more than 12 weeks. Their ages were 43.73 ± 11.56 years and 46.38 ± 13.27 years respectively, and no significant difference was between the two groups ($P = 0.377$). The parameters values and the comparisons were shown in Table 1 and 2.

Except for HDL-C and Lipoprotein- α , the other parameters of the four weeks before death were significantly lower than those of survival group (all $P < 0.05$). After three weeks treatment, in survival group, lipids parameters had recovered. However, CHOL, HDL-C, LDL-C and ApoA-I values in one week before death

E-POSTER ABSTRACTS

were still significantly lower than that of survival group.

Conclusions:

Lipids metabolism disorder may worsen the prognosis of HBV-ACLF, especially hypolipidemia (CHOL, LDL-C and Lipoprotein- α). More treatment and related mechanism research need to be paid to improve serum lipid in HBV-ACLF.

Keyword(s) : Lipids metabolism; Hepatitis B virus related acute-on-chronic liver failure (HBV-ACLF); Prognosis

1638 - Indole 3 carbaldehyde mitigates fibrosis progression in MASH with T2DM via the SIRT1 TGF β SMAD signaling pathway

Lu Li¹, Ying-lan Ji¹, Rao-rao Wang¹, Ya-na Zhu¹, Yong Jiang¹

The Second Hospital Of Tianjin Medical University, Department Of Gastroenterology, Tianjin-China¹

Background / Hypothesis:

Hyperglycemia is an independent risk factor for the accelerated progression of metabolic dysfunction-associated steatohepatitis (MASH) to liver fibrosis, with the underlying mechanisms not yet fully elucidated. Microbial metabolites have emerged as critical components that mediate the metabolic effects in various diseases. However, the role of gut-derived metabolites in the development of liver fibrosis in MASH with type 2 diabetes mellitus (T2DM) remains unclear.

Materials and Methods:

A diabetic metabolic dysfunction-associated steatohepatitis (T2DM-MASH) mouse model was successfully established by high-fat diet (HFD) feeding combined with intraperitoneal injections of streptozotocin (STZ) and carbon tetrachloride (CCl₄). Metabolomics screening was conducted to identify characteristic metabolites associated with T2DM-MASH. Indole-3-carbaldehyde (3-Ald) was orally administered at two doses (25 and 50 mg/kg) for 6 weeks. The protective effect of Indole-3-carbaldehyde (3-Ald) on T2DM-MASH was assessed through in vivo experiment.

Results:

The induction of T2DM-MASH model was validated by metabolic disturbances (hyperglycemia, dyslipidemia), hepatic injury, and histopathological evidence of steatohepatitis (steatosis, inflammation, fibrosis). Fecal

3-Ald levels were significantly reduced in T2DM-MASH and inversely correlated with fasting blood glucose, histopathological fibrosis stage and lobular inflammation score. 3-Ald supplementation significantly ameliorated the biochemical results (glucose, cholesterol, triglycerides, alanine transaminase (ALT), aspartate transaminase (AST), $p < 0.05$) and pathological features of T2DM-MASH. Moreover, ultrastructural intestinal damage was observed in T2DM-MASH mice, while administration of 3-Ald restored gut barrier function by upregulating tight junction proteins (ZO-1, occludin; $p < 0.05$), leading to a significant reduction in plasma LPS ($p < 0.05$). Mechanistically, 3-Ald supplementation reduced TNF- α levels ($p < 0.05$), increased MMP-1 and SIRT1 levels ($p < 0.05$), and reduced α -SMA, TIMP-1, TGF- β 1, p-Smad2 and p-Smad3 levels ($p < 0.05$) in T2DM-MASH mice compared to vehicle control, leading to an alleviation of inflammation and fibrosis. The hepatoprotective and antifibrotic effects of 3-Ald were mostly dose-dependent.

Conclusions: Our findings, for the first time, underscore the potential of the microbial metabolite 3-Ald to attenuate fibrosis progression in T2DM-MASH by regulating the SIRT1/TGF- β /SMAD pathway, offering novel insights and promising therapeutic strategies for its management.

Keyword(s) : Metabolic dysfunction-associated steatohepatitis; Type 2 diabetes mellitus; Indole-3-carbaldehyde; Liver fibrosis; SIRT1/TGF- β /SMAD pathway

1639 - TRPV4 Cooperates with HBx to Promote HBV Replication Through a Calcium Mediated Positive Feedback Loop

Yu Zhang¹, Minghui Li¹, Huichun Xing¹, Jun Cheng¹
Beijing Ditan Hospital Of Capital Medical University, Department Of Hepatology, Beijing-China¹

Background / Hypothesis: Hepatitis B virus (HBV) infection continues to impose a significant worldwide health burden. A primary obstacle to cure is the persistence of covalently closed circular DNA (cccDNA), which current therapies cannot eradicate. Therefore, further decoding of the HBV life cycle is imperative for developing novel antiviral strategies. We have previously demonstrated that the host factor TMEM203, which modulates calcium signaling, acts as a suppressor of HBV replication. This discovery offers compelling evidence for the critical role of intracellular

E-POSTER ABSTRACTS

calcium signaling in facilitating the viral replication process.

Materials and Methods:In this study, utilizing two HBV stable cell models (HepAD38 and HepG2.2.15 cells), we performed both knockdown and overexpression of the TRPV4 gene. The levels of hepatitis B surface antigen (HBsAg) and e antigen (HBeAg) in the cell culture supernatant were quantified by enzyme-linked immunosorbent assay (ELISA). HBV DNA in the supernatant, intracellular HBV DNA, and covalently closed circular DNA (cccDNA) were measured by quantitative real-time PCR (qPCR). Intracellular HBV core protein expression was detected by western blot analysis, while HBV RNA levels were assessed using reverse transcription qPCR (RT-qPCR). The effect of TRPV4 on HBx protein stability was evaluated using a protein half-life assay. Intracellular calcium levels were monitored by immunofluorescence. The physical interaction between TRPV4 and HBx was examined by co-immunoprecipitation (Co-IP). Furthermore, the regulatory role of TRPV4 in HBV nucleocapsid assembly was investigated using native agarose gel electrophoresis and a DNA release assay.

Results:In this study, we found that transient receptor potential vanilloid 4 (TRPV4) notably enhances HBV reproduction by investigating the effects of several calcium ion-related molecules on HBV replication. The in-depth study showed a positive feedback loop is established between TRPV4 and HBx: TRPV4 elevates HBx levels by augmenting its transcription and stabilizing the protein, while HBx upregulates TRPV4 expression via TBP, leading to increased cytosolic calcium. This reciprocal regulation ultimately activates the Pyk2/Src pathway to enhance HBV replication.

Conclusions:In conclusion, TRPV4 could interact with HBV core protein and regulate HBV during transcription and replication. These data suggest that TRPV4 exerts multifaceted HBV-related synergistic factors and may serve as a therapeutic target for CHB.

Keyword(s) : TRPV4, HBV, cccDNA, HBx, Calcium signaling

1643 - PREDICTIVE SCORING MODEL FOR HEPATOCELLULAR CARCINOMA AMONG FILIPINO PATIENTS A 10 YEAR RETROSPECTIVE STUDY

Jessica Kristy Quiza¹, Jenny Limquiaco²

Chong Hua Hospital Cebu, Internal Medicine, Cebu-Philippines¹ Chong Hua Hospital Cebu, Internal Medicine - Adult Gastroenterology, Cebu-Philippines²

Background / Hypothesis:

Hepatocellular carcinoma (HCC) remains a leading

cause of cancer-related mortality globally. Early risk stratification models integrating clinical and biochemical markers are essential to improve detection and management, particularly among Filipino patients who bear a significant disease burden. This study aimed to develop and validate a predictive scoring model for HCC based on demographic, clinical, and laboratory data.

Materials and Methods:

A retrospective review of 400 patient records, comprising 200 HCC cases and 200 controls without HCC, was conducted. Variables analyzed included age, sex, body mass index, comorbidities, liver function tests, hematological parameters, and tumor marker alpha-fetoprotein (AFP). Binomial logistic regression identified independent predictors of HCC. Model performance metrics such as accuracy, sensitivity, specificity, and area under the receiver operating characteristic curve (AUC) were evaluated.

Results:

Significant predictors of HCC included AFP levels ($p < 0.001$), prothrombin time (INR) ($p = 0.012$), platelet count ($p < 0.001$), and smoking status ($p = 0.008$). Age, ALT, albumin, and platelet-to-lymphocyte ratio were not independently significant. The model attained an accuracy of 73.5%, sensitivity of 78.0%, specificity of 69.3%, and an AUC of 0.834, demonstrating robust discrimination between HCC and non-HCC patients.

Conclusions:

The developed predictive scoring model effectively identifies Filipino patients at elevated risk for HCC, supporting targeted screening and early intervention. Implementation of this model in clinical practice is recommended to improve disease prognosis. Further prospective validation is warranted to optimize clinical utility.

Keyword(s) : Hepatocellular carcinoma, predictive model, alpha-fetoprotein, prothrombin time, platelet count

1644 - Epidemiological Clinical and Therapeutic Profile of Chronic Hepatitis B in a North African Cohort Determinants of Advanced Fibrosis

Rajae Belhocine¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Salma Sebbah¹, Fatima Zohra Ajana¹, Maryeme Kadiri¹

University Hospital Center Ibn Sina, Mohammed V

E-POSTER ABSTRACTS

University, Department Of Hepato-gastroenterology, Medicine C, Rabat-Morocco ¹

Background:

Chronic hepatitis B virus (HBV) infection remains a major global health challenge and a leading cause of cirrhosis and hepatocellular carcinoma (HCC). Despite therapeutic advances, functional cure is rarely achieved, especially in endemic regions. This study aimed to describe the epidemiological, clinical, virological, and therapeutic profiles of chronic HBV infection and to identify factors associated with advanced fibrosis (F3–F4) in a cohort followed over two decades in a North African tertiary center.

Materials and methods:

This retrospective analytical study included 124 patients diagnosed with chronic HBV between 2005 and 2025. Demographic, clinical, biochemical, serological, and histological data were collected, including HBV markers, fibrosis assessment by elastography or biopsy, and viral co-infections. Therapeutic outcomes assessed were biochemical and virological response, HBeAg seroconversion, and HBsAg loss. Logistic regression analysis identified independent predictors of advanced fibrosis.

Results:

The mean age 46.8 years, with a sex ratio M/F of 0.9. Most patients were asymptomatic at diagnosis (75.8%). Abdominal ultrasound revealed signs of chronic liver disease in 16.9%, hepatic steatosis in 16.1%, and features of portal hypertension in 12%. Comorbidities included alcohol use (10.5%), diabetes mellitus (11.3%), and smoking (11.3%). HBsAg was positive in 96.8% of patients, and 7.2% were HBeAg-positive, with a median HBV DNA level of 9.2×10^6 IU/mL. Fibrosis assessment showed F0–F1 in 67.3%, F2 in 18.5%, and advanced fibrosis (F3–F4) in 9.7%.

Antiviral therapy was mainly tenofovir disoproxil fumarate (56.5%), followed by entecavir (3.2%), tenofovir alafenamide (1.6%), pegylated interferon (1.6%), and lamivudine (0.9%), while 37.9% were managed with clinical surveillance. During follow-up, HBV DNA decreased to a median of 10 IU/mL in treated patients. Biochemical response was achieved in 89.5% of treated cases, HBeAg seroconversion occurred in 88.8% of initially positive patients, and HBsAg loss was documented in 5.6%.

Advanced fibrosis was significantly associated with alcohol use, diabetes, age >50 years, and HCV co-infection ($p < 0.05$). Viral load strongly correlated with fibrosis severity ($r = 0.72$, $p < 0.001$), although some discordant cases were observed. In multivariate analysis, male sex, family history of cirrhosis, and

presence of portal hypertension were independent predictors of advanced fibrosis (all $p < 0.05$).

Conclusion:

Chronic HBV infection in this cohort was often silent and detected at early stages. Despite effective viral suppression, HBsAg loss remained rare. The role of alcohol, metabolic factors, and age in fibrosis progression underscores the need for early detection, individualized management, and improved access to antiviral therapy to support HBV elimination goals.

Keyword(s) : Chronic hepatitis B, antiviral therapy, fibrosis, predictors, epidemiology

1645 - The dynamic of APRI and FIB 4 scores over a 10 year period in HCV cirrhotic patients after virological cure with direct acting antivirals therapy

Anca Saran ¹, Violeta Molagic ², Alina-elena Orfanu ², Anca Flueratoru ³, Nicoleta Mihai ², Catalin Tiliscan ¹, Aida Isabela Adamescu ¹, Isabela Staicu ¹, Sorin Stefan Arama ⁴, Victoria Arama ¹

University Of Medicine And Pharmacy, Infectious Diseases, Bucharest-Romania ¹ University Of Medicine And Pharmacy, Infectious Diseases, Bucharest-Romania ² National Institute For Infectious Diseases, Infectious Diseases, Bucharest-Romania ³ University Of Medicine And Pharmacy, Physiopathology, Bucharest-Romania ⁴

Background / Hypothesis: Direct Acting Antivirals (DAA) have started being used in Romania since 2015 according to National Protocols for treatment. In the first years, the evaluation of liver fibrosis was made using FibroMax, but presently, the National Protocol for HCV treatment has added the APRI and FIB-4 scores along with Fibromax for fibrosis staging.

Materials and Methods: This prospective study was conducted between 2015 and 2025 in "Matei Balș" National Institute for Infectious Disease. It evaluates the dynamic of other liver tests besides Fibromax to identify easier methods to evaluate the fibrosis for patients treated with DAA and who achieved SVR. The patients were evaluated using FibroTest, AST to Platelet Ratio Index (APRI) and Fibrosis-4 score (FIB-4) at baseline, at 6 months post-end of treatment (post-EOT), at 1-year post-EOT and yearly afterwards.

Results: In this study, 169 patients with HCV compensated cirrhosis were evaluated at baseline. At

E-POSTER ABSTRACTS

treatment initiation, the median value of Fibrotest was 0.84, the median APRI score was: 1.15 and the median FIB-4 score was: 3.45. APRI and FIB-4 were correlated with the liver fibrosis – graded by Fibrotest ($p=0.03$ for APRI and $p<0.001$ for FIB-4). At 6 months post EOT, 107 patients were analyzed using APRI and FIB-4. The median value for APRI at the 6 months evaluation was 0.45 and the median value for FIB-4 was 2.12. Regarding the correlation between the two fibrosis scores and FibroTest, both are statistically significant correlated ($p=0.03$ for APRI and $p<0.001$ for FIB-4). At 1-year post-EOT, for 71 patients evaluated, the median APRI score was 0.42 and the median FIB-4 score was 1.96. For this evaluation, only FIB-4 correlated statistically with FibroTest ($p=0.019$). At 2 years post-EOT, 44 patients were evaluated and APRI had a median value of 0.41 and FIB-4 had a median value of 2.03 but no longer correlate with the values of FibroTest. At the last evaluation, at 7 years post-EOT, 27 patients had a median value for APRI of 0.38 and for FIB-4 of 2.02, without any correlation with FibroTest. The difference in the number of patients between baseline and the end of follow-up is due to the pandemic when most patients were lost from follow-up.

Conclusions: APRI and FIB-4 prove to be easier non-invasive markers of liver stiffness, highly correlated at baseline and at 6 months post-EOT with Fibrotest, accurate for the diagnosis of cirrhosis, and FIB-4 can be a useful score for monitoring the liver fibrosis post-EOT.

Keyword(s) : APRI, FIB-4, fibrosis, DAA

1648 - Predictive factors of complications and treatment response in patients with autoimmune hepatitis A 8 Year Single Center Study

Ouafae Dahri¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Selma Sabbah¹, Fatima Zohra Ajana¹, Maryeme Kadiri¹
Mohammed V University, Ibn Sina Hospital,
Hepatogastroenterology C, Rabat-Morocco¹

Background:

Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease that can lead to severe complications. Identifying predictors of complications and treatment response is crucial for risk stratification and optimizing management. This study aimed to determine factors associated with complications and response to

immunosuppressive therapy in AIH patients.

Materials and Methods:

We conducted an 8-year retrospective single-center study (2017–2025) including 48 AIH patients diagnosed according to simplified IAHG criteria. Demographic, clinical, biochemical, and histological data were collected. Complications included ascites, gastrointestinal bleeding, and hepatic encephalopathy. Therapeutic response was classified as complete or partial based on biochemical normalization. Statistical analysis used Chi-square/Fisher's tests for categorical variables and Student's t-test for continuous variables; significance was set at $p<0.05$.

Results:

The cohort included 48 patients (median age 38 years; male/female ratio 0.2). Autoimmune comorbidities were frequent (75%), mainly primary biliary cholangitis (55.6%) and autoimmune thyroiditis (52.8%). Clinically, jaundice (70.2%), hepatomegaly (60.9%), and splenomegaly (43.5%) were common. Cytolysis occurred in 87.5%, cholestasis in 85.4%, and hepatocellular insufficiency in 41.7%. Histology revealed lymphoplasmacytic infiltrate (86.8%), interface hepatitis (71.7%) and advanced fibrosis F3–F4 (63.5%). Portal hypertension was present in 54.2%. Complications occurred in 39.6% of patients, primarily ascites, GI bleeding, and hepatic encephalopathy. Portal hypertension (OR 12.1, $p<0.001$) and F4 cirrhosis (OR 11.0, $p<0.001$) were independent predictors. Patients already decompensated at diagnosis (initial complications) and those with portal hypertension were more likely to show partial response to immunosuppressive therapy (OR 2.9, $p\approx 0.04$). Age, sex, autoimmune comorbidities, hepatocellular insufficiency, autoantibody profile, and histology did not significantly influence treatment response.

Conclusion:

Portal hypertension and cirrhosis strongly predict complications in AIH. Presence of initial decompensation and portal hypertension at diagnosis is associated with partial response to therapy. Early identification and monitoring of high-risk patients are essential to optimize outcomes.

E-POSTER ABSTRACTS

1650 - A Pilot Study on Hepatitis B Core Related Antigen (HBcrAg) as a Novel Marker for Monitoring Antiviral Therapy in Chronic Hepatitis B Patients

Pravinkumar Rejliwal¹

Max Superspeciality Hospital, Gastroenterology And Hepatology, Ghaziabad-India¹

Background / Hypothesis:

Chronic Hepatitis B (CHB) affects over 400 million people worldwide and remains a major cause of cirrhosis and hepatocellular carcinoma. Although nucleos(t)ide analogue (NA) therapy effectively suppresses viral replication, optimal criteria for safe treatment discontinuation remain unclear. Covalently closed circular DNA (cccDNA), the key reservoir sustaining HBV persistence, cannot be evaluated routinely. Hepatitis B core-related antigen (HBcrAg), which correlates with intrahepatic cccDNA and HBV DNA levels, has emerged as a promising surrogate biomarker. This pilot study hypothesized that combined negativity of HBV DNA and HBcrAg could predict sustained remission following NA cessation in CHB patients, and that HBcrAg may serve as a reliable marker to guide treatment discontinuation.

Materials and Methods:

This pilot observational study included 59 adult CHB patients attending the Liver Clinic, Max Super Speciality Hospital, Vaishali, who had received at least four years of NA therapy (entecavir/tenofovir) and achieved HBV DNA negativity at baseline. Patients with cirrhosis, hepatitis C co-infection, autoimmune hepatitis, alcohol-related liver disease, or HCC were excluded. HBcrAg was quantified using a chemiluminescent enzyme immunoassay with a lower detection threshold of 3 log U/mL. Patients who achieved both HBV DNA and HBcrAg negativity discontinued NA therapy and were followed for one year, with assessments at 6-monthly intervals including LFTs, HBV DNA and HBcrAg. Relapse was defined as HBV DNA >2000 IU/mL, reappearance of HBcrAg, or ALT/AST elevation >1.5 × ULN.

Results:

Of 59 patients (mean age 35.9 ± 11.4 years; 76.3% male), 83.1% were HBeAg-negative. All achieved HBV DNA negativity at baseline. After NA cessation, 56/59 patients (94.9%) remained HBV DNA-negative at 6 months, while 3 patients (5.1%) developed virological

relapse. Patients who relapsed demonstrated reappearance of both HBV DNA and HBcrAg. Those who maintained remission had persistently negative HBcrAg throughout follow-up, supporting its value as a surrogate of minimal residual cccDNA activity. No significant biochemical flares or ALT elevations were observed among sustained responders. HBcrAg negativity at cessation strongly correlated with relapse-free status on short-term follow-up.

Conclusions:

In this pilot Indian cohort, combined HBV DNA and HBcrAg negativity at the time of NA cessation was associated with a high rate (94.9%) of sustained viral suppression at 6-month follow-up. HBcrAg proved to be a useful non-invasive biomarker for monitoring antiviral therapy and predicting early relapse after treatment withdrawal. Although long-term follow-up is required, these findings support the incorporation of HBcrAg into treatment-cessation algorithms to improve individualized management of CHB.

Keyword(s) : Chronic Hepatitis B; HBcrAg; HBV DNA; cccDNA surrogate marker; Nucleos(t)ide analogue cessation; Virological relapse; Antiviral therapy monitoring

1651 - The dynamic of alpha fetoprotein in patients with hepatitis C cirrhosis after direct acting antivirals therapy over a 10 year period

Anca Saran¹, Violeta Molagic², Alina-elena Orfanu², Anca Flueratoru³, Nicoleta Mihai⁴, Catalin Tiliscan¹, Aida Isabela Adamescu⁵, Isabela Staicu⁵, Sorin Stefan Arama⁶, Victoria Arama¹

University Of Medicine And Pharmacy "Carol Davila", National Institute For Infectious Diseases "Matei Bals", Infectious Diseases, Bucharest-Romania¹ University Of Medicine And Pharmacy "Carol Davila", Infectious Diseases, Bucharest-Romania² National Institute For Infectious Diseases "Matei Bals", Infectious Diseases, Bucharest-Romania³ University Of Medicine And Pharmacy "Carol Davila", National Institute For Infectious Diseases "Matei Bals", Infectious Diseases, Bucharest-Romania⁴ University Of Medicine And Pharmacy "Carol Davila", Infectious Diseases, Bucharest-Romania⁵ University Of Medicine And Pharmacy "Carol Davila", Physiopathology, Bucharest-Romania⁶

Background / Hypothesis: For patients with hepatitis C virus (HCV) infection, after the virological cure, the main concern is monitoring the dynamic of liver

E-POSTER ABSTRACTS

fibrosis and the occurrence of hepatic complications (liver decompensation or hepatocellular carcinoma (HCC)).

Materials and Methods:The objective of this study is to evaluate the dynamics of AFP for cirrhotic patients who achieved SVR after treatment with DAA. We conducted a prospective study on HCV compensated cirrhosis patients, monitored in "Matei Bals" National Institute for Infectious Diseases between 2015 - 2025. The patients were evaluated at baseline, at 6 months post end of treatment (EOT), 1 year after EOT, and once a year afterwards. The monitoring included the evaluation of FibroTest and AFP at each visit.

Results:Since November 2015, 169 patients with HCV cirrhosis were enrolled in the study. Before starting the DAA treatment, the median value of AFP was 9.71 ng/ml, with a minimum 0.1 ng/ml and a maximum 253.8 ng/ml. At the 6 months post-EOT visit, 73 patients were evaluated, with a median AFP of 4.9 ng/ml, with a statistically significant decrease from baseline ($p < 0.005$). At 1 year post-EOT, 45 patients were evaluated, with the median AFP of 4.1 ng/ml, without any statistically significant difference from the second visit ($p = 0.3$). At 2 years post-EOT, 28 patients were evaluated, with an AFP median value of 3.3 ng/ml, without any significant difference from the previous evaluation ($p = 0.89$). At 3 years post-EOT, 30 patients were evaluated, with a median value of AFP of 0.85 ng/ml, with a statistically significant decrease from the previous year ($p = 0.009$). At 7 years post-EOT, 19 patients were evaluated, with a median AFP of 3.9 ng/ml, without any significant difference from the evaluation at 3 years post-EOT, but the difference from baseline until the end of monitoring remains statistically significant ($p = 0.006$). None of the patients who were evaluated at 7 years post-EOT developed HCC. The difference in the number of patients between baseline and the end of follow-up is due to the pandemic when most patients were lost from follow-up.

Conclusions:Although the difference of AFP between the 3 years post-EOT visit and 7 years post-EOT visit is not statistically significant, there seems to be an increase in value, which means that cirrhotic HCV

patients need to be closely monitored at least once a year to be able to diagnose the early stages of liver complications predicted by the increase of the value of AFP.

Keyword(s) : fibrosis, DAA, AFP, cirrhosis

1654 - Long Term Prognosis of Acute HBV Cases

Selma Tosun¹, Feyza Ozsalar²

University Of Health Sciences Turkey, Izmir Faculty Of Medicine, Izmir City Hospital, Infectious Diseases And Clinical Microbiology, Izmir-Türkiye¹ Izmir City Hospital, , Izmir-Türkiye²

Background / Hypothesis:The study aimed to investigate the long-term prognosis of cases diagnosed with acute viral hepatitis B virus (HBV) infection.

Materials and Methods:Following ethical committee approval, the characteristics and long-term prognosis of acute viral hepatitis B cases hospitalized and monitored at İzmir Bozyaka Training and Research Hospital and İzmir City Hospital were evaluated both through the hospital automation system and by face-to-face interviews with patients who came for follow-up, and by checking their current results. Acute exacerbations of chronic hepatitis and autoimmune hepatitis were excluded.

Results:Data was obtained from a total of 104 patients, 70 of whom were male (67.3%), born between 1991 and 1941. Forty-three point three percent of the cases were born between 1985 and 1990, 27.9% between 1974 and 1984, and 12.5% between 1973 and 1963. The years with the highest number of cases were 2010 (14 cases), 2025 (11 cases), 2009 (9 cases), 2012-2014-2017-2024 (8 cases), 2008 (7 cases), 2011-2013-2016 (8 cases), 2018-2023 (3 cases), 2022 (2 cases), and 2019 (1 case). A significant increase in cases was observed between 2024 and 2025. Approximately 90% of the cases were found to be sexually transmitted. When the long-term follow-up results of the cases were evaluated, as of November 2025, anti-HBs was detected in half of the 104 patients whose data was available (52 individuals); 13 individuals (12.5%) remained HBsAg positive and were undergoing follow-up/treatment; 10 patients (9.6%) had isolated anti-HBcIgG positivity; 1 patient underwent liver transplantation due to fulminant course, 1 patient was referred to an organ transplant center due to high INR, and 1 patient died due to fulminant course and liver failure. Twenty-four patients (23%) did not attend follow-up appointments, and no recent visits were found in the automated records; therefore, no

E-POSTER ABSTRACTS

information could be obtained about the outcome of these patients. Two patients have not yet completed the 6-month follow-up period, and their HBsAg positivity continues.

Conclusions: Thanks to the national HBV vaccination program implemented in our country since 1998, acute HBV cases have decreased significantly in children and adolescents. However, acute HBV cases continue to be seen in the adult age group, predominantly transmitted through sexual contact. Therefore, we believe that screening adults, especially those in their sexually active years, for HBV and vaccinating seronegative individuals will make a significant contribution, in line with the strategies emphasized in the 2025-2030 version of the Viral Hepatitis Prevention and Control Program in our country.

Keyword(s) : HBV, acute infection, prognosis

1655 - Alcoholic Liver Disease with Sarcopenia Association with Increased Fall Risk and Impaired Activity of Daily Living

Xiaofang Zhao ¹, Lingchen Kong ¹, Shibo Ji ¹, Yingying Zhao ¹, Minghui Li ², Huichun Xing ¹

Beijing Ditan Hospital, Capital Medical University, Center Of Liver Diseases Division 3, Beijing-China ¹

Beijing Ditan Hospital, Capital Medical University, Center Of Liver Diseases Division 2, Beijing-China ²

Background / Hypothesis:

To analyze the association of sarcopenia, fall risk, and activity of daily living (ADL) in patients with alcoholic liver disease (ALD)

Materials and Methods:

A cross-sectional study was conducted involving patients hospitalized in the Third Department of Liver Diseases at Beijing Ditan Hospital, Capital Medical University, between January 2021 and December 2024.

Results:

The prevalence of sarcopenia in ALD patients was 34.9%, and the rate of ADL decline was 44.2%. The proportion of patients with ADL decline was significantly higher in the sarcopenia group than in the non-sarcopenia group (24% vs. 20.2%, $\chi^2 = 17.204$, $P < 0.001$). Spearman's correlation analysis indicated that the occurrence of sarcopenia in ALD patients was negatively correlated with ADL scores at admission and discharge, albumin level, hemoglobin level, body mass index (BMI), and blood phosphorus level, and positively correlated with fall risk score (all $P < 0.05$). Binary logistic regression analysis identified the following risk factors for sarcopenia in ALD patients:

age (OR = 1.056, 95% CI: 1.017–1.096, $P = 0.005$), admission ADL score (OR = 0.960, 95% CI: 0.938–0.982, $P < 0.001$), discharge ADL score (OR = 0.941, 95% CI: 0.910–0.974, $P < 0.001$), fall risk score (OR = 1.028, 95% CI: 1.007–1.050, $P = 0.009$), albumin level (OR = 0.853, 95% CI: 0.783–0.930, $P < 0.001$), hemoglobin level (OR = 0.984, 95% CI: 0.970–0.998, $P = 0.022$), blood phosphorus level (OR = 0.127, 95% CI: 0.025–0.630, $P = 0.012$), and BMI (OR = 0.689, 95% CI: 0.588–0.808, $P < 0.001$). Multivariate regression analysis demonstrated that discharge ADL score (OR = 0.940, 95% CI: 0.898–0.985, $P = 0.009$), albumin level (OR = 0.834, 95% CI: 0.737–0.943, $P = 0.004$), and BMI (OR = 0.677, 95% CI: 0.565–0.811, $P < 0.001$) were independent risk factors for sarcopenia in ALD patients.

Conclusion

The prevalence of sarcopenia in ALD patients was 34.9%, and the rate of ADL decline was 44.2%. Sarcopenia was associated with decreased ADL, increased fall risk, hypoalbuminemia, anemia, and low body weight. Low BMI, advanced age, hypoalbuminemia, impaired ADL, and high fall risk were risk factors for sarcopenia, while discharge ADL score, albumin level, and BMI were independent influencing factors for sarcopenia (all $P < 0.05$).

Discussion

It demonstrates that patients with ALD and sarcopenia commonly exhibit reduced ADL and an increased risk of falls. It is therefore essential to develop a systematic nursing care plan focused on fall prevention and ADL improvement for this population.

Keyword(s) : Sarcopenia, Alcoholic Liver Disease, Fall Risk, activity of daily living

1657 - Research on gut microbiota characteristics of PBC patients at different ALBI grades based on machine learning

Han Shi ¹, Qi Wang ², Ronghua Jin ³

Beijing Hospital, Endocrinology And Metabolism, Beijing-China ¹ Beijing Ditan Hospital, Hepatology, Beijing-China ² Beijing Ditan Hospital, -, Beijing-China ³

Background / Hypothesis:

The Albumin-Bilirubin (ALBI) score and grade are widely used to stratify patients with primary biliary cholangitis (PBC) into different disease statuses and risk levels. Recent studies have increasingly highlighted the role of gut microbiota in autoimmune liver diseases. This study aimed to investigate the differences in gut microbiota among PBC patients with varying ALBI grades.

Materials and Methods:

E-POSTER ABSTRACTS

Clinical data and stool samples were collected from outpatient and inpatient PBC patients between 2019 and 2022. Gut microbiota profiles were obtained using 16S rDNA sequencing of stool samples. We analyzed alpha diversity, beta diversity, LEfSe analysis and pathway function prediction. Additionally, various machine learning methods—including random forest (RF), lasso, gradient boosting machine (GBM) and support vector machine (SVM)—were employed to identify key features and to build and validate predictive models using bootstrap techniques.

Results:

Clinical characteristics of ALBI grade 1 patients were comparatively better than those of ALBI grade 2 and 3 patients, including multiple laboratory indices. Gut microbiota analysis revealed that species richness and balance were higher in ALBI grade 1 patients. Both the comparison of the most abundant genera and the linear discriminant analysis (LDA) in LEfSe demonstrated that *Lachnospira* had a higher abundance and better discriminative ability in ALBI grade 1. Pathway function prediction indicated that sulfur metabolism was upregulated in higher ALBI grades. Furthermore, RF identified 10 specific genera, which were then used to build and validate models for discriminating PBC patients according to their ALBI grades. All three models, developed using different machine learning methods, demonstrated good discrimination ability (mean AUC 0.75–0.80).

Conclusions:

This study highlights significant differences in gut microbiota profiles among PBC patients with different ALBI grades. The increased abundance of *Lachnospira* and upregulation of sulfur metabolism pathways are notable in patients with lower ALBI grades. The machine learning models developed based on gut microbiota features offer promising tools for discriminating between PBC patients with varying disease severities, which could enhance the precision of treatment strategies.

Keyword(s) : primary biliary cholangitis, albumin-bilirubin grade, gut microbiota, machine learning

1658 - Exploring Factors Influencing Public Intention to Receive Hepatitis E Vaccination Based on the Theory of Planned Behavior

Chaoqian Huang¹, Shu Li¹, Chao Cai¹, Mingqin Lu¹

The First Affiliated Hospital Of Wenzhou Medical University, Department Of Infectious Disease And Hepatology, Wenzhou-China¹

Background / Hypothesis:

The study applied the Theory of Planned Behavior (TPB), including attitude, subjective norms, and perceived behavioral control, to identify factors influencing public intention and actual behavior regarding hepatitis E (HEV) vaccination, with the goal of informing strategies to improve vaccine uptake.

Materials and Methods:

From December 2023 to April 2024, an anonymous online questionnaire was used to collect data on HEV vaccination intention and outcomes, TPB-related scores, levels of knowledge and attention regarding the HEV vaccine, demographic characteristics, current health status, past health behaviors, and hepatitis-related social exposure. Chi-square tests and binary logistic regression were used to identify factors associated with vaccination intention and actual vaccination behavior.

Results:

A total of 651 valid responses were obtained. Among them, 158 participants (24.23%) were unwilling to receive the HEV vaccine, while 493 (75.73%) expressed willingness; among those willing, 41 individuals (6.30%) had actually been vaccinated. Significant differences in willingness ($p < 0.05$) were observed across age, education, occupation, hepatitis-related vaccination history within the past 10 years, knowledge and attention toward the HEV vaccine, and TPB dimensions (attitude, subjective norms, and perceived behavioral control). Logistic regression identified attitude ($p < 0.001$, $\text{Exp}(B)=3.515$), subjective norms ($p < 0.001$, $\text{Exp}(B)=3.515$), perceived behavioral control ($p=0.014$, $\text{Exp}(B)=1.880$), and attention ($p=0.043$, $\text{Exp}(B)=1.568$) as independent predictors of vaccination intention. Among those expressing willingness, binary analysis indicated that attention ($p=0.027$, $\text{Exp}(B)=4.148$), knowledge ($p=0.019$, $\text{Exp}(B)=2.424$), perceived behavioral control ($p=0.039$, $\text{Exp}(B)=2.819$), and hepatitis-related vaccination in the past 10 years ($p=0.047$, $\text{Exp}(B)=2.119$) influenced actual vaccination behavior.

Conclusions:

The TPB model effectively evaluates public intention to receive the HEV vaccine. A clear gap exists between intention and actual vaccination. Prior hepatitis-related vaccination, knowledge level, attention toward the HEV vaccine, and perceived behavioral control all affected vaccination behavior. Strengthening public education and communication may improve intention, while

E-POSTER ABSTRACTS

simplifying procedures and optimizing costs may further support vaccination uptake.

Keyword(s) : Hepatitis E vaccine, Vaccination intention, Theory of Planned Behavior, Perceived behavioral control, Public health behavior

1659 - Efficacy Analysis of Prednisone Tablets Combined with Azathioprine in the Treatment of Autoimmune Hepatitis A Single Center Retrospective Cohort Study

Menyao He¹, Wei Sun¹, Qian Li¹, Yuyu Li¹, Cao Ma¹, Hong Yu², Xu Wu¹, Xiaozhong Wang³, Feng Guo³
Xinjiang Medical University, Department Of Hepatology, Affiliated Hospital Of Traditional Chinese Medicine, Urumqi-China¹ Department Of Infectious Diseases, Central Hospital Of Karamay City, Xinjiang, Karamay City-China² Xinjiang Medical University, Xinjiang Uygur Autonomous Region Hospital Of Traditional Chinese Medicine, Urumqi-³

Background / Hypothesis: To evaluate the biochemical and immunological response rates at 3 and 6 months in patients with autoimmune hepatitis (AIH) treated with prednisone tablets combined with azathioprine (AZA).

Materials and Methods: A total of 84 patients with pathologically confirmed AIH between January 2022 and June 2025 were enrolled in this study. Clinical data, liver biopsy results, and follow-up data at 3 and 6 months of treatment were collected. The treatment regimen consisted of prednisone tablets (0.5 mg/kg) combined with azathioprine (50 mg/day) for a 6-month induction period. The primary endpoints were biochemical response (defined as normalization of ALT and AST levels) and immunological response (defined as normalization of immunoglobulin G levels) at 3 and 6 months of treatment.

Results: 1. Baseline characteristics: Among the 84 patients, 69 (82.14%) were female and 15 (17.86%) were male, with a mean age of 51.61 ± 12.31 years. Of these, 50 patients (59.52%) completed both the 3- and 6-month treatment and follow-up, with complete data available.

2. Efficacy analysis: At 3 months of combination therapy, the biochemical response rate was 64.0% (32/50), and the immunological response rate was

54.0% (27/50). At 6 months, the biochemical response rate increased to 86.0% (43/50), and the immunological response rate reached 82.0% (41/50).

3. The combination therapy was well-tolerated, with common adverse effects including moon face and weight gain.

Conclusions: This study demonstrates that the combination of prednisone tablets and azathioprine achieves significant short-term biochemical and immunological responses in AIH patients during the induction period, with a favorable safety profile.

Keyword(s) : Autoimmune hepatitis; Prednisone tablets; Azathioprine; Treatment response

1660 - Four Year Survival in Giant Hepatocellular Carcinoma A Case Report on Long Term Disease Control Following Multimodal Therapy

Lu Zhang¹, Shan Zhong¹, Yan Zhang¹, Huan Deng¹, Ren-jun Wan¹, Zhi Zhou¹

The Second Affiliated Hospital, Chongqing Medical University, Department Of Infectious Diseases, Key Laboratory Of Molecular Biology For Infectious Diseases (ministry Of Education), Institute For Viral Hepatitis, Chongqing-China¹

Background: Hepatocellular carcinoma (HCC) is the most common primary liver malignancy and a leading cause of cancer-related mortality worldwide. Targeted therapy, immunotherapy, interventional approaches, and radiotherapy have become essential components in the management of intermediate- and advanced-stage HCC. However, significant challenges persist due to the lack of precise strategies for drug selection and the difficulty in optimizing the balance between treatment efficacy and patient safety.

Method: This report summarizes the clinical data of a patient diagnosed with advanced massive hepatocellular carcinoma. A comprehensive review of the patient's medical history, physical examination findings, laboratory results, and imaging studies was conducted. The management strategy, including the anti-tumor treatment regimen administered during hospitalization, and subsequent follow-up outcomes are also documented.

Results: A 58-year-old male with giant hepatocellular carcinoma (154mm×123mm) was successfully treated with combination therapy of atezolizumab and

E-POSTER ABSTRACTS

bevacizumab, after 6-month treatment, he achieved partial response (83mm×68mm). To alleviate tumor burden, control newly emerged local lesions, and treat portal vein tumor thrombus in this patient with advanced hepatocellular carcinoma, three additional sessions of TACE and localized radiotherapy were administered. Ultimately, the patient has achieved an overall survival duration of approximately 4 years till now. However, proteinuria was observed during course of therapy. Following dose reduction of bevacizumab, the patient's proteinuria markedly improved, as indicated by a substantial decrease in urinary protein quantification. Notably, the patient's tumor status has remained stable following the reduced dosage of bevacizumab. He is currently alive with good healthy condition. Over the course of nearly four years of treatment, the treatment intervals and dosage of bevacizumab were adjusted according to the patient's condition, which not only reduced adverse reactions but also maintained therapeutic efficacy, achieving individualized treatment.

Conclusions: The multimodal and combination therapy of target therapy, immunotherapy, interventional therapy, and radiotherapy may present as a more favorable treatment alternative for patients with advanced HCC. This case may provide safety and efficacy evidence supporting clinical practice adjustments of bevacizumab dosage in response to treatment-related toxicities. The emergence of new local lesions during the treatment of advanced hepatocellular carcinoma does not necessarily indicate the failure of the systemic treatment regimen. Treatment adjustments should not be made hastily, instead, a comprehensive analysis must be conducted, as the currently available systemic treatment options are very limited.

Keyword(s): Hepatocellular carcinoma, combination therapy, atezolizumab, bevacizumab, proteinuria, TACE, radiotherapy

1663 - Diagnostic prediction model of porto-sinusoidal vascular disease patients with gamma glutamyl transferase elevation

Weihua Cao¹, Yao Xie¹, Minghui Li¹

Beijing Ditan Hospital, Capital Medical University, Hepatology Division 2, Beijing-China¹

Background / Hypothesis:

More and more patients diagnosed with porto-sinusoidal vascular disease (PSVD) are experiencing gamma-glutamyl transferase (GGT) elevation. There are

currently no non-invasive diagnostic indicators for PSVD patients. This study aims to establish a diagnostic prediction model of PSVD patients with GGT elevation.

Materials and Methods:

This retrospective study included patients who underwent liver biopsy were diagnosed with PSVD at Beijing Ditan Hospital as shown in Figure 1. Patients were stratified into two groups based on the GGT level: patients with GGT elevation >ULN confirmed as PSVD (PSVD+Abnormal GGT group), and patients with normal GGT level (PSVD+Normal GGT group). Clinical features and risk factors were analyzed to identify features specific to PSVD with persistent GGT elevation. Nomogram model was used for diagnostic prediction of PSVD patients with GGT elevation.

Results:

A total of 290 PSVD patients who underwent liver biopsy were enrolled in this study, including PSVD+Normal GGT group (n=156) and PSVD+Abnormal GGT group (n=134). Among them, the proportion of females was higher than that of males, with an even greater female predominance observed in the PSVD+Abnormal GGT group. Compared to the Normal GGT group, the PSVD+Abnormal GGT group exhibited higher levels of white blood cell count, platelet (PLT) count, alanine aminotransferase (ALT), aspartate aminotransferase (AST), GGT, prothrombin activity (PTA), and liver stiffness measurement (LSM), as shown in Table 1. Liver pathology findings revealed a higher proportion of architectural disturbance in the PSVD+Abnormal GGT group (Table 2). Stratified analysis of the two patient groups demonstrated that the PSVD+Abnormal GGT group had significantly higher proportions of females, concomitant portal hypertension, $PLT \geq 150 \times 10^9/L$, $LSM \geq 10$ kPa, and $FIB-4 > 3.25$ compared to the PSVD+Normal GGT group (Table 3). Univariate and multivariate logistic regression analysis revealed that sex [OR 0.406, 95%CI (0.223-0.738), $p=0.003$], ALT [OR 1.032, 95%CI (1.021-1.230), $p=0.016$], and $LSM < 10$ [OR 3.298, 95%CI (1.664-6.535), $p=0.001$] emerged as independent risk factors for PSVD patients with elevated GGT, as shown in Table 4. Nomogram model revealed that AUC 0.772, 95% CI (0.717-0.827), and The specificity of this model is 0.821.

Conclusions:

Sex, ALT, PTA, and LSM were independent influencing factors for PSVD patients with GGT elevation. Nomogram model can effectively predict the disease

E-POSTER ABSTRACTS

risk of PSVD patients in the population with elevated GGT.

Keyword(s) : porto-sinusoidal vascular disease, gamma-glutamyl transferase, alanine aminotransferase, liver stiffness measurement, nomogram model

1665 - ADAR2 Deficiency Ameliorates Metabolic Dysfunction Associated Steatohepatitis (MASH) and Fibrosis in Mice

Tzu-chi Hung ¹, Yun-wen Chen ¹

National Cheng Kung University, Pharmacology, Tainan-Taiwan ¹

Background / Hypothesis:

Metabolic dysfunction-associated steatohepatitis (MASH) is a chronic, progressive liver disease characterized by steatosis, inflammation, and fibrosis. ADAR2, a member of the adenosine deaminases acting on RNA (ADARs) family, catalyzes the adenosine-to-inosine editing of double-stranded RNA; however, its specific role in MASH remains unclear.

Materials and Methods:

This study aimed to explore the function of ADAR2 in MASH pathogenesis. We employed a choline-deficient, L-amino acid-defined high-fat diet (CDAHFD) to induce MASH in mice. ADAR2^{+/+}/GluR-BR/R mice (wild type, WT) and ADAR2^{-/-}/GluR-BR/R mice (ADAR2 KO) mice of both sexes were fed either a normal chow diet (ND) or CDAHFD for 4 to 6 weeks.

Results:

The results demonstrated that male ADAR2 KO mice exhibited significantly improved glucose tolerance compared to WT mice following CDAHFD feeding. Furthermore, ADAR2 KO mice fed the CDAHFD showed attenuated hepatic lipid accumulation and upregulated expression of genes related to fatty acid beta-oxidation. In addition, hepatic levels of inflammatory markers—including TNF-beta, CD68, and F4/80—were significantly lower in the ADAR2 KO group. Moreover, ADAR2 deficiency alleviated CDAHFD-induced liver fibrosis.

Conclusions:

These findings suggest that ADAR2 plays a detrimental role in MASH progression and highlight ADAR2 as a promising therapeutic target for the disease.

Keyword(s) : MASH, ADAR2, fibrosis

1666 - Diagnostic Performance of Non Invasive Fibrosis Scores Compared with Liver Biopsy in Chronic Hepatitis B

Zerrin Yulugkural ¹, Hasan Yilmaz ¹, Merve Aytekin ¹

Habibe Tülin Elmaslar Mert ¹, Figen Kuloglu ¹

Trakya University, Infectious Diseases And Clinical Microbiology, Edirne-Türkiye ¹

Background:

Liver biopsy is considered the gold standard for grading liver fibrosis. However, as it is an invasive and costly procedure with potential for serious complications, interest in non-invasive tests to reduce the need for biopsy has increased.

Materials and Methods:

A total of 553 patients with chronic hepatitis B who underwent liver biopsy at our university hospital between January 1, 2014 and July 1, 2024 were included. Epidemiological, clinical, and laboratory data and Ishak fibrosis scores obtained from liver biopsy were retrospectively retrieved from the hospital information system. Concurrently with biopsy, the aspartate aminotransferase (AST)-alanine aminotransferase (ALT) ratio (AAR), AST-to platelet ratio index (APRI), fibrosis-4 score (FIB-4), and age-platelet index (API) were calculated. The diagnostic performance of these non-invasive tests in assessing Ishak fibrosis scores was evaluated. Diagnostic accuracies of APRI, FIB-4, API, and AAR were compared using ROC curve analysis and the DeLong test. In addition, multivariable logistic regression models were constructed to assess the added diagnostic value of combining non-invasive scores.

Results:

Among the 553 patients, 243 (43.9%) were female and 310 (56.1%) were male. When an Ishak fibrosis score of ≥ 3 was used as the threshold, FIB-4 (AUC = 0.804; 95% CI: 0.768–0.836), APRI (AUC = 0.779; 95% CI: 0.742–0.813), and API (AUC = 0.775; 95% CI: 0.738–0.809) demonstrated significant diagnostic performance. A small but statistically significant difference was observed between FIB-4 and API ($p = 0.029$), whereas no significant difference was found between APRI and FIB-4 or between APRI and API. When an Ishak fibrosis score of ≥ 4 was used as the threshold, FIB-4 (AUC = 0.833), APRI (AUC = 0.791), and API (AUC = 0.803) demonstrated significant discriminative ability, with no statistically significant differences among the three scores. In both analyses, AAR showed poor discriminatory performance for fibrosis (AUC = 0.538; $p = 0.139$ and AUC = 0.505; $p = 0.894$, respectively), and APRI, FIB-4, and API were significantly superior to AAR ($p < 0.001$). To evaluate the contribution of combining non-invasive tests to diagnostic performance, three

E-POSTER ABSTRACTS

logistic regression models were constructed. Among these, only Model I created for fibrosis score ≥ 3 showed a statistically significant difference compared to FIB-4 alone ($p = 0.047$).

Conclusions:

In our study, FIB-4, APRI, and API demonstrated comparable performance; however, FIB-4 was determined with higher sensitivity for excluding fibrosis. Its accessibility, low cost, and reproducibility suggest it as an option for initial fibrosis evaluation.

Keyword(s) : Hepatitis B, Fibrosis, Non-invasive, FIB-4

1667 - Combination of carvedilol and variceal band ligation is superior to carvedilol alone in primary prophylaxis of variceal bleed in cirrhotics with high risk varices A randomized controlled trial

Jata Shankar Kumar¹, Pabitra Sahu¹, Premasis Kar¹
Max Hopsital, Vaishali, Gastroenterology, Ghaziabad-India¹

Background / Hypothesis: Portal hypertension-related variceal bleeding is a major cause of morbidity and mortality in cirrhosis. Both non-selective beta-blockers (NSBBs) like carvedilol and endoscopic variceal ligation (EVL) are recommended for primary prophylaxis. However, the efficacy of combining EVL with carvedilol in high-risk varices remains uncertain. This study evaluates whether combination therapy is superior to carvedilol alone in preventing first variceal bleed.

Materials and Methods: This prospective, single-center, randomized controlled trial included 80 cirrhotic patients with high-risk varices (large size or red color signs) and no prior history of bleeding. Patients were randomized 1:1 to receive either carvedilol alone or carvedilol plus scheduled EVL sessions. Carvedilol was initiated at 6.25 mg/day and titrated to the maximum tolerated dose. EVL was performed every 3 weeks until variceal eradication. Patients were followed for 12 months. The primary endpoint was incidence of first variceal bleeding. Secondary endpoints included mortality, hospitalization for bleeding, and adverse events.

Results: Seventy-two patients completed the study ($n=36$ in each arm). No significant differences were found in baseline demographic or clinical parameters,

including age, ensuring comparability between the groups. Intention-to-treat analysis showed that the combination group had a significantly lower incidence of first variceal bleed compared to those in the carvedilol-alone group after 1 year (22.2 % vs. 50 %, $p = 0.014$). Overall mortality after 1 year was lower in combination group although without a statistically significant difference (11.1 % vs. 19.4 %, $p = 0.325$). Mortality due to bleeding after 1 year was also lower in combination group but without a statistically significant difference (5.6 % vs. 13.9 %, $p = 0.232$). Variceal bleeding was the most common cause of death in both group (5.6 % vs. 13.9 %, $p = 0.232$). Both groups had similar adverse event profiles.

Conclusions: The combination of EVL and carvedilol is superior to carvedilol alone for primary prophylaxis of variceal bleeding in cirrhosis patients with high-risk esophageal varices and there is no significant difference in adverse events between two groups. This dual-modality approach should be considered in primary prophylaxis protocols for this high-risk group.

Keyword(s) : Cirrhosis, Portal Hypertension, Variceal bleed, carvedilol, Endoscopic variceal ligation, Primary prophylaxis

1668 - Metabolic Steatosis in Chronic Hepatitis B High Prevalence but No Impact on Fibrosis or Antiviral Response in a Moroccan Cohort

Ismail Qarch¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Selma Sabbah¹, Fatima Zohra Ajana¹, Maryeme Kadiri¹
Mohamed V University, Gastroenterology C Department, Ibn Sina Hospital, Rabat-Morocco¹

Background / Hypothesis:

The coexistence of chronic hepatitis B virus (HBV) infection and metabolic-associated steatotic liver disease (MASLD) is increasingly recognized. MASLD, defined by hepatic fat accumulation in the presence of metabolic risk factors such as diabetes, dyslipidemia, or hypertension, may theoretically influence liver fibrosis progression and antiviral therapy response. However, its clinical significance in HBV-infected patients remains unclear. This study aimed to determine the prevalence of MASLD in chronic HBV, characterize associated demographic and metabolic features, and evaluate its impact on fibrosis and virological response.

E-POSTER ABSTRACTS

Materials and Methods:

We conducted a single-center retrospective study including 124 patients followed for chronic HBV infection. MASLD was defined as imaging-confirmed steatosis associated with at least one metabolic risk factor. Patients were classified into two groups: HBV + MASLD (Group A) versus HBV without steatosis (Group B). Demographic data, metabolic comorbidities (hypertension, diabetes, dyslipidemia), virological parameters (HBsAg, HBeAg, HBV DNA), fibrosis stage ($\geq F2$), and antiviral treatment response were collected. Statistical analyses included Chi-square and Mann-Whitney tests, with multivariate logistic regression for independent associations.

Results:

MASLD was identified in 50 patients (40.3%). Patients with MASLD were older (49.3 vs 46.2 years; $p=0.31$) and predominantly female (64% vs 41%; $p=0.023$). Metabolic comorbidities were more common in the MASLD group but did not reach statistical significance. Virological profiles, including HBsAg/HBeAg status and median HBV DNA (1870 vs 2450 IU/mL; $p=0.85$), were similar between groups. The prevalence of significant fibrosis ($\geq F2$) was comparable (28% vs 30%; $p=0.95$). Antiviral response rates did not differ (83% vs 78%; $p=0.75$).

Conclusions:

MASLD occurs in nearly 14% of patients with chronic HBV, more frequently in older individuals and women. In this cohort, MASLD did not aggravate fibrosis nor affect antiviral response, indicating it acts as a background metabolic factor rather than an aggravating cofactor. These findings support the continued use of standard antiviral strategies without adjustment solely based on MASLD presence. Clinicians should continue to monitor metabolic comorbidities to optimize overall liver health. Future prospective studies with larger cohorts are warranted to confirm these findings and clarify long-term outcomes in HBV patients with metabolic steatosis.

Keyword(s) : MASLD , HBV , Fibrosis

1669 - "Serum Prothrombin Induced by Vitamin K Antagonist II (PIVKA II) Biomarker in diagnosis of Hepatocellular Carcinoma"

Dr Sourav Kumar Saha Sabuj¹

Bcps, Hepatology, Dhaka-Bangladesh¹

Hypothesis: PIVKA-II is a superior to AFP in as diagnostic marker for diagnosis of Hepatocellular carcinoma (HCC).

Materials and Methods: This cross-sectional observational study was conducted in the Department of Hepatology, Dhaka Medical college & Hospital, during the period from February 2024 to February 2025. Total 30 patients having cytological (FNAC proved) evidence of HCC irrespective of aetiologies were included in the study as case and another 30 patients with cirrhosis were included in control group and 28 have healthy group. Serum PIVKA-II and AFP levels were measured by (ELISA) method and compared. Quantitative data were analyzed by mean and standard deviation; and comparison was done between two groups by unpaired t test or Mann-Whitney U test. Qualitative data were analyzed by frequency and percentage; and comparison was done between two groups by Chi-Square (2) test or Fisher's Exact test. To determine the optimal cut-off values for PIVKA-II and AFP to diagnose HCC, ROC curves were created. Youden's index was calculated as an index of sensitivity and specificity

Results: Among 88 patients, 30 patients had HCC, age ranged from 30 to 81 years and 30 patients had cirrhosis without HCC, age ranged from 18 to 69 years and Healthy population 28 individual, age range from 19 to 75. Both serum AFP and PIVKA-II level were significantly higher in HCC patients compared to patients with cirrhosis (p value <0.001). The median PIVKA-II value was 66.8ng/ml (IQ range, 0.76-9.80) and 48.9 (IQ range 1.45-3.20 ng/ml) and 17.6ng/ml (IQ range , 0.50-1.70) in HCC ,cirrhosis and healthy individual groups respectively. The results showed that the AUC increased after the addition of serum AFP to the PIVKA-II level (AUC 0.882 vs 0.0.872 and 0.862 respectively, $p<0.001$). The prediction of HCC by PIVKA-II only the sensitivity was 80% and specificity was 86% (at the cut-off value 6.80 ng/ml) and by AFP alone 66.7% and 81%(at the cut-off value 58.5 ng/ml) respectively. Combination of serum AFP and PIVKA-II level increases the sensitivity to 90% at the cost of specificity to 84%. For combined performance of serum AFP and PIVKA-II in predicting early stage of HCC AUC was 0.882 (90%CI 0.813- 0.994). Youden's index found the best sensitivity and specificity 87% and 65% in correctly differentiating HCC stage from cirrhosis and healthy individual

E-POSTER ABSTRACTS

Conclusion: The results of the study highlighted the added value of PIVKA-II and AFP combination for HCC detection rather than a single biomarker alone.

Keyword(s) : HCC - Hepatocellular carcinoma, PIVKA-II- Protein Induced by Vitamin K Absence or Antagonist-II, AFP - Alpha-fetoprotein

1670 - Evaluation of anti HBs titers in children who received vaccine + HBIG at birth because their mothers were HBsAg positive in subsequent years

Selma Tosun¹, Dilek Yilmaz²

University Of Health Sciences Turkey, Izmir Faculty Of Medicine, Izmir City Hospital, Infectious Diseases And Clinical Microbiology, Izmir-Türkiye ¹ University Of Katip Celebi , Izmir City Hospital, Department Of Pediatrics, Pediatric Infectious Disease Unit, Izmir-Türkiye ²

Background / Hypothesis: The objective was to evaluate anti-HBs titers in children who received vaccine+HBIG at birth in subsequent years.

Materials and Methods: HBV test results obtained in subsequent years from children of female patients with chronic HBV infection who had received vaccine+HBIG at birth were requested. The study was initiated in 2019 following ethical committee approval. Evaluations were performed during routine follow-up visits through face-to-face interviews and by reviewing results available from the mothers or accessed via the automation system.

Results: Data from a total of 323 children were evaluated in the study. The children's birth years ranged from 1990 to 2024. The timing of HBV marker testing for children varied greatly; only 39 children (12%) were tested for HBV markers in the first year of life, while the rate of HBV testing in the first 5 years of life was 44.3% (143/323).

The number of children with negative anti-HBs titers : (≤ 9 IU/mL) was 132 (40.8%), those with low-titer positive titers (10-50 IU/mL) was 104 (32.2%), and those with positive titers (≥ 51 IU/mL) was 87 (26.9%). The distribution of children with negative antiHBs titers by birth year is as follows: 12 between 1990 and 1997; 3 between 1998 and 1999; 31 between 2000 and 2005; 41 between 2006 and 2010; 34 children between 2011 and 2015, and 11 children between 2016 and 2020. The periods after vaccination + HBIG administration during which anti-HBs was tested and negativity was detected were as follows: 45 children after 1-5 years; 36 after 6-10 years; 27 after 11-15 years; 16 after 16-20 years; and 8 children after 21 years or more. No acute or chronic HBV infection developed in any of the children.

Conclusion: A decrease in antibody titers over time, even falling below protective levels, is an expected outcome following HBV vaccination. This decline to below protective levels is more frequently observed in infants who received vaccine + HBIG at birth. In our study data, anti-HBs titers fell below the protective level within a few years in 40.8% of the children included in the study, and low antibody titers were determined in 32.2%. The rate of testing pregnant women's children for HBV was also found to be very low. It would be beneficial for both HBsAg-positive pregnant women and the physicians monitoring them to be thoroughly informed about the procedures to be performed during pregnancy, at delivery, and thereafter.

Keyword(s) :

1671 - "Bitter Remedy Bitter Consequence" Mahogany Seeds Causing Herb Induced Liver Injury

Dr.kartik Chaudhary¹, Dr.(prof)nagina Agarwal¹

Abvims & Rml Hospital, General Medicine, New Delhi-India ¹

Background / Hypothesis:

Herbal and traditional remedies are increasingly implicated in herb-induced liver injury (HILI), a subset of drug-induced liver injury. Mahogany (Swietenia spp.) seeds are commonly consumed for glycemic control despite absence of validated safety data. This case highlights mahogany seed-associated HILI and reinforces the necessity of eliciting detailed herbal intake history in patients presenting with unexplained hepatitis.

Materials and Methods: A 58-year-old female with type 2 diabetes mellitus consumed crushed mahogany seeds daily for approximately four weeks as an alternative therapy. She presented with jaundice and malaise. Laboratory evaluation demonstrated hepatocellular injury. Comprehensive investigations including viral hepatitis (A, B, C, E), autoimmune profile, metabolic tests, and abdominal imaging excluded other etiologies. Causality assessment was performed using the Roussel Uclaf Causality Assessment Method (RUCAM). The herbal agent was discontinued and the patient was managed conservatively with serial monitoring.

Results:

The patient exhibited marked transaminase elevation

E-POSTER ABSTRACTS

(>10× upper limit of normal) along with significant hyperbilirubinemia, consistent with acute hepatocellular injury. Total bilirubin levels were markedly elevated at presentation, correlating clinically with icterus. Following cessation of mahogany seed intake, there was progressive improvement in both serum bilirubin and liver enzymes, with near normalization observed over an 8-week period. The Roussel Uclaf Causality Assessment Method (RUCAM) score indicated a probable causal relationship between mahogany seed consumption and hepatotoxicity.

Conclusions: Mahogany seeds represent a potential hepatotoxic herbal agent capable of inducing clinically significant hyperbilirubinemia and hepatocellular injury. This case emphasizes the importance of recognizing unregulated herbal products as reversible causes of liver dysfunction. Prompt identification and withdrawal of the offending agent leads to favorable outcomes, highlighting the critical role of clinician vigilance and patient awareness in preventing HILI.

Keyword(s) : Mahogany seeds, Herb-induced liver injury, HILI, Drug-induced liver injury, DILI, Hyperbilirubinemia, Hepatocellular injury, Swietenia species, Herbal toxicity, Alternative medicine, Roussel Uclaf Causality Assessment Method, Jaundice, Reversible hepatotoxicity, Diabetes self-medication

1674 - CMV Hepatitis Masquerading as Prolonged Cholestatic Phase of Hepatitis A

Dr.kartik Chaudhary¹, Dr.bishal Gupta¹, Dr.(prof)ritesh Gupta¹, Dr.(prof)nagina Agarwal¹
Abvims & Rml Hospital, General Medicine, New Delhi-India¹

Background / Hypothesis:

Prolonged cholestatic hepatitis A is an uncommon complication that may lead to diagnostic confusion, particularly when accompanied by atypical biochemical abnormalities such as iron overload. Superimposed cytomegalovirus (CMV) infection in immunocompetent individuals further complicates the clinical picture and may mimic chronic liver diseases. This case highlights the importance of systematic evaluation to differentiate reversible hepatic insults from irreversible disorders such as hereditary hemochromatosis, thereby preventing misdiagnosis and overtreatment.

Materials and Methods: A 19-year-old immunocompetent male presented with progressive jaundice, pruritus, dark urine, and weight loss for seven weeks following acute hepatitis A infection. Investigations revealed marked cholestasis with disproportionately elevated bilirubin and mild transaminitis. Comprehensive evaluation included viral serology, CMV PCR, autoimmune and metabolic panels, iron studies, immunodeficiency profile, imaging, and liver biopsy. CMV infection was confirmed by positive CMV DNA PCR and serology. The patient received intravenous ganciclovir alongside supportive management and was monitored closely for clinical and biochemical response.

Results: Initial laboratory findings showed severe hyperbilirubinemia (61.75 mg/dL), elevated alkaline phosphatase, high transferrin saturation (95.7%), and ferritin (565 ng/mL). Liver biopsy demonstrated secondary iron overload without evidence of genetic hemochromatosis. CMV DNA levels were 3.5×10^3 copies/mL. Following antiviral therapy, bilirubin levels gradually decreased, CMV DNA became undetectable within three weeks, and symptoms improved significantly. Transient anemia and reactive thrombocytosis were observed as treatment-related effects. Over follow-up, both cholestasis and iron indices normalized without chelation therapy.

Conclusions: This case illustrates a rare triad of prolonged post-hepatitis A cholestasis, secondary reversible iron overload, and CMV hepatitis in an immunocompetent individual. The findings emphasize the need for detailed histological and virological assessment in persistent cholestasis with atypical biochemical patterns. Early recognition and targeted therapy lead to complete resolution, reinforcing the reversibility of secondary iron overload when the primary hepatic insult is addressed.

Keyword(s) : Prolonged cholestasis, Hepatitis A, CMV hepatitis, Secondary iron overload, Hyperbilirubinemia, Immunocompetent host

1675 - Magnitude of Clostridium Difficile Infection in Hospitalized Egyptian Cirrhotic Patients

E-POSTER ABSTRACTS

Mohamed Abdel-samiee ¹, El-sayed Tharwa ¹, Ashraf Abou-gabal ¹, Azza Abd El-aziz ²

National Liver Institute, Menoufia University, Hepatology And Gastroenterology, Shebin El-kom-Egypt ¹ National Liver Institute, Menoufia University, Microbiology, Shebin El-kom-Egypt ²

Background / Hypothesis:

Watery diarrhea is the cardinal clinical symptom of Clostridium Difficile infection that causes a spectrum of manifestations ranging from asymptomatic carrier state to severe fulminant disease with toxic megacolon. The basis for symptomatic responses range is related to host and pathogen factors. The aim was to study the prevalence of Clostridium Difficile infection in hospitalized cirrhotic patients and its possible risk factors.

Materials and Methods:

This study was carried out on 200 cirrhotic patients admitted to National Liver Institute hospital divided into 2 groups: 100 asymptomatic patients and 100 patients with diarrhea. Direct stool toxin detection was done using an assay named RIDASCREEN® Clostridium Difficile Toxin A/B test; an enzyme immunoassay (EIA) for the qualitative determination of toxins A and B of Clostridium difficile in stool.

Results:

Among 200 patients with mean age of (51.81±12.94), EIA revealed 16 and 32 positive cases in both groups. In group I; there was statistical significance in ALT, serum creatinine (p<0.05) and bilirubin level (p<0.01) as regard EIA test result. Also, statistical significance was found (p<0.05) as regard duration of antibiotic and PPI intake. Logistic regression analysis revealed that gender and duration of PPIs use were independent factors in group I while the patient's age, duration of antibiotic use and GGT serum level were independent factors in group II for clostridium difficile infection development.

Conclusions:

Clostridium difficile infection is not an uncommon infection in hospitalized cirrhotic patients. Risk factors were antibiotic intake, gastric acid suppression, old age, long hospital stay and/or history of malnutrition.

Keyword(s) : Clostridium Difficile; Cirrhotic; Magnitude

1678 - Identification and validation of cuproptosis related genes for early warning of acute liver failure

Xiaoxuan Liu ¹, Qi Yang ¹, Wenling Wang ¹, Li Bai ¹, Yu Chen ¹

Fourth Department Of Liver Disease, Beijing Youan Hospital, Capital Medical University, Beijing-China ¹

Background / Hypothesis:

Acute liver failure (ALF) is a life-threatening syndrome characterized by rapid onset of liver dysfunction. Cuproptosis, a copper-dependent form of programmed cell death, is increasingly recognized as a potential contributor to liver injury. However, the potential involvement of cuproptosis-related genes (CRGs) in ALF has not been fully investigated. Herein, we aimed to identify and validate CRGs that may play an early warning role in the pathogenesis of ALF.

Materials and Methods:

We analyzed GEO microarray datasets related to ALF (GSE14668, GSE38941, and GSE96851) to identify differentially expressed genes (DEGs). These DEGs were then intersected with key module genes obtained from Weighted Gene Co-Expression Network Analysis (WGCNA) to define ALF-specific DEGs. Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analyses were subsequently performed on these ALF-specific DEGs. Further intersection with cuproptosis-related genes (CRGs) yielded ALF-specific cuproptosis-related genes (ALF-CRGs). A nomogram model based on these hub genes was constructed and validated using an independent dataset (GSE62029). The model's early warning performance was assessed by Receiver Operating Characteristic (ROC), calibration curves, and decision curve analysis (DCA). Experimental validation was performed using quantitative real-time PCR in D-Galactosamine/Lipopolysaccharide (D-GalN/LPS)-induced ALF mice and immunohistochemistry (IHC) in clinical liver tissues. To explore the underlying regulatory pathways, we analyzed immune infiltration and its correlations, and predicted miRNA/transcription factor (TF) networks.

Results:

Nine ALF-CRGs were identified, among which four hub genes (FDX1, ATP7B, CYP1A1, and MT1M) were selected through machine learning. The nomogram constructed using these hub genes demonstrated excellent early-warning performance (AUC > 0.90).

E-POSTER ABSTRACTS

Experimental validation confirmed that FDX1, ATP7B, and MT1M were downregulated in liver tissues from ALF mice and patients, while CYP1A1 expression was confirmed at the transcript level. Immune infiltration analysis suggested that these CRGs may influence immune microenvironment alterations during ALF. The miRNA/TF network prediction further identified potential upstream regulators of these hub genes. Conclusions:

Our findings support a critical role of cuproptosis in ALF and identify several hub genes with potential as early-warning biomarkers. The validated hub genes and their regulatory networks provide new insights into potential therapeutic targets for ALF.

1680 - Artificial Intelligence Predicts Sex Specific Risk of Metabolic Dysfunction Associated Steatotic Liver Disease

Mohamad Jamalnia ¹, Giovanni Targher ², Amedeo Lonardo ³, Seyed Taghi Heydari ⁴, Kamran Bagheri Lankarani ⁴

Shiraz University Of Medical Sciences, Gastroenterohepatology Research Center, Shiraz-Iran ¹ University Of Verona, Department Of Medicine, Verona-Italy ² Azienda Ospedaliero-universitaria Di Modena (-2023), Department Of Internal Medicine, Modena-Italy ³ Shiraz University Of Medical Sciences, Health Policy Research Center, Institute Of Health, Shiraz-Iran ⁴

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is known to exhibit sex differences in epidemiology, metabolic drivers, the progression to fibrosis, and extrahepatic consequences. However, whether artificial intelligence (AI) models learn and perform differently across sexes remains unclear. This project aimed to train sex-specific machine learning (ML) classifiers based upon routinely collected clinical variables to evaluate sex-specific patterns of learning and diagnostic performance for both the presence of MASLD and the severity of MASLD.

Materials and Methods:

In this cross-sectional study, a total of 446 adults undergoing routine evaluation at a cardiology referral center were enrolled. Presence (no vs yes) and severity of MASLD (no steatosis vs mild vs moderate-to-severe steatosis) were assessed by abdominal

ultrasonography. Participants underwent train/test splitting (7:3) into a training set (127 men, 185 women) and an independent test set (55 men, 79 women). Eight ML algorithms were trained using two methods: (1) combined-sex models where the training data was the full population dataset, and (2) sex-specific models with separate training for men and women. Model performance to predict the presence and severity of MASLD was evaluated on the unseen test dataset by calculating the area under the curve (AUC) and F1-score. An additional analysis based upon thresholds for rule-in and rule-out was performed. Sex-specific feature importance rankings were compared to assess differential patterns of learning.

Results:

MASLD prevalence was 63.6%, with 41.2% of patients having mild and 22.4% having moderate-to-severe steatosis. Sex-specific modeling improved diagnostic performance in men but remained suboptimal in women. For MASLD presence, AUC/F1-scores of the top-performing models were 0.769/0.856 in the overall data set, 0.793/0.897 in men, and 0.681/0.794 in women. For MASLD severity, the corresponding scores were 0.761/0.671 overall, 0.723/0.608 in men, and 0.718/0.571 in women. Threshold-based analyses demonstrated acceptable rule-in and rule-out performance in men, whereas both capacities were limited in women. Notably, feature importance profiles differed markedly by sex, showing distinct learning patterns.

Conclusions:

ML classifiers trained on routine clinical data reveal pronounced sex-specific learning patterns in MASLD prediction. These models perform better in men, suggesting that widely used clinical variables are more informative for male MASLD phenotypes, while failing to capture female-specific determinants. The observed divergence underscores the need for sex-stratified model development, incorporation of female-specific metabolic and hormonal factors, and balanced datasets to reduce diagnostic inequities. Integrating sex-specific analytic frameworks may enhance ML-driven MASLD risk stratification and support more equitable, individualized clinical care.

1682 - AWARENESS OF HEPATITIS B VIRUS REACTIVATION AMONG PHYSICIANS MANAGING PATIENTS RECEIVING IMMUNOSUPPRESSIVE THERAPY A CROSS SECTIONAL STUDY OF 150 PHYSICIANS

Ece Demirkirkan¹, Yusuf Yiğit¹, Alper Gündüz¹, Meliha Meriç Koç¹, Özlem Altuntaş Aydın¹
Başakşehir Çam Ve Sakura Şehir Hastanesi, Enfeksiyon Hastalıkları, İstanbul-Türkiye¹

Background / Hypothesis: Hepatitis B virus (HBV) reactivation is a clinically important issue that can result in severe outcomes among patients receiving immunosuppressive therapy. The risk of reactivation depends on the degree and duration of immunosuppression and the patient's serological status. International guidelines recommend comprehensive HBV screening in all candidates for immunosuppressive therapy and advise antiviral prophylaxis or close monitoring based on individual risk. This study aimed to assess physicians' knowledge, screening habits, and clinical management related to HBV reactivation.

Materials and Methods: This cross-sectional study was conducted using an online questionnaire completed by 150 physicians from various specialties involved in the management of patients undergoing immunosuppressive treatment. The 30-item survey evaluated demographic characteristics, frequency of prescribing immunosuppressive therapy, HBV screening practices, antiviral prophylaxis preferences, management strategies in suspected reactivation, and familiarity with guideline recommendations. Descriptive statistics were used for analysis.

Results: Specialties of the participating physicians included Infectious Diseases (n=41), Internal Medicine (n=29), Dermatology (n=21), Neurology (n=18), Pulmonology (n=14), Oncology (n=12), Hematology (n=8), and Rheumatology (n=6).

A total of 94.7% of physicians reported that immunosuppressive treatments increase the risk of HBV reactivation, and the same proportion acknowledged that reactivation can occur in anti-HBc

(+)/HBsAg (-) individuals. Additionally, 7.9% believed anti-HBs positivity completely eliminates reactivation risk. Routine HBV screening before immunosuppressive therapy was performed by 82.9%, while 13.2% screened only selected patients and 3.9% did not screen at all. Frequently requested tests included HBsAg (90.8%), anti-HBs (78.9%), and anti-HBc (59.2%).

Regarding antiviral prophylaxis duration, 56.6% adjusted duration according to risk, whereas 23.7% preferred six months and 14.5% preferred twelve months of prophylaxis.

Timing preferences for antiviral initiation showed that most physicians started therapy before immunosuppression: 60.3% one month before, 24.7% one week before, and 17.8% on the same day. Only 2.7% initiated antiviral therapy after immunosuppressive treatment had already begun, a clinically relevant finding due to the potential risk of reactivation. The APASL 2021 guideline recommends starting antiviral prophylaxis prior to immunosuppressive therapy.

For suspected HBV reactivation, 51.3% of physicians ordered HBV DNA and ALT as initial tests, while 25% preferred consultation with a specialist.

Conclusions: Although awareness of HBV reactivation risk was generally high, considerable heterogeneity was observed in HBV serologic screening, anti-HBc test utilization, initiation of prophylaxis, and duration of antiviral therapy. Notably, 40.8% of physicians did not request anti-HBc before initiating immunosuppressive treatment. These findings highlight the need for improved guideline adherence and targeted educational strategies to reduce HBV reactivation risk in immunosuppressed patients.

1683 - Hepatic Steatosis Beyond Fat A Clinical Anthropometric and Metabolic Exploration of an At Risk Population

Chaima Hsain¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Salma Sebbah¹, Fatima Zohra Ajana¹, Maryeme Kadiri¹
Ibn Sina University Hospital, Mohammed V University, Hepatogastroenterology C, Rabat - Yacoub El Mansour-Morocco¹

E-POSTER ABSTRACTS

Background / Hypothesis:

Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD) has emerged as the dominant form of liver steatosis, strongly driven by metabolic abnormalities. Identifying clinical and biochemical features associated with progression is essential. This study aimed to characterize the anthropometric, metabolic and fibrosis profiles of patients with hepatic steatosis and to explore factors associated with evolution toward MASH.

Materials and Methods:

A retrospective study was performed over 7 years, including 103 adults with ultrasound-confirmed steatosis. Demographic variables, anthropometric measurements, metabolic risk factors, biochemical markers, lipid profiles, non-invasive fibrosis scores (FIB-4, APRI) and ultrasound findings were collected. Cardiometabolic comorbidities and weight evolution during follow-up were assessed. MASLD was defined as steatosis with at least one cardiometabolic abnormality. Exploratory comparisons were conducted between MASH and non-MASH groups.

Results:

The mean age was 51 ± 11.7 years, with women representing 83.5% of the cohort. Mean BMI was 30.8 ± 4.8 kg/m², with 52.5% obesity and 41.4% overweight. Diabetes was present in 25.2%, hypertension in 24.3%, dyslipidemia in nearly half of patients, and coronary artery disease in 7.8%. MASLD criteria were fulfilled in 68% of cases, and MASH was diagnosed in 10.7%. Biochemical analyses showed only moderate elevations in ALT (30 ± 25.6 IU/L), AST (27 ± 19 IU/L), and GGT (68 ± 83.7 IU/L), while the lipid profile confirmed substantial metabolic impairment. Advanced fibrosis was uncommon, with high-risk FIB-4 found in 2.9% and elevated APRI in 5.7%. Among the 84 fibrosis assessments, F1 predominated (64.3%), while F3–F4 accounted for only 8.4%. Severe steatosis (S3) was observed in 38.2% of patients. During a mean follow-up of 32.2 months, weight loss remained limited (2.1% on average), and only 15.3% achieved $\geq 5\%$ reduction. Type 2 diabetes emerged as the only metabolic feature enriched in MASH patients (45.4% vs 22.8%), whereas obesity (36.3% vs 52.2%) and hypertension (27.3% vs 23.9%) did not differ significantly, suggesting no association with disease progression in this cohort.

Conclusions:

This real-world cohort underscores the heavy

metabolic burden of MASLD. While advanced fibrosis was infrequent, the presence of MASH and the minimal weight reduction achieved over time highlight the need for more intensive, diabetes-focused metabolic interventions to modify disease trajectory.

Keyword(s) : MASLD , DT2 , MASH

1684 - Patient reported health is decreased in high risk MASH defined by noninvasive biomarkers of fibro inflammation in Japanese Adults

Kento Imajo ¹, Anneli Andersson ², Marika Hancock ², Elizabeth Shumbayawonda ², Masato Yoneda ³, Atsushi Nakajima ³

Shin-yurigaoka General Hospital, Department Of Gastroenterology, Kawasaki-Japan ¹ Perspectum Ltd, ,, Oxford-United Kingdom ² Yokohama City University Graduate School Of Medicine, Department Of Gastroenterology And Hepatology, Yokohama-Japan ³

Background / Hypothesis:

Studies on how individuals with metabolic dysfunction-associated steatotic liver disease (MASLD) or steatohepatitis (MASH) report their health are sparse, particularly in the non-North-American population. Change in patient reported outcomes is an important factor in assessing improvement following interventions and a reliable baseline and its association with biomarkers is needed. We aim to demonstrate how commonly used noninvasive biomarkers in MASLD/MASH associate with patient-reported health.

Materials and Methods:

Health-related quality of life (HRQoL) data was collected through the EQ-5D-5L instrument as part of a single-site prospective observational study at Shin-yurigaoka General Hospital, Japan. The analyses consider the dimensions of health scoring, Japanese specific index values and biomarker metrics. Lower health scores suggest poorer HRQoL. High risk disease states were defined as corrected T1 (cT1) ≥ 875 ms; liver fat content (LFC) $\geq 10\%$; magnetic resonance elastography (MRE) ≥ 3.54 kPa; vibration-controlled transient elastography (VCTE) ≥ 12 kPa; Enhanced liver fibrosis (ELF) ≥ 9.8 and FIB-4 ≥ 1.3 and MASH as cT1 ≥ 800 ms and LFC $\geq 5\%$.

Results:

N=143 (median age of 58 years [55, 66]; 38% Female; 23% with type 2 diabetes; median body mass index 27 kg/m²) participants with suspected MASLD were

E-POSTER ABSTRACTS

recruited. The domain where patients most commonly reported problems were anxiety and depression (29%), followed by ability to perform usual activities (5%). The mean [SD] EQ-5D-5L health score was 0.88 [10] and decreased slightly with age ($R_s = -0.22$; $p < 0.05$) but was not associated with sex. Correlations were observed between health score and cT1, MRE, VCTE, ELF and FIB-4, (-0.40; -0.53; -0.42; -0.45; -0.40; all $p < 0.001$), while no correlation was observed with liver fat content. The mean health score was significantly lower in those with elevated cT1, MRE, VCTE, ELF and FIB-4 (0.82 [12], 0.81 [12], 0.86 [11], 0.83 [11] and 0.85 [11]; $p < 0.001$, respectively) compared to those without, while elevated LFC did not impact the health score. This can be compared to a mean health index in a Japanese population (40–79 years old) of 0.88–0.95 and in a global MASH trial population of 0.85.

Conclusions:

Reduced patient-reported health was seen for those with elevated noninvasive biomarkers for high-risk MASH or fibrosis, but not for steatosis. These HRQoL results may increase the awareness of disease burden on patients, and longitudinal research is warranted to better understand how changes in liver fibro-inflammation is associated with improved patient reported health outcomes.

Keyword(s) :

1685 - Chronic Portal Vein Thrombosis and Risk of Decompensation Experience of a Moroccan Center

Chaima Hsain¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Salma Sebbah¹, Fatima Zohra Ajana¹, Maryeme Kadiri¹

Ibn Sina University Hospital, Mohammed V University, Hepatogastroenterology C, Rabat - Yacoub El Mansour-Morocco¹

Background / Hypothesis:

Chronic portal vein thrombosis (PVT) represents a major cause of non-tumoral portal hypertension (PHT) and exposes patients to a substantial risk of clinical decompensation. However, reliable predictors of this outcome remain insufficiently defined. We hypothesized that specific clinical and radiological variables, particularly the degree of liver fibrosis and the anatomical extension of thrombosis, could independently predict PHT decompensation in patients with chronic PVT.

Materials and Methods:

We conducted a retrospective, monocentric study including all patients with chronic PVT managed between 2010 and 2025 in a Moroccan tertiary referral center. Eligible patients were aged ≥ 18 years, had chronic liver disease or cirrhosis, and radiologically confirmed chronic PVT. Exclusion criteria included hepatocellular carcinoma and tumor-related thrombosis. Collected variables comprised demographic data (age, sex), comorbidities, hepatic and thrombophilic etiologies, and detailed radiological characteristics (type of thrombosis, degree and direction of extension, involvement of portal branches, splenic vein, and hepatic fibrosis stage). The primary endpoint was PHT decompensation. Factors associated with decompensation were analyzed using univariate analysis (significance threshold $p < 0.05$), followed by multivariate logistic regression to identify independent predictors.

Results:

Eighty-three patients were included (mean age 44.9 ± 13.7 years; 77% female). PHT decompensation occurred in 31 patients (37.3%). In univariate analysis, advanced fibrosis F3–F4 (OR 4.91; 95%CI 1.36–17.68; $p = 0.015$), hepatitis C etiology (Fisher $p = 0.049$), and extension to the left portal branch (OR 3.06; 95%CI 1.02–9.16; $p = 0.045$) were significantly associated with decompensation. Extension to the splenic vein showed a strong trend without reaching significance (OR 3.14; $p = 0.052$). Other parameters—including thrombosis type, patient comorbidities, age, sex, and thrombophilic etiologies—were not significantly associated. In multivariate analysis, only advanced fibrosis remained an independent predictor of PHT decompensation (adjusted OR 4.19; 95%CI 1.08–16.26; $p = 0.038$).

Conclusions:

In this chronic PVT cohort, PHT decompensation was frequent, affecting more than one-third of patients. Advanced liver fibrosis (F3–F4) emerged as the strongest independent predictor of decompensation, while extension of thrombosis to the left branch or splenic vein demonstrated a contributive but non-significant trend after adjustment. These findings underscore the central role of fibrosis evaluation in risk stratification, management decisions, and long-term follow-up of patients with chronic PVT.

1686 - Preoperative volume estimation versus actual graft weight in living donor liver

E-POSTER ABSTRACTS

transplantation a retrospective analysis

Tonguç Utku Yılmaz¹, Hamdi Karakayali¹, Emre Tunçtan¹, Furkan Çeşitli¹, Zehra Ikbāl Karabal²

Acibadem University Faculty Of Medicine,
Transplantation And General Surgery, Istanbul-Türkiye

¹ Acibadem University Faculty Of Medicine, Medicine Faculty, Istanbul-Türkiye ²

Background / Hypothesis:In living donor liver transplantation (LDLT), accurate estimation of liver graft weight is critical to ensure adequate graft-to-recipient weight ratio (GRWR), ideally greater than or equal to 1% of recipient body weight, while minimizing donor risk. Insufficient GRWR is associated with increased complications and mortality. Preoperative radiological volumetric assessments are essential, but discrepancies of 10% or greater between calculated volume and measured weight are occasionally reported. This study compares preoperatively calculated liver volume with measured graft weight during surgery and analyzes factors contributing to significant discrepancies at Acibadem Atakent Hospital.

Materials and Methods:This retrospective study was conducted at the Organ Transplant Unit of Acibadem Atakent Hospital. Six hundred twenty-three donors who underwent hepatectomy between November 2015 and November 2024 were included. Data collected from patient records included donor demographics, preoperative laboratory values, calculated liver volume, and actual excised graft weight from operative notes. Statistical analysis (SPSS) assessed agreement between calculated volume and measured weight. Cases with 10% or greater discrepancy were analyzed to identify risk factors.

Results:The cohort included 623 donors (45.9% female, 54.1% male). Mean calculated estimated liver volume was $1216.30 \pm 139.81 \text{ cm}^3$, and mean excised graft weight was $733.82 \pm 270.73 \text{ grams}$. Statistically significant positive correlation existed between estimated liver volume and total liver volume ($r=0.684$, $p=0.001$). Notably, 298 cases (47.8%) exhibited 10% or greater difference between calculated volume and measured weight. Cases with 10% or greater discrepancy had statistically significantly lower liver Hounsfield unit values ($p=0.011$) and higher hepatic steatosis rates ($p=0.001$) compared to cases with less than 10% difference. Additional findings showed

higher cholesterol ($p=0.003$) and triglyceride levels ($p=0.001$) in the high-discrepancy group.

Conclusions:The substantial discrepancy rate (47.8%) highlights challenges in accurately predicting graft weight using preoperative radiological methods. Significant discordance was strongly associated with lower liver Hounsfield unit values and increased steatosis. Preoperative hepatic steatosis represents a critical factor contributing to volume-weight mismatch in LDLT donors. Enhanced preoperative assessment including steatosis evaluation may improve graft weight prediction and guide donor selection, potentially improving safety for both donors and recipients.

Keyword(s) : living donor liver transplantation, graft volume, graft weight, hepatic steatosis, Hounsfield unit

1687 - Validation of Agile 3+ and Agile 4 for MASLD with advanced fibrosis and cirrhosis in a Canadian cohort

Nashla Hamdan-perez¹, Chinmay Bera², Heather Kosick³, Maxwell Tong⁴, Keyur Patel¹
Uhn Toronto, Medicine, Toronto-Canada ¹ University Of Arkansas, Medicine, Little Rock-United States ² Sunnybrook Health Sciences, Medicine, Toronto-Canada ³ Uhn Toronto, Toronto Center For Liver Disease, Toronto-Canada ⁴

Background / Hypothesis:

Agile 3+ and Agile 4 are combined non-invasive tests (NIT) based on parameters that include age, AST/ALT, platelets, gender, presence of diabetes and liver stiffness measurement (LSM by VCTE), and proposed to identify patients with advanced fibrosis or cirrhosis in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). There are few external validation studies. Our aim was to assess the diagnostic performance of Agile 3+ and Agile 4 in comparison with other simple serum markers scores, and LSM by VCTE, for the identification of MASLD advanced fibrosis ($\geq F3$) and cirrhosis on biopsy.

Materials and Methods:

This is a retrospective single-center cohort study that included adult patients with biopsy-proven MASLD between 2010 – 2025. Alternate causes of liver disease were excluded, and patients included based on clinical review, available laboratory parameters, VCTE, and histopathology. Diagnostic test performance was

E-POSTER ABSTRACTS

assessed using validated thresholds for NIT and Agile 3+ <0.451 and ≥ 0.679 to rule-out and rule-in $\geq F3$ using the area under the receiver operating characteristic (AUROC). For Agile 4 thresholds for NIT were <0.251 and ≥ 0.565 to rule-out and rule-in cirrhosis

Results:

Our cohort included 175 patients, with mean age 50 ± 13 years, mostly male (53.3%), mean BMI 31.7 ± 5.7 kg/m² with prevalence of diabetes mellitus 43.8%, F3-4 63.4%, and cirrhosis 33.3%. Using established thresholds, the proportion of patients with indeterminate scores were Agile+3 (0.451-0.679) 15.7%, LSM (8-12 kPa) 29%, FIB-4 (1.3-2.67) 39.3%, NFS (-1.455-0.676) 35%, APRI (0.5-1.5) 43.2%. For our overall cohort, all NITs had high specificity for F3-4, with AUROC > 0.80 for Agile 3+ and VCTE. Agile 4 had an AUROC 0.79 ($p < 0.0001$) with a sensitivity of 33.3% and specificity of 92.9% to rule-in cirrhosis. Proportion of patients with indeterminate scores for Agile 4 (0.251-0.565) 10.6%, FIB-4 (1.67 – 3.48) 30.8% and APRI (1 – 2) 17.1%.

Conclusions:

In our tertiary center cohort, Agile3+ had a good diagnostic performance for advanced fibrosis, with relatively lower proportion of patients classified in the indeterminate zone at specified thresholds. Agile 4 showed good performance to rule in cirrhosis. Further validation of Agile 3+ and Agile 4 in lower prevalence cohorts is required.

Keyword(s) : agile, biopsy, fibrosis, non-invasive

1688 - Evaluation of HBsAg anti HBcIgG anti HBs and anti HCV test results for individuals who visited primary level Family Health Centers (12 years of data covering the province of Izmir and its districts)

Selma Tosun¹, Ali Emre Çetinkol², Metin Kizilelma³
University Of Health Sciences Turkey, Izmir Faculty Of Medicine, Izmir City Hospital, Infectious Diseases And Clinical Microbiology, Izmir-Türkiye¹ Izmir Provincial Public Health Directorate, Pediatrics, Izmir-Türkiye² Izmir Provincial Public Health Directorate, Dr, Izmir-Türkiye³

Background / Hypothesis: The aim was to evaluate the

results of HBsAg, anti-HBcIgG, anti-HBs, and anti-HCV tests performed on individuals who visited primary care Family Health Centers in the province of Izmir, located in western Turkey.

Materials and Methods: Blood samples taken from individuals living in Izmir province and its districts at Family Health Centers are processed at the Provincial Public Health Laboratory; results can be retrieved from the automation system. HBsAg, anti-HBcIgG, anti-HBs, and anti-HCV tests performed over the last 12 years (2012-2024) were examined using patient numbers in accordance with the Personal Data Protection Law; after excluding duplicate data, the distributions by age, gender, and year were evaluated. Ethical committee approval and Provincial Health Directorate permits were obtained for the study. Test results from individuals who visited Izmir City Hospital between October 2023 and October 2024 were evaluated using the same method as the control group.

Results: According to records from the specified years (2012-2024), among the total of 346,952 individuals who underwent HBsAg testing at the primary level, HBsAg positivity was 2.28%; anti-HBcIgG was detected in 10.64% of 56,292 individuals; anti-HBs was detected in 42.1% of 301,842 individuals; and anti-HCV was detected in 0.57% of 256,034 individuals. Among individuals who visited the hospital, these rates were 2.56% among 56,260 individuals for HBsAg; 24% in 17,312 individuals tested for anti-HBcIgG; 46.9% in 42,369 individuals tested for anti-HBs; and 0.34% in 45,673 individuals tested for anti-HCV (Table 1).

According to the Family Health center examinations, the age groups with the highest prevalence of HBsAg positivity are those born between 1973 and 1941 (52-84 years old); followed by those born between 1984 and 1974 (aged 41-51) and those born between 1990 and 1985 (aged 35-40). Similar results were found among hospital patients, with seropositivity increasing with age. Anti-HBcIgG positivity also increases significantly with age, reaching 40-50% seropositivity in those over 50 years of age. Anti-HBs positivity is significantly higher in those born after 1998, when the national HBV vaccination program began. Anti-HBs positivity in older age groups is thought to be associated with past HBV infection. Anti-HCV positivity is also quite low in the community, and it is noteworthy that individuals with positivity are mostly aged 60 and above.

Conclusion: In conclusion, the national HBV vaccination program has significantly reduced HBsAg positivity and the rate of infection through exposure to the virus in children and young adults.

Ondokuz Mayıs University Faculty Of Medicine, Department Of Internal Medicine, Samsun-Türkiye ¹
Ondokuz Mayıs University Faculty Of Medicine, Department Of Gastroenterology, Samsun-Türkiye ²

Background: Hepatic amyloidosis is a rare manifestation of systemic amyloidosis. While mild liver enzyme abnormalities are common, presentation as acute liver failure (ALF) is exceedingly rare and carries a high mortality risk.

Case Presentation: We report the case of a 71-year-old man with progressive jaundice and cholestatic liver enzyme abnormalities. Initial suspicion of drug-induced liver injury due to recent statin initiation was excluded. Laboratory evaluation revealed marked hyperbilirubinemia, coagulopathy, and hypoalbuminemia. Liver biopsy demonstrated massive sinusoidal amyloid deposition with Congo red positivity and apple-green birefringence, confirming an infiltrative pathology. Immunohistochemistry was negative for AA amyloid, and no monoclonal gammopathy was detected. Despite supportive therapies including plasmapheresis and hemodialysis, the patient developed multiorgan failure and died.

Conclusion: Massive sinusoidal amyloid deposition can lead to rapidly progressive ALF with high mortality. Early tissue diagnosis is critical to identify infiltrative hepatic disease and to avoid delays in management, including consideration of liver transplantation.

Keyword(s) : Hepatic amyloidosis, Acute liver failure, Sinusoidal amyloid deposition, Cholestasis

1691 - Effects of biological agents on hepatitis B virus reactivation in patients who are negative for hepatitis B surface antigen and positive for antibodies against hepatitis B core antigen

Atiye Ayrik Demir ¹, Orhan Yildiz ², Bilgehan Aygen ²
Kayseri City Hospital, Department Of Infectious Diseases And Clinical Microbiology, Kayseri-Türkiye ¹
Erciyes University Faculty Of Medicine, Department Of Infectious Diseases And Clinical Microbiology, Kayseri-Türkiye ²

Background / Hypothesis:

In HBsAg-negative, anti-HBc IgG-positive individuals, the risk of hepatitis B virus reactivation (HBVr) associated with immunosuppressive therapy varies depending on the immunosuppressive potency of the biological agent used. This study aimed to evaluate the development of HBVr in HBsAg-negative, anti-HBc IgG-positive patients receiving medium- or high-risk biological agents.

Materials and Methods:

A total of 172 patients identified as HBsAg-negative and anti-HBc IgG-positive were retrospectively evaluated. Patients were classified into moderate- and high-risk groups according to the HBVr risk associated with the biological agents used. Rituximab and ocrelizumab were categorized as high-risk agents, while anti-TNF- α agents (adalimumab, infliximab, golimumab, certolizumab, etanercept), the IL-6 inhibitor tocilizumab, and the IL-12/23 inhibitor ustekinumab were considered moderate-risk agents. Demographic and clinical characteristics, treatment details, concomitant immunosuppressive medications, and antiviral prophylaxis status were recorded. Virological and serological data obtained during follow-up were reviewed, and the occurrence of HBVr was assessed.

Results:

The mean age of the study population was 52.3 ± 11.0 years. The most common indications for biological agent therapy were ankylosing spondylitis (30.2%) and rheumatoid arthritis (29.7%). While 20.9% (n=36) of patients received high-risk agents, 79.1% (n=136) received moderate-risk agents. The median follow-up duration was 28.5 months (12–60 months) in the high-risk group and 36 months (12–96 months) in the moderate-risk group. All patients in the high-risk group received antiviral prophylaxis at treatment initiation, and no HBVr events were observed. In contrast, only 33.1% (n=45) of patients in the moderate-risk group received prophylaxis, while 66.9% (n=91) were monitored without prophylaxis. Among those not receiving prophylaxis, only one patient experienced virological reactivation without clinical or biochemical hepatitis. This patient had an initial anti-HBs level of ≥ 1000 IU/L, which remained stable during follow-up.

Conclusions:

Antiviral prophylaxis is effective in preventing HBV reactivation in HBsAg-negative, anti-HBc IgG-positive

E-POSTER ABSTRACTS

individuals receiving moderate- or high-risk biological agents. For patients treated with moderate-risk agents, regular virological monitoring may serve as a safe alternative to universal prophylaxis, allowing timely identification and management of the rare reactivation events that occur.

1692 - Fibrosis Regression Patterns in Chronic Hepatitis B Evidence from Longitudinal Non Invasive Biomarkers

Hamza Benazzouz¹, Mohamed Borahma¹, Fatimazahra Chabib¹, Nawal Lagdali¹, Selma Sebbah¹, Fatimazahra Ajana¹, Maryeme Kadiri¹

Ibn Sina University Hospital, Faculty Of Medicine And Pharmacy Of Rabat. Mohammed V University, Medecine C Hepatogastroenterology Departement, Rabat-Morocco¹

Introduction:

Liver fibrosis in chronic hepatitis B is a dynamic process that may improve with sustained antiviral therapy. Non-invasive biomarkers such as FIB-4 and APRI are increasingly used to monitor fibrosis over time, yet real-world data describing how fibrosis evolves under treatment or surveillance remain limited. This study aimed to assess fibrosis progression, stability, or regression using non-invasive scores in treated and untreated patients.

Material and Methods:

A retrospective, descriptive, and analytical study was conducted over eight years in a gastroenterology department and included 125 chronic hepatitis B patients. FIB-4 and APRI comparisons before and after antiviral therapy were performed using the Wilcoxon signed-rank test. Fibrosis evolution was categorized as regressive, stable, or progressive based on predefined score variations.

Results:

A total of 125 patients were included in the study, with a mean age of 46.9 ± 12.3 years and a sex ratio M/F of 1.15.

Regarding past medical history, 18(14.4%) were active smokers, 10(8%) had diabetes, 8(6.4%) reported alcohol consumption, 7(5.6%) had dyslipidemia.

Clinically, asthenia was the most frequent presenting symptom, reported in 46(36.8%) patients, followed by abdominal pain in 28(22.4%). Signs of portal hypertension were noted in 10(8%) cases while upper

gastrointestinal bleeding (hematemesis or melena) was observed in 3(2.4%) patients.

Baseline imaging revealed hepatic steatosis in 22(17.6%), chronic hepatopathy in 16(12.8%), radiological signs of portal hypertension in 12(9.6%), and hepatocellular carcinoma in 3(2.4%).

Fibrosis assessment methods included FibroScan in 56(44.8%) patients, liver biopsy in 56(44.8%), and combined evaluation in 5(4%). Before treatment, fibrosis stages were distributed as follows: F0 in 14(11.2%), F1 in 76(60.8%), F2 in 22(17.6%), F3 in 2(1.6%), and F4 in 11(8.8%). Median non-invasive fibrosis scores at baseline were FIB-4=1.65[0.81–2.48] and APRI=0.57[0.26–1.11].

Regarding antiviral management, tenofovir disoproxil fumarate was prescribed in 75 (60%) patients, entecavir in 5(4%), whereas 38(30.4%) were managed under surveillance without antiviral therapy.

After 18 months, 91(72.8%) patients had evaluable follow-up. Median FIB-4 decreased to 0.90[0.62–1.40] ($p=0.006$), and APRI declined to 0.25[0.19–0.37] ($p<0.001$). According to biological evolution scoring, Fibrosis regression was observed in 58(64.2%) patients, stability in 17(18.6%), and progression in 16(17.4%). Among patients under surveillance, no significant change in FIB-4 was observed (1.47vs1.30; $p=0.688$), while APRI showed a mild, non-significant decline (0.435vs0.281; $p=0.375$).

Conclusions:

Antiviral therapy significantly improved non-invasive fibrosis scores, reflecting meaningful fibrosis regression in most patients despite varied baseline stages. These findings highlight the antifibrotic benefit of sustained viral suppression and support the routine use of non-invasive biomarkers for long-term fibrosis monitoring.

1693 - Evaluation of Artificial Intelligence in Clinical Decision Support Application to Chronic Hepatitis B Cases According to the 2025 EASL Guidelines

Meriem Amine¹, Ahlame Benhamdane¹, Samir Mrabti¹, Salma Azammam¹, Chaimae Hiji¹, Tarik Addajou¹, Ilham El Koti¹, Fedoua Rouibaa², Hassan Seddik²
Gastroenterology Department Ii, Mohamed V Military Teaching Hospital, Rabat-Morocco¹ Gastroenterology, Mohamed V Military Teaching Hospital, Rabat-Morocco²

Background / Hypothesis:

Chronic hepatitis B (HBV) encompasses a broad

E-POSTER ABSTRACTS

spectrum of clinical presentations requiring individualized therapeutic strategies. The 2025 EASL guidelines introduce updated recommendations for antiviral treatment, including treatment initiation criteria, preferred therapeutic options, monitoring of virological response, and criteria for treatment discontinuation.

The objective of this study was to assess the conformity of clinical decisions generated by an artificial intelligence model in a series of chronic hepatitis B clinical scenarios, comparing them with the 2025 EASL guideline recommendations. The evaluation focused on therapeutic indications, the choice of antiviral agents, virological response management, and decisions regarding treatment cessation.

Materials and Methods:

We conducted a retrospective descriptive study based on a comparative analysis of 22 fictitious clinical cases of patients followed for chronic HBV infection. These cases were classified into three categories according to complexity: simple cases, specific cases, and complex cases.

For each scenario, ChatGPT's responses concerning treatment indications, antiviral drug selection, virological response management, and treatment discontinuation decisions were compared with the 2025 EASL guidelines to assess their conformity.

Results:

Therapeutic indications showed full compliance (100%) in simple cases, despite occasional limitations in the treatment options proposed. In complex cases, indications also reached 100% compliance; however, the therapeutic propositions were incomplete in 50% of situations. For example, in pregnant women, ChatGPT mentioned only tenofovir disoproxil fumarate and omitted tenofovir alafenamide, now recommended by EASL 2025.

Among specific cases, compliance with indications and treatment choices remained high (100%), but omissions were frequent (42.85%), particularly regarding specialized treatments such as interferon for hepatitis delta or immunoglobulins in transplant recipients.

Concerning virological response management, treatment strategies were generally appropriate in 66.66% of cases. Non-compliant management was mostly observed in cirrhotic patients lacking virological response.

Regarding treatment discontinuation,

recommendations were correctly applied in most situations (66.66%). Nevertheless, some errors persisted, notably in HBeAg-negative, non-cirrhotic patients in whom management diverged from guideline indications.

Conclusions:

This study demonstrates that ChatGPT generally aligns well with the 2025 EASL guidelines for chronic hepatitis B management but exhibits notable gaps, particularly in the selection of specific therapeutic options. These findings underscore the essential role of clinical expertise and the need for continuous updating of artificial intelligence tools to ensure optimal patient care.

Keyword(s) : Chronic Hepatitis B , Artificial Intelligence , EASL 2025 Guidelines

1695 - CHATGPT FOR PATIENT QUESTIONS ABOUT CIRRHOSIS USEFUL BUT NOT INFALLIBLE

Meriem Amine¹, Samir Mrabti¹, Ahlam Benhamdane¹, Salma Azammam¹, Chaimae Hiji¹, Tarik Addajou¹, Ilham El Koti¹, Fedoua Rouibaa², Hassan Seddik²
Gastroenterology Department Ii, Mohamed V Military Teaching Hospital, Rabat-Morocco¹ Gastroenterology, Mohamed V Military Teaching Hospital, Rabat-Morocco²

Background / Hypothesis:

Patients with cirrhosis often lack knowledge about how to manage and prevent complications related to their disease. ChatGPT, a natural language processing model developed by OpenAI, could offer support by providing clear and understandable answers to patients. While it has been used in medical applications, such as test preparation and report writing, few studies have evaluated its ability to accurately answer clinical questions specific to diseases like cirrhosis. This study aims to evaluate the accuracy and completeness of ChatGPT's responses in order to assess its effectiveness as an informational tool for patients.

Materials and Methods:

We analyzed 44 frequently asked questions about cirrhosis posed by patients in Facebook support groups, categorizing them into four

E-POSTER ABSTRACTS

groups: basic knowledge (19 questions), diagnosis (3 questions), treatment (15 questions), and lifestyle (7 questions). A liver

specialist evaluated the answers on a scale from 1 to 4:

1. Complete
2. Correct but insufficient
3. Contains both correct and incorrect information
4. Completely incorrect

Results:

The results show that for basic knowledge, 47.3% of answers were complete, 31.5% were correct but insufficient, and 21.05% contained incorrect information. Regarding diagnosis, 66.6% of answers were correct but lacked detail, while 33.3% were complete. For treatment, 33.3% of answers were complete, 40 % were correct but insufficient, and 20% contained errors. Finally, for lifestyle, 42.8% of answers were complete, 28.5% were correct but insufficient, and 14.28% contained errors. Notably, no ChatGPT answer was deemed completely incorrect.

The model demonstrated its ability to provide detailed answers to questions related to basic knowledge and lifestyle. It offered comprehensive explanations of the symptoms, etiology, and prognosis of both compensated and decompensated cirrhosis, as well as risk factors and lifestyle changes that may influence outcomes. While the model provided correct answers in areas like diagnosis and treatment, most responses were rated as correct but insufficient.

Conclusions: This study shows that while the model was able to provide complete and useful answers on basic and lifestyle topics, there is still room for improvement, particularly in more technical areas such as diagnosis and treatment of cirrhosis. It is crucial that medical information is regularly updated to ensure its accuracy and relevance. Additionally, this analysis emphasizes the importance of consulting healthcare professionals for personalized medical advice tailored to each individual situation.

1696 - Characterizing Primary Biliary Cholangitis in Men Clinical Biological and Histological Profile

Rajaa Boukhraiss ¹, Mohamed Borahma ¹, Fatima Zahra Chabib ¹, Nawal Lagdali ¹, Selma Sebbah ¹, Fatima Zohra Ajana ¹, Meryem Kadiri ¹
Université Mohammed V, Rabat, Morocco, Department Of Hepatogastroenterology C, Rabat-Morocco ¹

Background / Hypothesis:

Primary biliary cholangitis (PBC) predominantly affects women, and male presentation remains uncommon and insufficiently characterized. Emerging evidence suggests that men may present with more advanced disease and a distinct clinical course. This study aimed to describe the clinical, biochemical, immunological, and histological features of male PBC patients and to provide an exploratory comparison with female patients in a single-center cohort.

Materials and Methods:

We conducted a retrospective single-center study including all PBC patients followed between 2016 and 2025. Diagnosis was established according to EASL criteria, based on cholestatic liver tests, anti-mitochondrial antibodies (AMA-M2), and/or compatible liver histology. Clinical, biochemical, immunological, and histological data were collected. Descriptive comparisons between men and women were performed; no formal statistical analysis was conducted due to the limited number of male patients.

Results:

Among 106 PBC patients, 10 were men. Mean age at diagnosis was 52.5 years in men versus 49.2 years in women. Associated autoimmune diseases were present in 60% of men and 54.2% of women. Signs of portal hypertension were observed in 50% of men versus 39.6% of women. Bone disease prevalence was similar (70% vs. 68.8%).

Liver biochemistry showed elevated alkaline phosphatase in 90% of men and 77% of women; GGT elevation was noted in 80% versus 87.5%. Marked cytotoxicity was more frequent in men (30% vs. 16.7%). Anti-M2 antibodies were positive in 70% of men and 75% of women; AMA-negative PBC with specific autoantibodies was rare in both sexes. Advanced fibrosis (F3–F4) was identified in 60% of men versus 54.2% of women. Liver biopsy was performed in 40% of men and 34.4% of women. UDCA response (Paris II criteria) was achieved in 50% of men versus 58.3% of women. PBC–autoimmune hepatitis overlap was diagnosed in 30% of men versus 16.7% of women.

Conclusions:

In our cohort, men with PBC tended to present with more advanced fibrosis, higher rates of cytotoxicity,

E-POSTER ABSTRACTS

slightly lower UDCA response, and increased prevalence of PBC–AIH overlap. These exploratory findings suggest that male PBC may represent a distinct, potentially more severe phenotype, emphasizing the need for clinical vigilance and multicenter studies to further characterize this subgroup.

1697 - Combined use of fibrate and statin to reduce the risk of hepatocellular carcinoma a population based cohort study

Won Sohn¹, Kyoung A Ko¹, Hyunwoo Oh¹, Cheol-young Park¹

Kangbuk Samsung Hospital - Sungkyunkwan University, Internal Medicine, Seoul-South Korea¹

Background: This study investigated the reduced risk of hepatocellular carcinoma (HCC) by the use of fibrates as an add-on to statins.

Methods: This population-based cohort study was conducted from the Korean National Health Insurance Service from 2010 to 2019 in Korea. We compared the incidence of HCC between statin users and those taking fibrates and statins for dyslipidemia, matched using age, sex, and hypertriglyceridemia.

Results: We analysed 789,958 individuals, including 394,979 statin users and 394,979 who were matched users of combined fibrate-statin therapy. During the 1,644,037.6 person-years of follow-up, 791 HCC cases were observed in the statin group, whereas 703 HCC cases were observed in the fibrate-statin group during 1,646,939.6 person-years of follow-up. The HCC incidence rates per 1,000 person-years were 0.48 and 0.43 in the statin and fibrate-statin groups, respectively. The risk of HCC was lower in the fibrate-statin group compared to the statin-only group in the unadjusted and adjusted models (hazard ratio [HR] 0.89 with 95% confidence interval [CI]: 0.80–0.98 and adjusted HR [aHR] 0.74 with 95% CI: 0.67–0.83). The reduction of HCC development by fibrate-statin increased as the duration of fibrate administration lengthened (aHR 0.76 with 95% CI: 0.68–0.86 in the use of fibrate and statin for <1 year; and aHR 0.71 with 95% CI: 0.61–0.82 for >1 year).

Conclusions: Fibrates as an add-on to statin were associated with a reduced risk of HCC compared to statins. Further prospective studies are needed to clarify the role of fibrate on the risk of HCC.

1699 - Endoscopic Management of Complications from Ruptured Hepatic Hydatid Cysts into the Bile Ducts

Meriem Amine¹, Ahlame Benhamdane¹, Samir Mrabti¹, Salma Azammam¹, Chaimae Hiji¹, Tarik Addajou¹, Ilham El Koti¹, Fedoua Rouibaa², Hassan Seddik²
Gastroenterology Department Ii, Mohamed V Military Teaching Hospital, Rabat-Morocco¹ Gastroenterology, Mohamed V Military Teaching Hospital, Rabat-Morocco²

Background / Hypothesis:

Liver hydatid cyst(LHC)is a parasitic disease caused by the development of the tapeworm Echinococcus granulosus.Fistulization in the bile ducts is one of the most common complications. Endoscopic treatment is essential due to the risks associated with surgery.The objective of our study was to evaluate the contribution of endoscopic retrograde cholangiopancreatography(ERCP)in the diagnostic and,more importantly,therapeutic management of ruptured LHC in the bile ducts.

Materials and Methods:

This was a retrospective, descriptive and analytical study, conducted from January 2002 to August 2025, involving 50 patients with LHC fistulized in the bile ducts.ERCP and endoscopic biliary sphincterotomy were performed in all patients.Overall success was defined as definitive emptiness of the common bile duct.Statistical analysis was performed using SPSS 24.0software

Results:

During the study period,4.6%(n =50)of ERCPs were performed for hepatic hydatid cysts ruptured into the bile ducts.The mean age was 46.1±14.8 years,with 66% male patients(M/F ratio: 1.94).ERCP was performed preoperatively in 52.2%and postoperatively in 47.8%of cases.Main indications included acute cholangitis(44.9%) and persistent external biliary fistula(34%).Sphincterotomy was done in 96% of cases, with hydatid material successfully extracted in 87.8%.Nasobiliary drainage was required in 24%, and biliary stenting in 8%.The overall success rate was 96%, with a complication rate of 8% (hemobilia and post-sphincterotomy bleeding). Jaundice resolved within 5–10 days, and external fistulas closed by day 10 in most cases.

E-POSTER ABSTRACTS

Conclusions:

Our study confirms that endoscopic treatment of ruptured hydatid cysts in the bile ducts is an effective therapeutic alternative, with a low rate of immediate complications (8%) and good long-term outcomes.

1700 - Artificial intelligence based prediction of ursodeoxycholic acid response in primary biliary cholangitis comparison of two large language models

Jaouhara Lahsini¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Selma Sebbah¹, Fatima Zohra Ajana¹, Maryeme Kadiri¹
Ibn Sina University Hospital, Mohammed V University, Department Of Medicine C, Rabat-Morocco¹

Background / Hypothesis:

Primary biliary cholangitis (PBC) is a chronic autoimmune disease characterized by progressive destruction of the intrahepatic bile ducts. Ursodeoxycholic acid (UDCA) is the standard treatment, and therapeutic response is a major prognostic factor. The recent rise of large language models (LLM) paves the way for their use as potential clinical decision support tools.

This study aimed to compare the performance of two general purpose chatbots (A and B) in predicting the 12-month biological response to UDCA, defined according to Paris II criteria, and to determine which of the two could be the most relevant.

Materials and Methods:

The study included 142 patients with PBC, followed between 2010 and 2025 in a tertiary hepatology department. Clinical, biological, immunological, and histological data available at the start of treatment were collected from medical records.

The actual response at 12 months was defined according to the Paris II criteria, which served as the gold standard. The data were entered into two LLM (chatbot A: ChatGPT and chatbot B: Claude) using an identical prompt in order to obtain a prediction of responder or non responder status.

Predictive performances were evaluated using: accuracy, sensitivity, specificity, and ROC-AUC.

Results:

Chatbot A (ChatGPT) showed high predictive performance. It achieved an AUC of 0.84, with 85% accuracy, 82% sensitivity, and 79% specificity, indicating good discriminative ability and satisfactory agreement between predicted and observed outcomes. Chatbot B (Claude), however, showed substantially lower performance. The generated model displayed limited discrimination, with an AUC of 0.50 and an overall accuracy of approximately 53%. Sensitivity at 64.3% and specificity at 60.7% reflected an insufficient ability to distinguish responders from non responders.

Conclusions:

This study shows that Chatbot A demonstrates good discriminative performance in predicting UDCA response in PBC, with satisfactory concordance with outcomes observed at 12 months. In contrast, Chatbot B exhibits limited performance and insufficient discrimination between responders and non responders.

These results suggest that LLM based tools could assist clinical decision-making in hepatology, but should not replace clinical judgment. Their variable performance across models also highlights the need for further validation before clinical implementation.

1701 - Seronegative primary biliary cholangitis clinical biochemical and histological profile with comparison to seropositive disease

Jaouhara Lahsini¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Selma Sebbah¹, Fatima Zohra Ajana¹, Maryeme Kadiri¹
Ibn Sina University Hospital, Mohammed V University, Department Of Medicine C, Rabat-Morocco¹

Background / Hypothesis:

Primary biliary cholangitis (PBC) is an autoimmune cholestatic disease characterized by progressive destruction of intrahepatic bile ducts. While most patients present with anti mitochondrial antibodies (AMA) or specific PBC-related autoantibodies (anti-gp210, anti-sp100), a subset remains seronegative, making diagnosis more challenging. This study aimed

E-POSTER ABSTRACTS

to describe the clinical, biochemical, and histological features of seronegative PBC (snPBC) and compare them with seropositive forms.

Materials and Methods:

We conducted a retrospective descriptive study including all patients diagnosed with snPBC between 2010 and 2025 in a tertiary hepatology department. Diagnosis relied on cholestatic liver tests and compatible liver histology in the absence of AMA and PBC-specific autoantibodies. Clinical, biochemical, immunological, and histological data were collected. Statistical analysis was performed using Jamovi.

Results:

Sixty-seven snPBC patients were included (mean age 49 years; female-to-male ratio of 3:1). Jaundice was reported in 52%, asthenia in 44%, and pruritus in 32%. Signs of portal hypertension were observed in 40% of cases. Immunologically, all patients were negative for AMA, anti-gp210, and anti-sp100. Biochemically, 61% had cytocholestasis and 39% had isolated cholestasis. Histology showed Scheuer stages: 15% stage 1, 43% stage 2, 33% stage 3, and 9% stage 4. Fibrosis staging revealed advanced fibrosis (F3–F4) in 58% of patients. Associated autoimmune conditions included PBC-autoimmune hepatitis overlap (21%), autoimmune thyroiditis (13.5%), and Sjögren's syndrome (6%). According to Paris II criteria, 57% responded to UDCA and 28% were non-responders. Comparison with seropositive PBC revealed no significant differences regarding demographics, fibrosis severity, portal hypertension, autoimmune associations, or UDCA response.

Conclusions:

Seronegative PBC in our cohort predominantly affected middle-aged women and frequently presented with advanced fibrosis and associated autoimmune diseases. Despite its distinct immunological profile, snPBC did not significantly differ from seropositive PBC in clinical severity or treatment response, suggesting a comparable prognosis and similar therapeutic management.

1702 - Combining Interferon α and Nucleos(t)ide Analogues to Enhance Early Virological Response in Chronic Hepatitis B

Xiaoxue Chen ¹, Weihua Cao ¹, Yao Xie ¹, Minghui Li ¹
Beijing Ditan Hospital, Capital Medical University, Hepatology Division 2, Beijing-China ¹

Background / Hypothesis:

This study evaluated the efficacy of different combination strategies of interferon-alpha (IFN α) and nucleos(t)ide analogues (NAs) in patients with chronic hepatitis B (CHB), focusing on the impact of different administration sequences (initial combination vs. sequential add-on) on virological and serological responses.

Materials and Methods:

A retrospective cohort study was conducted, enrolling 145 patients with CHB. Participants were divided into three groups based on their treatment regimen: initial combination (concurrent IFN α and NAs for 48 weeks), initial IFN α (12 or 24 weeks) followed by add-on NAs (total 48 weeks), and initial NAs (12 or 24 weeks) followed by add-on IFN α (total 48 weeks). Virological, serological, and biochemical markers were collected at baseline, 12, 24, and 48 weeks of combination therapy. The primary endpoints were the virological response rate and HBsAg seroconversion rate at week 48.

Results:

Baseline characteristics were comparable among the three groups, except for HBeAb levels. After 48 weeks, the initial combination group showed a significant reduction in HBV DNA and HBeAg ($P < 0.001$), and demonstrated an earlier and sustained decline in HBsAg from week 12 ($P < 0.01$). No significant differences were observed in the HBV DNA negative rate or HBsAg seroconversion rate.

Conclusions:

Initial combination therapy demonstrated stronger advantages in early viral suppression and HBeAg reduction. Although it did not improve seroconversion outcomes, initiating IFN α and NAs simultaneously optimizes virological and serological responses, providing a new theoretical basis for improving clinical cure strategies for CHB.

1703 - First Case Report of Tenofovir Disoproxil Fumarate Induced Perichondritis A Case Study from the Perspective of Seronegative Autoimmune Processes

Yeşim Çağlar ¹, Gülce Eylül Aldemir ¹

Balikesir University Faculty Of Medicine, Infectious
Disease And Clinical Microbiology, Balikesir-Türkiye ¹

Background: Tenofovir disoproxil fumarate (TDF) is a safe and potent drug treatment of HBV infection. However, due to the activation of the immune system and the increase in inflammatory processes, some side effects may be observed, although not frequently. This article presents the first case report of perichondritis caused by TDF and will investigate the possible relationship between tenofovir and inflammatory processes.

Case Report: A 43-year-old female patient with a 10-year history of chronic HBV infection. She presented with fatigue and right upper quadrant pain. Liver function tests were normal. HBsAg: 5222, Anti-HBe: positive, HBV DNA: 135.014 IU/mL (fluctuating). AFP: 3,27 µg/L, USG were normal. Liver biopsy; modified Knodell HAI: 4/18, Fibrosis: 1 was detected. HBV focal diffuse (+) positive. TDF treatment was started. The patient also requested treatment.

In the second month of treatment, the patient presented with complaints of redness and pain in both auricles, nausea, intense hair loss, and dry mouth. Physical examination revealed bilateral perichondritis. Hemogram and biochemical analyses were normal. Rheumatoid factor (RF): 21 IU/mL was detected as high. Other autoimmune and rheumatological markers and acute phase reactants were normal. The patient discontinued treatment. The perichondritis has regressed. The pain and nausea have resolved. However, hair loss and dry mouth persisted. RF elevation persisted during follow-up. During follow-up visits, the patient had an attack of perichondritis. Patient was referred to a rheumatology.

Discussion: The development of perichondritis, hair loss, and dry mouth following initiation of TDF therapy, along with negative serological tests, regression of perichondritis following discontinuation suggests a systemic seronegative autoimmune process. Despite elevated RF levels, negative anti-CCP and ANA results suggest the possibility of seronegative rheumatoid arthritis or relapsing polychondritis. Symptoms suggestive of exocrine gland involvement, such as dry mouth and foul-smelling sweating, may be significant

for seronegative Sjögren's syndrome, but similar symptoms can also be seen in systemic autoimmune diseases such as relapsing polychondritis. The possibility of an exocrine-involved seronegative autoimmune process has been strengthened. Perichondritis associated with tenofovir use has not been previously reported. However, there are some case reports regarding rare dermatological/immune side effects of TDF.

The incidence of side effects is not common. However, due to immune system activation and increased inflammatory processes, may be observed, although not frequently. In this case, the recurrence of perichondritis, hair loss, and dry mouth during and after TDF treatment suggests that an underlying latent autoimmune disease may have been triggered.

1704 - Case Report of Hematopoietic Disorder Complicated by Severe Liver Injury Clinical Features and Mechanistic Insights into the Co occurrence of Hemophagocytic Syndrome and Aplastic Anemia

Linmei Yao ¹, Xin Wei ¹, Zixuan Gao ¹, Shuojie Wang ¹, Ruyi Liu ¹, Yao Xie ¹, Minghui Li ¹

Beijing Ditan Hospital, Capital Medical University,
Department Of Hepatology Division 2, Beijing-China ¹

Abstract :

The patient is a 33-year-old woman who was admitted with the chief complaints of "fatigue, poor appetite, and yellow urine for 1 month, exacerbated by fever for 4 days." The clinical course was characterized by progressive liver failure, pancytopenia, and severe inflammatory response. Bone marrow cytology confirmed the diagnosis of hemophagocytic lymphohistiocytosis (HLH) combined with pure red cell aplasia (PRCA), forming a rare mixed hematopoietic dysfunction syndrome. By integrating the clinical progression, dynamic laboratory evolution, and therapeutic response, this study focuses on: (1) exploring the bidirectional pathogenic relationship between liver failure and HLH activation, with particular focus on the central role of hepatic dysfunction in promoting immune dysregulation and cytokine storm ; and (2) investigating the pathogenic interplay between aplastic anemia (AA) presenting as PRCA and HLH, specifically highlighting the critical role of immune microenvironment disruption in mediating lineage-specific hematopoietic suppression. This case provides unique insights into the complex interplay between liver failure and hematopoietic injury under systemic

E-POSTER ABSTRACTS

immune dysregulation, underscoring the clinical challenges in diagnosing and managing HLH-AA spectrum comorbidities.

1705 - Development of a Novel Animal Model for Acute on chronic liver failure (ACLF) in Metabolic dysfunction associated steatotic liver disease Confirmed the progression to ACLF in a non cirrhotic liver disease stage

Rui Zhao¹, Qi Yang¹, Hui Liu², Jingjing Chen¹, Jingran Jiao¹, Chengxuan Yao¹, Manman Xu¹, Xinli Mao³, Yu Chen¹

Beijing You'an Hospital, Capital Medical University, Fourth Department Of Liver Disease (difficult & Complicated Liver Diseases And Artificial Liver Center), Beijing-China¹ Beijing You'an Hospital, Capital Medical University, Department Of Pathology, Beijing-China² Taizhou Hospital Of Zhejiang Province Affiliated To Wenzhou Medical University, Department Of Gastroenterology, Linhai-China³

Background / Hypothesis:

Acute-on-chronic liver failure (ACLF) is a high-mortality syndrome triggered by acute insults in patients with chronic liver disease. Coagulopathy in critically ill patients largely precludes tissue sampling, underscoring the need for animal models as an alternative. Metabolic dysfunction-associated steatotic liver disease (MASLD), a growing public health concern, can progress to cirrhosis and subsequently increase MASLD-ACLF prevalence. While animal models exist for MASLD or ACLF separately, none replicates ACLF development on a MASLD background.

Materials and Methods:

Based on previous research, a MASLD model was established using B6-Alms1-del mice fed an ALMN diet (Western diet). Varying the modeling duration induced steatohepatitis in the mice. After LPS/D-GalN acute insult, serum was collected for liver function tests and liver tissues for histopathology and transcriptomics. Multiplex immunofluorescence was utilized to assess intestinal barrier damage and the potential gut-liver axis during ACLF progression.

Results:

Successful generation of MASLD-ACLF models exhibiting steatohepatitis was achieved. Compared to

the MASLD group, the MASLD-ACLF group showed extensive liver necrosis on H&E staining, along with typical histopathological features supporting ACLF diagnosis, including neutrophilic and lymphocytic infiltration, Mallory bodies, cholestasis, and portal inflammation, concurrent with characteristic steatotic manifestations. Hepatic fibrosis was assessed via α -SMA and Sirius red staining. Serum levels of AST, ALT, ALB, TBIL, GLU, CREA, and TBA were altered. Decreased Muc-2 and Occludin indicated gut barrier impairment. Transcriptomics revealed changes in tissue remodeling, phagocytosis, bile acid metabolism, and neutrophil phenotype markers. Hallmark gene set analysis pathways revealed IL6-JAK-STAT3 and Interferon Alpha Response pathways enriched in MASLD-ACLF group.

Conclusions:

This study successfully established and validated the first MASLD-ACLF animal model. Pathological evidence confirmed progression to ACLF at a non-cirrhotic liver disease stage. Given the growing public health challenge posed by MASLD-ACLF, this model provides a platform enabling direct tissue analysis and longitudinal investigation, thereby facilitating the exploration of disease mechanisms and the development of therapeutic strategies.

1706 - Bushen granule plus entecavir improved the effectiveness for HBeAg negative chronic hepatitis B A multicenter randomized double blind placebo controlled clinical trial

Longshan Ji^{*1}, Xin Zhang^{*1}, Jinghao Zhang^{*1}, Xiaojun Zhu¹, Lingying Huang¹, Hua Lyu², Man Li^{#3}, Xuehua Sun^{#1}, Yueqiu Gao^{#1}

Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Department Of Hepatopathy, Shanghai-China¹ National Monitoring Center For Medical Services Quality Of Tcm Hospital, /, Shanghai-China² Shanghai Key Laboratory Of Traditional Chinese Clinical Medicine, /, Shanghai-China³

Background / Hypothesis:

Nucleoside analogs are the first-line therapeutic drugs for the treatment of chronic hepatitis B (CHB), but loss of HBsAg is rarely achieved. Bushen granule (BSG), as the experimental traditional Chinese medicine, is widely used to treat CHB in China alongside NAs. However, there are no clinical data about entecavir (ETV) plus BSG treating HBeAg negative CHB patients. In this paper, we aimed to assess the efficacy of BSG in

E-POSTER ABSTRACTS

promoting the loss of HBsAg in HBeAg negative CHB patients.

Materials and Methods:

A multicenter, double-blind, placebo-controlled randomized clinical trial involving 555 HBeAg negative CHB patients was conducted from April 2019 to August 2022. (Clinical Trials Registration: ChiCTR1900021370). Patients were randomized into the treatment group (administration of ETV 0.5 mg/day plus BSG 36.0g/time, 2 times/day, n=278) and control group (administration of ETV 0.5 mg/day plus placebo 36.0g/time, 2 times/day, n=277). The treatment period was 120-week. The primary outcomes were the rate of HBsAg loss and the decline of HBsAg at week 120. Secondary outcomes included the change of LSM, CAP and biochemical items.

Results:

Two hundreds and twenty eight patients (82.01%) in the treatment group and 227 patients (81.65%) in the control group completed the study. The rate of HBsAg loss at week 120 in the treatment group was markedly higher than that in the control group (4.4% vs. 0.9%, $P=0.020$). Further sub-group analysis showed that in the sub-group with HBsAg < 1500 IU/ml, the HBsAg loss rate in the treatment group was more remarkable than that in the control group (10.1% vs. 1.9%, $P=0.013$). In the sub-group with HBsAg $\geq$ 1500 IU/ml, the HBsAg decline was much greater in the treatment group than that in the control group. BSG was well tolerated without any severe side effects.

Conclusions:

BSG plus ETV combination treatment increased the rate of HBsAg loss in HBeAg-negative CHB patients, particularly in patients with baseline HBsAg < 1500 IU/ml.

1707 - Analysis of Risk Factors and Fibrosis Severity in Type 2 Diabetic Patients with Metabolic Associated Fatty Liver Disease A Cross Sectional Study

Taolong Zhou¹, Xiaoliang Li¹, Mingxing Huang¹, Kefeng Li²

The Third People's Hospital Of Zhuhai, The Digitalized Diabetes And Liver Disease Co-management Center, Zhuhai-China¹ Macao Polytechnic University, Centre For Artificial Intelligence Driven Drug Discovery, Macao-China²

Background / Hypothesis:

Metabolic associated fatty liver disease(MAFLD) is closely related to type 2 diabetes mellitus (T2DM). However, the exact risk factors, severity of liver injury, and degree of fibrosis in T2DM patients within our country and the Asia-Pacific region require further clarification. This study aimed to investigate the risk factors for MAFLD, the extent of liver injury and fibrosis, and identify independent interrelated risk factors in T2DM patients at our institution.

Materials and Methods:

This cross-sectional study consecutively enrolled 1350 T2DM patients from our digitalized diabetes and liver disease co-management center between June 2023 and June 2025. All patients were diagnosed based on the MAFLD criteria (evidence based on liver transient elastography concurrently with overweight/diabetes or metabolic dysfunction). We collected demographic data, diabetes duration, anthropometric parameters (BMI, waist circumference), biochemical indicators (fasting blood glucose, HbA1c, blood lipids, liver enzymes), non-invasive liver fibrosis indices (Liver Stiffness Measurement, LSM), and medication history. Multivariable logistic regression models were used to analyze independent risk factors for MAFLD.

Results:

Among the 1350 enrolled T2DM patients (mean age 52.4 ± 10.8 years, 54% male), the overall prevalence of MAFLD, diagnosed based on liver transient elastography evidence concurrently with overweight/diabetes or metabolic dysfunction, was 62.5% (844/1350). Multivariable regression analysis, after adjusting for age and sex, revealed that the following factors were independently associated with MAFLD in T2DM patients:

- Obesity (OR = 2.85, 95% CI: 2.32-3.51, $P < 0.001$)
- Central obesity (elevated waist circumference): OR = 2.41, 95% CI: 1.98-2.93, $P < 0.001$)
- Hypertriglyceridemia (OR = 2.12, 95% CI: 1.75-2.57, $P < 0.001$)

E-POSTER ABSTRACTS

- Lower HDL-C level (HDL-C <1.0 mmol/L [male] / <1.3 mmol/L [female]: OR = 1.68, 95% CI: 1.38-2.05, P<0.001)
- Higher ALT level (OR = 1.92, 95% CI: 1.55-2.38, P<0.001)
- Poorer glycemic control (OR = 1.55, 95% CI: 1.26-1.91, P<0.001)
- Among diabetic patients with MAFLD, the proportion with LSM suggestive of significant liver fibrosis (>7.3 kPa) reached 15.3%, which was significantly higher than in diabetic patients without MAFLD (P<0.001).
- The association between diabetes duration and MAFLD did not reach statistical significance (P=0.06).

Conclusions: This study demonstrates a high prevalence of MAFLD among T2DM patients at our institution, and patients with comorbid MAFLD have a significantly higher risk of liver fibrosis. Obesity, dyslipidemia, elevated liver enzymes, and poor glycemic control are independent risk factors for MAFLD in T2DM patients. Diabetes duration showed no independent association with MAFLD. These findings emphasize the importance of routine MAFLD screening in T2DM patients and active management of these modifiable risk factors to prevent hepatic and extra-hepatic

1709 - Neck circumference and the risk of metabolic dysfunction associated steatotic liver disease in non obese individuals without visceral obesity

Kyoung A Ko¹, Hyunwoo Oh¹, Jung Hee Kim², Ju-yeon Cho³, Jae Yoon Jeong⁴, Won Sohn¹
Kangbuk Samsung Hospital, Gastroenterology, Seoul-South Korea¹ Hallym University Dongtan Sacred Heart Hospital, Gastroenterology, Dongtan-South Korea² Columbia University Irving Medical Center, Digestive And Liver Disease, New York-United States³ Ewha Womans University Mokdong Hospital, Gastroenterology, Seoul-South Korea⁴

Background / Hypothesis: This study aimed to examine the association between neck circumference and metabolic dysfunction-associated steatotic liver disease (MASLD) in non-obese individuals without visceral obesity.

Materials and Methods: A cross-sectional analysis was performed using nationally representative data from the Korea National Health and Nutrition Examination Survey 2019–2020. Non-obesity was defined as body

mass index (BMI) <25 kg/m². Visceral obesity was defined as a waist circumference ≥90 cm for men and ≥85 cm for women. Increased neck circumference was defined as ≥37.7 cm for men and ≥32.8 cm for women. Multivariable logistic regression was performed to assess the association between neck circumference and MASLD in non-obese individuals without visceral obesity, and adjusted odds ratios (aORs) and 95% confidence intervals (CIs) were reported.

Results: This study included 4,065 non-obese adults without visceral obesity (1,521 men and 2,544 women) aged ≥40 years. The mean neck circumference was 36.5 cm in men and 31.9 cm in women, with 25.3% (n=1,027) classified as having an increased neck circumference. The overall prevalence of MASLD was 3.5% (n=141) and was significantly higher among individuals with increased neck circumference compared with those with normal neck circumference (7.6% vs. 2.1%, P < .001). Increased neck circumference was independently associated with MASLD (aOR 1.95, 95% CI: 1.26-2.99, P = .003).

Conclusions: Increased neck circumference is independently associated with MASLD in non-obese individuals without visceral obesity. Neck circumference may serve as a simple and practical anthropometric marker to identify at-risk individuals who may be overlooked by conventional measures such as BMI or waist circumference.

1710 - Mn Tannic Acid Immunomodulators Potentiate PDGFRβ CAR T Cell Function Through Enhanced proliferation for Synergistic Anti Hepatic Fibrosis Therapy

Xinyu Wang¹, Yüemin Feng¹, Songbo Zhao², Qiang Zhu³

Shandong Provincial Hospital Affiliated To Shandong First Medical University, Department Of Gastroenterology, Jinan-China¹ Shandong Provincial Hospital Affiliated To Shandong First Medical University, Department Of Central Laboratory, Jinan-China² Shandong Provincial Hospital Affiliated To Shandong First Medical University, Department Of Infectious Diseases, Jinan-China³

Background / Hypothesis: Chimeric antigen receptor (CAR)-T cell therapy has

E-POSTER ABSTRACTS

obtained considerable success in treating malignant tumors, and is now being increasingly used to treat a number of other chronic immune diseases. However, the therapeutic efficacy of the treatment for hepatic fibrosis remains to be demonstrated due to the complex pathogenic microenvironment in the liver resulting in negative cause-induced inhibition of cell expansion capacity, limited infiltration capacity, and severe cellular exhaustion and senescence.

Materials and Methods:

Here, we creatively developed Mn-tannic acid (MT) nanoparticle immunomodulators with uniform particle size and excellent T1-weighted MRI imaging performance through the coordination reaction of tannic acid and Mn^{2+} . It possessed the property of remodeling the pathophysiological microenvironment of liver fibrosis and improved the phenotype and cytotoxicity of CAR-T cells. In addition, MT nanoparticles formed strong bonds with multidentate ligands of PDGFR β CAR-T cell membrane proteins via hydrophobic interactions and hydrogen bonding, which was designed for targeting activated hepatic stellate cells (aHSCs).

Results:

MT nanoparticles exhibited enhanced cytotoxicity of PDGFR β CAR-T cells against target cells in vitro. In vivo studies demonstrated that PDGFR β CAR-T cell therapy enhanced by MT nanoparticles could synergistically improve anti-fibrotic treatment outcomes with real-time MRI-guided monitoring of therapeutic response. Crucially, MT nanoparticles had been shown to remodel the hepatic fibrotic microenvironment effectively by alleviating the pro-inflammatory response and oxidative stress, which further enhanced the synergistic therapeutic effect of PDGFR β CAR-T cells and modulated the infiltration of endogenous hepatic immune cells while inhibiting stellate cell activation. In addition, we discovered a novel mechanism by which MT nanoparticles enhanced the proliferation and thus the killing ability of PDGFR β CAR-T cells through upregulating the activity of the RAS signaling pathway. MT nanoparticles could impart superior phenotypes to CAR-T cells.

Conclusions:

Overall, our well-designed MT nanoparticle-modified PDGFR β CAR-T cell immunotherapy strategy demonstrated excellent anti-fibrotic effects, providing

a promising therapeutic regimen for hepatic fibrosis. It also expanded the therapeutic approach of the adoptive cellular therapy embellished with a novel biomaterials, backed by solid evidence and guidance.

1711 - Rougan Formula Alleviates Liver Fibrosis by Suppressing Macrophage Glycolysis via Downregulation of the Tenascin C HIF 1 α PFKFB3 Pathway

Qian Li ¹, Jiaping Zheng ¹, Zhili Huang ¹, Longshan Ji ¹, Xiaohui Liang ¹, Yueqiu Gao ¹, Man Li ¹
Shanghai University Of Traditional Chinese Medicine, Shanghai Key Laboratory Of Traditional Chinese Clinical Medicine, Shanghai-China ¹

Background / Hypothesis:

Liver fibrosis is a core pathological process in the progression of chronic liver diseases to cirrhosis and hepatocellular carcinoma, with limited effective treatment options. Rougan Formula(RGF) is the experienced formula for treating liver fibrosis. In this study, we aimed to explore the relevant mechanism of RGF treating liver fibrosis.

Materials and Methods:

A CCL₄-induced liver fibrosis mouse model and an LPS-stimulated RAW264.7 macrophage model were established. Transcriptomic and single-cell sequencing, co-culture assays, TNC silencing, and TNC-knockout techniques were applied to analyze the effects of Rougan Formula on macrophage polarization, glycolysis, and HSC activation. Serum pharmacochimistry and mass spectrometry were used to identify bioactive components of Rougan Formula and validate their inhibitory effects on TNC and liver fibrosis.

Results:

Different doses of RGF can alleviate inflammation and fibrosis in CCL₄-induced models. Transcriptome sequencing confirmed that RGF decreased the expression levels of liver TNC and PFKFB3. Single cell sequencing revealed that RGF significantly inhibited the expression of pro-inflammatory macrophage subpopulation, which was associated with glycolysis. Further experiments showed that RGF significantly reduced the expression levels of GLUT1, TLR4, and HIF-1 α in liver tissues, and decreased iNOS, CD86, CD80,

E-POSTER ABSTRACTS

TNC, TLR4, HIF-1 α , and PFKFB3 in primary liver macrophages. In vitro, RGF-containing serum reduced glycolysis and pro-inflammatory cytokine levels in RAW264.7 cells and inhibited JS1 cell activation in co-culture systems. In addition, liver fibrosis was alleviated in TNC-KO models. TLR4 and PFKFB3 expression levels were attenuated and glycolysis level was reduced after TNC silencing or knockout. In addition, the anti-fibrotic effects of RGF formula was in TNC-KO models.

Conclusions:

Rougan Formula exerts anti-fibrotic effects by downregulating TNC in macrophages, inhibiting TLR4/HIF-1 α /PFKFB3-mediated glycolysis and pro-inflammatory polarization, and subsequently suppressing HSC activation.

1712 - Implementation of a Bidirectional Protection Model for Infection Control in a Dedicated Chronic Hepatitis B Outpatient Clinic A Comprehensive Approach to Break the Chain of Bloodborne Transmission

Yanzhi Duan¹, Li Zhu¹, Xiaoliang Li¹, Mingxing Huang¹

The Third People's Hospital Of Zhuhai, Zhuhai engineering technology research center of occupational And Mental Health, Zhuhai-China¹

Background / Hypothesis:

Chronic hepatitis B (CHB) remains a major public health challenge in China, with an estimated 75 million affected individuals. Despite global efforts toward viral hepatitis elimination by 2030, China's diagnosis and treatment rates remain suboptimal. In outpatient settings managing high volumes of CHB patients, frequent blood exposure, invasive procedures, and environmental contamination pose significant infection risks. We developed and implemented a novel "Bidirectional Protection Model" to enhance infection control while ensuring patient-centered care.

Materials and Methods:

Guided by national disinfection standards, our multidisciplinary team at Zhuhai Third People's Hospital integrated spatial design, workflow optimization, staff training, digital health tools, and

environmental hygiene into a closed-loop, full-process infection control system. The model features: (1) Physical zoning—separate clinical, auxiliary, and clean office areas with distinct patient and staff/utility pathways; (2) Personnel management—mandatory HBV vaccination with antibody monitoring and tiered training for all staff, including support personnel; (3) Digital innovation—an online appointment system limiting patient flow and an electronic medical record platform integrating HBV DNA and liver function data for risk-stratified triage; (4) Micro-level environmental controls, including "one patient—one room—one disinfection," color-coded cleaning tools by risk zone, single-use probe covers for FibroScan devices, and traceable medical waste handling.

Results:

The model effectively minimizes cross-transmission risks among HBV-positive patients, protects HBV-negative individuals (including co-visitors and healthcare workers), and reduces environmental contamination. Patient convenience is enhanced through one-stop services (consultation, lab testing, liver stiffness measurement) and dedicated case managers for continuity of care. Community outreach further reduces stigma and improves early detection.

Conclusions: Our Bidirectional Protection Model transforms infection control from policy into practice, achieving dual goals: advancing CHB treatment coverage and ensuring biosafety for all clinic users. This scalable framework offers a practical blueprint for specialized hepatitis clinics across the Asia-Pacific region, particularly in resource-limited or rural settings where telemedicine and blockchain-based waste tracking could further extend its impact.

1714 - Development and External Validation of Machine Learning Based Prognostic Model for Liver Transplant Patients with HCC

Yeongseok Hwang¹, Juhyun Shim¹, Giwon Song², Jihyun An³, Sang Hyun Choi⁴, Namkuk Kim⁵, Hann Lee⁵, Subin Heo⁴, Dongho Lee⁶, Youngrok Choi⁷, Kwang-woong Lee⁷

Asan Medical Center, Gastroenterology, Seoul-South Korea¹ Asan Medical Center, Surgery, Seoul-South Korea² Hanyang University College Of Medicine, Gastroenterology, Seoul-South Korea³ Asan Medical Center, Radiology, Seoul-South Korea⁴ Asan Medical Center, Fusion Science, Seoul-South Korea⁵ Seoul National University Hospital, Radiology, Seoul-South

E-POSTER ABSTRACTS

Korea ⁶ Seoul National University Hospital, Surgery,
Seoul-South Korea ⁷

Background / Hypothesis:

Liver transplantation (LT) is an effective treatment option for unresectable, early-stage hepatocellular carcinoma (HCC) patients. Several eligibility criteria has been proposed, but there is a controversy which criteria can be an optimal cutoff for transplantation because of heterogeneity in LT recipients. By considering pre-transplant clinical variables applying competing risk analysis, we developed personalized prognostic criteria to predict post-transplant survival outcomes, aiming to enhance individualized prognostication.

Materials and Methods:

The internal (n=1,059) and external cohorts (n=398) who underwent LT for HCC from two tertiary hospitals in Korea were used and competing risk regression analyses for HCC-specific survival were conducted to develop a new prognostic model using Fine-Gray model. To prevent overfitting, five penalty-based methodologies like machine learning based approach were systematically evaluated through backward elimination with stratified 5-fold cross-validation. Prognostic accuracy was compared with Wolbers' C-index and compared with conventional LT criteria.

Results:

The FG model achieved the highest external validation performance (Wolbers' C index: 0.786), while conventional scores demonstrated considerably lower discrimination: Milan criteria (0.604), Up-to-Seven (UTS) criteria (0.567), and Metroticket 2.0 (0.651). In the time-dependent Area under ROC curve (AUROC) and Integrated Brier score (IBS), the FG models demonstrated higher performance, with AUROC values of 0.802 (compared with 0.612 and 0.575 for the Milan criteria and UTS, respectively; P-values <0.001), and IBS values of 0.065 for the FG models (compared with 0.093 and 0.082 for the Milan criteria and UTS, respectively).

Conclusions:

The FG model based on pre-transplant clinical variables showed superior prognostic performance compared with conventional LT criteria. Clinical decision based on this model enables to select the more optimal LT candidates with HCC.

1716 - Hemoperitoneum as Initial Presentation of Hepatocellular Carcinoma in Chronic Hepatitis C A Case Report

Federico Peralta ¹, Rafael Emmanuel Mendoza ¹, Jasmin Gundayao ¹, Suzette Grace Kho-herman ¹
St. Luke's Medical Center - Global City, Institute Of Digestive And Liver Diseases, Taguig City-Philippines ¹

Background: Spontaneous rupture of hepatocellular carcinoma (HCC) resulting in hemoperitoneum is a rare but potentially fatal complication. It often presents as a surgical emergency, typically in patients with underlying cirrhosis, and poses diagnostic and therapeutic challenges due to its abrupt onset and nonspecific symptoms.

Case Presentation: A 63-year-old Filipino male with no known pre-existing liver disease presented to the emergency department with sudden, severe abdominal pain and shock. On initial assessment, he was tachycardic and hypotensive, requiring fluid resuscitation. An urgent axial contrast-enhanced CT scan of the abdomen revealed a large hepatic mass in segment 5 with associated hemoperitoneum, suggestive of a ruptured hepatic tumor. Due to high perioperative risk, the patient was managed non-surgically with transarterial embolization (TAE) of the feeding vessel and ultrasound-guided abdominal pigtail catheter drainage. Further workup revealed previously undiagnosed liver cirrhosis and chronic hepatitis C infection. Direct-acting antiviral therapy with sofosbuvir and velpatasvir was initiated and was given for 3 months. Metastatic workup was negative. Following clinical stabilization, the patient successfully underwent liver segmentectomy and recovered. Patient had documented sustained virologic response (SVR) 12 weeks after the end of treatment.

Conclusion: This case highlights the rare and dramatic presentation of ruptured HCC as spontaneous hemoperitoneum in an initially undiagnosed cirrhotic patient. Prompt recognition and multidisciplinary coordination are critical to improve survival. Given its rarity and high mortality, clinicians should maintain a high index of suspicion in cirrhotic or high-risk patients presenting with unexplained abdominal pain and hemodynamic instability.

1718 - Pediatric MASLD prevalence in the NHANES from 2017 to 2020 and the role of aging related factors

Mengfei Liu¹, Jiao Zhao¹

Southern University Of Science And Technology, School Of Medicine, Shenzhen-China¹

Background / Hypothesis: Evidence suggests that accelerated biological aging is linked to metabolic dysfunction in adults. However, the association with pediatric Metabolic Dysfunction-associated Steatotic Liver Disease (MASLD) remains unclear. This study investigated the relationship between two clinical biomarker-based measures of biological age and MASLD risk in adolescents.

Materials and Methods: We analyzed data from 1,206 adolescents (ages 12–18) in the 2017–2020 National Health and Nutrition Examination Survey (NHANES). Biological age was estimated using the Klemmera-Doubal Method (KDM) and Phenotypic Age (PhenoAge), both calculated from nine clinical biomarkers. MASLD was defined by a controlled attenuation parameter (CAP) > 248 dB/m. Multivariable logistic regression assessed the association between accelerated biological aging (biological age minus chronological age) and MASLD. Differential and stratified analyses were also performed.

Results: The prevalence of MASLD was 23.5% (n=283) among the 1,206 included adolescents. After multivariable adjustment, accelerated biological aging was significantly and positively associated with MASLD risk, whether measured by KDM (OR = 1.11, 95% CI 1.08–1.14) or PhenoAge (OR = 1.17, 95% CI 1.13–1.22). Nonparametric analysis confirmed that participants with metabolic disorders exhibited more pronounced biological age acceleration ($P < 0.001$). Stratified analyses showed these associations were particularly strong in female adolescents ($P < 0.001$) and those who were overweight or obese ($P < 0.001$).

Conclusions: Accelerated biological aging is significantly associated with pediatric MASLD in U.S. adolescents, especially in female and overweight/obese individuals. These findings suggest that aging-related biological mechanisms may be critical contributors to the development and severity of pediatric MASLD.

1719 - Real world Analysis of HBV pgRNA Dynamics and Its Correlation with Conventional Markers in CHB Management

Wei Wang¹, Huiying Rao¹

Peking University People's Hospital, Peking University Hepatology Institute, Beijing-China¹

Background:

Patients with chronic hepatitis B typically undergo long-term treatment with nucleoside analogs and interferon, yet a complete cure is rarely achieved. The occurrence and progression of CHB are primarily associated with HBV cccDNA. HBV pgRNA in peripheral blood originates from cccDNA in liver tissue and can reflect HBV transcriptional activity. This study analyzes the dynamic changes of HBV pgRNA over time and compares pgRNA with HBsAg, HBeAg and HBV DNA in serum of CHB patients in the real world, aiming to evaluate the clinical utility of HBV pgRNA in management of CHB.

Methods:

This was a retrospective study. Fifty-nine patients with CHB who received more than three serum HBV pgRNA tests in a general hospital in Beijing from April 1, 2024 to April 1, 2025 were included. There were 39 males (66.1%) and 20 females (33.9%), with an average age of 43.10 ± 11.97 and 44.5 ± 7.51 years, respectively. Among the cases, serum HBV pgRNA was measured three times in 36 patients (61.02%), four times in 18 patients (30.51%), five times in 4 patients (6.78%), and six times in only 1 patient (1.69%). During the same period, HBsAg, HBeAg, and HBV DNA levels were analyzed in these patients, followed by comparative analysis with HBV pgRNA.

Results:

During the one-year study period, a total of 206 serum HBV pgRNA tests were performed in 59 patients, in which 97 tests showed undetectable levels or values below the detection limit (classified as 'negative'), while 109 tests showed values exceeding 300 copies/mL (classified as 'positive'). In the HBV pgRNA-negative group, the positive rates of HBsAg, HBeAg and HBV DNA were 92.22%, 14.10% and 11.70%, respectively. Conversely, the HBV pgRNA-positive group demonstrated higher positive rates for these markers at 99.00%, 80.61% and 54.45%, respectively. The median HBV pgRNA levels were 4.35 log copies/mL in HBeAg-positive cases and 2.69 log copies/mL in

E-POSTER ABSTRACTS

HBeAg-negative cases. Serial measurements revealed median HBV pgRNA levels of 4.51, 3.61, 3.68, 3.38, 3.73 and 2.65 log copies/mL at each respective time point during the observation period. Longitudinal analysis showed that 10 of 59 cases (16.9%) transitioned from HBV pgRNA-positive to negative status during the study period.

Conclusions:

HBV pgRNA detection demonstrated a strong correlation with HBeAg positivity and HBV DNA detection rates, while exhibiting only weak association with HBsAg positivity. Notably, HBV pgRNA levels were significantly elevated in HBeAg-positive cases compared to HBeAg-negative patients. Longitudinal analysis revealed a consistent downward trend in HBV RNA levels over time.

Keyword(s) :

1720 - Integrated experimental and transcriptomic analyses reveal the therapeutic mechanisms of the herbal formula WenQingYin against intrahepatic cholangiocarcinoma

Yue Chen¹, Yibin Feng¹

The University Of Hongkong, School Of Chinese Medicine, Hongkong-China¹

Background / Hypothesis: Intrahepatic cholangiocarcinoma (ICC) represents a highly aggressive and deadly malignancy with rising global incidence and limited effective therapies. The classic formula Wen Qing Yin(WQY) from the Ming Dynasty's Wan Bing Hui Chun has demonstrated therapeutic effects against ICC in clinical practice at the School of Chinese Medicine in the University of Hong Kong. Therefore, this study aims to reveal the effect and mechanism of WQY in the treatment of ICC.

Materials and Methods: In vitro experiments, we utilized HuCCT1 cell lines to perform MTT assays, colony formation analyses, and flow cytometry for Ki67, evaluating the suppressive effects of WQY on proliferation. The inhibitory impacts of WQY on cell migration and invasion were assessed via transwell and wound healing assays. Additionally, bulk RNA sequencing was conducted to detect the mechanisms underlying WQY's intervention in ICC, with verification of key pathway genes performed using RT-PCR. The differently expressed genes (DEGs) between the control and the WQY groups were screened out to perform further enrichment analyses including the Gene Ontology (GO) and the Kyoto Encyclopedia of Genes

and Genomes (KEGG). In vivo experiments, HuCCT1 xenografts model were established to observe the therapeutic efficacy of WQY in treating ICC. All studies used a concentrated WQY decoction, prepared by machine and concentrated via rotary evaporation.

Results: The IC50 values of WQY against Hucct1 cells were determined by MTT assay (Figure A). Our results confirmed that WQY significantly inhibited HuCCT1 cell proliferation, evidenced by reduced colony formation after 24-hour WQY treatment and decreased Ki-67-positive cells via flow cytometry, indicating fewer actively proliferating cells (Figure B-C). WQY suppressed the invasion and migration of Hucct1 cell. Transwell assays revealed dose-dependent inhibition of HuCCT1 cell invasion after 24-hour treatment, while wound healing assays showed similar reductions in migratory capacity (Figure D-E). Animal studies indicated that WQY strongly inhibited tumor growth in xenograft models of ICC, with significant reductions in tumor volume and weight in treated mice compared to the control group (Figure F-G). The enrichment analyses of DEGs showed that WQY may mainly affect KEGG pathways of ferroptosis and DNA replication and GO pathway of cellular response to nuclear DNA replication and cell cycle (Figure H-L). RT-PCR results indicated that the ferroptosis suppressor genes GPX4 and SLC7A11 were downregulated in WQY-treated cells (Figure M).

Conclusions: In conclusion, WQY demonstrated therapeutic efficacy against ICC, and these effects may be mainly achieved by upregulating ferroptosis, downregulating DNA replication.

1721 - Longitudinal Changes in Fibrosis Marker Monitoring Fibrosis Progression in People with HIV and Metabolic Dysfunction Associated Steatotic Liver Disease A Longitudinal Cohort Study

Wei Xu¹, Li Liu¹, Jun Chen¹, Wei Song¹, Yang Tang¹, Tangkai Qi¹, Zhenyan Wang¹, Renfang Zhang¹, Yinzhong Shen¹

Shanghai Public Health Clinical Center, Department Of Infection And Immunity, Shanghai-China¹

Background / Hypothesis:

Dynamic fibrosis-4 index (FIB-4) monitoring tracks fibrosis and stiffness progression and predicts clinical

E-POSTER ABSTRACTS

outcomes in metabolic dysfunction-associated steatotic liver disease (MASLD). This study aims to evaluate dynamic changes in FIB-4 and metabolic parameters in PWH during antiretroviral therapy and to identify risk factors for liver fibrosis progression (LFP).

Materials and Methods:

The diagnosis of MASLD necessitates the exclusion of excessive alcohol consumption, as well as other identifiable etiologies of fatty liver disease, and requires the presence of at least one component of metabolic syndrome. Liver fibrosis progression is defined as an increase in FIB-4. FIB-4 was dichotomised into low (<1.3) and high (≥ 1.3). Increases were defined as $\geq 20\%$ rise and to ≥ 1.3 in the low FIB-4 group, and $\geq 20\%$ rise in the high FIB-4 group. Metabolic parameters assessed at the beginning and end of the follow-up period included body weight, blood glucose, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, triglycerides, and total cholesterol.

Results:

From March 25, 2024, to December 10, 2024, 2,003 PWH were screened. After excluding those with excessive alcohol use or other liver diseases, 683 with MASLD were enrolled. After a median follow-up period of one year, 28 (3.9%) participants were lost to follow-up, 59 (8.3%) exhibited fibrosis progression, and 596 (83.8%) remained stable. In a multivariable logistic regression, both baseline age (OR = 1.10; 95% CI: 1.06–1.14; $P < 0.001$) and weight change (OR = 1.29; 95% CI: 1.21–1.38; $P < 0.001$) were independently associated with LFP. Regarding the association of obesity status transition with LFP, transition to obesity was independently associated with LFP (OR=6.56; 95% CI: 2.95–14.56; $P < 0.001$).

Conclusions: Liver fibrosis progression occurs in a non-negligible proportion of PWH and MASLD, even within a relatively short period of time. Weight gain and transition to obesity are associated with increased risk of LFP in PWH with MASLD.

Sarker Mohammad Sajjad Sajjad¹, M Beryan Tareq¹

Birdem, Ghpd, Dhaka-Bangladesh¹

Background / Hypothesis: Nonalcoholic steatohepatitis (NASH) frequently coexists with type 2 diabetes mellitus (T2DM) and can progress to liver fibrosis, cirrhosis, and hepatocellular carcinoma. Sodium-glucose co-transporter-2 (SGLT2) inhibitors improve metabolic and cardiovascular outcomes in T2DM; however, their potential benefit on hepatic fibrosis remains insufficiently defined. This study hypothesized that empagliflozin may reduce hepatic fibrosis and improve biochemical parameters in T2DM patients with magnetic resonance elastography (MRE)-confirmed NASH.

Materials and Methods: A prospective, randomized, open-label study was conducted at BIRDEM General Hospital, Dhaka, from April to October 2022. Ninety adults with T2DM and MRE-confirmed NASH were randomized (1:1) to receive either empagliflozin 10 mg/day plus standard antidiabetic therapy (Group A) or standard therapy alone (Group B) for at least 3 months. Primary outcome was change in liver stiffness measured by MRE. Secondary outcomes included liver enzymes, lipid profile, BMI, glycemic parameters, and fibrosis stage. Data were collected via clinical assessment and laboratory records and analyzed using SPSS v24. Statistical significance was defined as $p < 0.05$.

Results: Baseline demographic and clinical characteristics were comparable between groups ($p > 0.05$). After 3 months, Group A showed significant reductions in weight ($76.91 \pm 6.4 \rightarrow 73.52 \pm 6.8$ kg, $p < 0.001$) and BMI ($22.52 \pm 4.6 \rightarrow 21.47 \pm 4.6$ kg/m², $p < 0.001$). Glycemic control improved significantly, with reductions in fasting blood glucose, postprandial glucose, and HbA1c ($7.65 \pm 1.5 \rightarrow 7.27 \pm 1.47\%$, $p = 0.012$). Liver enzymes (AST, ALT, GGT) and lipid parameters (TC, TG, LDL) declined significantly in the empagliflozin group, whereas the control group showed minimal or non-significant changes. Liver stiffness significantly decreased in Group A ($3.40 \pm 0.40 \rightarrow 3.28 \pm 0.46$ kPa, $p = 0.031$), accompanied by improvement in fibrosis staging, while no meaningful improvement occurred in Group B.

Conclusions: Empagliflozin significantly improved liver

E-POSTER ABSTRACTS

stiffness, fibrosis stage, metabolic parameters, liver enzymes, and lipid profile in T2DM patients with NASH over a 3-month period. These findings support the therapeutic potential of SGLT2 inhibition for mitigating hepatic fibrosis. Larger, biopsy-based trials with longer follow-up are warranted to validate these results.

Keyword(s) : Empagliflozin, nonalcoholic steatohepatitis, liver fibrosis, magnetic resonance elastography, type 2 diabetes mellitus, SGLT2 inhibitors

1724 - Some biochemical characteristics among viral hepatitis associated HIV positive people in Mongolia

Indra Altankhuyag¹, Narantuya Purevsuren¹, Ariunaa Rooson², Sarantsetseg Amarsanaa³, Urlee Munkhsaikhan³, Solongo Sanduijav³, Uyanga Chagnaadorj³, Unenchimeg Puntsag³, Nyamtsengel Vangan³, Oyunbeleg Bayandorj³

National Center For Communicable Disease Mongolia, Aids/hiv/sti's Surveillance And Research Department, Ulaanbaatar-Mongolia¹ Global Fund Mongolia, , Ulaanbaatar-Mongolia² National Center For Communicable Disease Mongolia, , Ulaanbaatar-Mongolia³

Background / Hypothesis:

Viral hepatitis is one of the health concerns in Mongolia, the reported prevalence of hepatitis B surface antigen (HBsAg) was 9-10%, anti-hepatitis C virus ranged 11-25% and the prevalence of hepatitis D virus RNA was about 67.5% among HBsAg-positive people. 420 cases of HIV infection have been registered in Mongolia since 1992. Mongolia is a country with a low (less than 0.1%) prevalence of HIV infection in the population; however, the prevalence among men who have sex with men is 8.8%.

Materials and Methods:

A cross-sectional analytical study was conducted using data from 1992 to 2024. Data was collected from the AIDS, STIs Surveillance Department, and analyzed in the SPSS program as a descriptive prevalence survey. The Biochemical tests were performed on Biosystems BA200 used. We used all biochemical parameters that were analyzed at the time and first and fifth years after HIV diagnosis. The improvement or deterioration in the biochemical profiles, as well as the significance of the same, was analyzed using the chi-square test. The mean, standard deviation and distribution of the variables between the groups (HIV plus HBV; HIV plus HCV) were studied using a t-test and a p-value <0.05 was considered significant.

Results:

420 people are registered with HIV and AIDS in Mongolia, 21.0% (88/420) of them have a hepatitis virus infection. Among these individuals living with HIV 41.5% were HBsAg positive (HBV), 51.2% were anti-HCV positive, 7.3% had HBV and HCV co-infection. ART coverage rates exceeding among HIV+HBV, HIV+HCV and HIV+HBV+HCV were 94.1%, 90.5% and 100%. The mean ALT and AST levels of the study participants at diagnosis were 64.1 ± 110.3 and 66.7 ± 103.4 , and 44.3 ± 38.9 and 59.5 ± 60.6 in the first year after HIV diagnosis, 55.1 ± 58.4 and 59.2 ± 50.1 in the fifth year after HIV diagnosis. Both AST and ALT did not show an upward trend over follow-up and were not statistically significant. The mean ALT was high in HCV/HIV infection in comparison to HBV/HIV and it was also significant ($p < 0.05$). The mean ALT and AST levels were statistically significant ($p < 0.05$) depending on whether the antiretroviral therapy coverage. Conclusions: Approximately 21.0% of individuals living with HIV were co-infected with one or more hepatitis viruses. Although substantial differences in biochemical parameters were observed at the time of initial diagnosis, these differences diminished during follow-up. The extent of improvement varied depending on the type of hepatitis virus involved and on whether the patient was receiving antiretroviral therapy.

Keyword(s) : Mongolia, HIV, HBV, HCV, co-infection

1728 - T Lymphocyte Subsets Participate in the Pathogenesis of Primary Biliary Cholangitis

Wen Gao¹, Bin Xu¹, Zhan Guo Li²

Beijing Youan Hospital Affiliated To Capital Medical University, Department II Of Liver Diseases, Beijing-China¹ Peking University People's Hospital, Department Of Rheumatology And Immunology, Beijing-China²

Primary biliary cholangitis (PBC) is a chronic autoimmune liver disease characterized by non-suppurative destruction of small intrahepatic bile ducts, with immune dysregulation as a core pathogenic driver. This review synthesizes recent advances in understanding the roles of diverse T lymphocyte subsets in PBC initiation and progression. CD4⁺ T cell subsets, including Th1, Th17, Th2, T follicular helper (Tfh), and peripheral helper T (Tph) cells, orchestrate autoimmune activation and promote chronic inflammation, fibrosis, and humoral immunity by secreting pro-inflammatory cytokines (e.g., IFN- γ , IL-17, IL-21) and activating B cells. CD8⁺ tissue-resident memory T (Trm) cells, particularly CD69⁺CD103⁺

E-POSTER ABSTRACTS

subsets, directly mediate biliary epithelial cell (BEC) damage through cytotoxic molecules like perforin and granzyme B. Follicular regulatory T (Tfr) cells, which suppress excessive B and Tfh cell activity, show impaired function, with a reduced Tfr/Tfh ratio correlating with disease severity. Innate-like T cells, such as mucosal-associated invariant T (MAIT) cells and natural killer T (NKT) cells, accumulate in the liver to amplify inflammation and fibrosis via cytokine secretion and cytotoxicity. $\gamma\delta$ T cells bridge innate and adaptive immunity, while innate lymphoid cells (ILCs) modulate Th cell responses through subset-specific cytokine profiles. Regulatory T cells (Tregs), critical for immune tolerance, exhibit reduced numbers and dysfunction in PBC, and progenitor exhausted T (Tpex) cells sustain chronic immune activation under persistent antigen stimulation. These T cell subset abnormalities—including Treg/Th17 imbalance, pathogenic Trm accumulation, and dysregulated humoral immunity—collectively drive PBC progression. Understanding their sequential and interactive pathogenic mechanisms provides a foundation for targeted immunotherapies, such as Treg modulation, JAK pathway inhibition, and CAR-T therapy, offering new avenues to improve clinical outcomes for PBC patients.

1730 - Histone deacetylase inhibitor givinostat attenuates metabolic dysfunction associated steatotic hepatitis and liver fibrosis

Heming Huang¹

Tongji Hospital, Department Of Endocrinology And Metabolism, Shanghai-China¹

Background / Hypothesis:

Metabolic Dysfunction-Associated Steatotic Hepatitis (MASH) is a prevalent chronic liver disease with increasing global incidence. Hepatic inflammation is a key driver of disease progression from metabolic dysfunction-associated steatotic liver (MASL) to MASH; however, effective therapeutic options remain limited. This study investigated the therapeutic potential of givinostat, a histone deacetylase (HDAC) inhibitor, for the treatment of MASH.

Materials and Methods:

MASH was induced in mice using either a methionine- and choline-deficient (MCD) diet or a fructose, palmitate, and cholesterol (FPC) diet. The mice were treated with givinostat (10 mg·kg⁻¹·d⁻¹, intraperitoneally) for 8 or 10 weeks. After the treatment period, liver tissues were collected for analysis. In vitro

studies were conducted using human hepatocellular carcinoma cell line HepG2 and human fetal hepatocyte cell line L02 to assess the effect of givinostat on palmitic acid-induced lipid accumulation.

Results:

Givinostat administration significantly alleviated hepatic inflammation and attenuated fibrosis in MCD diet-induced MASH mice. RNA sequencing of liver tissues from these mice showed that givinostat potently suppressed the expression of inflammation-related genes and modulated a wide array of lipid metabolism-related genes. In both HepG2 and L02 cells, givinostat markedly reduced intracellular lipid accumulation induced by palmitic acid. The therapeutic benefits of givinostat were further confirmed in the FPC diet-induced MASH model, where it significantly ameliorated hepatic steatosis, inflammation, and liver injury.

Conclusions: Givinostat demonstrates efficacy in reversing diet-induced MASH in mouse models by improving steatosis, inflammation, and fibrosis. These findings suggest that givinostat may represent a promising therapeutic agent for the treatment of human MASH.

Keyword(s) : Metabolic Dysfunction-Associated Steatotic Hepatitis; inflammation; histone deacetylase inhibitor; givinostat; epigenetics

1733 - The ATP7B c.1543+40G>A Splice Site Variant was Confirmed as Pathogenic through Familial Segregation Analysis in the Genetic Diagnosis of Wilson Disease

Xiangsha Kong¹, Shaotian Qiu¹, Khulan Suvd-erdene², Huiying Rao¹, Bo Feng¹, Guangjun Song¹, Xiaohe Li¹, Nan Wu¹

Peking University People's Hospital, Peking University Hepatology Institute, Beijing-China¹ Peking University People's Hospital, Clinical Medicine, -China²

Background / Hypothesis:

A significant challenge in the genetic diagnosis of Wilson's disease (WD) is the interpretation of variants of uncertain significance (VUS).

The ATP7B c.1543+40G>A variant represents one such VUS with conflicting database classifications, impeding definitive diagnosis. This study aimed to determine the pathogenicity of the ATP7B c.1543+40G>A variant through comprehensive familial segregation analysis and in silico predictive modeling, and to assess its role in resolving diagnostic uncertainty.

Materials and Methods:

Genomic DNA was sequenced using next-generation

E-POSTER ABSTRACTS

sequencing (NGS) for the full-length ATP7B gene, with a tailored analytical pipeline enabling comprehensive variant screening and filtering. Identified variants were subsequently validated and assessed for zygosity via Sanger sequencing using specific primers and standard PCR amplification. Familial co-segregation analysis was conducted using Sanger sequencing of the proband's mother and sister. The potential impact of the identified variants on splicing was evaluated computationally using SpliceAI and MaxEntScan.

Results:

This study present a 30-year-old male proband with a clinical and biochemical profile consistent with WD, confirmed by a Leipzig score of ≥ 4 . Genetic analysis identified compound heterozygosity for two ATP7B variants: the known likely pathogenic c.2447+5G>T and the VUS c.1543+40G>A. Segregation analysis revealed that the proband's mother was a heterozygous carrier for c.1543+40G>A alone, while his asymptomatic sister also carried both variants in compound heterozygote. This confirmed the in trans inheritance of the VUS with a known pathogenic allele, fulfilling the ACMG/AMP criterion for segregation. In silico analysis confirmed the significant splice-disrupting effect of c.2447+5G>T, while predictions for c.1543+40G>A were benign. The co-segregation evidence enabled the reclassification of c.1543+40G>A from VUS to "Likely Pathogenic."

Conclusions:

This study provides definitive evidence for the pathogenicity of the ATP7B c.1543+40G>A variant through familial segregation analysis, underscoring the critical role of family-based genetic studies in resolving VUS and achieving a precise molecular diagnosis for Wilson's disease. The discordant phenotype between the heterozygous siblings further highlights the incomplete penetrance often associated with this disorder.

1734 - Diminished protection of Vitamin E in pediatric MASLD with lipid disorder findings from a national wide survey

Zitian Ren ¹, Jian Zhao ¹

Southern University Of Science And Technology,
School Of Public Health And Emergency Management,
School Of Medicine, Shenzhen-China ¹

Background / Hypothesis: The growing global prevalence of pediatric metabolic dysfunction-associated fatty liver disease (MASLD) is a significant concern, contributing to progressive liver fibrosis and

long-term hepatic morbidity. While Vitamin E is the most promising therapeutic candidate, its efficacy in randomized controlled trials remains inconsistent. Evidence from adult studies suggests that hyperlipidemia may diminish the protective effect of Vitamin E against MASLD. We investigated if this diminished protective association is present in adolescents with co-occurring lipid disorders by using cholesterol-adjusted serum α -tocopherol concentrations as a proxy for genuine biological protection.

Materials and Methods: We analyzed cross-sectional data from the 2017-2018 National Health and Nutrition Examination Survey (NHANES), including 305 adolescents aged 12 to 19 years. Pediatric MASLD was defined by expert consensus, requiring steatosis assessed by controlled attenuation parameter (CAP) > 236 dB/m plus at least one metabolic risk factor. Serum α -tocopherol was adjusted for total cholesterol using the residual method to correct for confounding by lipid levels. Lipid status was categorized as normal, borderline, or dyslipidemia based on established pediatric cutoffs. We used weighted logistic regression to examine the association between cholesterol-adjusted serum α -tocopherol and MASLD, stratified by lipid status.

Results: MASLD was identified in 98 participants (32.0%). Among adolescents with normal lipid status, higher cholesterol-adjusted serum α -tocopherol concentrations were inversely associated with MASLD across all models: fully adjusted odds ratio (OR) was 0.37 (95% confidence interval (CI), 0.17-0.84; $p=0.026$). Crucially, this significant protective association was abolished in adolescents with borderline and dyslipidemia lipid status, where no statistically significant association was observed. Sensitivity analysis confirmed these findings.

Conclusions: Our results suggest that the protective association between Vitamin E and MASLD is attenuated in the presence of lipid disorders in adolescents. This indicates a limited protective role of Vitamin E in pediatric MASLD when co-existing lipid dysfunction is present, underscoring the necessity for further research into the underlying mechanism.

Keyword(s) : MASLD, NHANES, Vitamin E, α -tocopherol, lipid disorder

1736 - An Increase in Regulatory B Cells and a Reduction in T Helper 17 Cells Play a Crucial Role in

E-POSTER ABSTRACTS

Achieving Tolerance in Liver Transplantation

Soon Kyu Lee ¹, Sung Won Lee ¹, Young Kyoung You ², Jong Young Choi ³

College Of Medicine, The Catholic University Of Korea, Division Of Hepatology, Department Of Internal Medicine, Seoul-South Korea ¹ College Of Medicine, The Catholic University Of Korea, Department Of Surgery, Seoul-South Korea ² College Of Medicine, Chung-ang University, Division Of Hepatology, Department Of Internal Medicine, Seoul-South Korea ³

Background / Hypothesis:

This study investigates the dynamics of regulatory B cells (Bregs) during immunosuppression (IS) tapering and their contribution to tolerance in liver transplantation (LT) patients.

Materials and Methods:

We prospectively enrolled 15 LT patients who had normal liver function, no history of rejection, and had undergone LT more than five years ago. Patients were followed up every three months, and IS doses were tapered by 25% every 6–9 months. At each visit, blood samples were collected, and the proportions of T cells and B cells were analyzed by flow cytometry. Confocal microscopy and in vitro analysis were also performed to assess Breg function in LT patients.

Results:

Over a median follow-up of 42 months, eight patients successfully discontinued IS without rejection (tolerance group). One patient experienced rejection (rejection group), while the remaining six patients reduced their IS dose to 25% without rejection (minimization group). During IS tapering, Treg cells and the Treg/Th17 ratio increased in the tolerance group but decreased before rejection in the rejection group (Figure A). Similarly, the tolerance group exhibited an increase in Bregs and the Breg/Th17 ratio, whereas a decrease was observed in the rejection group (Figure A, B). Moreover, a negative correlation between Bregs and Th17 cells and a significant positive association between Bregs and plasmablast B cells were identified. In liver tissue, confocal analysis showed a significant increase in Tregs and Bregs in the tolerance group compared to the rejection group (Figure C). In vitro analysis demonstrated a reduction in Th17 cells following Breg treatment, and vice versa (Figure D). Furthermore, treatment with Faecalibacterium, enriched in the tolerance group, led to an increase in

Bregs and IL-10 levels.

Conclusions:

During IS tapering, Bregs increase and contribute to the achievement of tolerance in LT patients. These findings suggest that Bregs may serve as potential biomarkers and therapeutic targets for promoting tolerance in LT.

1737 - Prognostic Impact of Cirrhosis in Patients with Hepatocellular Carcinoma and Concurrent MASLD Undergoing Surgical Resection

Shin-yu Tsai ¹, Chun-ting Ho ¹, Chia-jung Ho ¹, Yi-hsiang Huang ², Ming-chih Hou ³, Jaw-ching Wu ³, Chien-wei Su ¹

Taipei Veterans General Hospital, Division Of General Medicine, Taipei-Taiwan ¹ Taipei Veterans General Hospital, Department Of Medical Research, Taipei-Taiwan ² Taipei Veterans General Hospital, Institute Of Clinical Medicine, Taipei-Taiwan ³

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) has emerged as one of the major subtypes of liver disease and a growing etiology of hepatocellular carcinoma (HCC), especially in patients without viral hepatitis. Meanwhile, although cirrhosis is traditionally regarded as an important milestone in liver disease progression, the effect of cirrhosis on the outcome of HCC patients has been variable, particularly for those with concurrent MASLD. This study therefore aimed to determine whether cirrhosis influences baseline characteristics, overall survival (OS), or recurrence-free survival (RFS) in HCC patients with concurrent MASLD undergoing surgical resection.

Materials and Methods:

We retrospectively analyzed 460 treatment-naïve HCC patients with concurrent MASLD who received curative hepatic resection at a tertiary medical center between 2015 and 2023. Cirrhosis was determined by an Ishak fibrosis grade greater than 5 in the surgical specimen. Baseline characteristics were compared between the cirrhosis and non-cirrhosis groups. Univariate and multivariate Cox proportional hazards models were applied to identify independent risk factors for poor OS and RFS. OS and RFS were analyzed and compared using Kaplan–Meier survival analysis.

E-POSTER ABSTRACTS

Results:

After a median follow-up of 51.8 months (IQR, 13.3–72.0 months), 104 patients died, corresponding to a 5-year OS rate of 76.5%. Baseline demographics showed significant differences in tumor staging, tumor size, inflammatory activity, HCV positivity, and serum biochemistry, including platelet count, international normalized ratio (INR), albumin, aspartate transaminase (AST), and creatinine levels, between the cirrhosis and non-cirrhosis groups. The 5-year OS was comparable between the two groups, with 77.1% in patients with cirrhosis and 76.2% in those without cirrhosis ($p = 0.42$). Five-year RFS was likewise comparable between groups (50.6% vs. 53.2%, $p = 0.27$). Multivariate Cox proportional hazards models did not identify cirrhosis as an independent risk factor for poor OS or RFS.

Conclusions:

Despite differences in tumor characteristics, serum biochemistry, and inflammatory activity, cirrhosis did not significantly influence postoperative OS or RFS in HCC patients with concurrent MASLD undergoing surgical resection.

Keyword(s) : MASLD, Hepatocellular carcinoma, Cirrhosis

1741 - Alcohol Use–Related Outcomes Following Fecal Microbiota Transplantation in Steroid Ineligible Severe Alcohol Associated Hepatitis A Secondary Analysis of a Randomized Controlled Trial

Mohit Varshney¹, Rahul Khajuria², Shashtry Sm³, Sukriti Baweja⁴, Vinod Arora³, Chhagan Bihari⁵, Shiv Sarin³

Institute Of Liver And Biliary Sciences, Psychiatry And Addiction Medicine, New Delhi-India¹ Narayana Health, Hepatology, New Delhi-India² Institute Of Liver And Biliary Sciences, Hepatology, New Delhi-India³ Institute Of Liver And Biliary Sciences, Molecular And Cellular Medicine, New Delhi-India⁴ Institute Of Liver And Biliary Sciences, Pathology, New Delhi-India⁵

Background: Steroid-ineligible patients with severe alcohol-associated hepatitis (SAH) have high mortality with no established effective alternatives to corticosteroid therapy. Gut dysbiosis plays a significant pathogenic role in SAH. Fecal microbiota transplantation (FMT) by restoring microbial balance and gut permeability, has been shown to improve short-term survival, and reduce craving behavior in AUD-cirrhosis. However, the effect of FMT on alcohol

use behavior in SAH patients remains underexplored.

Methods: This is a secondary analysis from single-center, randomized controlled trial (2021–2023, ILBS, New Delhi; NCT05285592), 46 steroid-ineligible SAH patients (mDF > 120, sepsis, serum creatinine > 2mg/dl, or > 3 organ failure) between 18–70 years, were randomized in a 2:1 ratio, to receive FMT ($n=31$) or standard medical therapy (SMT, $n=15$). FMT was administered via nasoduodenal/jejunal tube once daily for 7 days using 100 mL fresh donor stool suspension using Institutional Protocol. Primary endpoint was 28-day survival, and secondary endpoints were changes in alcohol craving questionnaire-short form (ACQ-SF) index, relapse rates, MELD and mDF at 90 and 180 days. Microbiome profiling using 16S rRNA sequencing was also performed. In this study we present only the secondary end-points related to AUD. During the follow-up all patients received mandatory sessions of Brief Intervention Counseling from the Addiction medicine team.

Results: Among 46 randomized patients, baseline characteristics (mean age ~40 years, 97% male, mean MELD scores 31.7 vs 29.1; $p=0.8$, mDF 85.1 vs 84.1; $p=0.1$) were comparable between two groups. All patients tolerated 7 FMT doses. At 90 days, FMT recipients had significantly lower alcohol craving (ACQ-SF reduced from 3.5 ± 0.69 to 2.8 ± 0.80) compared to SMT (3.3 ± 0.80 to 3.4 ± 0.59 , $p=0.01$). Alcohol relapse was also significantly lower in the FMT group (19.2% vs. 53.8%, $p<0.05$). Lapse rates (any) at 180 days were lower with FMT (3.2% vs 13.3%), corresponding to a 76% relative risk reduction ($RR = 0.24$), although this did not reach statistical significance ($p = 0.24$) due to low event counts. Among these survivors, lapse (any) occurred in only 1/13 (7.7%) in the FMT arm compared with 2/4 (50%) in the SMT arm. Delta MELD at day 180 was significantly better in the FMT than the SMT group (-5.9 vs -0.7 , $p=0.016$). Longitudinal 16S Metagenome Analysis showed a decline in *Veillonella parvula*, *Lactobacillus agilis*, and *Akkermansia muciniphila*, indicating an early shift (Day 7 vs Day 0); which were further established on Day 30 analysis.

Conclusion: FMT could provide dual benefit in targeting hepatic and behavioral dimensions of alcohol-related liver disease

Keyword(s) : Alcoholic hepatitis, FMT, alcohol craving, steroid ineligible, gut-liver-brain axis, dysbiosis.

1742 - Pretreatment neutrophil to Lymphocyte Ratio as a Predictive Marker for Tumor Response to Atezolizumab plus Bevacizumab in Hepatocellular Carcinoma A Multicenter Retrospective Study

E-POSTER ABSTRACTS

Young Mi Hong¹, Jun Sik Yoon², Yu Rim Lee³, Jae Hyun Yoon⁴, Hyun Young Woo⁵, Sang Youn Hwang⁶, Yeo Wool Kang⁷, Joonho Jeong⁸, Sung-bum Cho⁹, Jung Eun Song¹⁰

Pusan National University School Of Medicine, Internal Medicine, Yangsan-South Korea¹ Inje University College Of Medicine, Internal Medicine, Busan-South Korea² Kyungpook National University School Of Medicine, Internal Medicine, Daegu-South Korea³ Chonnam National University School Of Medicine, Internal Medicine, Gwangju-South Korea⁴ Pusan National University And Biomedical Research Institute, Pusan National University Hospital, Internal Medicine, Busan-South Korea⁵ Dongnam Institute Of Radiologic & Medical Sciences, Internal Medicine, Busan-South Korea⁶ Dong-a University College Of Medicine, Internal Medicine, Busan-South Korea⁷ University Of Ulsan College Of Medicine, Internal Medicine, Ulsan-South Korea⁸ Chonnam National University Medical School, Internal Medicine, Gwangju-South Korea⁹ Catholic University Of Daegu School Of Medicine, Internal Medicine, Daegu-South Korea¹⁰

Background / Hypothesis:

Atezolizumab combined with bevacizumab has been used in the treatment of advanced hepatocellular carcinoma (HCC). However, reliable predictive biomarkers for evaluating tumor response to this therapy remain limited. This study aimed to identify predictive factors in patient with HCC undergoing treatment with atezolizumab and bevacizumab.

Materials and Methods:

This multicenter retrospective study included 943 patients with HCC who received atezolizumab plus bevacizumab. Factors associated with tumor response were analyzed.

Results:

According to the Response Evaluation Criteria in Solid Tumors, the rates of complete remission, partial response, stable disease, and progressive disease were 2.9 %, 22.9 %, 48.8 % and 25.5 %, respectively. The objective response rate (ORR) and disease control rate (DCR) were 25.8 % and 74.6 %, respectively.

Progression free survival and overall survival were significantly associated with best tumor response ($P < 0.001$). Multivariate analysis identified BCLC stage (HR = 0.478, 95% CI = 0.278 – 0.821, $P = 0.007$) and neutrophil-to-lymphocyte ratio (NLR) (HR = 0.670, 95% CI = 0.488 – 0.920, $P = 0.013$) as independent predictive factors for objective tumor response. The

ORR and DCR were 31.2 % and 77.2 %, respectively, in the NLR <2 group, and 23.7 % and 73.5 %, respectively, in the NLR ≥ 2 group ($P < 0.001$).

Conclusions:

Pretreatment NLR was correlated with the tumor response, which was subsequently associated with survival outcomes. NLR may serve as a predictor of a lack of response to atezolizumab plus bevacizumab treatment. Therefore, NLR represents a readily measurable biomarker with the potential to support the timely identification of HCC patients who are more likely to benefit from atezolizumab and bevacizumab treatment.

1743 - Area deprivation and hepatitis C infection in Korea A multilevel analysis 2005 2020

Hwa Young Choi¹, Dahye Paik¹, Moran Ki¹

National Cancer Center, Public Health & Ai, Goyang-si Gyeonggi-do-South Korea¹

Background / Hypothesis:

Although the prevalence of hepatitis C virus (HCV) in Korea is decreasing, regional disparities remain. This study aimed to examine the impact and temporal changes in individual characteristics and regional health inequalities on HCV infection, to provide a framework for HCV elimination and management.

Materials and Methods:

This nationwide population-based multilevel case-control study was conducted using National Health Insurance Service (NHIS) and population census data from 2005, 2010, 2015, and 2020. The Area Deprivation Index (ADI) was calculated for each area (region/town) using population census data. Sex- and age-standardized HCV prevalences were estimated for each area using NHIS data. The association between area-level HCV and ADI was examined using correlation and linear regression analyses. Individual- and area-level HCV infection risks were estimated using logistic regression and multilevel logistic regression models incorporating sex, age, HCV prevalence, and ADI.

Results:

The HCV prevalence (per 100,000) decreased from 151 to 117 (2005–2020). The maximum inter-area ADI gap

E-POSTER ABSTRACTS

decreased modestly (34.64 to 32.50). ADI correlated with area HCV prevalence in all years, with stronger associations in high-prevalence areas ($\geq 200/100,000$). In logistic regression, residents of the most deprived areas had elevated risks versus the least deprived (2020 adjusted odds ratio 1.37). Multilevel models showed age (individual level) and area HCV prevalence (area level) were dominant determinants. Deprivation increased risk in ADI-only models, but not significance after adjusting for area HCV prevalence and individual factors.

Conclusions:

Effective HCV elimination requires tailored screening and treatment strategies that prioritize socioeconomically vulnerable areas among the high-prevalence areas.

1744 - Proteomics Biomarker for Predicting Responders to Atezolizumab and Bevacizumab Therapy in Hepatocellular Carcinoma

Ji Hoon Kim¹, Eunho Choi¹, Young-sun Lee¹, In Hee Kim², Jin Woo Lee³, Jung Hwan Yu³, Sung Bum Cho⁴, Yang Jae Yoo¹, Young Kul Jung¹, Hyung Joon Yim¹, Jong Eun Yeon¹

Korea University College Of Medicine, Internal Medicine, Seoul-South Korea¹ Jeonbuk National University Hospital, Internal Medicine, Jeonju-South Korea² Inha University School Of Medicine, Internal Medicine, Incheon-South Korea³ Chonnam National University Hwasun Hospital, Internal Medicine, Hwasun-South Korea⁴

Background / Hypothesis:

Atezolizumab with bevacizumab are now standard first-line treatments for advanced hepatocellular carcinoma (HCC). Despite their clinical success, predicting treatment response remains difficult due to the lack of validated biomarkers. This study aimed to explore circulating serum proteins as potential predictive biomarkers of immunotherapy efficacy in advanced HCC.

Materials and Methods:

HCC patients on atezolizumab and bevacizumab were classified as responders if they achieved stable disease, partial response, or complete response, and as non-responders if their disease progressed after three

therapy cycles. Differences in pre-treatment serum protein expression between these groups were evaluated using mass spectrometry-based proteomics.

Results:

Of 44 patients, non-responders (n = 12) showed elevated C-reactive protein and S100A9, while responders (n = 32) exhibited higher levels of proteins such as transferrin, transthyretin, APOC3, and clusterin. Network analysis identified APOC3 and CLU as central to protein interaction networks associated with treatment outcomes.

Conclusions:

These findings highlight circulating serum proteins as promising predictive biomarkers for immunotherapy response in advanced HCC, offering a potential tool for more personalized treatment selection.

Keyword(s) : HCC, immunotherapy, proteomics

1745 - Flare to Failure Hemoadsorption Therapy for Acute on Chronic Liver Failure in Chronic Hepatitis B Infection Unmasked During Antikoch's Therapy

Nathaniel Camangon¹, Adrian Bugayong¹, Ruth Ursula Cinco¹

Veterans Memorial Medical Center, Internal Medicine - Section Of Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Chronic Hepatitis B (CHB) is widespread in the Philippines and poses a risk of liver failure in the absence of therapy. This case illustrates CHB flare that occurred during pulmonary tuberculosis (PTB) treatment, which progressed to acute-on-chronic liver failure (ACLF). It highlights hemoadsorption as a potential bridging therapy where liver transplantation is not readily accessible.

Materials and Methods:

A 39-year-old woman with bacteriologically-confirmed PTB presented with jaundice, anorexia, and epigastric pain. Physical examination revealed jaundice but no stigmata of liver cirrhosis. Laboratory tests showed elevated transaminases, coagulopathy, hypoalbuminemia, hyperbilirubinemia, chronic hepatitis B infection, and newly-diagnosed diabetes. Abdominal ultrasound revealed hepatic steatosis. Anti-TB therapy was discontinued. Antiviral and hepatoprotective agents were started. Supportive care included dietary and electrolyte correction,

E-POSTER ABSTRACTS

management of hepatic encephalopathy, antibiotics, insulin therapy, and ICU admission.

Results:

Double plasma molecular adsorption system (DPMAS) was initiated as bridging therapy, resulting in clinical and biochemical improvements, including a reduction in hepatic encephalopathy from grade 3 to 1 and decrease in bilirubin. However, due to financial limitations, treatment intervals were suboptimal, reducing therapeutic effectiveness. The patient's condition deteriorated due to hospital-acquired infection which led to her demise.

Conclusions:

This case underscores the need for standardized protocols that include early etiological assessment, risk stratification, and the use of hemoadsorption guided by bilirubin levels and SOFA score trends. Simultaneously, government policy reforms are needed to minimize system-related barriers in liver transplantation and to improve access to advanced liver support therapies.

1746 - Decision Tree model using Exosomes to Predict Favorable Outcome of Atezolizumab and Bevacizumab Combination Therapy in Hepatocellular Carcinoma

Ji Hoon Kim ¹, Eunho Choi ¹, Young-sun Lee ¹, Jeong-an Gim ², Wonhyo Seo ³, Yang Jae Yoo ¹, Seong Hee Kang ¹, Tae Hyung Kim ¹, Sun Young Yim ¹, Young Kul Jung ¹, Yeon Seok Seo ¹, Hyung Joon Yim ¹, Jong Eun Yeon ¹
Korea University College Of Medicine, Internal Medicine, Seoul-South Korea ¹ Soonchunhyang University, Medical Science, Cheonan-South Korea ² Ewha Womans University, Pharmacy, Seoul-South Korea ³

Background / Hypothesis:

Atezolizumab combined with bevacizumab represents the current first-line treatment for advanced hepatocellular carcinoma (HCC). However, no biomarker has yet been firmly established to accurately predict patient responses to this regimen. Previous work from our research group suggested that miR-30a-5p could serve as a potential predictive biomarker. This study aimed to validate the clinical significance of this exosomal microRNA in a larger patient cohort.

Materials and Methods:

Patients with advanced HCC undergoing atezolizumab plus bevacizumab therapy were enrolled. After three treatment cycles, patients were classified as responders if they achieved stable disease, partial response, or complete response, and as non-responders if their disease progressed. Serum extracellular vesicles were isolated from blood samples collected prior to the therapy. Exosomal RNAs were extracted, which were profiled using next-generation small RNA sequencing. Decision tree analysis was employed to identify microRNAs capable of distinguishing responders from non-responders.

Results:

Samples from 13 responders and 11 non-responders were analyzed. Sequencing identified 1,076 microRNAs, among which let-7c-5p, miR-30a-5p, and miR-192-5p were significantly upregulated in responders. Consistent with previous findings, miR-30a-5p levels were markedly higher in responders, showing a significant difference ($p = 0.0039$). Decision tree analysis indicated that a miR-30a-5p expression level of 9.67 or greater effectively distinguished responders from non-responders. Similarly, random forest modeling identified miR-30a-5p as the most influential variable in predicting treatment response.

Conclusions:

miR-30a-5p demonstrates potential as a reliable exosomal biomarker for identifying patients with advanced HCC who are most likely to benefit from atezolizumab and bevacizumab therapy.

1748 - Analysis on the differences of clinicopathological characteristics in drug induced liver injury patients with positive or negative autoantibodies and different clinical types

Suwen Jiang ¹, Airong Hu ¹, Menghan Jin ², Haojin Zhang ³, Shiqi Yang ⁴, Shiyang Fan ³
Liver Diseases Center, Ningbo Institute Of Liver Diseases, Ningbo No. 2 Hospital, Hepatology Department, Ningbo-China ¹ Ningbo University Health Science Center, Hepatology Department, Ningbo-China ² School Of Medicine, Shaoxing University, Hepatology Department, Shaoxing-China ³ Graduate School Of Wenzhou Medical University, Hepatology Department, Wenzhou-China ⁴

E-POSTER ABSTRACTS

Background: To investigate the differences in clinical and pathological characteristics among patients with drug-induced liver injury (DILI) by autoantibody status and R value-based clinical types to inform clinical practice.

Methods: This study included 138 patients hospitalized from January 2016 to July 2023 with biopsy-confirmed DILI. Patients were grouped by autoantibody results (positive/negative), liver histopathological changes ($< G2$ and $\geq G2$, $< G3$ and $\geq G3$, $< G4$ and $\geq G4$, $< S2$ and $\geq S2$, $< S3$ and $\geq S3$, $< S4$ and $\geq S4$, mild pathological injury [$< G2$ + $< S2$] and significant pathological injury [$\geq G2$ and/or $\geq S2$]) and R values for DILI classification ($R \geq 5$: hepatocellular injury type; $2 < R < 5$: mixed type; $R \leq 2$: cholestatic type), with clinicopathological characteristics compared.

Results: Of the enrolled patients, 79 were autoantibody-negative and 59 were autoantibody-positive, including 59 cases (100.00%) positive for anti-nuclear antibody and 8 cases (13.56%) positive for anti-mitochondrial antibody. Traditional Chinese Medicine (including single herbs, herbal dietary supplements, or compound preparations) accounted for the highest proportion of medications causing DILI (55/138, 39.86%). Significantly higher serum globulin (GLB) ($t = 2.983$), alkaline phosphatase ($Z = 2.042$), and adenosine deaminase (ADA) ($Z = 2.582$), and a lower albumin (ALB)/GLB ratio ($t = 2.211$), were found in the autoantibody-positive versus negative group (all $P < 0.05$). The autoantibody-positive group had a higher mean Ridit value for liver inflammation activity grade (G) ($u = 2.302$, $P = 0.021$) and a higher proportion of $\geq G3$ and $G4$ ($\chi^2 = 4.471$, 6.478 ; $P = 0.034$, 0.011). The $R \geq 5$, $2 < R < 5$, and $R \leq 2$ groups differed significantly in serum total bilirubin (TBiL) ($H = 11.166$), alanine aminotransferase (ALT) ($H = 109.01$), aspartate aminotransferase (AST) ($H = 75.663$), ALT/AST ratio ($H = 23.096$), adenosine deaminase (ADA) ($H = 34.013$), and gamma-glutamyl transferase (GGT) ($H = 9.831$) (all $P < 0.01$). The $2 < R < 5$ group had the highest mean Ridit value for G and proportion of $\geq G3$ grades, with significant differences among the three groups ($\chi^2 = 7.385$, 7.163 ; all $P < 0.05$). Independent risk factors for G severity were ALB, GGT, and ALT/AST; for advanced fibrosis stage (S) were ALT/AST, platelet count, and ALB; and for combined G/S severity were GGT, ALB

and ALT/AST.

Conclusions: The clinical and pathological features of DILI vary across different disease states. Autoantibody-positive DILI and mixed-type DILI ($2 < R < 5$) are associated with more severe liver inflammation grades.

1749 - Seroprevalence and Epidemiological Features of Hepatitis E Virus Infection in South Korea Analysis of KNHANES Serum Samples

In Hee Kim¹, Chang Hun Lee¹, Hwa Young Choi², Won-mook Choi³, Byeong Geun Song⁴, Moran Ki², Sook-hyang Jeong⁵

Jeonbuk National University Hospital, Internal Medicine, Jeonju-South Korea¹ National Cancer Center, Cancer Control And Population Health, Graduate School Of Cancer Science And Policy, Goyang-South Korea² Asan Medical Center, University Of Ulsan College Of Medicine, Gastroenterology, Liver Center, Seoul-South Korea³ Samsung Medical Center, Sungkyunkwan University School Of Medicine, Medicine, Seoul-South Korea⁴ Seoul National University Bundang Hospital, Seoul National University College Of Medicine, Internal Medicine, Seongnam-South Korea⁵

Background / Hypothesis: Epidemiological data on hepatitis E virus (HEV) prevalence in South Korea remain limited. This study aimed to comprehensively assess the national seroprevalence of HEV, with analyses stratified by sex, age, and region.

Materials and Methods: A total of 840 blood samples were selected based on sex, age, and regional distribution from participants of the 2020 Korea National Health and Nutrition Examination Survey (KNHANES). All sera were qualitatively stored at the National Biobank of Korea.

Results: Among the 840 samples analyzed, 182 (21.7%) were positive for anti-HEV IgG only, 15 (1.8%) for anti-HEV IgM only, and 13 (1.5%) for both IgG and IgM. The remaining 630 samples (75.0%) were negative for both antibodies. Anti-HEV IgG positivity was higher in males (28.3%) than in females (18.1%) and showed a marked increase with age, rising from 3.0% in those aged 10–39 to 50.6% in those aged 70 and older. Compared to anti-HEV IgG-negative individuals, those who were IgG-positive were significantly older and showed higher liver fibrosis indices based on FIB-4. The anti-

E-POSTER ABSTRACTS

HEV IgM positivity rate was 3.3% (28/840), with the highest prevalence in the 40–59 age group. Among IgM-positive individuals, 13 (46.4%) were also IgG-positive. No significant differences in age or sex were observed between IgM-positive and IgM-negative individuals. Similarly, APRI and FIB-4 scores did not differ significantly between the two groups. Although elevations in AST and ALT were more frequent among IgM-positive individuals, these differences were not statistically significant. Real-time reverse transcription PCR performed on all 28 IgM-positive samples yielded negative results for HEV RNA.

Conclusions: This nationwide serological analysis revealed a substantial seroprevalence of both anti-HEV IgG and IgM among the Korean population, indicating significant past and recent exposure to HEV. These findings highlight the importance of hepatitis E as a public health concern in South Korea.

Keyword(s) : Viral hepatitis, Hepatitis E, Epidemiology

1752 - Exploring the Associations of Liver PDFF with Mortality and Disease Incidence A Prospective Study in the UK Biobank

Yingxin Sun¹, Tianyi Xia¹, Shenghong Ju¹
Zhongda Hospital, Medical School Of Southeast University, Radiology, Nanjing-China¹

Background / Hypothesis:

Nonalcoholic fatty liver disease (NAFLD) is closely associated with obesity, diabetes, and cardiovascular disease. Clinical assessment often relies on biopsy or limited imaging, and population-level age- and sex-specific trajectories and long-term outcomes remain unclear. Previous studies using proton density fat fraction (PDFF) provided some insights but had limited sample sizes and lacked comprehensive modeling of nonlinear trends and systematic evaluation of mortality and comorbidities. This study leveraged a large UK Biobank cohort to characterize PDFF distributions and their associations with mortality and metabolic and cardiovascular traits.

Materials and Methods:

We analyzed 37,358 UK Biobank participants with liver PDFF data (median age 64 years; median PDFF 4.8%). Age- and sex-specific distributions and nonlinear trends were assessed using bootstrap resampling and generalized additive models (GAMs). Imaging-derived variables were standardized. Associations between PDFF and all-cause or cancer-specific mortality were examined using Cox proportional hazards models with restricted cubic splines (RCS), adjusting for age, sex, and BMI. Phenome wide association studies (PheWAS)

and Pearson correlations were performed to link PDFF with clinical and biomarker traits.

Results:

PDFF exhibited nonlinear age trajectories, with postmenopausal women exceeding men. High PDFF was significantly associated with increased all-cause mortality ($P < 0.001$), while low PDFF conferred protective effects. Tumor-specific mortality showed a similar pattern, with hazard ratios exceeding 1.0 at lower PDFF levels. PheWAS identified positive associations between PDFF and fatty liver (K76.0), type 2 diabetes (E11.9), and diverticular disease without perforation or abscess (K57.3). PDFF correlated positively with BMI, waist circumference, triglycerides, ALT, and GGT, and inversely with HDL, SHBG, and vitamin D; multiple metabolic and cardiovascular polygenic risk scores were also positively associated with PDFF.

Conclusions:

Liver PDFF is a robust, noninvasive marker of metabolic and mortality risk, providing valuable information for population screening and individual risk assessment. Incorporating PDFF into clinical evaluation may improve early detection and guide preventive interventions.

Keyword(s) : Liver, PDFF, UKBB

1755 - Role of IL 16 in autoimmune hepatitis

Wen Gao¹, Bin Xu¹, Yanjun Wang²

Beijing Youan Hospital Affiliated To Capital Medical University, Department Ii Of Liver Diseases, Beijing-China¹ Beijing Youan Hospital Affiliated To Capital Medical University, Beijing Institute Of Hepatology, Beijing-China²

Background / Hypothesis: Autoimmune hepatitis (AIH) is a T cell-mediated chronic liver inflammation with unclear pathogenesis, facing challenges like difficult diagnosis and suboptimal therapy, necessitating novel molecular targets. Interleukin-16 (IL-16), a proinflammatory cytokine regulating T cell function, is linked to inflammatory diseases and liver injury, but its role in AIH—including tissue/serum expression differences and correlation with AIH biomarkers (ALT, AST, IgG)—remains undefined.

Materials and Methods: A case-control study design was adopted, with 30 AIH patients selected as the study group and 30 healthy individuals with completely matched gender and age as the control group. IL-16 in the serum of the two groups was detected by ELISA, IHC, and proteomics. In addition, the concentrations of serum autoantibodies, immunoglobulins (with IgG as

E-POSTER ABSTRACTS

the core indicator), and related cytokines (including IL-18, soluble CD48 (sCD48), follicle-stimulating hormone (FSH), and transforming growth factor- β (TGF- β)) were simultaneously detected in both groups.

Results: There was no statistically significant difference in the serum IL-16 between the AIH patient group and the HC group ($P > 0.05$); however, IL-16 in the liver tissue of AIH patients was significantly higher than that in the healthy control group, and the difference was statistically significant ($P < 0.01$). Further correlation analysis showed that the serum IL-16 in AIH patients had a certain correlation with ALT, AST, and IgG, suggesting that IL-16 may be closely related to the degree of liver inflammatory injury and the state of immune activation in AIH patients.

Conclusions: The results of this study confirm that IL-16 is involved in the pathogenesis of AIH, providing experimental evidence for clarifying the regulatory role of IL-16 in the progression of AIH and the feasibility of using it as a potential therapeutic target for AIH. Meanwhile, it is suggested that although there is no significant difference in serum IL-16 between the two groups, its correlation with key pathological indicators of AIH still supports its potential as a candidate biomarker for auxiliary diagnosis of AIH, which can provide a new reference direction for the early identification of the disease.

1756 - Recombinant human thrombopoietin promotes platelet recovery in hepatocellular carcinoma patients receiving interventional therapy combined with targeted and immunotherapy (SYNERGY TPOACT) a retrospective cohort study

Lifu Zhu ¹, Wei Fan ¹, Zi Wang ², Xiaochun Peng ³, Pan Wang ⁴, Fayong Hu ⁵, Yu Dai ¹, Yang Liu ¹, Yi Gong ¹, Heping Yin ¹, Xinkai Fan ¹, Hangyun Peng ⁵, Jinglei Wang ⁵, Guiyou Zhou ⁵, Yanlin Lyu ⁶

Guizhou Provincial People's Hospital, Hepatobiliary Surgery, Guizhou Province-China ¹ Guizhou Provincial People's Hospital, Department Of Oncology, Guizhou Province-China ² Guizhou Provincial People's Hospital, Interventional Radiology, Guizhou Province-China ³ Guizhou Provincial People's Hospital, Physical Examination Center, Guizhou Province-China ⁴ Zunyi Medical University, Physical Examination Center, Guizhou Province-China ⁵ Guizhou Provincial People's Hospital, Intensive Care Unit, Guizhou Province-China ⁶

Background / Hypothesis:

Combination regimens involving interventional therapy (TACE/HAIC), tyrosine kinase inhibitors (TKIs), and

immune checkpoint inhibitors (ICIs) have become the standard of care for advanced hepatocellular carcinoma (HCC). However, cumulative myelosuppression frequently leads to severe thrombocytopenia, necessitating dose reduction or treatment interruption. While recombinant human thrombopoietin (rhTPO) is effective in chemotherapy-induced and immune thrombocytopenia, evidence in this specific population remains limited.

Materials and Methods:

This retrospective study included 60 HCC patients who developed thrombocytopenia (platelets $\leq 80 \times 10^9/L$) after combined interventional, targeted, and immunotherapy at Guizhou Provincial People's Hospital, China (March 2022-March 2025). All patients received subcutaneous rhTPO. The primary endpoint was overall response rate (ORR), defined as complete response (CR: platelets $\geq 100 \times 10^9/L$) or partial response (PR: platelets increase $\geq 25 \times 10^9/L$). Secondary endpoints included platelet counts, platelet increments analyzed by rhTPO treatment durations and across BCLC stages, and changes in liver/renal function and coagulation parameters.

Results:

Baseline clinical characteristics were comparable across subgroups. Most patients were BCLC stage C (50.0%) and Child-Pugh class B (55.0%). The mean baseline platelet count was $51.93 \times 10^9/L$. Following rhTPO administration, the ORR was 68.3% (CR:38.3%, PR:30.0%). Platelets increased by a mean of $47.76 \times 10^9/L$ ($p < 0.0001$, 95% CI: 36.81-58.70). Mean platelet increments at 3, 5, and 7 days were $25.21 \times 10^9/L$, $42.43 \times 10^9/L$, and $64.91 \times 10^9/L$, respectively, peaking at day 7. Efficacy was consistent across BCLC stages. Notably, a treatment duration ≥ 7 days was significantly associated with achieving ORR (OR=7.45, 95%CI: 1.95-28.50, $p=0.003$). No treatment-related hepatorenal toxicity or thromboembolic events were observed.

Conclusions:

rhTPO is effective and safe for improving treatment-related thrombocytopenia in HCC patients receiving interventional therapy combined with targeted and immunotherapy. Our findings suggest that a minimum treatment duration of 7 days yields optimal platelet recovery. Prospective trials are needed to validate these findings and guide clinical practice.

Keyword(s) : rhTPO, platelet, HCC, interventional therapy combined with targeted and immunotherapy

1759 - Value of Preoperative Contrast Enhanced CT based Radiomics for Predicting CK19 Positive

E-POSTER ABSTRACTS

Hepatocellular Carcinoma

Yawen Wang¹, Shenghong Ju¹

Zhongda Hospital Affiliated Of Southeast University
Hospital, Department Of Radiology, Nanjing-China¹

Background / Hypothesis: Prediction of cytokeratin 19 (CK19) may help determine treatment strategies for hepatocellular carcinoma (HCC).

Materials and Methods: This multi-center retrospective study enrolled patients with pathologically confirmed HCC who underwent preoperative contrast-enhanced CT between February 2012 and November 2023. Based on postoperative immunohistochemical staining results for CK19, patients were categorized into CK19-positive (n=101) and CK19-negative (n=397) groups. Radiomics features were extracted from the tumor region on non-contrast, arterial, and portal venous phase CT images after image registration. In the training cohort, feature dimensionality reduction was performed using Maximum Relevance - Minimum Redundancy (mRMR) and the Least Absolute Shrinkage and Selection Operator (LASSO) regression. A radiomics model was subsequently constructed using logistic regression. The model was validated in internal and external test cohorts using pathology as the gold standard. A hybrid model integrating radiomics features with significant clinical-radiological characteristics was also developed. Model performance for predicting CK19-positive HCC was evaluated using the Area Under the Receiver Operating Characteristic Curve (AUC), and clinical utility was assessed via Decision Curve Analysis (DCA).

Results: A total of 498 patients (median age 57 years; 407 males) were included and allocated into training (n=239), internal test (n=103), and external test (n=156) cohorts. Multivariate logistic regression identified AFP >400 ng/ml (OR=4.05, 95% CI: 2.12–7.74, P<0.01) and peritumoral arterial enhancement (OR=2.15, 95% CI: 1.10–4.23, P=0.026) as independent predictors of CK19-positive HCC. The radiomics model achieved AUCs of 0.68 and 0.77 in the internal and external test cohorts, respectively. The hybrid model demonstrated superior performance, with AUCs of 0.77 and 0.78 in the internal and external test cohorts, respectively.

Conclusions: The hybrid model, integrating preoperative contrast-enhanced CT radiomics features with clinical-radiological indicators, effectively predicts CK19-positive HCC, demonstrating good generalizability and promising clinical utility.

Keyword(s) : CT Radiomics, Hepatocellular Carcinoma, Cytokeratin 19, Combined Mode

1760 - Comparison of effectiveness between phentermine topiramate and liraglutide in obese patients with metabolic dysfunction associated steatotic liver disease

Sung Jun Park¹, Yeonjung Ha², Kwan Sik Lee², Young Eun Chon²

Cha Gumi Medical Center, Cha University, Internal Medicine, Gumi-South Korea¹ Cha Bundang Medical Center, Cha University, Internal Medicine, Seongnam-South Korea²

Background / Hypothesis: Anti-obesity drugs improve hepatic inflammation in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). We aimed to compare the effects of phentermine/topiramate and liraglutide in obese MASLD patients

Materials and Methods: This retrospective study included 438 obese MASLD patients (body mass index >25 and detection of fatty liver on ultrasound) who received phentermine/topiramate (n=320) or liraglutide (n=118) for more than 12 months. Steatosis was assessed using the hepatic steatosis index (HSI) and controlled attenuation parameter (CAP). Fibrosis was assessed using the fibrosis index based on four factors (FIB-4), and liver stiffness (LS). Improvements in steatosis and fibrosis were compared at 12 months after treatment initiation.

Results: After applying propensity score matching, the baseline characteristics of the phentermine/topiramate group (n=108) and the liraglutide group (n=108) were comparable. Both groups showed significant reductions in steatosis (phentermine/topiramate: CAP, 321→299 dB/m; HSI, 40.6→37.0; liraglutide: CAP, 306→288 dB/m; HSI, 40.3→39.3, all p<0.05), but fibrosis improvement was only observed in the liraglutide group (phentermine/topiramate: FIB-4, 0.905→0.881, p=0.416; LS, 6.7→5.6 kPa, p=0.487; liraglutide: FIB-4, 0.838→0.717, p=0.025, LS, 6.0→4.9 kPa, p=0.011) after 12 months of treatment compared with baseline values. The Phentermine/topiramate group showed significantly greater steatosis reduction than the liraglutide group (Δ HSI, -9.32% vs. -1.87%, p<0.001; Δ CAP: -10.15% vs. -5.22%, p<0.001). However, the

E-POSTER ABSTRACTS

percentage of fibrosis reduction did not differ significantly between phentermine/topiramate and liraglutide groups (Δ FIB-4, 1.58% vs. -3.83%, $p=0.297$; Δ LS: -7.37% vs. -12.50%, $p=0.144$).

Conclusions: In obese patients with MASLD, phentermine/topiramate treatment resulted in better steatosis improvement, but the effect on fibrosis improvement was minimal in both groups.

Keyword(s) : fibrosis, liraglutide, with metabolic dysfunction-associated steatotic liver disease, phentermine/topiramate, steatosis

1761 - Expression of ALOX15 in the Development and Reversal of Liver Fibrosis and Its Effects on Macrophage Inflammatory Cytokine Secretion

Yuanying Zhao¹, Chenxue Hou¹, Qi Wang², Yue Li¹
Beijing Ditan Hospital, Clinical Laboratory, Beijing-China¹ Beijing Ditan Hospital, Center Of Liver Diseases, Beijing-China²

Background / Hypothesis: Liver fibrosis represents a critical step in the progression of chronic liver disease to cirrhosis and hepatocellular carcinoma. It is known that liver fibrosis can be reversed upon removal of the causative factors, with inflammatory mediators such as IL-6 and TNF- α secreted by macrophages regulating this process. ALOX15 participates in inflammation and lipid metabolism, but its role in reversing liver fibrosis and its effects on macrophage inflammatory function remain unclear. This study aims to elucidate the mechanism by which ALOX15 participates in reversing liver fibrosis through regulating macrophage inflammatory factors.

Materials and Methods: Proteomics analysis was performed to examine the hepatic protein expression profile in a mouse model of reversed liver fibrosis. Protein and mRNA expression levels of ALOX15 in liver tissue were determined via Western blotting and real-time quantitative PCR. Liver tissue samples were collected from 60 patients with liver fibrosis. The expression of ALOX15 in these samples was analyzed to assess its correlation with clinical staging of liver fibrosis. Additionally, in the mouse macrophage cell line RAW264.7, ALOX15 expression was knocked down using small interfering RNA (siRNA). Following inflammation induction with 1 μ g/mL LPS, levels of inflammatory cytokines including IL-6 and TNF- α were measured in cell culture supernatants and cells via WB

and qPCR.

Results: Proteomics analysis revealed that ALOX15 protein expression was significantly downregulated in both serum and liver tissues of mice in the liver fibrosis reversal model. Compared with normal mouse liver tissue, ALOX15 expression levels were markedly elevated in the liver fibrosis model group. In the 4-week and 12-week fibrosis reversal groups, ALOX15 expression exhibited a graded decrease as reversal duration increased. Analysis of clinical samples demonstrated that ALOX15 expression levels in liver tissue from patients with liver fibrosis showed a significant positive correlation with the severity of liver fibrosis. Following ALOX15 knockdown in RAW264.7 cells, mRNA expression levels of LPS-induced intracellular IL-6, TNF- α , and IL-1 β were significantly downregulated, and the protein secretion levels of these inflammatory factors in cell culture supernatants were also markedly reduced.

Conclusions: ALOX15 expression is downregulated in the reversal of mouse liver fibrosis and positively correlates with clinical fibrosis severity. Furthermore, ALOX15 participates in fibrosis reversal by regulating macrophage inflammatory cytokine secretion, suggesting its potential as a target for monitoring fibrosis reversal.

Keyword(s) : liver fibrosis; ALOX15; RAW264.7

1762 - From Liver to Spine Spinal Metastatic Compression as the Initial Manifestation of Hepatocellular Carcinoma

Jason Phowira¹, Alfiyyah Rizqy¹, Kemal Fariz Kalista¹, Mohamad Saekhu², Tiara Aninditha³
Faculty Of Medicine, Universitas Indonesia, Jakarta, Indonesia, Department Of Internal Medicine, Jakarta-Indonesia¹ Faculty Of Medicine, Universitas Indonesia, Jakarta, Indonesia, Department Of Neurosurgery, Jakarta-Indonesia² Faculty Of Medicine, Universitas Indonesia, Jakarta, Indonesia, Department Of Neurology, Jakarta-Indonesia³

Background:

Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality with a high propensity for metastatic spread, occurring in approximately one-third of patients. Although HCC commonly metastasizes to bone, spinal metastases are a serious but relatively rare (1.5-7.3%) complication with a poor prognosis. The anatomically critical location of the spinal cord necessitates prompt diagnosis and urgent

E-POSTER ABSTRACTS

therapeutic intervention to avert permanent neurological deterioration and functional loss. Treatment goals prioritize maintaining function, quality of life, and reducing pain.

Case Illustration:

We present a 71-year-old male who presented with progressive pain radiating from the back to the epigastric since 2 months prior to admission, characterized by stabbing, burning, and pressure sensations with numerical rating scale 8-9. A month later, the patient developed bilateral lower limb weakness and reported difficulty ambulating. Upon hospital admission, neurological examination confirmed upper motor neuron (UMN) type paraparesis with sensory level at T9 and bilateral proprioceptive dysfunction. Imaging revealed multiple nodules in the left hepatic lobe suggestive of HCC, with magnetic resonance imaging (MRI) of the thoracic spine demonstrating light compression of the T8 vertebral body corpus with marked post-contrast enhancement, suggesting metastatic pathology. Laboratory investigations showed elevated alpha-fetoprotein (AFP) 1626 ng/mL and carcinoembryonic antigen (CEA) 8.8 ng/mL. Histopathological and immunohistochemical analyses of surgical specimens confirmed metastatic carcinoma likely originating from hepatic tissue. The tumor cells were positive for CAM5.2, Glypican-3, arginase-1, HepPar1, and weakly positive for AFP and BSEP. The patient underwent hemilaminectomy with spinal cord decompression and tumor removal on day 9 of hospitalization, followed by plans to start physiotherapy and immunotherapy with atezolizumab-bevacizumab. Patient's neurological symptoms improved following surgical decompression and tumor removal.

Conclusion:

This case underscores the need for clinicians to consider hepatic malignancy with spinal metastasis as a potential cause of progressive myelopathy. In patients with current or a history of malignancy, any new or unexplained radicular pain, including epigastric pain possibly related to radiculopathy from spinal stenosis, should raise suspicion for spinal metastasis and prompt diagnostic evaluation. Early recognition through imaging and biomarkers, followed by timely surgical decompression and tumor removal, can help alleviate symptoms and prevent further neurological deterioration. Despite intervention, overall survival remains limited, emphasizing the importance of early management in optimizing outcomes for this devastating complication.

Keyword(s) : hepatocellular carcinoma, spinal metastasis, vertebral canal stenosis, myelopathy, hemilaminectomy

1763 - Cirrhosis in Transition Rapid Metabolic and Alcoholic Rise with Declining Viral Burden in an Indian Tertiary Center

Udit Vaish¹, Priyanka Jadhav¹, Smita Patil¹

Dr. D.y. Patil School Of Medicine, General Medicine, Navi Mumbai-India¹

Background / Hypothesis:

The Indian landscape for cirrhosis has been historically dominated by viral hepatitis and alcoholic liver disease. With the national rollout of affordable antivirals, this study assessed the changing aetiology, clinical presentation, and complication profile of cirrhosis at a tertiary- care centre in Mumbai, India (2024–2025).

Materials and Methods:

A cross-sectional analysis of 140 consecutive cirrhosis patients admitted between April 2024 and April 2025. Aetiology, clinical features, and complications were documented and compared with historic Indian data. Statistical analysis used chi-square and ANOVA tests, with $p < 0.05$ considered significant.

Results:

Mean age 54.7 ± 13.3 years; 77.9 % male.

Alcoholic liver disease (ALD) predominated (74.3 %, 95 % CI 66.6–81.0), followed by metabolic-associated steatohepatitis (MASH, 14.3 %), hepatitis B (6.4 %), and hepatitis C (2.9 %).

Viral causes showed a marked decline versus past Indian cohorts (> 20 %).

Common complications included ascites (65.7 %), encephalopathy (26.4 %), varices (24.3 %), spontaneous bacterial peritonitis (6.4 %), and hepatorenal syndrome (2.9 %).

Alcohol-related cases exhibited higher encephalopathy and infection rates ($p < 0.05$).

E-POSTER ABSTRACTS

Conclusions:

Indian cirrhosis aetiology has pivoted decisively toward metabolic and alcohol-related disease, mirroring Western trends. Declining viral causes underscore the success of antiviral programs, while the rapid rise of MASH highlights the need for early metabolic screening and tighter public-health interventions across urban India.

Keyword(s) : Cirrhosis, Etiological trends, MASH, Viral hepatitis decline, India

1764 - Multidisciplinary management of diffuse intraductal papillary neoplasm of the bile duct in an elderly patient with limited therapeutic options

Edzil Marice Forteza¹, Wilmyr Hababag²

De Los Santos Medical Center, Internal Medicine, Quezon City-Philippines¹ De Los Santos Medical Center, Gastroenterology, Quezon City-Philippines²

Background / Hypothesis:

Intraductal Papillary Neoplasm of the Bile Duct (IPNB) is a rare biliary precursor lesion with high malignant potential. Curative treatment requires complete surgical resection, but advanced age, frailty, and multilevel ductal involvement may limit the feasibility of definitive therapy. This case highlights the hepatobiliary, oncologic, and ethical considerations when both surgery and standard systemic regimens are contraindicated.

Materials and Methods:

A 77-year-old female presented with recurrent obstructive jaundice and cholangitis. Endoscopic Retrograde Cholangiopancreatography (ERCP) revealed diffuse intraductal lesions involving the common bile duct, common hepatic duct, and central intrahepatic ducts, necessitating repeated stent exchanges for biliary decompression. Histopathology confirmed high-grade IPNB. Due to frailty and severe three-vessel coronary artery disease, the patient was deemed unsuitable for surgical resection. Persistent cytopenias prompted bone marrow evaluation prior to systemic therapy consideration.

Results:

The patient's course was dominated by recurrent biliary

obstruction requiring sequential endoscopic palliation. Bone marrow evaluation confirmed a coexisting Myelodysplastic Neoplasm (MDS), explaining her persistent anemia and thrombocytopenia. Although systemic therapy is not routinely indicated for non-invasive IPNB, its diffuse involvement and high-grade dysplasia warranted consideration. However, the established gemcitabine–cisplatin regimen posed unacceptable myelosuppressive risk. Consequently, the multidisciplinary team redirected management toward safer, lower-intensity systemic options while continuing endoscopic drainage to prevent cholangitis.

Conclusions:

For elderly patients with diffuse high-grade IPNB and prohibitive comorbidities, both curative and standard palliative therapies may be untenable. This case demonstrates how structured multidisciplinary evaluation enables a realistic, patient-centered strategy focused on durable biliary drainage and safe therapeutic modification. It underscores the need for individualized hepatobiliary management when conventional treatment pathways are not feasible.

1765 - Synergistic Hepatoprotection via SREBP 1c PPAR α FXR CYP7A1 and Insulin Signaling Modulation by Empagliflozin and Cholestyramine in STZ induced diabetic rats

Mohd. Ibrahim Khan¹, Danish Ahmed¹

Sam Higginbottom University Of Agriculture Technology And Sciences, Department Of Pharmaceutical Sciences, Prayagraj-India¹

Background / Hypothesis:

Diabetes mellitus accelerates blood glucose levels and hepatic lipotoxicity through insulin resistance, increased de novo lipogenesis (DNL), mitochondrial dysfunction, and impaired bile-acid recirculation. Empagliflozin (SGLT2 inhibitor) ameliorates glucotoxicity and reduces hepatic fat via enhanced β -oxidation and improved adipose liver function. In contrast, Cholestyramine, a bile-acid sequestrant (BAS), interrupts enterohepatic circulation, activating hepatic cholesterol to bile acid conversion and reducing hepatic triglyceride stores through FXR, FGF15/19 modulation. The combined hepatic effects of these complementary pathways have not been well

E-POSTER ABSTRACTS

characterized.

Materials and Methods:

Diabetic STZ rats were treated with Empagliflozin (10mg/Kg), Cholestyramine [5% w/w], and their combination for 04 weeks, followed by assessment of hepatic enzymes, lipid profile, and oxidative markers. Liver histology was evaluated to determine hepatoprotective effects.

Results:

Empagliflozin lowered glucose and improved insulin sensitivity while reducing steatosis. Cholestyramine reduced hepatic triglycerides. Combined therapy showed maximal benefit, with approximately 60% TG reduction, improved oxidative stress (decreased MDA, increased SOD & CAT). Synergy reflected simultaneous correction of glucotoxicity and bile acid dysregulation, leading to suppressed DNL and enhanced hepatic metabolic balance.

Conclusions:

Empagliflozin and Cholestyramine synergistically improve glucose, lipid, and bile acid metabolism, providing strong hepatoprotection. Their combined therapy may prevent hepatic deterioration and support recovery in acute liver failure, offering a promising adjunctive metabolic liver intervention.

Keyword(s) : Diabetes; Liver Failure; Empagliflozin; Cholestyramine; STZ

1766 - Association Between Baseline Hepatic Nodules and Their 3 Month Dynamic Changes with Hepatocellular Carcinoma Risk in HBV Cirrhosis Patients on Antiviral Therapy

Yaxin Li¹, Yuwei Wang¹, Yueyang Yu¹, Ying Han¹, Huiguo Ding¹

Beijing You'an Hospital Affiliated To Capital Medical University, Department Of Gastroenterology And Hepatology, Beijing-China¹

Background / Hypothesis:

The impact of hepatic nodules detected by ultrasound on hepatocellular carcinoma (HCC) risk in patients with HBV-related cirrhosis receiving nucleoside analogues (NAs) remains unclear. We investigated the association between baseline hepatic nodule status, 3-month dynamic changes, and HCC risk.

Materials and Methods:

The real-world cohort included 1,209 treatment-naïve patients with HBV-related cirrhosis who received NAs antiviral therapy for more than 1 year. Patients were

stratified by baseline hepatic nodule presence. Nodule characteristics were categorized by size (≥ 10 mm vs. < 10 mm), echogenicity (hyperechoic vs. non-hyperechoic), shape (regular vs. irregular), and number (single vs. multiple). Patients were further classified based on 3-month nodule dynamics: no nodules, stable nodules, or progressive nodules. Cox proportional hazards models assessed the association between hepatic nodule status and HCC risk. Cumulative HCC incidence was analyzed using Kaplan-Meier curves and log-rank tests.

Results:

Among 1,209 patients, 806 had no baseline hepatic nodules and 403 had nodules. Of a subset of 354 patients (29.3%) completing 3-month ultrasound follow-up, 187 had no nodules, 97 had stable nodules, and 70 had progressive nodules. Baseline hepatic nodules were associated with increased HCC risk (aHR, 1.700; 95% CI, 1.363-2.119, $P < 0.001$). During a median follow-up time of 7.0 years, 323 patients (26.7%) developed HCC. 1-, 3-, and 5-year cumulative incidences of HCC were 8.3%, 17.1%, 21.5%, respectively. The Kaplan-Meier curves showed that patients with hepatic nodules had a significantly higher cumulative incidence of HCC than those without hepatic nodules (Log-rank $P < 0.001$). We further found Larger nodules (≥ 10 mm) had a higher cumulative incidence of HCC compared to smaller nodules (Log-rank test $P = 0.002$). No significant differences were observed by echogenicity, shape, or number. The Kaplan-Meier curves showed that the risk of developing HCC was significantly different between 3-month hepatic nodules growth, with the lowest cumulative incidence in patients without hepatic nodules and highest in those with progressive hepatic nodules (Log-rank test $P = 0.020$).

Conclusions:

Baseline hepatic nodules and their 3-month progression are significantly associated with HCC in patients with HBV-related cirrhosis patients receiving NAs therapy, highlighting personalized surveillance strategies.

1767 - Comparison of Treatment Efficacy and Safety Profile of Atezolizumab Plus Bevacizumab in BCLC B and C Patients with Hepatocellular Carcinoma

Chan Joong Bae¹, Jae Hyun Yoon¹, Sung Bum Cho², Young Eun Seo², Jin Young Seo³

E-POSTER ABSTRACTS

Chonnam National University Hospital,
Gastroenterology And Hepatology, Gwanju-South
Korea ¹ Chonnam National University Hwasun Hospital
And Medical School, Gastroenterology And
Hepatology, Hwasun-South Korea ² Chonnam National
University Hospital, Internal Medicine, Gwanju-South
Korea ³

Background / Hypothesis:

Hepatocellular carcinoma (HCC) imposes a considerable global burden, and rigorous evidence to guide therapeutic stratification across BCLC B and C remains limited. Atezolizumab plus bevacizumab (ATE/BEV) is established as first line therapy for advanced HCC, yet effectiveness and safety between BCLC B and C in practice are undefined. Real world BCLC B cohorts are heterogeneous and include patients who are TACE non eligible, such as those with TACE refractoriness, huge HCC, multinodular HCC, or hypovascular HCC. We conducted a multicenter real world analysis comparing ATE/BEV across BCLC B and C, assessing overall and progression free survival, objective response, disease control, and treatment related adverse events.

Aim :

Investigate the real-world tumor response and survival outcome between BCLC-B and BCLC-C after ATE/BEV treatment

Investigate clinical characteristics of BCLC-B and BCLC-C undergoing ATE/BEV treatment

Materials and Methods:

Multi-institutional retrospective cohort study (10 academic hospitals in Korea)

Inclusion criteria

≥ 18 years old

Patients diagnosed as unresectable HCC who underwent atezolizumab plus bevacizumab 2020.07. – 2024.11.

Exclusion criteria

Insufficient clinical records

Patients with duration of ATE/BEV treatment < 3 months

Results:

Baseline characteristics were largely balanced between BCLC B and BCLC C, including mean age (68.34 vs 66.07 years, $p=0.040$), gender distribution (85.7% vs

87.1%, $p=0.709$), and maximum tumor diameter (6.57 vs 6.87 cm, $p=0.604$). Notably, BCLC B had a higher mean tumor count (2.99 vs 2.18, $p<0.001$). Disease control rates were comparable (75.9% vs 68.3%, $p=0.090$), whereas the objective response rate was numerically higher in BCLC C but did not reach statistical significance (15.7% vs 25.6%, $p=0.056$). Kaplan–Meier estimates showed no significant difference in overall survival between groups (median 11.13 vs 10.82 months; $p=0.799$).

Conclusions:

ATE/BEV demonstrated comparable effectiveness in BCLC B and BCLC C in real world practice. BCLC B patients, particularly those unsuitable for TACE, achieved meaningful disease control and survival. Our findings support expanding the role of ATE/BEV as a viable first line option in intermediate stage HCC when TACE is limited or not appropriate. Further studies are needed to refine patient selection for ATE/BEV in BCLC B HCC.

Keyword(s) : Atezolizumab-Bevacizumab, Hepatoceular carcinoma, BCLC, Tumor response, Real-world data

1770 - Serum HBV Markers Reflect Intrahepatic cccDNA and Transcriptional Activity in a Phase Dependent Manner in Chronic HBV Infection

Hye Seon Kim ¹, Jae Mo Han ¹, Jung Eun Jang ¹, Hee Sun Cho ², Kwon Yong Tak ², Soon Kyu Lee ², Ji Won Han ², Pil Soo Sung ², Sung Won Lee ², Jung Hyun Kwon ², Si Hyun Bae ², Hyun Woong Lee ³, Jeong Won Jang ²

The Catholic University Of Korea, Medical Science, Seoul-South Korea ¹ The Catholic University Of Korea, Internal Medicine, Seoul-South Korea ² Gangnam Severance Hospital, Internal Medicine, Seoul-South Korea ³

Background / Hypothesis: cccDNA maintains HBV persistence through its transcriptional activity. We hypothesized that host immunity, reflected by the CHB natural phase, influences HBV transcription and serum markers, thereby altering their correlation with cccDNA activity. We aimed to identify serum markers that differentially reflect intrahepatic cccDNA and its activity.

E-POSTER ABSTRACTS

Materials and Methods: A total of 406 liver tissue samples from CHB patients were analyzed according to natural phase. Serum markers (HBsAg, HBcrAg, HBV RNA) and intrahepatic markers (iHBVDNA, cccDNA, pgRNA) were quantified using commercial assays and qPCR. Viral genome diversity was assessed by Shannon entropy and nucleotide diversity.

Results: Intrahepatic and serum HBV markers were significantly higher in HBeAg-positive than in HBeAg-negative patients. Most of all HBV markers showed a decreasing trend with increasing age. In HBeAg-positive phases, serum HBV RNA and HBcrAg correlated well with intrahepatic cccDNA, particularly in the immune-tolerant (IT) phase ($r=0.439$ and 0.503 , respectively) and immune-active (IA) phase ($r=0.500$ and 0.443), whereas their correlations were weak in HBeAg-negative hepatitis (ENH) and absent in inactive-carrier (IC). For intrahepatic pgRNA, strong correlations with serum HBV RNA and HBcrAg (all $r>0.400$) were observed in IT and IA, decreasing in ENH ($r=0.369$, $r=0.326$). The best serum markers for cccDNA transcriptional activity (pgRNA/cccDNA) were HBV RNA (IA: $r = 0.586$; ENH: $r=0.524$) and HBcrAg (IA: $r=0.576$; ENH: $r=0.399$). Notably, no serum markers reflected transcriptional activity in the IT and IC phase. Shannon entropy and nucleotide diversity were lowest in IT phase and highest in IC phase, indicating genetic homogeneity in IT and high viral heterogeneity in IC.

Conclusions: Serum HBcrAg and HBV RNA serve as indicators of intrahepatic cccDNA and its activity, though their performance varies by CHB phase. The limited reliability of these markers in IT and IC phases likely reflects a restricted dynamic range, due to saturation and upper-range clustering of cccDNA-derived markers in IT and viral heterogeneity in IC phase. These findings support their phase-specific utility for noninvasive monitoring, treatment decisions, and the design of future cure-focus.

Keyword(s) : Hepatitis B virus, cccDNA, pgRNA, HBV phase

1772 - HLA Variants and Oral Microbiome Signatures Associated with Antibody Mediated Rejection Post Living Donor Liver Transplantation

Rosmy Babu¹, Manjeet Kaur¹, Viniyendra Parmecha², Chhagan Bihari¹

Ilbs, Pathology, Gurgaon-India¹ Ilbs, Liver Transplantation Surgery, Delhi-India²

Background / Hypothesis:

Antibody-mediated rejection (ABMR) remains a key complication after living donor liver transplantation and may be influenced by host immunogenetics like HLA. We hypothesized that specific HLA alleles may harbor specific oral microbiome profiles and that these combined factors may influence the risk of ABMR.

Materials and Methods:

In this prospective study, 180 donor–recipient pairs undergoing living donor liver transplantation were evaluated. Pre-transplant saliva and blood samples were subjected to 16S rRNA sequencing and high-resolution HLA typing using NGS platforms. Microbial diversity and taxonomic abundance were analyzed using DADA2, QIIME2, GLM-based association models, and LEfSe. HLA amino-acid mismatches were quantified with HLA-EMMA. Clinical follow-up extended to one year for ABMR diagnosis based on Banff 2016 criteria.

Results:

ABMR occurred in 15/180 recipients (8.3%). A significantly higher HLA Class II mismatch burden was observed in those who developed ABMR compared with those with stable graft function, particularly at DPB1, DQB1, and DR loci (median mismatch DPB1: 2 vs 0; DQB1: 2 vs 0; DR: 2 vs 1). At the phylum level, HLA-DRB1*08 correlated with Actinobacteriota, HLA-DPB1*575 with Campylobacterota, and HLA-C*05 with Fusobacteriota. LEfSe identified >4-LDA enrichment of Veillonella, Streptococcus, and Enterobacter in HLA-DQB1*06 carriers who developed ABMR, while Lautropia and Burkholderiaceae were enriched in HLA-DQB1*04 as shown in Figure 1. These taxa have established associations with mucosal inflammation and systemic immune activation. Alpha diversity did not differ by zygosity, suggesting microbial structure rather than richness differs with HLA background.

Conclusions:

HLA polymorphisms and class II mismatch burden influence oral microbial composition in liver transplant recipients. Combined host-genetic and microbiome profiles may help identify patients at increased risk for antibody-mediated rejection. As microbiota are modifiable, these findings support future exploration of oral-microbiome-based interventions to complement immunologic risk assessment and potentially reduce ABMR incidence.

1773 - Siwu Decoction Inhibits Hepatocellular Carcinoma via Tumor Necroptosis Induced Suppression of Myeloid Derived Suppressor Cells

Zixin Feng¹, Ning Wang¹

The University Of Hong Kong, School Of Chinese Medicine, Hong Kong-Hong Kong SAR, China¹

Background / Hypothesis:

Hepatocellular carcinoma (HCC) remains a leading cause of cancer-related mortality worldwide. While sorafenib, as a first-line systemic treatment for advanced HCC, provides survival benefits, its therapeutic efficacy is substantially limited by acquired resistance and the immunosuppressive tumor microenvironment (TME). Myeloid-derived suppressor cells (MDSCs) are major contributors to this immunosuppression, facilitating tumor progression and therapy failure. Siwu Decoction (SWD), a classic traditional Chinese medicine formula known for nourishing the liver and regulating blood circulation, has shown potential in cancer treatment. We hypothesized that SWD could suppress HCC by modulating the TME through induction of tumor necroptosis and subsequent inhibition of MDSCs, thereby offering a complementary approach to overcome the limitations of current therapies like sorafenib.

Materials and Methods:

SWD was prepared from four herbs and its chemical profile was characterized by HPLC and LC-MS/MS. Its anti-HCC effects were evaluated in vitro on human HCC cell lines and in an orthotopic HCC mouse model. Tumor growth and metastasis were monitored. The role of MDSCs was investigated using adoptive transfer experiments and flow cytometry. Necroptosis was inhibited using Necrostatin-1 (Nec-1). The combination effect of SWD with sorafenib and the activity of its component, Albiflorin, were also assessed.

Results:

SWD significantly inhibited HCC growth and lung metastasis in mice without toxicity. It induced necroptosis in HCC cells, evidenced by upregulation of necroptosis-related proteins. SWD reduced intratumoral MDSCs but did not affect circulating MDSCs or directly induce MDSC apoptosis. Instead, supernatant from SWD-treated HCC cells triggered

MDSC apoptosis. Adoptive transfer of MDSCs or Nec-1 treatment reversed SWD's anti-tumor effects.

Combining SWD with sorafenib enhanced efficacy without additional toxicity. Albiflorin, a key component of SWD, mirrored its effects by inducing necroptosis and suppressing MDSCs.

Conclusions:

SWD inhibits HCC by inducing tumor cell necroptosis, which indirectly leads to MDSC apoptosis and alleviates immunosuppression in the TME. Albiflorin is identified as a primary active compound responsible for these effects. These findings support SWD as a promising adjuvant therapy for HCC, particularly in combination with sorafenib, by targeting both tumor cells and the immunosuppressive microenvironment.

1774 - An Innovative Integrated "Screen to Treat" Model with a Three Tier Network Significantly Enhances Viral Hepatitis Screening Efficiency and Linkage to Care in Zhuhai China A Comparative Study

Xiaofang Peng¹, Yanzhi Duan², Weili Yang², Jiujun Hu³, Zhuochao Wang¹, Kefeng Li⁴, Mingxing Huang¹

The Third People's Hospital Of Zhuhai, Zhuhai Engineering Technology Research Center Of Occupational And Mental Health, Zhuhai-China¹ The Third People's Hospital Of Zhuhai, Zhuhai engineering technology research center of occupational And Mental Health, Zhuhai-China² The Third People's Hospital Of Zhuhai, Zhuhai engineering technology research center of occupational And Mental Health, Zhuhai-China³ Macao Polytechnic University, Centre For Artificial Intelligence Driven Drug Discovery, Macao-China⁴

Background / Hypothesis:

China bears a disproportionate burden of global liver cancer, with 92% of cases attributable to chronic hepatitis B (HBV). To achieve the WHO's 2030 elimination goal, innovative and scalable screening strategies are essential for identifying asymptomatic adults who missed neonatal vaccination programs. This study aimed to develop and evaluate a novel, integrated model designed to improve screening efficiency, coverage, and linkage to care.

Materials and Methods:

We conducted a comparative study in Zhuhai among permanent residents aged 20-70. Phase one (Jan-July

E-POSTER ABSTRACTS

2025) utilized a conventional hospital-led screening model. Phase two (July-Nov 2025) implemented our innovative strategy, founded on a three-tier collaborative network integrating government for oversight, a tertiary hospital for technical support, and community health centers for frontline implementation. This structure enabled a comprehensive "screen-to-treat" pathway with diversified delivery through fixed community sites and mobile on-site services. The workflow incorporated digital tools (electronic consent, mobile app for results) and rapid 15-minute point-of-care testing. This system facilitated immediate linkage to care, including on-site health education, HBV vaccination for susceptible individuals, and a "green channel" referral with subsidized follow-up services for seropositive individuals, all managed by a precise follow-up system. A multi-faceted public health campaign amplified the initiative to enhance public awareness.

Results:

The innovative model demonstrated markedly superior efficiency, screening 40,026 individuals in four months compared to the traditional model's 5,086 in seven. In total, 45,112 individuals were screened (median age 37; 58.96% male). The overall prevalence of HBsAg was 5.28%, with a significantly higher rate in males than females (5.95% vs. 4.31%, $P < 0.001$), peaking at 6.73% in the 40-49 age group. The prevalence of anti-HCV was 0.299%, and seven cases of HBV-HCV co-infection were identified. Critically, the model successfully linked 2,512 seropositive individuals to care and facilitated HBV vaccination for 2,218 susceptible persons.

Conclusions: Our innovative screening model, which integrates a three-tier network, a full-chain service pathway, and public health outreach, is significantly more effective than traditional hospital-centric approaches in expanding screening coverage and ensuring linkage to care. This integrated system offers a robust, replicable, and scalable blueprint for accelerating progress towards viral hepatitis elimination. Its success in a region with a large mobile population makes it highly applicable to other urban centers across Asia facing similar public health challenges.

Keyword(s) :

1777 - Metabolic Dysfunction Particularly Diabetes Accelerates Liver Disease Progression in Chronic Hepatitis B

Zi-xing Wang ¹, Ke Yin ², Yu-yun Song ¹, Yan-pei Mai ¹, Ying-ying Lin ¹, Xiao-xiao Wang ¹, Hui-ying Rao ¹, Feng Liu ¹

Peking University People's Hospital, Peking University Hepatology Institute, Beijing-China ¹ Peking University People's Hospital, Peking University Hepatology Institute, Beijing-China ²

Background / Hypothesis: The impact of metabolic dysfunction on adverse outcomes in chronic hepatitis B (CHB) patients remains controversial. Understanding the relationship between metabolic risk factors and hepatic outcomes is crucial for improving patient management.

Aims: To evaluate the impact of concomitant metabolic risk factors and fatty liver conditions on adverse hepatic outcomes in CHB patients.

Materials and Methods: We analyzed data from an outpatient CHB cohort (2009–2025), categorizing 7,817 patients into four groups: CHB alone ($n=3,804$), CHB with metabolic dysfunction-associated fatty liver disease (MAFLD, $n=1,154$), CHB with simple fatty liver ($n=600$), and CHB with metabolic risk factors only (MET, $n=2,259$). Multivariate Cox regression models were used to assess risks of hepatocellular carcinoma (HCC) and decompensated liver cirrhosis (DLC), adjusting for age, sex, antiviral treatment, and fibrosis stage. Patients with baseline decompensated cirrhosis were excluded.

Results: During a maximum of 16-year follow-up, only MET was independently associated with increased risk of DLC (adjusted HR [aHR] = 2.55; 95% CI: 1.77-3.68), but not HCC (adjusted HR [aHR] = 1.30; 95% CI: 0.94-1.80). Stratification revealed that diabetes mellitus (DM) conferred significantly higher risks of both HCC (aHR = 1.63; 95% CI: 1.13-2.34) and DLC (aHR = 2.65; 95% CI: 1.83-3.83) in the CHB+MET group. Hypertension (HP) was most strongly linked to DLC (aHR = 1.65; 95% CI: 1.13-2.41). In the CHB+MAFLD group, DM was significantly associated with HCC (aHR = 6.15; 95% CI: 1.74-21.77). No significant associations were observed for simple fatty liver.

Conclusions: Metabolic dysfunction, particularly diabetes mellitus, significantly increases the risk of adverse hepatic outcomes in CHB patients. DM is a key driver of both HCC and DLC, highlighting the importance of comprehensive metabolic assessment for risk stratification and management optimization in CHB.

E-POSTER ABSTRACTS

1780 - NHSL3 Knockout Enhances Sorafenib Sensitivity by Promoting G1 Phase Accumulation in Huh 7 Hepatocellular Carcinoma Cells

Gökhan Yildiz ¹, Soner Karabulut ²

Karadeniz Technical University Faculty Of Medicine, Medical Biology, Trabzon-Türkiye ¹ Karadeniz Technical University Graduate School Of Health Sciences, Medical Biology, Trabzon-Türkiye ²

Background / Hypothesis: Liver cancer is the sixth most commonly diagnosed cancer worldwide and the third leading cause of cancer-related mortality.

Hepatocellular carcinoma (HCC) accounts for nearly 85% of all liver cancers. One major reason for the poor survival of HCC patients is the high resistance of HCC cells to current chemotherapeutic agents. Sorafenib is the first and most widely used systemic therapy for advanced HCC. Therefore, identifying molecular regulators that influence the treatment response of HCC cells to sorafenib is essential. NHS Like 3 (NHSL3) is upregulated in HCC and correlates with poor clinical outcomes; however, its cellular functions remain unknown. This study aimed to elucidate the roles of NHSL3 in cell cycle regulation in sorafenib-treated and untreated Huh-7 cells.

Materials and Methods: NHSL3 knockout (KO) Huh-7 cells were generated using the CRISPR/Cas9n method. Cell viability was measured using the WST-1 assay, and half-maximal inhibitory concentration 50 (IC50) values were calculated. Cell cycle phase distribution was assessed via propidium iodide (PI) staining. Levels of key cell cycle regulatory proteins were analyzed by Western blotting.

Results: Following 24 hours of sorafenib treatment, IC50 values were 13.39 μ M for control Huh-7 cells and 5.81 μ M for NHSL3 KO cells, indicating a 2.3-fold increase in sorafenib sensitivity in NHSL3 KO cells. Treatment with 5 μ M sorafenib for 24 hours increased the G1 phase population from 55% to 74% in control cells, and from 64% to 84% in NHSL3 KO cells ($p < 0.0001$ for all). Sorafenib also reduced the S phase population from 38% to 18% in control cells and from 28% to 10% in NHSL3 KO cells ($p < 0.0001$ for all). Western blot analyses revealed that sorafenib-treated NHSL3 KO cells exhibited significant upregulation of phosphorylated (p)-CHK2 (Thr68) and p-WEE1 (Ser642) ($p < 0.0001$ for both). In contrast, levels of p-CDK1 (Tyr15) ($p = 0.02$), Cyclin E2 ($p = 0.0002$), Cyclin A2 ($p < 0.0001$), and Cyclin B1 ($p < 0.0001$) were markedly reduced in sorafenib-treated NHSL3 KO cells relative to control cells.

Conclusions: These findings suggest that NHSL3 functions as a potential oncogenic regulator in HCC by contributing to sorafenib resistance. Loss of NHSL3 enhances G1 phase accumulation through downregulation of Cyclin E2/A2/B1 and activation of the CHK2-WEE1-CDK1 regulatory axis, supporting the concept that targeting NHSL3-driven signaling may improve therapeutic sensitivity and provide a basis for developing new treatment strategies in HCC.

1784 - Whole Exome Sequencing Identifies PNPLA3 and Rare ABCC8 Variants as Genetic Risk Factors for Metabolic Dysfunction-Associated Steatotic Liver Disease in South Asians

Dr. Asma Shabbir ¹, Dr. Ambrina Khatoon ², Prof.

Zaigham Abbas ³, Prof. Talat Mirza ⁴

Ziauddin University & Jinnah Sindh Medical University, Pathology, Karachi-Pakistan ¹ Ziauddin University, Molecular Medicine, Karachi-Pakistan ² Ziauddin University, Gastroenterology & Hepatology, Karachi-Pakistan ³ Ziauddin University, Research, Karachi-Pakistan ⁴

Background / Hypothesis:

Non-alcoholic fatty liver disease (NAFLD), recently redefined as metabolic dysfunction-associated steatotic liver disease (MASLD), is reported to have a prevalence of 30.05%. It is a multifactorial disease where genetic predisposition plays a significant role in individual susceptibility. In this study, we aim to identify pathogenic variants contributing to MASLD in a Pakistani South Asian cohort, followed by their validation in an expanded dataset.

Materials and Methods:

A total of 200 individuals with NAFLD were meticulously selected. The study involved a comprehensive clinical evaluation, including detailed medical history, ultrasound examinations, laboratory investigations, and transient elastography. Furthermore, a case-control analysis was carried out, with six cases selected from the NAFLD cohort and six controls identified from the general population. Whole blood from all the participants ($n=12$) was collected for DNA extraction, and whole-exome sequencing (WES) was employed. Bioinformatics analysis involved alignment of sequences with the human reference genome GRCh38 (hg38) using the Burrow-Wheeler aligner software, Genome Analysis Toolkit, and the

E-POSTER ABSTRACTS

SnEff tool. Variant interpretation and classification adhered to the American College of Medical Genetics guidelines. Furthermore, various prediction tools were applied, and candidate variants were identified. This was followed by a validation phase where the identified variants were subsequently validated in 52 MASLD patients by Sanger sequencing and compared with 96 ethnically matched controls from the Punjabi Pakistani (PJL) cohort of the 1000 Genomes Project. Statistical analyses were conducted using SPSS version 28.

Results:

ClinVar analysis showed the following common variants: SUMO4 (rs237025), PRKCQ (rs2236379) & MBL2 (rs1800450). Further, two variants in the validation cohort showed a significant association with MASLD

PNPLA3 rs738409: The G allele had a minor allele frequency (MAF) of 0.47 in MASLD cases compared to 0.20 in the PJL cohort ($p=0.001$). The GG genotype was present in 34.6% of cases and 7.3% of the PJL cohort, showing a strong association with disease risk. GC heterozygotes were similarly distributed in both groups.

- ABCC8 rs146378237: The T allele had a MAF of 0.36 in MASLD cases but was absent in all PJL cohort (MAF=0). The TT genotype was seen in 19.2% of cases, and TC in 34.6%, indicating a potentially rare but high-penetrance association.

Conclusions: This study reaffirms the role of PNPLA3 and highlights a novel potential association with ABCC8 rs146378237 in MASLD. The marked enrichment of these variants in cases compared to reference controls underscores the importance of integrating common and rare variants in understanding MASLD susceptibility in Pakistani South

Keyword(s) : MASLD, PNPLA3, ABCC8, whole exome sequencing

1786 - Environmental Risk Factors and Comorbidity Profiles Associated With Autoimmune Hepatitis in Korea A Nationwide Case-Control Study

Kyung-ah Kim ¹, Hwa Young Choi ²

Inje University Ilsan Paik Hospital, Internal Medicine, Goyang-South Korea ¹ Graduate School Of Cancer Science And Policy, National Cancer Center, Cancer Control And Policy, Goyang-South Korea ²

Background/hypothesis: Autoimmune hepatitis (AIH) is a chronic immune-mediated liver disease with poorly understood environmental and clinical triggers. This

study aimed to evaluate infectious exposures, medication-related risks, and comorbidity patterns associated with AIH using a nationwide Korean database.

Materials and Methods: In this population-based case-control study, 10,081 patients with incident AIH were matched to 201,620 controls. We analyzed (1) infectious diseases within 1 year before AIH diagnosis, (2) medication exposures within 6 months, and (3) lifetime comorbidities. Differences were assessed using proportions, p-values, and Cohen's h effect sizes.

Results: AIH patients had significantly higher rates of recent infections, including acute hepatitis A (1.32% vs. 0.02%), hepatitis B (0.31% vs. 0.04%), and hepatitis C (0.30% vs. 0.01%). COVID-19 and influenza were also modestly more frequent. Toxic/drug-induced hepatitis (DILI) was markedly more common (16.97% vs. 0.31%; $h=0.74$). Several medications were more commonly used in AIH patients, including statins, amoxicillin-clavulanate, TNF- α inhibitors, interferons, fimasartan, and IV methylprednisolone. AIH cases exhibited a substantially higher burden of autoimmune comorbidities: hypothyroidism (25.95% vs. 15.42%), systemic lupus erythematosus (4.58% vs. 0.12%), sicca syndrome (8.32% vs. 1.23%), rheumatoid arthritis, systemic sclerosis, and inflammatory bowel disease. Strong associations were seen with primary biliary cholangitis (10.26% vs. 0.03%; $h=0.62$) and primary sclerosing cholangitis. Metabolic diseases such as diabetes (39.71% vs. 32.22%) were also more prevalent.

Conclusions: AIH in Korea is associated with increased rates of preceding infections, greater exposure to hepatotoxic medications, and a broad spectrum of autoimmune comorbidities. These findings provide insight into potential environmental and clinical factors related to AIH and may help refine future research on its pathogenesis.

1787 - Metagenomic Study on Adult Cases of Hepatitis of Unknown Etiology No Consistent Novel Pathogen Identified Amidst Highly Heterogeneous Viral Communities

Xinxin Li ¹, Yao Xie ¹, Minghui Li ¹

Beijing Ditan Hospital, Capital Medical University, Beijing, Beijing-China ¹

Background / Hypothesis: To conduct unbiased

E-POSTER ABSTRACTS

pathogen screening and microbial community characterization in adult patients with hepatitis of unknown etiology using metagenomic approaches, aiming to identify novel or underexplored pathogenic agents.

Materials and Methods: This study enrolled 49 patients with rigorously excluded known etiologies. Fifty-nine samples (44 plasma, 15 stool) were subjected to ultra-multiplex targeted RNA sequencing (covering 139 RNA viruses) and metagenomic sequencing. Pathogen profiles and viral community structures were systematically analyzed through a bioinformatics pipeline.

Results: Targeted sequencing detected hepatitis C virus in one sample, while none of the remaining samples revealed predefined RNA viruses. Metagenomic analysis identified no novel or rare pathogenic virus consistently enriched across patients. Goose circovirus and influenza A virus were sporadically detected, with the former showing high homology to avian-derived strains but no significant case enrichment, and the latter presenting only as a low-titer singleton. Both exhibited ambiguous causal relationships with hepatitis. Viral community profiling demonstrated significant divergence between plasma and stool samples, revealing niche-specific patterns.

Conclusions: Our study failed to identify a unifying pathogenic agent in this adult hepatitis cohort, suggesting a heterogeneous etiological landscape potentially involving unknown pathogens, host immune responses, and environmental interactions.

Keyword(s) : Hepatitis of unknown etiology, Metagenomics, Viruses, Goose circovirus, Influenza A virus

1788 - Yinchenhao Decoction Suppresses Metabolic Associated Fatty Liver Disease Inflammatory Injury by Regulating Monocyte Superoxide Metabolism

Xinting Li ¹, Yaru Liu ¹, Pingping Yao ¹, Yiyang Hu ¹, Yu Zhao ¹

Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Institute Of Liver Diseases, Shanghai, China ¹

Background / Hypothesis: Yinchenhao Decoction (YCHT), a classic traditional Chinese medicine formula for damp-heat (DH) syndrome, was investigated for its regulatory effects on peripheral monocytes in metabolic-associated fatty liver disease (MAFLD) patients with DH syndrome.

Materials and Methods: We retrospectively analyzed clinical data from 367 MAFLD patients. Single-cell RNA sequencing of peripheral blood mononuclear cells (PBMCs) from DH syndrome patients revealed distinct monocyte metabolic patterns. In vitro, THP-1 cells stimulated with LPS and IFN- γ were treated with YCHT to assess its effects on inflammation and mitochondrial oxidative stress. A high-fat high-sugar (HFHS) diet-induced MASH mouse model was used to evaluate YCHT's therapeutic effects, with monocyte-derived macrophages (MoMFs) detected by flow cytometry.

Results: MAFLD patients with DH syndrome showed significantly higher serum ALT levels. Their monocytes were enriched in inflammatory response pathways and exhibited active ROS production. In vitro, YCHT dose-dependently suppressed the elevation of IL-1 β , CCL2, IL-6, and TNF- α in THP-1 cells, corrected TLRs-MYD88 pathway activation, reduced ATP and ROS levels, and increased SOD activity. In HFHS-fed mice, YCHT treatment reduced body weight, liver NAS scores, hepatic TG content, and serum ALT levels. It also decreased hepatic expression of IL-1 β , IL-6, IFN- γ , and Ccl-2, accompanied by reduced recruitment of F4/80+ macrophages and MoMFs.

Conclusions: YCHT ameliorates MAFLD inflammatory injury in DH syndrome by correcting peripheral monocyte hyper-oxidative metabolism, inhibiting monocyte migration to the liver, and reducing subsequent liver damage.

1789 - Correlation Between Liver Stiffness and Cognition in MASLD Patients Based on MRE and Neurovascular Coupling Assessment

Zhuoru Jiang ¹, Bing Zhang ¹, Qian Chen ¹, Jun Chen ¹, Jie Li ²

Nanjing Drum Tower Hospital, Radiology, Nanjing-China ¹ Nanjing Drum Tower Hospital, Infectious Diseases, Nanjing-China ²

Background / Hypothesis: Metabolic dysfunction-associated steatotic liver

E-POSTER ABSTRACTS

disease (MASLD) has emerged as the leading cause of chronic liver disease in younger adults. Alarming, MASLD may disrupt brain function even without cirrhosis. Magnetic resonance elastography (MRE), a non-invasive imaging technique that quantifies liver stiffness with high precision, has revolutionized hepatic fibrosis assessment. However, the neurological implications of liver stiffness measured by MRE in non-cirrhotic young MASLD patients remain unclear. This study aimed to characterize the impact of non-cirrhotic MASLD with elevated liver stiffness on brain health using multimodal neuroimaging techniques.

Materials and Methods:

This was a prospective cohort involving 78 MASLD outpatients without cirrhosis [median age 26 years, (18-33)]. Using the Mayo criteria defining 2.5 kPa as the threshold for normal liver or inflammation, patients were stratified by MRE into low liver stiffness (LLS, $MRE < 2.5$ kPa, $n=38$) and high liver stiffness (HLS, $MRE \geq 2.5$ kPa, $n=40$) groups using a cutoff of 2.5 kPa in MRE. Participants underwent neuropsychological assessments, hepatic MRE, and multimodal brain magnetic resonance imaging (MRI), including resting-state fMRI and arterial spin labeling (ASL) for cerebral blood flow (CBF) and regional homogeneity (ReHo) analyses. Neuroimaging data were processed using SPM12, with voxel-wise comparisons and global CBF-ReHo coupling analyses. Statistical analyses included t-tests and nonparametric methods, adjusted for age and education.

Results:

Forty MASLD patients with high liver stiffness (HLS; $MRE \geq 2.5$ kPa) and 38 age-, gender-, and education-matched patients with low liver stiffness (LLS; $MRE < 2.5$ kPa) underwent resting-state fMRI. Global neurovascular coupling was evaluated by examining across-voxel correlations between CBF and ReHo, whereas regional coupling was assessed using the CBF/ReHo ratio. Compared to LLS, HLS patients exhibited significantly reduced global CBF-ReHo coupling ($p=0.044$) and regionally elevated CBF/ReHo ratios in the right temporal pole: superior temporal gyrus (TPOsup). Crucially, these abnormalities were undetectable by unimodal CBF or ReHo analyses. In HLS patients, higher CBF/ReHo ratios were significantly associated with more pronounced clinical deficits and accelerated cognitive decline. Furthermore, HLS

patients showed decreased functional connectivity between the left superior temporal gyrus and right TPOsup.

Conclusions:

These findings reveal novel neurovascular coupling disruptions in non-cirrhotic MASLD patients with elevated liver stiffness (≥ 2.5 kPa), providing insights into associated neuropathological mechanisms.

Keyword(s) : Metabolic dysfunction-associated steatotic liver disease, resting-state functional magnetic resonance imaging, neurovascular coupling, magnetic resonance elastography

1790 - Prognostic utility of the Ammonia to ULN ratio (AMM ULN) for predicting 28 day mortality and liver related complications in hospitalized patients with decompensated cirrhosis.

Nikhil Nagre¹, Pabitra Sahu¹, Premashis Kar¹
Max Superspecialty Hospital, Medical Gastroenterology, Ghaziabad-India¹

Background / Hypothesis: Short-term risk stratification in hospitalized patients with decompensated cirrhosis remains difficult, and routinely available prognostic scores do not fully capture metabolic contributors such as hyperammonemia. Although ammonia plays a key role in the pathophysiology of hepatic decompensation, its clinical prognostic use is not standardized. This study was designed to evaluate the predictive performance of the ammonia-to-upper-limit-of-normal ratio (AMM-ULN) for 28-day mortality and major liver-related complications, and compared it with MELD-Na and Child-Turcotte-Pugh (CTP).

Materials and Methods: A prospective observational study was conducted on 96 adults hospitalized with decompensated cirrhosis. Baseline venous ammonia was standardized using the institutional ULN (118 $\mu\text{mol/L}$) to derive the AMM-ULN ratio. Outcomes assessed over 28 days included mortality and key complications—hepatic encephalopathy (HE), variceal bleeding (VB), ascites, coagulopathy, and spontaneous bacterial peritonitis (SBP). Optimal cut-off for mortality prediction was identified using the ROC-Youden index. Associations were evaluated using Mann-Whitney U tests and logistic regression (univariable and adjusted for age, MELD-Na, and CTP). Discriminative performance was assessed using ROC-AUC.

E-POSTER ABSTRACTS

Results: Among 96 included patients, the 28-day mortality rate was 16.7%. Median AMM-ULN was 1.47 (IQR 1.06–2.07). Non-survivors had significantly higher AMM-ULN values compared with survivors (1.64 vs. 1.39). ROC analysis identified an optimal AMM-ULN cut-off of 1.48 ($\approx 175 \mu\text{mol/L}$), yielding 75% sensitivity and 56% specificity. AMM-ULN demonstrated an AUC of 0.72, outperforming CTP (0.63) and showing slightly better discrimination than MELD-Na (0.69). Each 0.5-unit rise in AMM-ULN increased mortality odds (OR 2.46; 95% CI 1.38–4.38; $p=0.002$), remaining independently predictive after adjustment (adjusted OR 2.12; 95% CI 1.07–4.19; $p=0.032$). Higher AMM-ULN values were significantly associated with HE ($p<0.01$), VB, ascites, coagulopathy (all $p<0.05$), and SBP on univariable analysis, with independent associations confirmed where complete-case analysis permitted.

Conclusions: AMM-ULN is a simple, inexpensive biomarker that independently predicts short-term mortality and major complications in decompensated cirrhosis. A cut-off of 1.48 effectively identifies high-risk patients. Its prognostic performance is comparable to MELD-Na and superior to CTP, supporting its integration into early inpatient triage and risk-stratification pathways. Overall, AMM-ULN consistently predicted mortality and major complications, highlighting its value as a simple and effective biomarker.

Keyword(s) : cirrhosis, mortality, Ammonia-to-ULN ratio, liver-related complications

1791 - Formulation of the second viral hepatitis action plan in Hong Kong carrying forward the achievements for final push towards elimination

Bonnie Chun Kwan Wong¹, Zenith Hin Yam Wu¹, Chin Man Poon¹

Department Of Health, Special Preventive Programme, Hong Kong-Hong Kong SAR, China¹

Background / Hypothesis:

In Hong Kong, about 5.6% of the population, amounting to 410000 people, have hepatitis B, which is associated with about 80% of the local liver cancer cases. Among people with hepatitis B, 40% remained undiagnosed and 70% did not have any medical follow-up. Since the launch of the inaugural Hong Kong Viral Hepatitis Action Plan 2020-2024, a comprehensive set of initiatives has been implemented to strengthen the prevention and control of viral hepatitis and lay a solid foundation towards

eliminating its public health threat. To carry forward this momentum, the second action plan will be promulgated in 2025, with a view to further lowering viral hepatitis-related morbidity and mortality in Hong Kong, especially liver cancer.

Materials and Methods:

Since the establishment of the Steering Committee on Prevention and Control of Viral Hepatitis (SCVH) in 2018, regular meetings have been held to advise the Government on the overall policy, targeted strategies and effective resource allocation related to the prevention and control of viral hepatitis. Membership comprised representatives of academia, experts in different medical specialties, public healthcare providers and the Government. With valuable advice from the SCVH, the second Hong Kong Viral Hepatitis Action Plan 2025-2030 is formulated.

Results:

In the Action Plan 2025-2030, priority actions have been developed along four strategic axes, namely heightening awareness, tracking health sector response, preventing new infections and expanding access to screening, care and treatment. The most prominent initiative would be the roll-out of a new programme to subsidise population-based hepatitis B screening for groups with higher risk of infection, coupled with an enhancement facilitating management of adult patients with chronic hepatitis B (CHB) in primary care. Public awareness campaigns and professional training for healthcare workers would be launched to support the screening and management of hepatitis B in primary care level. For prevention, sustaining and maintaining high coverage of preventive measures against mother-to-child transmission of HBV would be the key to realise a hepatitis B-free generation.

Conclusions:

In view of the substantial size of population affected by hepatitis B in Hong Kong, empowering the community and primary care for screening and management of stable CHB patients would be critical to address the capacity constraints of specialist care and avoid system overload. The new programme would enable early identification of people with hepatitis B in the community and early treatment for CHB to reduce the risk of complications, thereby progressing towards the global targets of diagnosis and treatment coverage.

1792 - Undiagnosed Metastatic Hepatocellular Carcinoma presenting as Breast Mass in an Adult Male A Case Report

Emerald T. Gersava¹, Jovonie B. Cacal¹

Veterans Memorial Medical Center, Internal Medicine - Section Of Gastroenterology, Quezon City-Philippines¹

Background: Breast cancer among males is rare and accounts for only ~1% of all cases. Metastasis to the breast is rarer even in both sexes especially those arising from extramammary tissues. This case presents a first-ever report of hepatocellular carcinoma (HCC) metastatic to the breast in a male patient in the Philippines.

Case Presentation: A 68-year-old hypertensive male, heavy smoker and chronic alcohol drinker, consulted for a two-month history of an enlarging left breast mass. Physical examination showed a non-movable, hard left breast mass (~5x4 cm), icterisia, abdominal distention with positive fluid wave test, and jaundice. Breast ultrasound revealed an irregular, non-movable mass with macrocalcifications. A core-needle biopsy and histopathology confirmed results consistent with malignancy. Immunohistochemical staining was positive for Glypican-3 and HepPar1, congruent with metastatic carcinoma of hepatic origin. Further work-up disclosed elevated AFP levels, negative viral hepatitis serology, and ascitic fluid analysis compatible with portal hypertension from liver cirrhosis. Palliative treatment was initiated, however, worsening infection led to the patient's deterioration and subsequent demise.

Discussion: Hepatocellular carcinoma, often linked to chronic liver disease and cirrhosis, commonly metastasizes to the lungs, lymph nodes, and bones. Metastatic breast cancer from HCC is extraordinarily unusual with less than ten reported cases worldwide in both sexes, two (2) of which are male. Management of breast metastasis from HCC is often confounded by undiagnosed chronic liver disease. Thorough history and physical examination, balanced with appropriate interpretation of laboratory tests are important resources. Treatment options are limited which include systemic chemotherapy, radiotherapy, supportive and symptomatic treatment. Prognosis is poor with majority of patients dying within a year of diagnosis.

Conclusion: This case emphasizes the critical

importance of vigilance for rare malignancies in atypical patient populations. It highlights the need for prompt and comprehensive diagnostic evaluations for early interventions to improve patient outcomes in metastatic HCC.

Keyword(s) : Hepatocellular carcinoma (HCC), breast metastasis, breast mass

1793 - Effectiveness and Safety of 96 Week Tenofovir Amibufenamide in Patients with Hepatitis B Virus Related Hepatocellular Carcinoma A Retrospective Real World Study

Yuehang Wang¹, Ruyue Chen¹, Xuejing Yu¹, Zhuangzhuang Zhai¹, Qinglei Zeng¹

The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases, Zhengzhou-China¹

Background / Hypothesis:

Currently, there is a lack of data on the effectiveness and safety of tenofovir amibufenamide (TMF) for patients with hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC) in real-world settings. The aim of this study was to evaluate the 96-week real-life effectiveness and safety profiles of TMF in patients with HBV-related HCC.

Materials and Methods:

This retrospective study enrolled HBV-related HCC patients who underwent antiviral treatment with TMF (25 mg/day) or entecavir (ETV) (0.5 mg/day) following HCC surgery at four hospitals in Henan Province, China, from August 2018 to November 2025. The primary endpoint was HBV DNA undetectable (less than 10 IU/mL) rate at week 96. The secondary endpoints included the rate of alanine aminotransferase (ALT) normalization, changes in lipid profile dynamics at 96 weeks, and short-term survival rate, with comparisons between the two groups.

Results:

A total of 80 patients were enrolled, with 40 patients in the TMF group and 40 in the ETV group. Baseline characteristics were as follows: the mean age was 56.8 ± 12.6 years in the TMF group and 54.6 ± 8.7 years in the ETV group ($P = 0.357$); baseline HBV DNA levels were $1.65 \pm 1.66 \log_{10}$ IU/mL vs. $0.08 \pm 0.35 \log_{10}$ IU/mL ($P = 0.164$); and ALT levels were 32.60 (21.40, 44.25) U/L vs. 29.50 (18.50, 43.75) U/L ($P = 0.613$). At 96 weeks of treatment, the HBV DNA undetectable rates were 85.0% (95% confidence interval [CI], 74.0% to 96.1%) in the TMF group versus 95.0% (95% CI, 88.25% to 100%) in the ETV group ($P = 0.136$), the ALT normalization rate was significantly higher in the TMF group than that in the ETV group (92.5% [95% CI,

E-POSTER ABSTRACTS

84.3% to 100%] vs. 90.0% [95% CI, 80.7% to 99.29%], $P = 0.692$). In terms of lipid profile, The intra-group comparison showed that the high-density lipoproteins level in the ETV group decreased compared to baseline (-6.14 [-6.14, 0.23], $P = 0.07$), with no statistically significant difference from baseline in the TMF group. Additionally, during the 96-week follow-up of ETV or TMF treatment, there were 2 deaths in the TMF group and 5 deaths in the ETV group ($P = 0.235$).

Conclusions:

This study demonstrate that TMF exhibits favorable effectiveness and safety in the treatment of HBV-related HCC patients; notably, TMF showed a better lipid profile compared to ETV. Further large-scale studies are needed to confirm these findings.

1794 - Ferulic acid loaded liposomes mitigate Hepatic Ischemia Reperfusion Injury in a rat model associated with Liver Transplantation via altering apoptosis mitochondrial function and TLR 4 NF B NLRP3 inflammatory pathway

Deepika Singh¹

Sihass, Department Of Pharmaceutical Sciences, Allahabad-India¹

Background / Hypothesis: Hepatic ischemia-reperfusion (I/R) injury is a significant challenge in liver transplantation, leading to severe oxidative stress, inflammation, and hepatocellular damage. Effective therapeutic interventions are necessary to improve transplant success and reduce post-transplant complications. In this study, we investigated the protective effects of ferulic acid-loaded liposomes (FA-LPs) against hepatic I/R injury in a rat model that is associated with liver transplantation. FA, a natural phenolic compound with potent antioxidant and anti-inflammatory properties, was encapsulated in liposomes to enhance its bioavailability and targeted delivery to liver tissues.

Materials and Methods:

Ferulic acid-loaded liposomes were fabricated and characterized using sophisticated instrument. RAW 264.7 cells under the hypoxia/reoxygenation model were used and treated with FA-LPs at 1, 10, and 20 M. All the rats were split into five groups and given FA-LPs (3, 6, 9 mg/kg b.w.) for 14 days and then underwent a liver transplant. Using liver enzymes, cytokine status, hepatocyte death level, TUNEL, neutrophil and pro-

inflammatory cytokines protein, and mRNA expression, the potential of FA-LPs against hepatic ischemia-reperfusion injury were estimated.

Results:

Our findings demonstrated that FA-LPs effectively attenuated liver injury by modulating inflammatory pathways and reducing oxidative damage. Histopathological analysis revealed significant reductions in hepatocellular necrosis, inflammatory cell infiltration, and tissue damage in FA-LP-treated rats compared to untreated controls. Biochemical assessments showed that FA-LPs significantly lowered serum levels of liver injury markers, including alanine aminotransferase (ALT) and aspartate aminotransferase (AST) while enhancing antioxidant enzyme activity. Additionally, FA-LPs suppressed the expression of pro-inflammatory cytokines such as TNF- α , IL-6, and IL-1 β , while upregulating anti-inflammatory mediators. Mechanistically, FA-LPs exerted their protective effects by inhibiting NF- κ B signaling and reducing oxidative stress through the activation of the Nrf2/HO-1 pathway. These molecular interactions contributed to reduced hepatocyte apoptosis and improved mitochondrial function, thereby preserving liver architecture and function post-transplantation. It also reduced TLR-4, p-IB, p-IKK, p-IKK, NLRP3, p-P65MyD88, TNF- α , cleaved caspase-1, IL-1, IL-6 and IL-18.

Conclusions: Overall, our study highlights FA-LPs as a promising nanotherapeutic strategy for mitigating hepatic I/R injury in liver transplantation. By leveraging their anti-inflammatory and antioxidant properties, FA-LPs offer a potential approach to improve liver graft survival and patient outcomes. Further studies and clinical evaluations are warranted to explore their translational potential in liver transplant medicine.

1795 - Turning the Tide Successful Management of a Complicated Case of Acute on Chronic Liver Failure with Double Plasma Molecular Adsorption System

Emerald T. Gersava¹, Ruth Ursula C. Cinco¹

Veterans Memorial Medical Center, Internal Medicine - Section Of Gastroenterology, Quezon City-Philippines¹

E-POSTER ABSTRACTS

Background: Acute-on-chronic liver failure (ACLF) is a distinct syndrome among patients with chronic liver disease (CLD) who had a sudden hepatic decompensation involving one or more organs. Liver support systems such as the double plasma molecular adsorption system (DPMAS) are emerging treatment modalities for patients with ACLF while awaiting liver transplantation. We present a case of alcoholic hepatitis that triggered ACLF complicated by infections and variceal bleeding in a young adult patient.

Case Presentation: A 39-year-old Canadian male, heavy alcohol drinker with a three-year history of cirrhosis, presented with progressive jaundice. Physical examination revealed ictericia, ascites, and jaundice. Laboratory work-up showed hyperbilirubinemia, coagulopathy, an AST:ALT ratio of 4, and a MELD-Na score of 33—findings consistent with severe alcoholic hepatitis. Steroid therapy was initiated. Further evaluation revealed spontaneous bacterial peritonitis (SBP) on ascitic fluid analysis and amoebiasis on fecalysis; appropriate antibiotics were started. The patient subsequently developed variceal bleeding, for which endoscopic variceal ligation was performed. Despite these interventions, his clinical condition deteriorated with development of encephalopathy West-Haven Grade 2-3, acute kidney injury, and further increase in INR and bilirubin trends. Hence, the diagnosis of ACLF was entertained. He underwent two sessions of DPMAS, resulting in significant clinical and biochemical improvement and eventual discharge.

Conclusions: This case underscores the critical significance of a multidisciplinary approach in the diagnosis and management of ACLF and highlights the potential role of DPMAS. It emphasizes the need for prompt and comprehensive diagnostic evaluation and timely interventions to improve outcomes in patients with ACLF.

Keyword(s) : case report, Acute-on-chronic liver failure, DPMAS, hepatic failure

1796 - A novel flavonoid Galangin modulates hepatic ischemia–reperfusion injury and regulates TLR 4 NF κ B NLRP3 inflammatory pathway following orthotopic liver transplants in rat models.

Deepika Singh ¹

Sihas, Department Of Pharmaceutical Sciences, Allahabad-India ¹

Background / Hypothesis: Hepatic ischemia can result in

metabolic issues and an inflammatory milieu inside the liver, which may produce early graft malfunction, hepatic pathological damage, apoptosis, or rejection of the graft. In this study, we used orthotopic liver transplant rat models to examine the possibility of flavonoid Galangin in alleviating hepatic IRI and its underlying causes.

Materials and Methods:

We performed orthotopic liver transplantation using a novel magnetic anastomosis approach. Following liver transplantation, hepatic IRI rat models were treated with intraperitoneally 10–20 and 30 mg b.w. of Galangin. Western blotting, qRT-PCR, terminal deoxynucleotidyl transferase dUTP nick-end labeling staining, hematoxylin–eosin staining, immunosorbent assay, qRT-PCR, and hepatic and non-hepatic parameters were used to analyze the impact of Galangin on hepatic IRI. Oxidative stress profile and proinflammatory cytokines were also evaluated. **Results:** Galangin significantly reduces liver function levels (AST, ALP, ALT, and AFP) and serum levels of proinflammatory cytokines (IL-1, IL-18, and TNF- α) in rats following liver transplantation. It also attenuates hepatocyte apoptosis and reduces histopathological changes (degree of coagulation necrosis, architectural anomalies, and hepatocyte vacuolization), according to our in vivo assays. Furthermore, Galangin attenuates the inflammatory response and neutrophil infiltration (IL-1 β , IL-18, IL-6, TNF- α , Ly6G and CD11b, and macrophage M2 polarization) caused by hepatic IRI and decreased the expression of TLR-4/NF- κ B/NLRP3 inflammatory pathway related proteins in rats following liver transplantation (TLR-4, MyD88, p-IKK α , p-IKK β , p-IKK, p-IkB α , p-P65, NLRP3, ASC, Cleaved caspase-1, IL-1 β , IL-18, TNF- α and IL-6). **Conclusions:** Our research demonstrated that Galangin suppresses hepatic inflammatory response after liver transplantation via modifying the TLR-4/NF- κ B/NLRP3 inflammatory pathway.

1797 - Stellate Cell-Derived Complement Component 7 as a Determinant of Fibrosis Progression and Liver Related Events in MASLD An Integrated Multi Omics Study

Naoyuki Fujimori ¹, Takefumi Kimura ², Shohei Kondo ², Takanobu Iwadare ², Naoki Tanaka ³
Shinshu-ueda Medical Center, Gastroenterology, Ueda-

E-POSTER ABSTRACTS

Japan ¹ Shinshu University School Of Medicine, Gastroenterology, Matsumoto-Japan ² Shinshu University, Biomedical Scien, Matsumoto-Japan ³

Background / Hypothesis:

Risk assessment in metabolic dysfunction-associated steatotic liver disease (MASLD) still relies on surrogate markers that do not adequately predict clinically meaningful outcomes, particularly liver-related events (LREs). We aimed to discover a mechanistically relevant biomarker that reflects both fibrogenic activity and future clinical risk through an integrative multi-omics approach.

Materials and Methods:

Transcriptomic and plasma proteomic screens were jointly analyzed in biopsy-proven MASLD to identify fibrosis-associated candidate markers. Findings were examined in an independent vibration-controlled transient elastography (VCTE) cohort. Spatial transcriptomics, single-nucleus RNA sequencing, and RNAscope in situ hybridization were employed to determine hepatic cellular origins. Functional significance was evaluated through siRNA-mediated knockdown in LX-2 hepatic stellate cells (HSCs). LRE risk was assessed using Cox regression and Kaplan-Meier analysis.

Results:

Complement component 7 (C7) emerged as one of the most strongly upregulated molecules across omics layers. Spatial mapping and snRNA-seq localized C7 expression predominantly to activated HSCs within fibrotic niches, whereas endothelial-cell expression was reduced in MASLD. Serum C7 levels rose proportionally with fibrosis stage and liver stiffness across cohorts. A serum threshold of ≥ 140 $\mu\text{g/mL}$ identified individuals at markedly higher risk for LREs. This threshold remained independently predictive after adjustment (HR 4.5). C7 demonstrated superior diagnostic ability for LREs (AUROC 0.90), outperforming FIB-4, autotaxin, APRI, and AAR. In vitro C7 silencing attenuated expression of key extracellular matrix genes (LAMA2, LAMB1, COL6A3), supporting its direct contribution to fibrogenic remodeling.

Conclusions:

C7 represents a mechanistically validated biomarker that captures both fibrotic burden and LRE risk in MASLD. Its stellate cell-specific induction and functional involvement in extracellular matrix regulation suggest utility for clinical stratification and potential therapeutic targeting.

1801 - Fibrotic Burden in Metabolic Dysfunction associated Steatotic Liver Disease Identifies Cardiovascular and Mortality Risk in Type 2 Diabetes

Tae Seop Lim ¹, Sujin Kwon ¹, Sunga Bae ¹, Hye Yeon Chon ¹, Seol A Jang ¹, Ja Kyung Kim ¹, Chul Sik Kim ¹, Seok Won Park ¹, Kyoung Min Kim ¹
Yonsei University College Of Medicine, Yongsin Severance Hospital, Internal Medicine, Yongsin-si-South Korea ¹

Background / Hypothesis: Metabolic dysfunction-associated steatotic liver disease (MASLD) frequently coexists with type 2 diabetes, but its added impact on cardiovascular disease (CVD) and mortality, and whether fibrosis assessed by the fibrosis-4 (FIB-4) index improves risk prediction, remain unclear. We evaluated the associations of MASLD and fibrosis severity with incident CVD and all-cause mortality in adults with type 2 diabetes.

Materials and Methods: We analyzed 30,330 UK Biobank participants with type 2 diabetes without prevalent CVD. MASLD was defined by fatty liver index ≥ 60 . The FIB-4 index was categorized as low (<1.3), indeterminate ($1.3-2.67$), or high (>2.67).

Results: Over a median follow-up of 13.6 years, 6,402 incident CVD events and 4,369 deaths occurred. MASLD demonstrated higher crude rates of both CVD and mortality than non-MASLD. After comprehensive adjustment for demographic and metabolic factors, MASLD remained independently associated with all-cause mortality (hazard ratio [HR] 1.16; 95% CI, 1.07–1.26) but not with incident CVD (HR 1.04; 95% CI, 0.98–1.12). Among participants with MASLD, only the high FIB-4 group showed significantly increased CVD risk compared with non-MASLD participants after multivariable adjustment (HR 1.24; 95% CI, 1.04–1.48), while elevated mortality risk persisted across all FIB-4 strata relative to non-MASLD.

Conclusions: Among individuals with type 2 diabetes, MASLD was associated with higher cardiovascular and mortality risk, and fibrosis severity further refined this risk. Incorporating simple fibrosis assessment, such as the FIB-4 index, into diabetes care may enhance clinical risk stratification.

1807 - Increased risk of decompensation in patients with clinically significant portal hypertension awaiting endoscopic variceal screening a metropolitan Australian study

Brandon-joe Cilia ¹, Hannah Nicholas ¹, Neeraj Bhala ¹, Ashok Raj ¹

The Royal Melbourne Hospital And The University Of Melbourne, Gastroenterology And Hepatology, Melbourne-Australia ¹

Background / Hypothesis: The Baveno VII guidelines recommend non-selective β -blockers (NSBBs) for those with chronic liver disease (CLD) and clinically significant portal hypertension (CSPH). In Australia, many centres still perform endoscopy in all patients with cirrhosis. Little data exist on the potential negative impact of time on the waitlist. We investigated the clinical outcomes of patients with cirrhosis awaiting endoscopic variceal surveillance, between those with and without CSPH.

Materials and Methods: Retrospective cohort study of patients with CLD awaiting endoscopic variceal screening at a large tertiary Australian centre, between July 2020 and March 2024. Primary outcomes were hepatic decompensation, liver-related hospitalisation, and liver-related mortality while on the endoscopy waitlist. CSPH was determined noninvasively by ultrasound or elastography prior to waitlisting. Kaplan-Meier curves were constructed, using the log-rank test for significance with two-tailed P values < 0.05. Hazard ratios (HR) with 95% confidence intervals (CI) were also reported using the Mantel-Haenszel method.

Results: Two hundred and thirty-eight patients (170 (71.4%) with CSPH; 68 (28.6%) without CSPH) were included. Median wait time for endoscopy was 18 (IQR 7–44) weeks. CSPH was associated with a higher rate of hepatic decompensation (42.4% versus 8.8%, $P < 0.001$ - primarily due to ascites (HR 3.03, 95% CI 1.73–5.33, $P < 0.001$), hepatic encephalopathy (HR 2.55, 95% CI 1.13–5.76, $P = 0.025$), and variceal bleeding (HR 3.21, 95% CI 1.01–10.21, $P = 0.048$)), liver-related hospitalisation (HR 2.68, 95% CI 1.46–4.91, $P = 0.001$) and liver-related mortality (HR 3.23, 95% CI 1.12–9.31, $P = 0.03$). Of those with CSPH, 33.8% (23 patients) maintained NSBB use during follow-up, with a 63% reduction in liver-related admissions compared to 133 who did not receive NSBBs (HR 0.37, 95% CI 0.015–

0.88, $P = 0.025$). The remaining 14 received NSBB for <30 days. Overall, 167 (70.2%) underwent endoscopy and 46% had oesophageal varices.

Conclusions: Patients with CLD and CSPH had worse liver-related outcomes while awaiting endoscopy compared to those without CSPH. These data support early identification of CSPH and management guided by Baveno VII guidelines, rather than endoscopy for all, with scope for quality improvement projects of the use of NSBB to improve liver outcomes.

1808 - Overshadowed by Immunotherapy Unmasking Chemotherapy Related Hepatic Vascular Injury (SOS Pattern) and Managing Catastrophic Hemorrhage

Xinhua Ren ¹, Ligai Liu ¹, Ying Fan ¹, Qi Wang ¹

Beijing Ditan Hospital, Capital Medical University, The Center For Liver Diseases, Beijing-China ¹

Background:

The integration of immune checkpoint inhibitors (ICIs) with conventional chemotherapy and novel targeted agents treats advanced malignancies, but complicates the diagnosis of drug-induced liver injury (DILI). The primary clinical dilemma involves distinguishing immune-related adverse events (irAEs) from non-immune-mediated hepatotoxicity, specifically vascular pathologies like Sinusoidal Obstruction Syndrome (SOS). In the context of multi-agent regimens, cumulative drug toxicity often results in atypical clinical and radiological phenotypes, complicating diagnosis and management. Furthermore, this multifactorial injury induces severe hepatic parenchymal fragility, which significantly increases the risk of life-threatening hemorrhage during invasive diagnostic procedures. This report highlights the diagnostic conundrum of discordant pathological and radiological findings and underscores the critical role of Transarterial Embolization (TAE) in managing catastrophic hemorrhagic complications.

Case Description:

A 65-year-old male with refractory metastatic squamous cell carcinoma of the head and neck underwent extensive treatment with complex regimens, including Albumin-bound Paclitaxel, Carboplatin, and Pembrolizumab. Following disease progression, he was enrolled in a clinical trial for an investigational targeted

E-POSTER ABSTRACTS

agent (HMPL-453). Shortly after the first cycle, he developed severe DILI, characterized by an ALT surge to 800–1000 U/L and total bilirubin peaking at 98 μ mol/L. Serological testing revealed positive HBsAb, HBeAb, and HBcAb, but HBV DNA remained undetectable, effectively ruling out viral reactivation. Despite this, DILI attribution remained challenging. A percutaneous liver biopsy was performed to clarify the etiology but was complicated by immediate intra-operative hemorrhage. Pathology indicated that SOS could not be excluded. Conversely, subsequent imaging revealed diffuse dilation of Grade III hepatic arteries with increased flow, a finding inconsistent with classic SOS features. Post-discharge, the patient sustained blunt abdominal trauma from a fall, causing liver rupture and catastrophic intraperitoneal hemorrhage. Emergency TAE was successfully employed to arrest the bleeding and stabilize the patient.

Conclusion:

This case exemplifies the extreme challenge of DILI attribution in patients receiving complex, combined therapeutic modalities. The stark discordance between pathology and imaging—where histology suggested SOS-pattern injury while radiology demonstrated compensatory arterial dilation—confirms that multi-drug interactions can yield "chameleon-like" phenotypes. This uncertainty mandates extreme caution against the reflexive diagnosis of irAEs. Moreover, the cumulative chemical insult renders the liver critically vulnerable to mechanical trauma and invasive procedures. Consequently, transjugular liver biopsy (TJLB) should be strongly preferred over the percutaneous route in such high-risk profiles to avoid hemorrhagic events. Finally, this case validates TAE as an indispensable, life-saving rescue intervention for catastrophic hepatic hemorrhage in the oncologic setting.

Keyword(s) : drug-induced liver injury (DILI), chemo-immunotherapy, Sinusoidal Obstruction Syndrome (SOS) -Pattern, Transarterial Embolization (TAE)

1809 - Transcriptomic Deconvolution Characterizes Intrahepatic Neutrophils in On treatment Chronic Hepatitis B Patients with Liver Fibrosis

Wenyue Wu¹, Wen Zhang¹, Hong Li¹, Ziyang Pan¹, Haodong Ma¹, Caihong Wang¹, Yameng Sun¹, Wei Chen¹, Hong You¹

Beijing Friendship Hospital, Capital Medical University, Liver Research Center, Beijing-China¹

Background / Hypothesis:

the dynamics and functional heterogeneity of intrahepatic neutrophils in chronic hepatitis B (CHB) liver fibrosis during antiviral therapy (AVT) remain poorly characterized.

Materials and Methods:

transcriptomic data from 54 liver biopsies collected from 28 patients at baseline, 78 weeks, and 260 weeks of AVT were analyzed, together with single-cell RNA sequencing (scRNA-seq) data from five CHB liver fibrosis patients (GSE186343). Deconvolution approaches were applied to assess temporal changes and phenotypic heterogeneity of intrahepatic neutrophils throughout AVT.

Results:

The intrahepatic neutrophil fraction increased at week 78 of AVT ($P = 0.252$) and reached statistical significance by week 260 ($P < 0.001$), accompanied by persistent decreases in effector CD8⁺T cells, B cells, and natural killer cells. Based on median neutrophil fractions, patients were categorized into Neu-low and Neu-high groups. The Neu-low group exhibited elevated expression of liver fibrosis-specific matrisome gene. Gene set enrichment analysis indicated enrichment of extracellular matrix remodeling, immune response, and cell cycle pathways in the Neu-low group, whereas metabolic pathways were downregulated. Re-analysis of scRNA-seq data from the GSE186343 dataset identified two pro-inflammatory intrahepatic neutrophil subclusters (NEU-C1 and NEU-C3) and one immunosuppressive subcluster (NEU-C2). Notably, the proportion of NEU-C2 was lower in treatment-naïve Neu-low patients but progressively increased during AVT.

Conclusions:

our study reveals that distinct neutrophil subsets undergo dynamic remodeling during long-term AVT, with the expansion of the immunosuppressive NEU-C2 subset potentially restoring intrahepatic adaptive immunity and contributing to immune homeostasis. These findings provide insight into neutrophil-mediated regulation of fibrosis and reveal potential therapeutic targets for CHB patients receiving AVT.

1810 - Regulatory Mechanism of EEF2 lactylation in Calcium Homeostasis Dysregulation of MASLD Hepatocytes

E-POSTER ABSTRACTS

Miaomiao Tian¹, Huiling Cao², Yuzhu Song³, Jianni Qi², Zhen Yang³

Shandong Provincial Hospital Affiliated To Shandong First Medical University, Gastroenterology, Ji Nan-China¹ Shandong Provincial Hospital Affiliated To Shandong First Medical University, Central Laboratory, Ji Nan-China² Shandong Provincial Hospital Affiliated To Shandong First Medical University, Infectious Diseases Department, Ji Nan-China³

Background / Hypothesis:Metabolic dysfunction-associated steatohepatitis (MASLD) ranks among the most prevalent chronic liver diseases of the 21st century. During MASLD progression, disrupted lactate metabolism leads to hepatic lactate accumulation. Our prior research confirmed that lactate promotes hepatic lipid deposition and lipid peroxidation, yet its precise mechanisms in MASLD pathogenesis remain unclear. Furthermore, lipid accumulation within steatotic hepatocytes disrupts intracellular calcium homeostasis, thereby accelerating the progression of metabolic dysfunction-associated steatohepatitis (MASH) and hepatocellular carcinoma. Protein modification omics results indicate that eEF2 undergoes lactylation. Simultaneously, the core calcium homeostasis regulatory axis ($\text{Ca}^{2+}/\text{CaM}$)-eEF2K-eEF2-Thr56 phosphorylation plays a crucial role in maintaining protein translation elongation. However, whether this process reciprocally influences intracellular calcium signaling dynamics remains unclear. Our study demonstrates that eEF2 undergoes both phosphorylation and lactylation modifications during MASLD progression. Therefore, the roles of eEF2 phosphorylation and lactylation in MASLD progression warrant further investigation.

Materials and Methods:Using a palmitic acid (PA)-induced in vivo MASLD mouse model and in vitro cell model to evaluate changes in lactate levels and fatty liver indicators. Simultaneously, intracellular Ca^{2+} levels were measured by flow cytometry. Lactic acid-modified eEF2 protein was identified using immunoprecipitation-mass spectrometry (IP-MS) and immunoprecipitation techniques. Lactic acid modification sites were localized by constructing eEF2 mutant plasmids, and changes in relevant indicators following site mutations were analyzed to validate in vivo and in vitro experimental results.

Results:In PA-induced in vitro MASLD cell models and MASLD mice, lactate levels were significantly elevated. Lactic acid levels positively correlated with fatty liver markers, and lactate production was markedly enhanced in both MASLD models. During MASLD progression, eEF2 underwent simultaneous phosphorylation and lactate production. Treatment with a targeted mutant eEF2 plasmid revealed that site-specific mutations improved hepatic steatosis, lipid peroxidation, and macrophage infiltration by regulating calcium homeostasis.

Conclusions:Taken together, dysregulated lactate metabolism impairs lactate modification of eEF2, thereby disrupting calcium homeostasis remodeling and promoting MASLD progression. The pathological feedback loop "elevated calcium → crosstalk between eEF2-Thr56 phosphorylation and lactylation → insufficient calcium pump translation → worsening calcium homeostasis" reveals a novel "translation-metabolism" cross-talk mechanism in MASLD, providing theoretical support for targeting eEF2 as a therapeutic intervention for MASLD.

Keyword(s) : MASLD; Lactate; eEF2; Lactylation; phosphorylation; Ca^{2+} homeostasis

1811 - Combination with glucocorticoids during artificial liver support system treatment does not improve the survival rate of Acute on chronic liver failure patients A retrospective cohort study

Ta Fuxia Ta¹, Zheng Jianming Zheng¹, Wang Bingyao Wang¹

Huangshan Hospital Fudan University, Infection Disease, Shanghai-China¹

Background / Hypothesis: To investigate retrospectively the efficacy of glucocorticoids in acute-on-chronic liver failure (ACLF) patients receiving artificial liver support system (ALSS) therapy.

Materials and Methods: ACLF patients treated with ALSS were categorized into glucocorticoids-treated group and control group based on whether they receive glucocorticoids treatment. Propensity score matching (PSM) was utilized in a 1:1 ratio to balance baseline characteristics. Subgroups were stratified by the Model for End-Stage Liver Disease (MELD) scores and Chinese Group on the Study of Severe Hepatitis B ACLF 2.0 (COSSH-ACLF 2.0)

E-POSTER ABSTRACTS

scores. Survival outcomes were analyzed by using Kaplan-Meier curves and log-rank tests. Univariate and multivariate analyses identified predictors of 90-day transplant-free survival (TFS).

Results:

From 2014 to 2025, a total of 124 ACLF patients treated with ALSS were included and 100 patients (control: n=50; glucocorticoids: n=50) were matched by PSM. The glucocorticoids group received dexamethasone at an average dose of 5 mg/d before each ALSS procedure. At 90 days, overall survival was comparable between control and glucocorticoids groups (72.0% vs. 67.8%, $p = 0.6636$), with TFS rates of 58.1% versus 67.8% ($p = 0.3553$). Patients with MELD scores > 24 or COSSH-ACLF 2.0 scores > 7.3 exhibited significantly lower 90-day TFS (both $p < 0.0001$). Glucocorticoids treatment failed to show a survival benefit in any subgroup. Overall infections show no statistically significant between control group and glucocorticoids group (36% vs 30%, $p = 0.3912$). In the univariate analysis, neutrophil count, serum creatinine, blood urea nitrogen (BUN), INR, PT, APTT, ALSS procedures, baseline MELD scores > 24 and COSSH-ACLF 2.0 scores > 7.3 were 90-day mortality predictors. Multivariate analysis confirmed that BUN (HR = 1.19, 95% CI = 1.04–1.37, $p = 0.013$), ammonia (HR = 1.02, 95% CI = 1.01–1.03, $p = 0.005$), ALSS procedures (HR = 0.51, 95% CI = 0.32–0.80, $p = 0.003$), and new infections (HR = 3.99, 95% CI = 1.16–13.74, $p = 0.028$) as independent 90-day mortality determinants.

Conclusions:

Glucocorticoids therapy did not improve transplant-free survival in ACLF patients undergoing ALSS. Key prognostic factors included BUN, ammonia levels, and new infections.

Keyword(s) : acute-on-chronic liver failure, artificial liver support system, glucocorticoids, survival

1814 - Weight Reduction and Its Association With CAP and Liver Stiffness in MASLD

Seong Kyun Na¹

Inje University College Of Medicine, Internal Medicine, Seoul-South Korea¹

Background / Hypothesis: The Controlled attenuation parameter (CAP) and the liver stiffness (LS) of transient elastography (TE) are widely used to measure the degree of fatty liver and liver fibrosis. We investigated whether there were significant changes in CAP and LS according to the amount of weight loss in patients with

metabolic dysfunction-associated liver disease (MASLD).

Materials and Methods: The patients with MASLD at Jeju National University Hospital in Korea who had TE tests more than once while losing body weight were analyzed. CAP and LS were compared between the time of the first test and the time of the weight was most lost during the follow-up.

Results: A total of 410 patients were analyzed and 74.6% of patients lost body weight during the follow-up period. The mean age was 51.97 years (standard deviation (SD): 15.10), the mean body mass index (BMI) was 28.71 (SD: 4.21). Patients who lost weight were divided into 5 groups according to the amount of weight loss (WL), and all groups showed significant CAP change (-25.62 in the 0 to 3% WL group, -21.52 in the 3 to 5% WL group, -41.92 in the 5 to 7% WL group, -32.79 in the 7 to 10% WL group, -74.16 in the more than 10% WL group, all p -values < 0.05). The mean LS change by group was +0.75 in the 0 to 3% WL group, -0.30 in the 3 to 5% WL group, +0.40 in the 5 to 7% WL group, -0.40 in the 7 to 10% WL group, -1.31 in the more than 10% WL group, and was significant only in the more than 10% WL group ($p=0.002$). In multivariable analysis, weight change percentage, baseline BMI, and weight loss duration were significantly associated with CAP change, and weight change percentage, baseline BMI, and weight loss duration were significantly associated with LS change.

Conclusions: In patients with MASLD, there was a significant correlation between weight loss and CAP, and LS decreases significantly when weight loss is greater than 10% of baseline body weight.

Keyword(s) : MASLD; weight reduction; controlled attenuation parameters; liver stiffness

1817 - Comparison between Plasma Exchange and Dual plasma molecular adsorption system combined with Plasma Exchange on Acute on Chronic Liver Failure A retrospective cohort study

Ta Fuxia Ta¹, Zheng Jianming Zheng¹, Wang Bingyao Wang¹

Huashan Hospital, Fudan University, Infection Disease, Shanghai-China¹

Background / Hypothesis:

To compare the efficacy and safety of dual plasma molecular adsorption system (DPMAS) combined with plasma exchange (PE) versus PE alone in patients with

E-POSTER ABSTRACTS

acute-on-chronic liver failure (ACLF).

Materials and Methods:

A retrospective cohort study included ACLF patients receiving DPMAS + PE (n=51) or PE alone (n=57) from 2014 to 2025. Propensity score matching (PSM) was performed in a 1:1 ratio to balance baseline characteristics. Survival analyses of two groups and subgroups classified by the model for end-stage liver disease (MELD) and Chinese Group on the Study of Severe Hepatitis B ACLF 2.0 (COSSH-ACLF 2.0) score were performed. Cox regression analyses identified factors for 90-day transplant-free survival (TFS).

Results:

After PSM, 102 patients (DPMAS + PE: n=51; PE: n=51) were analyzed. The DPMAS + PE and PE groups showed comparable 90-day overall survival (66.5% vs. 64.7%, $P=0.848$) and TFS (66.5% vs. 57.9%, $P=0.406$). MELD scores = 23 and COSSH-ACLF 2.0 scores = 7.0 were optimal mortality prediction thresholds. Patients with MELD scores > 23 and COSSH-ACLF 2.0 scores > 7 exhibited significantly lower 90-day TFS (both $P<0.05$). Subgroup analyses revealed a non-significant survival trend favoring DPMAS + PE in high-risk subgroups (MELD scores > 23, $P=0.271$; COSSH-ACLF 2.0 scores > 7, $P=0.128$). New infections show no statistically significant between DPMAS + PE and PE group (39.2% vs 29.4%, $P=0.297$). Univariate analysis identified hepatic encephalopathy, blood urea nitrogen (BUN), INR, PT, APTT, baseline MELD scores > 23 and COSSH-ACLF2.0 scores > 7 as significant predictors of 90-day TFS. Multivariate analysis confirmed hepatic encephalopathy (HR = 3.03, 95% CI: 1.10–8.36, $P = 0.032$), BUN (HR = 1.20, 95% CI: 1.02–1.40, $P = 0.024$), and INR (HR = 2.70, 95% CI: 1.14–6.36, $P = 0.024$) as independent prognostic factors of 90-day TFS.

Conclusions:

DPMAS combined with PE showed comparable 90-day survival and safety to PE alone in ACLF, with a potential survival trend in high-risk subgroups.

Keyword(s) : artificial liver support system, dual plasma molecular adsorption system, plasma exchange, acute-on-chronic liver failure, survival

1823 - Study on Risk Factors for Hepatocellular Carcinoma in Chronic Hepatitis B Patients Treated with Interferon

Huihui Lu¹, Weihua Cao¹, Yao Xie¹, Minghui Li¹
Beijing Ditan Hospital, Capital Medical University,
Department Of Hepatology Division 2, Beijing-China¹

Background / Hypothesis:

To investigate the risk factors for hepatocellular carcinoma (HCC) in chronic hepatitis B (CHB) patients treated with interferon.

Materials and Methods:

A retrospective study was conducted, enrolling 2,034 CHB patients who received interferon antiviral therapy at the affiliated hospital of Capital Medical University between September 2008 and January 2019. Baseline data, including demographic characteristics, virological markers, serological indicators, clinical biochemistry, imaging data, and antiviral treatment information, were collected. The Kaplan-Meier method was used to assess the cumulative incidence and risk of HCC, and multivariate Cox regression analysis was employed to identify independent risk factors for HCC development in these patients.

Results:

Among the 2,034 interferon-treated patients, the median follow-up time was 4.64 (2.46–7.02) years, and 28 patients developed HCC. The HCC group (n=28) had significantly higher baseline age (43 vs. 32 years, $P < 0.001$), AFP level (9.40 vs. 4.20 ng/ml, $P < 0.001$), proportion of baseline cirrhosis (67.9% vs. 9.7%, $\chi^2=98.56$, $P < 0.001$), and male gender proportion (96.4% vs. 70.1%, $P=0.001$) compared to the non-HCC group. Baseline PLT level was significantly lower in the HCC group (110.40 vs. $167.00 \times 10^9/L$, $P=0.002$). However, there were no significant differences in baseline HBV DNA load (4.74 vs. 5.52 log₁₀ IU/mL, $P > 0.05$), ALT (55.60 vs. 76.75 U/L, $P > 0.05$), TBIL (14.80 vs. 14.20 $\mu\text{mol/L}$, $P > 0.05$), ALB (45.60 vs. 45.80 g/L, $P > 0.05$), proportion of baseline HBeAg positivity (67.7% vs. 67.5%, $P > 0.05$), or proportion of fatty liver (36.6% vs. 42.9%, $P > 0.05$) between the two groups. Kaplan-Meier analysis showed that baseline age, gender, presence of cirrhosis, HBV DNA level, PLT level, and AFP level were statistically significant for the cumulative incidence of HCC in interferon-treated patients. The presence of fatty liver during follow-up, baseline HBeAg status, AST level, TBIL level, and ALB level showed no statistical significance (all $P > 0.05$). Multivariate Cox regression analysis of age, gender, baseline cirrhosis, HBV DNA level, PLT level, and AFP level revealed that the presence of baseline cirrhosis was an independent risk factor for HCC in interferon-treated CHB patients ($P < 0.001$, HR=15.097, 95%

E-POSTER ABSTRACTS

CI=3.447-66.323). Age, gender, baseline HBV DNA level, PLT level, and AFP level were not independent risk factors (all $P > 0.05$)

Conclusions:

Liver cirrhosis is an independent risk factor for HCC development in interferon-treated patients. Preventing or delaying the onset of cirrhosis is key to reducing HCC incidence in CHB patients receiving interferon therapy.

Keyword(s) : Chronic hepatitis B; Antiviral therapy; Interferon; Hepatocellular carcinoma; Risk factors

1826 - Primary biliary cholangitis with concomitant fatty liver disease a reappraisal of clinical features UDCA treatment response and prognostic implications

Xinyue Ma¹, Chunyang Huang¹, Xue Yang¹, Xiao Lin¹, Wen Gao¹, Bin Xu¹, Yanmin Liu¹

Beijing You'an Hospital, Second Department Of Liver Disease Center, Beijing-China¹

Background / Hypothesis: Concomitant fatty liver disease (FLD) is not uncommon in patients with primary biliary cholangitis (PBC), yet its associations with clinical features, treatment response, and prognosis remain unclear. This study aimed to characterize the clinical phenotype and non-invasive fibrosis profiles of treatment-naïve PBC patients with FLD, and to evaluate the impact of FLD on biochemical response and 1-year GLOBE scores following ursodeoxycholic acid (UDCA) therapy. Subgroup analyses were further performed in patients with varying degrees of cirrhosis to clarify the clinical significance of FLD under different backgrounds of hepatic injury.

Materials and Methods: A total of 504 treatment-naïve PBC patients were retrospectively enrolled and categorized according to the presence of FLD on ultrasonography. Liver stiffness status was further classified as definite cirrhosis, suspected cirrhosis, or non-cirrhosis. Baseline biochemistry, immunoglobulins, white blood cell and platelet counts, ALBI score, and FIB-4 index were recorded. Biochemical response at 1 year was defined by Paris I/II criteria, and deep response by complete normalization of ALP and TBIL. The 1-year GLOBE score was calculated to estimate transplant-free survival. Group differences were assessed using the Mann-Whitney U test and χ^2 /Fisher's exact test. Multivariable logistic regression was used to evaluate whether FLD independently predicted treatment response or prognosis, with

additional stratification by cirrhosis status.

Results: 47 patients (9.3%) had FLD, of whom 93.6% exhibited ultrasonographic cirrhosis. Compared with non-FLD patients, the FLD group showed significantly lower baseline ALP, GGT, TBIL, IgA, and IgG, higher albumin and platelet counts, and more favorable ALBI, FIB-4, and GLOBE scores (all $P < 0.05$). These differences persisted within the cirrhosis subgroup. Among 229 patients with 1-year follow-up, FLD patients demonstrated a higher overall biochemical response rate (72.4% vs. 53.0%), but this difference disappeared after stratification by cirrhosis status. Similarly, the lower 1-year GLOBE scores observed in the FLD group were no longer significant after stratification. Multivariable analyses showed that FLD was not independently associated with biochemical response or deep response (all $P > 0.05$).

Conclusions: Although PBC patients with FLD exhibit milder cholestasis, fibrosis burden, and immunologic activity, along with a trend toward better 1-year biochemical response and GLOBE scores, these advantages largely dissipate after adjusting for cirrhosis status and baseline disease severity. FLD does not independently influence treatment response or prognosis, and likely represents an accompanying phenotype linked to disease stage rather than a causal modifier of PBC progression or UDCA responsiveness.

Keyword(s) : Biochemical response, Fatty liver disease, Primary biliary cholangitis;

1827 - Identification of Ferroptosis Related Biomarkers and Hub Genes in Non Alcoholic Fatty Liver; an In Silico Transcriptomic Analysis

Eiman Sehar¹, Iqra Aslam¹, Aqsa Batool¹, Maryam Latif¹, Aayan Shaheer Sheikh², Nadeem Sheikh¹
University Of The Punjab, Institute Of Zoology,, Lahore-Pakistan¹ McMaster University, Life Sciences, Hamilton-Canada²

Background / Hypothesis:

Non-alcoholic fatty liver disease (NAFLD) is a widespread metabolic condition, with non-alcoholic fatty liver (NAFL) reflecting an initial yet clinically significant stage. Ferroptosis, an iron-dependent lipid peroxidation-driven form of cell death, has appeared as a principle determinant to hepatic injury. However, ferroptosis-associated biomarkers in NAFL persist as inadequately characterized.

Materials and Methods:

This study designed to identify potential ferroptosis-related biomarkers using an in silico transcriptomic analysis. RNA-seq dataset GSE126848 was retrieved

E-POSTER ABSTRACTS

from the GEO database. Out of 57 samples, 15 NAFLD and 14 normal-weight samples were selected.

Differential expression analysis was carried out using DESeq2 with cutoffs of adjusted $p < 0.05$ and $|\log_2FC| \geq 1$, resulting in 1247 significant DEGs, including 633 upregulated and 614 downregulated genes.

Ferroptosis-related driver, suppressor, and marker genes were downloaded from FerrDb V3, duplicates were eliminated, and intersection with DEGs using Venny 2.1.0 detected 126 ferroptosis-related genes. STRING was used to build PPI networks, and visualization was done using Cytoscape V3.10.4. Hub genes were identified based on combined in-degree and out-degree scores.

Results:

Among the 126 ferroptosis-related DEGs, 52 genes were classified as drivers, 86 genes as suppressors, and 3 genes as markers. Using a minimum required interaction score of 0.4, STRING network analysis yielded 121 nodes, 331 edges, and significant PPI enrichment $p\text{-value} < 1e-16$. Cytoscape degree analysis underscored top ten hub genes—TGFB1, KDR, NOTCH1, EZH2, SERPINE1, SNAI2, BIRC5, IGF1R, PPARGC1A, and FOXM1—as key regulators of ferroptosis in NAFL. KEGG enrichment analysis highlighted substantial involvement of the HIF-1 ($FDR = 6.26 \times 10^{-5}$), PI3K-Akt ($FDR = 2.2 \times 10^{-4}$), and PPAR ($FDR = 5.5 \times 10^{-3}$) signaling pathways, emphasizing dysregulated metabolic and oxidative stress pathways associated with NAFL pathogenesis.

Conclusions:

This study systematically identified ferroptosis-related biomarkers and hub genes in NAFL, offering novel insights into disease mechanism. These candidate genes may function as potential diagnostic biomarkers or therapeutic targets, necessitating subsequent experimental and clinical validation.

1828 - Association of CORE Score with Parenchymal Liver Disease in HBsAg Positive Patients

Gölnur Kul¹, Asli Haykir Solay¹, Tuba Gümüş¹, Şule Mertel¹, Gürkan Değirmencioğlu², Yusuf Coşkun³, Ediz Tütüncü¹

Ankara Etlik City Hospital, Department Of Infectious Diseases And Clinical Microbiology, Ankara-Türkiye¹

Ankara Etlik City Hospital, Department Of General Surgery, Ankara-Türkiye² Ankara Etlik City Hospital, Department Of Gastroenterology, Ankara-Türkiye³

Background / Hypothesis: Chronic liver diseases due to hepatitis B infection may progress to serious

complications such as cirrhosis and hepatocellular carcinoma. Various non-invasive, serum-based scores (e.g., FIB-4, APRI, AST/ALT ratio) have been widely used in clinical practice to estimate disease progression in these patients. Recently, the CORE (Cirrhosis Outcome Risk Estimator) score has emerged as a novel model that uses routine biochemical parameters (age, sex, AST, ALT, GGT) to predict liver-related adverse outcomes with high accuracy (AUC 88%) (1). In this study, we aimed to investigate the association between the CORE score and parenchymal liver disease in HBsAg-positive patients.

Materials and Methods: HBsAg-positive patients followed up as outpatients in our hospital between January 1, 2023, and November 1, 2025 were included in this retrospective cross-sectional study. Laboratory data obtained from the electronic medical record system included age, sex, ALT, AST, GGT, ALP, platelet count, albumin, and AFP levels. Based on these parameters, APRI, FIB-4, AST/ALT ratio, and CORE risk scores were calculated. The CORE score was calculated individually using the online algorithm (<https://rickstra.shinyapps.io/CORE/>). The presence of parenchymal disease was defined by ultrasonographic findings such as fine/coarse granular or heterogeneous parenchyma. Patients were divided into two groups. Comparative analyses were conducted, and a $p\text{-value} < 0.05$ was considered statistically significant.

Results: Of the 208 patients included in the study, 133 were male. The mean age was 53.46 ± 13.46 years (range: 21–86). HBeAg was positive in 22 patients, and anti-HBe was positive in 191. Parenchymal liver disease was detected in 105 patients. Biochemical tests and scoring systems were compared according to the presence of parenchymal liver disease (see Table 1). Among the biochemical parameters, ALT, ALP, GGT, AFP, albumin, and platelet counts were significantly different between the two groups. Similarly, the AST/ALT ratio, APRI, FIB-4, and particularly the CORE risk score were significantly elevated in patients with parenchymal liver disease.

Conclusions: Our study showed that in patients with parenchymal liver disease, laboratory markers such as ALT, ALP, GGT, AFP, albumin, and platelet counts—as well as scoring systems like APRI, FIB-4, AST/ALT ratio, and notably the CORE risk score—were significantly higher. The CORE score stands out as a valuable predictive tool, as it can be calculated using only routine biochemical parameters and provides long-term risk estimation for liver-related events such as cirrhosis. These findings suggest that the CORE score may serve as an effective non-invasive marker for assessing the risk of chronic liver disease in HBsAg-

1829 - Clinical Challenges in Diagnosing Primary Testicular Lymphoma Report of Two Cases in Elderly Patients

Linhui Hu¹, Na Huo¹, Jing Liu², Yan Wang¹
Peking University First Hospital, Department Of Infectious Diseases, Beijing-China¹ Peking University First Hospital, Department Of Radiology, Beijing-China²

Background / Hypothesis: Primary testicular lymphoma (PTL) is a rare but highly aggressive subtype of non-Hodgkin lymphoma that originates in the testis. It predominantly affects elderly men and is characterized by frequent bilateral involvement and a high propensity for extranodal dissemination, resulting in poor prognosis. The disease often presents with nonspecific symptoms such as scrotal swelling and pain, making it easily confused with infectious or inflammatory conditions and leading to delayed diagnosis.

Materials and Methods: We describe two cases of PTL in men over 60 years of age who presented with fever and testicular pain. Case 1: A 66-year-old man experienced persistent fever for over three months. Pelvic contrast-enhanced MRI revealed bilateral epididymal lesions, suggesting the possibility of infection or tuberculosis (figure 1). Despite antibiotic and antituberculous therapy, symptoms persisted. PET/CT indicated a hematologic malignancy, prompting left epididymal–testicular excisional biopsy. Histopathology confirmed intravascular large B-cell lymphoma, establishing the diagnosis of PTL. Case 2: A 68-year-old man with a history of urologic malignancy presented with fever and left testicular swelling. Elevated inflammatory markers and poor response to antimicrobial therapy raised suspicion for a neoplastic process. Pelvic MRI demonstrated a left testicular mass (figure 2), and PET/CT suggested a malignant lesion involving the testis and epididymis with retroperitoneal lymph node metastases. Left orchiectomy was performed, and pathology indicated diffuse large B-cell lymphoma, confirming PTL.

Results: Both patients presented with nonspecific symptoms mimicking infectious diseases, resulting in diagnostic delay. Imaging examinations (ultrasound, MRI, PET/CT) provided important but non-definitive clues. Testicular biopsy is rarely performed due to

procedural risks and diagnostic limitations. In both cases, definitive diagnosis relied on postoperative histopathology combined with immunohistochemistry. These cases highlight that timely imaging and pathological examinations can significantly improve the diagnostic yield.

Conclusions: PTL should be considered in elderly males presenting with unexplained testicular swelling accompanied by systemic symptoms. Early integration of multimodal imaging and timely surgical intervention are essential to avoid diagnostic delay. Given its aggressive nature and high recurrence rate, prompt diagnosis and multidisciplinary management are crucial for improving clinical outcomes.

1830 - Integrative Analysis of Differentially Expressed Ferroptosis Related Genes in Cell Cycle Regulation of Hepatocellular Carcinoma

Aqsa Batool¹, Eiman Sehar¹, Iqra Aslam¹, Maryam Latif¹, Aayan Shaheer Sheikh², Nadeem Sheikh¹
University Of The Punjab, Institute Of Zoology,, Lahore-Pakistan¹ McMaster University, Life Sciences, Hamilton-Canada²

Background / Hypothesis:

Globally, Hepatocellular carcinoma (HCC) is the primary cause of liver-related deaths, and investigating its molecular pathways is essential for advancing clinical diagnosis and therapy. Ferroptosis, an iron-dependent programmed cell death pathway, has currently been implicated in tumor development, but its contribution to HCC is still not well understood.

Materials and Methods:

In this research work, we examined the microarray dataset GSE101685 (Homo sapiens, platform GPL570) using GEO2R to detect differentially expressed genes (DEGs) between 8 normal liver and 24 HCC tissues. Volcano plot and box plot were used to identify significant target genes. Ferroptosis-related genes (drivers, suppressors, and markers) were extracted from FerrDb V3, and overlapping genes were assessed through intersection analysis. A protein–protein interaction (PPI) network was generated by uploading shared genes to the STRING database, and hub genes were identified using the Analyze Network tool in Cytoscape based on node degree value. Gene Ontology term enrichment was determined for the selected biomarker candidates and included an analysis of biological processes and cellular

E-POSTER ABSTRACTS

components.

Results:

49 significant DEGs were obtained after removing duplicates from 54,675 probes, consisting of 19 upregulated and 30 downregulated genes. 12 ferroptosis-related genes were obtained from the intersection using the Venn tool, including 4 drivers and 9 suppressors. PPI network analysis revealed significantly higher connectivity than expected. No significant Reactome or KEGG pathway enrichment was observed, indicating that functional interpretation was mainly based on GO annotations. GO-BP enrichment demonstrated that these genes are markedly associated with mitotic processes and cell cycle regulation, and GO-CC highlighted their localization to nuclear structures, including the midbody, spindle, centromere, and kinetochore, emphasizing their involvement in chromosome segregation and mitotic regulation. Hub genes such as ECT2, KIF14, TOP2A, and BUB1 were extracted from the PPI network using the network analysis tool in Cytoscape, based on degree value, indicating their role in modulating the cell cycle.

Conclusions:

These findings reveal key ferroptosis-related genes differentially expressed in HCC that contribute to cell-cycle-driven tumor proliferation, providing potential targets and offering new perspectives into ferroptosis-mediated mechanisms in hepatocellular carcinoma.

Ardahan University, Department Of Pharmacy Services, Nihat Delibalta Göle Vocational High School, Ardahan-Türkiye⁴ Ataturk University, Department Of Gastroenterology, Faculty Of Medicine, Ezurum-Türkiye⁵

Background / Hypothesis: Ochratoxin A (OTA), a potent mycotoxin produced by *Aspergillus* and *Penicillium* species, poses a significant public health concern due to its hepatotoxic effects(1). As one of the most

common food contaminants, OTA can lead to multiple organ toxicities, particularly affecting liver(2). The hepatotoxic effects of OTA are known to be associated with several mechanisms, including oxidative stress, inflammation, and apoptosis(3, 4). OTA-induced ER stress is known to activate the unfolded protein response (UPR), in which GRP78 and IRE1 α play central regulatory roles(5). Epigallocatechin Gallate (EGCG), a primary green tea polyphenol, has potent antioxidant and anti-inflammatory effects(6). OTA-induced liver toxicity and the protective effects of antioxidant compounds have been previously reported in several studies(7-9). However, studies on EGCG's protective effect against OTA-induced liver injury are limited. Therefore, this study aims to demonstrate the hepatoprotective potential of EGCG against OTA-induced liver toxicity.

Materials and Methods: In this study, Albino Wistar rats(n=30) were divided into five groups and administered OTA (0.5 mg/kg/day) for 14 days to induce a liver toxicity model. Concurrently, two different doses of EGCG (50 and 100 mg/kg/day) were administered orally to evaluate its potential protective effects against OTA-induced liver injury. At the end of the experiment, hepatic mRNA expression levels of GRP78, IRE1 α and TNF α were analyzed using the RT-PCR method.

Results: GRP78 and IRE1 α mRNA expression, markers of ER stress, increased in the toxicity group compared to the healthy group, and GRP78 mRNA expression also increased dose-dependently in the treatment groups. IRE1 α mRNA expression decreased dose-dependently in the treatment groups. TNF α mRNA expression also increased in the toxicity group and decreased dose-dependently in the treatment groups.

Conclusions: The increase in GRP78 in the toxicity and treatment groups may indicate a protective adaptive response against ER stress due to its central role in the UPR. Studies have shown that GRP78 levels increase to restore ER homeostasis. The increase in IRE1 α in the OTA toxicity group indicates increased ER stress. The decrease in IRE1 α in the EGCG groups suggests that increased GRP78 increases cell survival and reduces the UPR. The increase in TNF α in the toxicity group

E-POSTER ABSTRACTS

indicates activation of inflammatory pathways, and EGCG treatment suppressed inflammation in a dose-dependent manner. These results demonstrate that EGCG exerts a hepatoprotective effect against OTA-induced liver injury by modulating ER stress and reducing inflammation. This study suggests EGCG as a new potential target for xenobiotic induced chronic liver diseases.

1833 - Multifunctional Dialysate for Renal Hepatic and Pulmonary Support

Adrian Dominik ¹, Stine Koball ¹, Jan Stange ¹
University Medicine Rostock, Nephrology, Rostock-Germany ¹

Background / Hypothesis:

By addition of albumin to dialysate solution both kidney and liver can be extracorporeally supported over one single dialyzer membrane. Here we present the addition of oxygenated hemoglobin to dialysate solution to further support lung function by removal of CO² and introduction of O² over the same hydrophilic membrane (Patent:US2022033933A1). This is a substantial improvement in biocompatibility compared to lipophilic membranes used in ECMO circuits and reduces system complexity.

Materials and Methods:

For the in-vitro experiments hemoglobin was added to albumin infused dialysate solution and recirculated against human blood intoxicated with kidney and liver failure toxins as well as CO². An EMIC² (Fresenius) hydrophilic dialysis membrane was used for therapy. Dialysate solution was regenerated by oxygen introduction. Control experiment was low flow ECCO²R (Fresenius).

Results:

Both systems show comparable capacity for removal CO² and introduction of O² while maintaining the capacity to remove water soluble toxins and albumin bound toxins. Creatinine was reduced from 715,3 to 113,1 µM and bile acids were reduced from 37,1 to 25,4 µM.

Conclusions:

The addition of hemoglobin to dialysate solution allows for additional lung support options in extracorporeal dialysis circuits. This avoids the need for bio-incompatible lipophilic ECMO membranes and reduces system complexity. Flow rates and hemoglobin concentration can be optimized for further mass transfer increase. The system is under current investigation.

Keyword(s) : Albumin dialysis; renal dialysis, dialysis, ECMO, membrane oxygenation, extracorporeal treatments, emerging technologies

1835 - Meta Analysis of Ferroptosis Related Differentially Expressed Genes in Hepatocellular Carcinoma

Iqra Aslam ¹, Aqsa Batool ¹, Eiman Sehar ¹, Maryam Latif ¹, Aayan Shaheer Sheikh ², Nadeem Sheikh ¹
University Of The Punjab, Institute Of Zoology,, Lahore-Pakistan ¹ McMaster University, Life Sciences, Hamilton-Canada ²

Background / Hypothesis:

Hepatocellular carcinoma (HCC) remains a clinically aggressive malignancy, and its ferroptosis-related biomarkers are not yet fully defined.

Materials and Methods:

To uncover human ferroptotic-regulatory patterns in HCC, we analyzed the microarray dataset GSE41804 (GPL570), consisting of 40 human liver samples (20 resected non-tumor liver tissues and 20 resected liver tumors). The data was analyzed using GEO2R analysis, FerrDb, PPI analysis through STRING db, KEGG pathway, and Cytoscape analysis.

Results:

GEO2R analysis using adjusted p-value < 0.05 and |log2FC| ≥ 1 yielded 2338 differentially expressed genes (DEGs), narrowed to 1571 unique DEGs, including 951 upregulated and 623 downregulated. These were intersected with human ferroptosis-related genes from FerrDb, resulting in 152 overlapping genes. Within this set, 68 were drivers (39 upregulated, 29 downregulated), 103 suppressors (53 upregulated, 51 downregulated), and 4 markers (2 upregulated, 2 downregulated), with some genes classified in multiple categories. STRING analysis of these 152 genes generated a protein-protein interaction network containing 148 nodes and 572 edges (p < 1.0e-16) with a medium-confidence interaction score of 0.4, demonstrating strong connectivity. KEGG pathway enrichment highlighted significant pathways associated with ferroptosis regulation and tumor biology,

E-POSTER ABSTRACTS

including the p53 signaling pathway, cytokine–cytokine receptor interaction and the PI3K–Akt signaling pathway, all linked to oxidative stress, immune modulation, and cell survival. Furthermore, hub genes such as ESR1, CDK1, FOXM1, CDKN2A, AURKA, TOP2A, ERBB2, BIRC5, CDH1, and AURKB, were prioritized from the PPI network using the network analyzer tool in Cytoscape, based on degree centrality, emphasizing underscoring their central roles in the ferroptosis network.

Conclusions:

Taken together, this human-centric integrative analysis highlights key ferroptosis-related biomarkers and pathways in HCC, defining a foundation for downstream studies for future mechanistic and therapeutic studies.

Keyword(s) :

1838 - Predictive Value of the aMAP Score for Hepatocellular Carcinoma Risk in Chronic Hepatitis B Patients Treated with Interferon

Huihui Lu¹, Weihua Cao¹, Yao Xie¹, Minghui Li¹
Beijing Ditan Hospital, Capital Medical University,
Department Of Hepatology Division 2, Beijing-China¹

Background / Hypothesis:

To evaluate the predictive value of hepatocellular carcinoma (HCC) risk prediction models in chronic hepatitis B (CHB) patients receiving interferon therapy.

Materials and Methods:

This study enrolled CHB patients who received interferon antiviral therapy in the Second Department of Liver Diseases at Beijing Ditan Hospital between September 2008 and January 2019. All patients received at least 12 weeks of interferon therapy. Baseline data, including demographic, virological, serological, clinical biochemical, and imaging parameters, as well as antiviral treatment information, were collected. The cumulative incidence of HCC was plotted using the Kaplan-Meier method. Non-imaging-based HCC risk prediction models were applied to stratify patients according to baseline HCC risk, and the accuracy of the risk scores was analyzed using the area under the receiver operating characteristic curve (AUC).

Results:

A total of 668 patients were enrolled, with a median age of 33 (27–41) years and a median follow-up of 6.47 (3.57–8.44) years. During follow-up, 12 patients developed HCC. The cumulative incidence rates of HCC

at 1, 3, 5, 8, and 10 years were 0.2%, 0.2%, 0.4%, 0.9%, and 1.2%, respectively. The AUCs for the PAGE-B, mPAGE-B, aMAP, and APA-B models at 1 year were 0.53 (95% CI: 0.50–0.57, $P > 0.50$), 0.74 (95% CI: 0.67–0.81, $P > 0.50$), 0.76 (95% CI: 0.73–0.79, $P > 0.50$), and 0.94 (95% CI: 0.92–0.97, $P > 0.50$), respectively. At 3 and 5 years, the AUCs for these models remained suboptimal. However, at 8 years, the AUCs improved to 0.75 (95% CI: 0.64–0.86, $P = 0.011$), 0.78 (95% CI: 0.64–0.92, $P = 0.004$), 0.82 (95% CI: 0.71–0.93, $P = 0.001$), and 0.78 (95% CI: 0.63–0.93, $P = 0.004$), respectively. At 10 years, the AUCs were 0.77 (95% CI: 0.68–0.86, $P = 0.001$), 0.80 (95% CI: 0.68–0.91, $P < 0.001$), 0.82 (95% CI: 0.72–0.92, $P < 0.001$), and 0.78 (95% CI: 0.66–0.91, $P = 0.001$), respectively. Among the four models, aMAP demonstrated the highest predictive ability.

Conclusions: CHB patients treated with interferon have a low risk of developing HCC. The aMAP score shows high accuracy in predicting long-term HCC risk in these patients.

Keyword(s) : Antiviral therapy; Interferon; Chronic hepatitis B; Hepatocellular carcinoma; Prediction model

1839 - Efficacy of long term albumin therapy in the treatment of decompensated cirrhosis.

Deepanshu Khanna¹, Pabitra Sahu¹, Premashis Kar¹,
Ayush Jasrotia¹, Abhijeet Bhalke¹, Nikhil Nagre¹
Max Superspeciality Hospital, Vaishali, Medical
Gastroenterology, Ghaziabad-India¹

Background / Hypothesis: Decompensated liver cirrhosis has a poor prognosis, with a median overall survival of two to four years, which is worse than for many oncological disorders. These patients are highly susceptible to infections due to increased systemic inflammation leading to kidney failure and death. The aim was to study the efficacy of albumin in reducing episodes of decompensation, preventing bacterial infection, kidney dysfunction and mortality.

Materials and Methods: Study involved patients with Child B or C cirrhosis with an albumin level below 3.0 g/dL, who were administered 20% human albumin weekly with standard medical treatment (SMT) for three months or till serum albumin levels were 4.0 g/dL (whichever is earlier) and compared with age and sex-matched controls who received only SMT. The primary end-point was six-month mortality and the secondary end-points were reduction in infections, kidney dysfunction, ascites recurrence, hepatic encephalopathy (HE), gastrointestinal (GI) bleed and

E-POSTER ABSTRACTS

complications of cirrhosis.

Results: From September 2021 to January 2023, 88 cases and 86 controls were taken and followed up for six months. Overall, six-month survival was not statistically significant between groups (95.1% vs. 91.9%; $p = 0.330$). The incidence of recurrence of ascites (34.09% vs. 59.3%, $p < 0.001$), kidney dysfunction (6.8% vs. 24.4%, $p < 0.001$), HE (15.9% vs. 37.2%, $p = 0.015$), spontaneous bacterial peritonitis (SBP) (3.4% vs 17.4%, $p = 0.002$) and non-SBP infections (7.9% vs. 18.6%, $p = 0.038$) were significantly less in cases as compared with controls; however, GI bleed (14.8% vs. 17.4%, $p = 0.632$) was not statistically significant.

Conclusions: Long-term human albumin acts as a disease-modifying treatment in patients with decompensated cirrhosis

Keyword(s) : Albumin; Cirrhosis; Decompensated cirrhosis; Long-term albumin; Weekly albumin.

1840 - Severe Hepatic Steatosis Attenuates Response to PEG IFN alpha 2b in HBsAg Clearance Favorable Chronic Hepatitis B Patients A Retrospective Cohort Study

Pengxuan Wu¹, Shan Ren¹, Jianxia Dong¹, Dacheng Sheng¹, Xinyue Meng¹, Jing Zhao¹, Sujun Zheng¹
Beijing Youan Hospital, First Department Of Hepatology, Beijing-China¹

Background / Hypothesis: Hepatic steatosis (HS) is a common comorbidity in chronic hepatitis B (CHB). This study aimed to investigate the impact of varying degrees of HS on the treatment response to pegylated interferon alpha (PEG-IFN α) in CHB patients who are considered favorable for HBsAg clearance.

Materials and Methods: In this multi-center, cohort study, we enrolled 499 HBeAg-negative CHB patients with HBsAg <1500 IU/mL, a population with favorable prospects for HBsAg clearance, who received 48 weeks of PEG-IFN α therapy. Using controlled attenuation parameter (CAP) measurements, patients were classified into two groups: CHB without HS (CHB) and CHB with HS (CHB+HS). The CHB+HS group was further subdivided into mild ($n = 90$), moderate ($n = 41$), and severe ($n = 118$) steatosis subgroups. The primary endpoint was the HBsAg clearance rate at week 48.

Results: An overall HBsAg clearance rate of 39.1%

(195/499) was achieved among the study patients, who were selected for their favorable cure profile and completed the 48-week PEG-IFN α therapy. Although no overall difference was observed between CHB and CHB+HS groups (41.2% vs 37.0%, $P > 0.05$), severe HS was associated with significantly reduced clearance rates (24.6%) compared to both the CHB group (41.2%, $P < 0.01$) and mild or moderate HS subgroups (45.6% and 53.7%, respectively). After adjusting for baseline characteristics using inverse probability of treatment weighting (IPTW), Cox regression analysis identified severe HS as an independent negative predictor of HBsAg clearance (HR = 0.582, 95% CI 0.364–0.931, $p = 0.02$). The significance remained after additional adjustment for age, sex, baseline HBsAg, ALT, AST, and fibrosis stage (adjusted HR = 0.570, 95% CI 0.341–0.954, $p = 0.03$).

Conclusions: In the HBsAg clearance-favorable population, severe hepatic steatosis is significantly associated with a reduced response to PEG-IFN α -2b therapy.

Keyword(s) : chronic hepatitis B; hepatic steatosis; pegylated interferon; HBsAg clearance; treatment response; controlled attenuation parameter; severity

1841 - Timing of endoscopic hemostasis does not affect the short term outcomes in acute variceal bleeding in liver cirrhosis patients.

Hee Bok Chae¹, Jin Soo Kim², Byung Yeon Kim², Jun Su Lee², Il Soon Jung², Ki Bae Kim²

Chungbuk National University Hospital, Internal Medicine, Cheongju-South Korea¹ Chungbuk National University Hospital, Internal Medicine, Cheongju-South Korea²

Background / Hypothesis: Endoscopic treatment are necessary for hemostasis in acute variceal bleeding, with most guidelines recommending that emergency endoscopy be performed within 12 h of hospital arrival. But, the evidence to support the timing of endoscopy is still few, so we want to double check the short-term clinical outcomes of the acute variceal bleeding in cirrhotic patients according to the timing of starting endoscopy from the arrival at emergency room.

Materials and Methods: The window of the patient enrollment started from Jan 1st 2015 to Jan 21st 2021. This retrospective study included 64 patients admitted with acute esophageal or stomach variceal bleeding of one tertiary hospital in Cheongju, South-Korea. The primary outcome was the mortality and rebleeding in 6 weeks from endoscopic treatment. We adjusted

E-POSTER ABSTRACTS

confounding factors using the propensity score matching (1:1) method. For these matched patients, we performed between-group comparisons of mortality and rebleeding using Fisher's exact test and Cox proportional hazards model.

Results: When dividing patients with two groups according to EGD timing (urgent group 1 < 12 hrs and non-urgent group 2 $\geq$ 12 hrs), only EGD time (251.6 ± 187.3 vs. 1316.9 ± 962 min, $p=0.001$) and BUN (36.6 ± 22.0 vs. 24.1 ± 13.8 mg/dL, $p=0.01$) out of thirty three baseline characteristics were different between the two groups. The 6 weeks mortality was 12.5% vs. 9.4% ($p=0.701$), the 6 week rebleeding was 12.5 vs. 9.4% ($p=0.395$). Also, the hospital mortality was 9.4 vs. 9.4% ($p=1.0$), hospital rebleeding rate was 3.1 vs. 3.1%, ($p=1.0$)

Conclusions: The timing of endoscopy was not associated with 6 week mortality or 6 week rebleeding rate. The more important factor on patient survival is not early endoscopic intervention, but the early and proper cardiopulmonary resuscitation and intensive care regarding to each patient's condition. A prospective study will be needed for establishing a more accurate optimal timing of endoscopy.

Keyword(s) : Cirrhosis; Endoscopy; Gastroesophageal varices; Timing

1842 - T MSCs Alleviate Autoimmune Hepatitis in a ConA Mouse Model by Inhibiting IL 21-Driven Inflammatory Responses

Long Xu¹, Wanwan Shi¹, Yan Wang¹, Guiqiang Wang¹
Peking University First Hospital, Department Of Infectious Disease, Beijing-China¹

Background / Hypothesis: Autoimmune hepatitis (AIH) is characterized by T cell hyperactivation and an imbalance of inflammatory cytokines, potentially leading to acute and severe autoimmune-mediated liver injury. T-MSCs (Trophoblast-derived mesenchymal stem cells) exhibit considerable immunomodulatory potential; however, their protective effects and the underlying mechanisms in AIH remain to be elucidated.

Materials and Methods: A ConA-induced acute liver injury model was established by intravenous injection of ConA (15 mg/kg). T-MSCs (1×10^6 cells/mouse) were administered intravenously 3 hours after ConA injection. Mice were euthanized 24 hours after T-MSC administration, and serum and liver tissues were collected. The hepatoprotective effects of T-MSCs were systematically evaluated by measuring serum biochemical markers (ALT, AST, LDH), performing

hematoxylin and eosin (HE) staining, quantifying inflammatory and necrotic areas, scoring liver pathology using the Ishak Histological Activity Index (HAI), and analyzing IL-21 expression through immunofluorescence.

Results: In the ConA-induced acute immune-mediated liver injury model, T-MSC treatment exerted significant protective effects across both biochemical and histopathological indicators. Serum analyses revealed that ALT and AST levels were markedly elevated following ConA administration but were significantly reduced after T-MSC infusion, with ALT ($p = 0.0022$) and AST ($p = 0.0003$) showing clear improvement. Additionally, LDH levels were significantly lower than those in the ConA group ($p = 0.0067$). Histological evaluation confirmed extensive hepatic necrosis and inflammatory infiltration in the ConA group, while T-MSC treatment significantly reduced the necroinflammatory area ($p < 0.0001$) and substantially lowered the Ishak HAI score ($p < 0.0001$). Immunofluorescence analysis demonstrated that IL-21 expression was markedly upregulated in the ConA group, whereas T-MSC administration led to a significant decrease in IL-21 signal intensity ($p = 0.0001$); quantification of IL-21 per tissue area also showed a notable reduction ($p = 0.0149$).

Conclusions: T-MSCs demonstrated pronounced hepatoprotective effects in the ConA-induced acute immune-mediated liver injury model by significantly reducing serum transaminase levels, alleviating tissue necrosis, improving Ishak inflammation scores, and suppressing IL-21 overexpression.

1844 - Yunpilishi Formula attenuates high fat diet induced obesity and fatty liver via inhibiting tPA

Yijing Zhang¹, Yueqiu Gao², Man Li³, Jie Shen⁴
Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Pharmacy Department/department Of Hepatology, Shanghai-China¹ Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Department Of Hepatology, Shanghai-China² Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Shanghai Key Laboratory Of Traditional Chinese Clinical Medicine, Shanghai-China³ Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Pharmacy

E-POSTER ABSTRACTS

Department, Shanghai-China ⁴

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) is the leading cause of chronic liver disease worldwide. Yunpilishi Formula (YPLS) is a traditional Chinese medicine that has been used in the clinical treatment of MAFLD. However, its underlying mechanism for treating MAFLD remains unclear. Recent studies showing that the interaction between tPA, PAI-1, and apoB regulates VLDL secretion, thereby influencing the level of lipid deposition in hepatocytes. We aim to explore whether YPLS treats MAFLD by regulating the tPA/PAI-1/apoB pathway.

Materials and Methods:

Ultra-high performance liquid chromatography-mass spectrometry (UPLC-MS) was used to identify the main components of YPLS. A mouse model of nonalcoholic fatty liver disease was constructed by feeding the mice a high-fat diet for 16 weeks. YPLS was administered for an additional 8 weeks, and Polyene Phosphatidylcholine was used as a positive control. Liver sections were subjected to histopathological assessment. The NovaSeq™ 6000 platform (Illumina) was used to analyze differentially expressed genes (DEGs). Candidate proteins and pathways were validated through qRT-PCR and western blot analysis.

Results:

Twenty-four ingredients were identified in YPLS extracts, which were considered to be key compounds in the treatment of MAFLD. YPLS administration attenuated obesity and fatty liver by reducing the body weight and liver weight in HFD-fed mice. More importantly, hepatic steatosis was significantly attenuated by YPLS administration both in vivo and in vitro. Transcriptome sequencing (RNA-seq) of mouse liver tissues identified 1023 DEGs associated with YPLS treatment. Bioinformatic analysis of DEGs revealed that regulating the lipid and atherosclerosis pathway was the main role of YPLS in MAFLD treatment. This finding also indicated that tPA might be the potential target of YPLS, which was subsequently verified both in vitro and in vivo. The results demonstrated that YPLS enhanced tPA activity, thereby inhibiting PAI-1 expression and promoting apoB lipidation. ApoB lipidation promotes the secretion of VLDL from hepatocytes, leading to reduced lipid accumulation in hepatocytes.

Conclusions:

Overall, our findings confirmed the protective effect of YPLS against MAFLD and revealed the underlying

molecular mechanism of regulating lipid metabolism.

Keyword(s) : tPA; PAI-1; Lipid secretion; MAFLD; Yunpilishi formula.

1845 - Inositol Hexaphosphate Prevent WD CCl₄ Induced Metabolic Dysfunction Associated Steatohepatitis in Mice

Zhao Chen¹, Feng Liu¹, Huiying Rao¹

Peking University Hepatology Institute, Peking University People's Hospital, Beijing-China ¹

Background / Hypothesis:

Metabolic dysfunction-associated steatohepatitis (MASH) is a significant global public health issue. Since inositol hexakisphosphate (IP6) mainly extracted from plants, have anti-oxidative and anti-tumor effects. This study aimed to explore the preventive effects and mechanisms of IP6 on MASH.

Materials and Methods:

A western diet combined with low doses of CCl₄ (WD/CCl₄) was used to induce NASH in mice and evaluate the protective effects of IP6. Phenotypic assessments included metabolic profiles, histopathology (H&E, Oil Red O, Masson's trichrome), and serum biochemistry. Assessments of transcriptomics, metabolomics, and lipidomics analyses were conducted to explore potential molecular mechanisms. Additionally, the effects of IP6 and INS in vitro using free fatty acid (FFA)-treated HepG2 cells and activated hepatic stellate cells were investigated. In vitro studies were conducted to test whether knocking down PEMT in HepG2 and LX-2 cells would abolish the beneficial effects of IP6 on MASH-related phenotypes.

Results:

The results showed that pretreatment with IP6 significantly reduced obesity, fibrosis and lipid accumulation, alleviated insulin resistance, and prevented hyperglycemia in MASH mice. IP6 also alleviated free fatty acid (FFA)- induced lipid accumulation in HepG2 cells. Transcriptomics analysis of the liver revealed that IP6 reversed MASH-related transcriptomic changes, suppressing the expression of pro-fibrotic, pro-inflammatory, and lipid-metabolic genes. Integrated metabolomics and lipidomics revealed that the preventive effect of IP6 against MASH was mediated through the rectification of disordered glycerophospholipid metabolism. Notably, knockdown

E-POSTER ABSTRACTS

of PEMT expression abolished the inhibitory effects of IP6 on lipid accumulation, as well as α -SMA and COL-1 expression, in in vitro assays.

Conclusions:

These findings provide evidence that IP6 can prevent the development of MASH by improving disorders in glycerophospholipid metabolism, at least partially through the upregulation of PEMT.

1847 - The Clinical Significance and Optimization Strategies of HBeAg Seroclearance in Chronic Hepatitis B Treatment

Yaqin Zhang¹, Yuanjiao Gao¹, Xinxin Li¹, Yao Xie¹, Minghui Li¹

Beijing Ditan Hospital, Capital Medical University, Department Of Hepatology Division 2, Beijing-China¹

HBeAg seroclearance represents a critical milestone in the treatment of HBeAg-positive chronic hepatitis B (CHB), which is closely associated with disease remission, functional cure, and reduced hepatocellular carcinoma risk. This review comprehensively explores the immunological mechanisms underlying HBeAg seroclearance, thoroughly examines its impact on the natural course of CHB and systematically analyzes the regulatory roles of antiviral drug efficacy, host immune status, and viral genotypes in HBeAg clearance. Integrating updated guidelines and evidence-based research, we propose optimized strategies for managing HBeAg-negative CHB, including goal setting, treatment cessation criteria, and long-term monitoring protocols. Our findings emphasize that HBeAg clearance not only signifies virological suppression but also reflects the dynamic equilibrium of host immune responses, thereby providing both theoretical foundation and practical support for achieving functional cure and reducing HCC risk in CHB patients.

Keyword(s) : Chronic hepatitis B, HBeAg, immune, Treatment, Functional cure

1850 - Curative Outcome in Hepatocellular Carcinoma A Case Report on Complete Pathologic Response After Multimodal Therapy

Jeremie Manarang¹, Janus Ong¹, Marika Zaphia Manago¹

The Medical City, Section Of Gastroenterology, Pasig City-Philippines¹

Introduction:

In recent years, despite the emergence of therapeutic advances for advanced hepatocellular carcinoma (HCC), complete pathological response following systemic therapy remains uncommon. Complete remission becomes even more rare when considering the entire spectrum of disease stages, particularly in patients with underlying cirrhosis and preserved liver function who may benefit most from surgical resection. In this report, we present a case of initially unresectable HCC in a patient with liver cirrhosis that was successfully downstaged through sequential locoregional therapy and systemic immunotherapy. This multimodal treatment approach eventually enabled curative surgical resection and resulted in complete pathological response, demonstrating the potential of contemporary combination therapies to achieve exceptional outcomes even in advanced disease.

Case Description:

This is a case of a 63-year-old male patient, diagnosed with HCC Barcelona Clinic Liver Cancer (BCLC) B, Albumin-Bilirubin (ALBI) Grade 2 initially presenting with right upper abdominal pain. Triphasic CT scan showed a lobulated, heterogeneous, 10 × 11 × 10.5 cm predominantly hypodense mass located in the right hepatic lobe (segments 5 and 6) exhibiting typical enhancement on arterial phase with subsequent washout during the portovenous phase. An additional smaller lesion with similar enhancement pattern was identified in segment 7, measuring 3.9 × 4.7 × 4.7 cm. Serologic tests supported the diagnosis of HCC with elevated AFP at 7,170 mg/mL and PIVKA-II at 3,359 mAU/mL. The patient then underwent SIRT using Yttrium-90 radioembolization targeted to the right hepatic lobe. In the same interventional session, a small arterially-enhancing lesion identified in segment 3 was treated with TACE using doxorubicin and etoposide. The patient was subsequently initiated on combination immunotherapy - atezolizumab and bevacizumab. After significant tumor downsizing, patient proceeded with bisegmentectomy of segments 5 and 6 with wedge resection of the segment 7 lesion. Final histopathological examination of the resected specimens revealed complete pathologic response with no residual viable tumor and with negative margins. All quarterly surveillance imaging studies on follow-up demonstrated no evidence of new hepatic lesions or extrahepatic metastatic disease, indicating sustained disease-free status.

E-POSTER ABSTRACTS

Conclusion:

This case report highlights the role of integrating systemic therapy with locoregional treatments in enhancing disease control and potentially improving outcomes in patients with intermediate to advanced disease.

1852 - Navigating Vascular Complexity Successful Locoregional Treatment of HCC with a Hepatic Arteriportal Fistula

Christine Velasquez¹, Sharlene Nicole Chan², Madaline Eternity Labio³

Makati Medical Center, Gastroenterology, Makati-Philippines¹ Makati Medical Center, Internal Medicine, Makati-Philippines² Makati Medical Center, Hepatology, Makati-Philippines³

BACKGROUND:

Hepatic arteriportal fistulas (HAPFs) are rare but clinically significant vascular abnormalities involving direct communication between the hepatic arterial and portal venous systems. In patients with hepatocellular carcinoma (HCC), their presence may alter hepatic perfusion dynamics, reduce the efficacy of intra-arterial therapies, and increase the risk of portal hypertension or hepatic infarction. Managing HCC in the setting of HAPF requires a nuanced approach that balances tumor control with preservation of hepatic function.

CASE PRESENTATION:

We present a case of a 77-year-old female with an incidentally detected hepatic mass, who presented with mild right upper quadrant abdominal pain. Imaging revealed a 3.0 cm arterial enhancing mass with venous washout in segment II and a 1.2 cm enhancing lesion in segment VII. Serum alpha-fetoprotein was elevated, and ultrasound-guided liver biopsy confirmed well-differentiated HCC.

MANAGEMENT AND OUTCOME

She was referred for transarterial chemoembolization (TACE) as initial therapy. Selective hepatic angiography identified tumoral blush from the middle hepatic and A2 arterial branches. Notably, early portal vein opacification suggested the presence of an arteriportal fistula. Superselective TACE was performed using doxorubicin, mitomycin, Lipiodol, alcohol, and EG-Gel until near-complete vascular stasis

was achieved. Given persistent residual enhancement, immediate adjunct microwave ablation (MWA) was performed under ultrasound and CT guidance.

Post-ablation imaging showed expected hypodense changes with air locules, consistent with coagulative necrosis. Follow-up MRI demonstrated absence of viable tumor with peripheral granulation and blood product deposition—indicative of effective tumor eradication.

CONCLUSION

This case underscores the critical role of multimodal locoregional strategies in managing complex HCC with vascular shunting. Identification of HAPF during angiography can guide therapy, as shunting may impair TACE effectiveness. The combination of superselective embolization with MWA enabled curative intent treatment while minimizing hepatic injury. For hepatologists, collaboration with interventional radiology is essential in tailoring therapy for patients with vascular variants or altered perfusion. In this setting, thermal ablation is a valuable adjunct to overcome the limitations of embolotherapy alone. This case adds to the growing evidence supporting individualized, anatomy-based strategies in advanced HCC management, particularly when complicated by arteriportal communications.

1853 - Surgical Site Infections Following Hepatectomy and Associated Risk Factors in a Tertiary Liver Surgery Center

Anh Nguyen Thi Van¹, Quang Vu Van¹

108 Military Central Hospital, Hepato - Biliary And Pancreatic Surgery, Ha Noi-Vietnam¹

Background / Hypothesis: Surgical site infection (SSI) is a significant postoperative complication following hepatectomy, contributing to prolonged hospitalization, increased healthcare costs, and higher postoperative morbidity. This study aimed to evaluate the incidence of SSI after hepatectomy and identify modifiable perioperative risk factors.

Materials and Methods:

A retrospective study was conducted on 372 adult patients who underwent hepatectomy at a tertiary

E-POSTER ABSTRACTS

hepatobiliary center in Vietnam during 2024. Patients were categorized into laparoscopic hepatectomy and open hepatectomy groups. Demographics, comorbidities, operative data, drain use, and postoperative transfusion were collected. SSI was defined using Centers for Disease Control 2021 criteria. Statistical analyses included Chi-square testing and logistic regression.

Results:The SSI incidence was 3.5 percent (13 of 372). Laparoscopic hepatectomy showed a lower SSI rate compared with open hepatectomy (1.9 percent versus 5.7 percent). Independent predictors of SSI included open surgery, postoperative transfusion, and drain placement. Patients with SSI had longer hospitalization (18.9 vs. 7.6 days). Most SSIs were superficial, with fewer deep or organ-space infections.

Conclusions:Laparoscopic hepatectomy reduces SSI incidence and improves recovery compared with open hepatectomy. Drain placement and transfusion were significant modifiable risk factors. Enhanced perioperative strategies focusing on selective drain usage and transfusion stewardship are recommended.

1854 - Cross Border Collaboration in Primary Sclerosing Cholangitis A Landmark Living Donor Liver Transplant by Makati Medical Center (Philippines) and Asan Medical Center (Korea)
Zyrah Lou Samar¹, Fatima Anne Apacible¹, Eternity Madelee Labio¹, Angelo Lozada¹, Suzette Grace Kho-herman¹, Jonathan Angelo Cruz¹
Makati Medical Center, Department Of Medicine, Section Of Gastroenterology, Makati City-Philippines¹

Introduction: Primary sclerosing cholangitis (PSC) remains one of the leading indications for liver transplantation. This case report features the first case of living donor liver transplantation at Makati Medical Center (MMC), performed in partnership with Asan Medical Center (AMC), highlighting the vital role of international collaboration and physician mentorship, enabling knowledge and skill transfer in complex medical and surgical procedures. The primary aim of this report is to illustrate how cross-border institutional collaboration and capacity-building can facilitate safe

implementation of high-complexity living-donor liver transplantation (LDLT) for PSC in resource-limited settings.

Case Presentation: We present a successful right-lobe LDLT in a 23-year-old male PSC and recurrent bacterial cholangitis, with his biological mother serving as the donor. Recovery for the donor was uncomplicated. On the other hand, recovery for the recipient was complicated by sepsis. After antibiotic treatment, he was able to recover well and at nearly six months post-transplant, he demonstrated preserved graft function and progressive return to baseline activities. The partnership between AMC and MMC began in 2023 with the signing of a memorandum of understanding for medical collaboration. It provides structured and comprehensive training program to enable the latter to perform LDLT independently.

Conclusion: Despite the high burden of end-stage liver disease in the Philippines, LDLT remains challenging due to limited institutional experience. Regional collaborations with neighboring countries are thus critical to augment capacity-building, cultivate technical and clinical proficiency to propel the country towards a new era of transplant medicine in the country.

Keyword(s) : Primary sclerosing cholangitis, living-donor liver transplantation, medical collaboration, transplant program development

1855 - Genotype Phenotype Correlation of ATP7B Mutations in Wilson Disease
Siqi Zhang¹, Wei Hou¹, Shan Tang¹, Haitian Yu¹, Sujun Zheng¹
Beijing You'an Hospital, Capital Medical University, Department Of Liver Diseases I, Beijing-China¹

Background / Hypothesis:

Wilson disease (WD) is an autosomal recessive disorder of copper metabolism caused by mutations in the ATP7B gene. Patients exhibit significant variability in age of onset, affected organs, and disease severity. Clarifying the relationship between genotype and phenotype is essential for understanding WD heterogeneity.

Materials and Methods:
We performed ATP7B gene sequencing in 289 WD patients recruited from two centers in China, analyzed

E-POSTER ABSTRACTS

mutation types and homozygous/heterozygous distributions, and selected the five most frequent mutation combinations for further analysis. Skewed continuous variables were compared using the Kruskal-Wallis test, and categorical data were analyzed with the chi-square or Fisher's exact test. Clinical features—including age at diagnosis, serum ceruloplasmin (CER), 24-hour urinary copper, Kayser-Fleischer (K-F) ring presence, and clinical subtype—were compared among genotype groups. Regression models were used to assess interactions between genotype and age at diagnosis on the risk of cirrhosis and liver failure. Survival curves were employed to evaluate the prognostic differences of loss-of-function (LOF) mutations across distinct age subgroups

Results:

The independent effect of genotype on cirrhosis risk approached statistical significance (LOF vs Missense mutation, $p=0.051$). Among diagnosis age < 12 years old, patients carrying two 2-LOF mutations had the shortest median survival time (2.0 years), which was significantly worse than the 0-LOF group (7.0 years, $p=0.010$). However, in patients ≥ 12 years old, no significant differences in survival rates were observed among groups, suggesting that the negative impact of LOF mutations is more pronounced in early-onset patients. Patients carrying the p.T1106M/p.R778L combination showed significantly later age at diagnosis, higher CER levels, and slightly lower urinary copper, suggesting a milder clinical phenotype. K-F ring positivity and clinical subtype differed among genotype groups. Interaction analysis revealed that the rate of age-related cirrhosis progression in the p.T1106M/p.R778L group was slower than in the p.R778L/p.R778L reference group, whereas interactions with liver failure risk were not significant.

Conclusions:

The interaction between genotype and age at diagnosis has a regulatory effect on cirrhosis risk, but shows limited impact on liver failure. Loss-of-function mutations significantly negatively affect prognosis in early-onset patients (< 12 years), though this effect is attenuated in late-onset patients. The p.T1106M/p.R778L combination can serve as a "mild-type" genetic marker, characterized by delayed disease onset, higher CER levels, and a slower progression to cirrhosis risk.

Keyword(s) :

1856 - THE VALUE OF ALBI AND ALBI PLT SCORE IN PREDICTING ESOPHAGEAL VARICES IN CIRRHOTIC PATIENTS

Dinh Thang Nguyen¹, Tu Huong Lam², Tan Phat Ho¹, Duy Thong Vo³

Cho Ray Hospital, Gastroenterology, Ho Chi Minh City-Vietnam¹ University Of Medicine And Pharmacy At Ho Chi Minh City, Internal Medicine, Ho Chi Minh City-Vietnam² University Medical Center Ho Chi Minh City, Gastroenterology, Ho Chi Minh City-Vietnam³

Background: Liver cirrhosis is a debilitating disease that often results in fatal complications, with esophageal variceal bleeding (EVB) being the most common. The issue of early detection and treatment of esophageal varices should be addressed. Recent studies have shown the role of ALBI and ALBI-PLT score in predicting esophageal varices. Objective: The aim of this study was to describe the clinical and laboratory characteristics of liver cirrhosis patients with esophageal varices and to evaluate the accuracy of the ALBI and ALBI-PLT score in predicting the presence of esophageal varices in these patients.

Materials and Methods: We conducted a cross-sectional study that enrolled 152 cirrhotic patients from November 2024 to May 2025 at the Gastroenterology Department of Cho Ray Hospital.

Results: The study population consisted of 152 cirrhosis patients, with 100 males and 52 females, ranging in age from 28 to 87 years (mean age of 56 years). The prevalence of portal hypertension in cirrhotic patients is 56%. The ALBI score has moderate predictive ability for the risk of having portal hypertension (AUC = 0.78), as well as for the risk of high-grade portal hypertension (AUC = 0.79). The ALBI-PLT score also demonstrates moderate predictive ability for the risk of having portal hypertension (AUC = 0.76) and high-grade portal hypertension (AUC = 0.77). The cutoff threshold for the ALBI score in predicting portal hypertension in cirrhotic patients is -2.76, with sensitivities and specificities in predicting portal hypertension being 96.5% and 90.3%, respectively. The negative predictive value is 20.4%, and the rate of missing high-grade portal hypertension is 9.7%. For the ALBI- PLT score, the cutoff threshold in predicting portal hypertension in cirrhotic patients is 2, with sensitivities and specificities in predicting portal hypertension being 96.5% and 87%, respectively. The negative predictive value is 15.8%, and the rate of missing high-grade portal hypertension is 4.8%.

E-POSTER ABSTRACTS

Conclusion: The results of our study demonstrate that the ALBI and ALBI-PLT score is a reliable predictor of esophageal varices in patients with liver cirrhosis.

Keyword(s) : Liver cirrhosis, esophageal varices, ALBI score, ALBI-PLT score

1858 - Analysis of risk factors for portal hypertension in early histological primary biliary cholangitis

Hongxiao Hao ¹, Xin Wei ¹, Min Chang ¹, Yao Lu ¹, Lu Zhang ¹, Yao Xie ¹, Minghui Li ¹

Beijing Ditan Hospital, Capital Medical University, Department Of Hepatology Division 2, Beijing-China ¹

Background / Hypothesis:

Primary biliary cholangitis (PBC) is a chronic progressive intrahepatic cholestatic disease. Its pathogenesis has not been fully elucidated and may be related to immune disorders caused by genetic factors and their interaction with environmental factors.

Materials and Methods:

A retrospective study was conducted on 110 patients diagnosed with histological early (stage I , II) PBC who underwent liver biopsy at Beijing Ditan Hospital from January 2020 to December 2023. Patients were divided into the portal hypertension group (n=27) and the control group (n=83) based on the presence of portal hypertension. Clinical data were compared between the two groups, and logistic regression analysis was performed to identify independent risk factors for portal hypertension in histological early PBC.

Results:

The most common symptom in both groups was fatigue. Abdominal distension and poor appetite were more common in the portal hypertension group (22.3% vs 8.4%) while itching was more common in the control group (18.1% vs 11.1%), but the differences were not statistically significant. The portal hypertension group had a higher proportion of patients with drug allergies and concomitant extrahepatic autoimmune diseases compared to the control group (29.6% vs 8.4%, $P<0.05$; 29.6% vs 13.3%, $P>0.05$, respectively), with no statistical significance in the latter. More patients in the portal hypertension group were histologically classified as stage II (63%) compared to the control group (39.8%), with a statistically significant difference. White blood cell count, hemoglobin, and platelet count were

lower in the portal hypertension group ($P<0.05$). Both groups showed elevated levels of gamma-glutamyl transferase, alkaline phosphatase, and total bile acid. Total bilirubin, alkaline phosphatase, and total bile acid were higher, while albumin, cholinesterase, and low-density lipoprotein were lower in the portal hypertension group, with statistical significance. The portal vein main trunk width and liver stiffness measurement were greater in the portal hypertension group ($P<0.05$). Drug allergy history and portal vein main trunk width were identified as independent risk factors for portal hypertension in histological early PBC.

Conclusions:

Portal hypertension occurs more frequently in patients with histological stage II PBC, with poorer liver function (higher TBIL, ALP, TBA, lower albumin, cholinesterase, and LDL) compared to the control group. Drug allergy history and portal vein main trunk width are independent risk factors for portal hypertension in histological early PBC, and there is no association between autoimmune antibodies and portal hypertension.

Keyword(s) : Primary biliary cholangitis; Early histological stage ; Portal hypertension

1859 - Unmasking Hepatic Tuberculosis A Case Series on Its Hepatobiliary Mimicry Diagnostic Hurdles and Management Challenges

Christine Velasquez ¹, Sharlene Nicole Chan ², Madaline Eternity Labio ³, Angelo Lozada ¹, Angelo Jonathan Cruz ¹, Suzette Kho Herman ¹, Roel Leonardo Galang ¹

Makati Medical Center, Gastroenterology, Makati-Philippines ¹ Makati Medical Center, Internal Medicine, Makati-Philippines ² Makati Medical Center, Hepatology, Makati-Philippines ³

BACKGROUND:

Hepatic tuberculosis (HTB) is a rare extrapulmonary manifestation of Mycobacterium tuberculosis, often misdiagnosed due to its nonspecific presentation and overlapping features with hepatic malignancy, cirrhosis, or cholestatic disease. Despite being endemic in countries like the Philippines, HTB continues to pose diagnostic and therapeutic dilemmas in clinical hepatology.

CASE SUMMARIES:

We present three distinct cases of hepatic TB illustrating the protean nature of the disease and the importance of histologic confirmation.

E-POSTER ABSTRACTS

Case 1: A 57-year-old male presented with progressive icterus, ascites, and peripheral edema. Imaging revealed a heterogenous hepatic mass with coarse calcifications. Liver biopsy confirmed *Mycobacterium tuberculosis* via GeneXpert and culture. Anti-TB treatment was withheld due to underlying cardiac dysfunction and renal compromise. Despite supportive care and empiric antibiotics for concurrent pneumonia, the patient expired from septic shock.

Case 2: A 47-year-old female, previously diagnosed with HTB, presented with fever and signs of cholangitis. She had developed severe adverse reactions to both first- and second-line anti-TB regimens and discontinued treatment after three months. Abdominal ultrasound revealed liver cirrhosis with coarse calcifications and hypoechoic nodules. She was managed with intravenous ertapenem for ESBL *E. coli* bacteremia, supportive hepatoprotective therapy, and was referred to the Tropical Disease Foundation (TDF) for further evaluation and individualized anti-TB management. Liver enzymes normalized after three weeks of inpatient care.

Case 3: A 32-year-old male experienced recurrent episodes of fever, jaundice, and tea-colored urine for three years. Imaging showed intrahepatic bile duct dilatation with narrowing of the common hepatic duct. Autoimmune and neoplastic workup was negative. Liver biopsy demonstrated granulomatous inflammation with necrosis and calcifications. QuantiFERON-TB Gold was positive. The patient was started on a 12-month anti-TB regimen, resulting in complete symptom resolution and normalization of liver function tests.

CONCLUSION

These cases emphasize that hepatic TB should be a key differential diagnosis in patients presenting with atypical liver lesions, biliary strictures, or cryptogenic cirrhosis—especially in endemic areas. Imaging alone is insufficient, and biopsy remains critical for diagnosis. Clinical vigilance, multidisciplinary input, and individualized therapy—particularly in drug-intolerant or systemically ill patients—are essential to improving outcomes and avoiding misdiagnosis or delayed treatment.

1860 - The Great Imitator in the Liver A Case of Syphilitic Hepatitis Presenting as Cholestatic Jaundice

Cleo Christille Lynn Lom-oc¹, Angelo Lozada¹
Makati Medical Center, Gastroenterology, Makati City-Philippines¹

Background / Hypothesis:

Syphilitic hepatitis is an uncommon hepatic manifestation of *Treponema pallidum* infection, occurring in approximately 0.2–3% of patients with secondary syphilis. It is characterized by mild cholestatic liver injury but can become fulminant in very rare cases. The condition remains under-recognized due to its rarity and variable presentation.

Materials and Methods:

A 37-year-old male presented with painless jaundice. He denied fever, abdominal pain, pruritus, and weight loss. He smoked vape but denied consumption of any medication, drugs, herbal supplements or alcohol overuse. He had no significant personal or family history, besides history of unprotected sexual relations. Physical exam revealed generalized jaundice, pedal edema, and a maculopapular rash over the cervical area, palms and lower extremities. Liver edge was non-palpable and nontender on palpation. No other stigmata of hepatic disease were present. Laboratory tests showed elevation of liver enzymes [aspartate aminotransferase (AST) 41 U/L, alkaline phosphatase (ALP) 860 U/L, and gamma-glutamyl transferase (GGT) 453 U/L] and hyperbilirubinemia (total bilirubin 11.6 mg/dL, direct bilirubin 10.3 mg/dL). Viral hepatitis panel, leptospirosis, dengue serologies and autoimmune hepatitis workup were all negative. Rapid plasma reagin test was reactive. Magnetic resonance cholangiopancreatography (MRCP) demonstrated cholelithiasis with acute calculous cholecystitis but no biliary obstruction. The constellation of cholestatic jaundice, systemic rash, and positive syphilis serology led to a diagnosis of syphilitic hepatitis in secondary syphilis. The patient was treated with a single dose of intramuscular benzathine penicillin G 2.4 million units. Repeat laboratory tests showed improvement of liver enzymes and hyperbilirubinemia.

Results:

Syphilitic hepatitis, also known as luetic jaundice, is a rare manifestation caused by spirochete dissemination to the liver, thereby inducing pericholangiolar inflammation and granulomatous cholestasis. Liver dysfunction does not usually lead to jaundice but it is common to find a disproportional increase in ALP and

E-POSTER ABSTRACTS

transaminases. The proposed diagnostic criteria include: (1) abnormal liver enzymes with cholestatic predominance, (2) serologic evidence of syphilis, (3) exclusion of other etiologies, and (4) improvement in liver enzyme after appropriate therapy. This case highlights the diagnostic challenge, as it can mimic biliary obstruction or autoimmune cholestatic disease.

Conclusions:

Syphilis is a venereal disease with multi-organ involvement hence described as 'The Great Imitator'. Clinicians should consider syphilitic hepatitis in cases of unexplained cholestatic jaundice, particularly when accompanied by systemic rash and unsafe sexual exposure. Early recognition is essential, as antibiotic therapy is simple, effective, and curative, preventing progression of systemic syphilis.

Keyword(s) : Syphilitic hepatitis; Secondary syphilis; Cholestatic jaundice; Treponema pallidum

1862 - Radiomics Based Skeletal Muscle Model at L3 for Predicting 90 Day Mortality in Acute on Chronic Liver Failure Superior to MELD Score

Siqi Zhang¹, Huina Chen², Wenyan Song³, Sujun Zheng¹, Yu Chen⁴, Zhongping Duan⁴, Ming Kong⁴
Beijing You'an Hospital, Capital Medical University, Department Of Liver Diseases I, Beijing-China¹ Beijing Tiantan Hospital, Capital Medical University, Department Of Liver Diseases I, Beijing-China² Beijing You'an Hospital, Capital Medical University, Department Of Radiology, Beijing-China³ Beijing You'an Hospital, Capital Medical University, Department Of Liver Diseases Iv, Beijing-China⁴

Background / Hypothesis:

Acute-on-chronic liver failure (ACLF) is a severe disease with high mortality, and accurate prognostic assessment is essential. Sarcopenia is associated with poor outcomes, and computed tomography (CT) at the third lumbar vertebra (L3) can quantify skeletal muscle mass. Radiomics allows extraction of quantitative features from these images, enabling deeper analysis of muscle-related prognostic factors.

Objective: This study aimed to develop a Radiomics Prognostic Model (RPM) combining L3 skeletal muscle radiomic features with clinical factors to predict 90-day mortality in ACLF patients.

Materials and Methods:

A total of 380 ACLF patients were enrolled and divided

into a training cohort (n=229) and a testing cohort (n=151). Radiomic features from L3-level skeletal muscle CT images were extracted, and a radiomics score was constructed using LASSO regression. Multivariate Cox regression combined the radiomics score with clinical risk factors to build a nomogram-based predictive model. Model performance and clinical utility were evaluated with calibration curves, receiver operating characteristic (ROC) analysis, and decision curve analysis.

Results:

The RPM included the radiomics score, total bilirubin, hepatic encephalopathy, INR, and creatinine as independent predictors. The model achieved AUCs of 0.80 (95% CI: 0.74–0.86) in the training cohort and 0.81 (95% CI: 0.74–0.88) in the testing cohort, significantly outperforming MELD and MELD-Na scores ($P < 0.05$). Decision curve analysis demonstrated that the RPM provided superior clinical net benefit.

Conclusions:

The RPM effectively predicts 90-day mortality in ACLF patients, integrating skeletal muscle radiomics with clinical factors, and offers a practical tool for individualized prognostic assessment.

Keyword(s) : Acute-on-chronic liver failure, Prognosis, Sarcopenia, Radiomics, Nomogram, Predictive model

1863 - Differentiating acute onset autoimmune hepatitis from drug induced autoimmune like hepatitis a multicenter study and score development

Haoyu Wen¹, Yu Chen¹, Qiuxiang Lin², Yujie Zhou¹, Tianyu Mao¹, Qi Miao¹, Zuxiong Huang², Yongfeng Yang³, Xiong Ma¹, Xiao Xiao¹

Renji Hospital, School Of Medicine, Shanghai Jiao Tong University; Shanghai Institute Of Digestive Disease, Division Of Gastroenterology And Hepatology, Key Laboratory Of Gastroenterology And Hepatology, Guangzhou-China¹ Mengchao Hepatobiliary Hospital Of Fujian Medical University, Department Of Hepatology, Fuzhou-China² The Second Hospital Of Nanjing, Affiliated To Nanjing University Of Chinese Medicine, Department Of Infectious Disease And Liver Disease, Nanjing-China³

Background: The incidence of acute-onset autoimmune hepatitis (A-AIH) is rising, but its diagnosis remains challenging, particularly in patients with a history of

E-POSTER ABSTRACTS

hepatotoxic drug exposure. The clinical presentations of A-AIH and drug-induced autoimmune-like hepatitis (DI-ALH) at onset are often indistinguishable, complicating their timely diagnosis.

Methods: This three-center retrospective study analyzed 238 cases of acute liver injury with autoimmune features following potential hepatotoxic drug exposure. Among them, 94 cases were diagnosed as A-AIH and 144 as DI-ALH. A comprehensive comparative analysis was conducted, focusing on clinical presentations, immunological characteristics, and histological features. The performance of diagnostic scoring systems for AIH and drug-induced liver injury in distinguishing the two conditions was evaluated. A multivariable logistic regression model was developed and independently validated to improve differentiation between A-AIH and DI-ALH.

Results: Compared to DI-ALH, A-AIH was characterized by higher immunoglobulin G (IgG) levels, reduced platelet counts, and elevated autoantibody titers. Histologically, A-AIH showed more severe features, including portal inflammation, interface hepatitis, fibrosis, and rosette formation. The 2022 AIH histological criteria demonstrated higher sensitivity but lower specificity than the 2008 criteria, with limited capacity to differentiate A-AIH from DI-ALH (AUC 0.62 vs. 0.59, $p = 0.616$). A novel diagnostic model, the Dx-AID score, which incorporates platelet count, IgG, autoantibodies, and histological features, showed high diagnostic accuracy in both the derivation cohort (AUC 0.84, 95% CI 0.77-0.91) and the validation cohort (AUC 0.83, 95% CI 0.72-0.94).

Conclusions: A-AIH and DI-ALH share many clinical similarities, but they differ in immunological and histological profiles. The Dx-AID score effectively integrates these key differences, providing a clinically actionable tool for early differentiation and guiding personalized treatment decisions.

Keyword(s) : drug-induced autoimmune-like hepatitis, autoimmune hepatitis, drug-induced liver injury, acute-onset

1864 - HONEYCOMBED LIVER HEPATIC MELIOIDOSIS A RARE MIMICKER OF PYOGENIC ABSCESS IN A NON EXPOSED DIABETIC PATIENT

Christine Velasquez¹, Sharlene Nicole Chan², Angelo Jonathan Cruz¹

Makati Medical Center, Gastroenterology, Makati-Philippines¹ Makati Medical Center, Internal Medicine, Makati-Philippines²

BACKGROUND

Melioidosis is a potentially life-threatening infection caused by *Burkholderia pseudomallei*, a Gram-negative bacterium endemic to Southeast Asia and northern Australia. Hepatic involvement is rare and often misdiagnosed as pyogenic liver abscess, particularly in regions like the Philippines where awareness remains limited. The infection is typically associated with risk factors such as diabetes mellitus and environmental or occupational exposure to contaminated soil or water.

CASE PRESENTATION

We report a case of hepatic melioidosis in a 44-year-old Filipino male with newly diagnosed type 2 diabetes mellitus and no known environmental or occupational exposure. He presented with two weeks of low-grade fever and dry cough but no abdominal symptoms. Laboratory evaluation showed anemia (Hb 9.4 g/dL), leukocytosis ($15.1 \times 10^3/\mu\text{L}$), elevated alkaline phosphatase, gamma-glutamyl transferase, and total bilirubin. Contrast-enhanced abdominal CT revealed multiple hepatic abscesses, the largest measuring 5.8 cm.

MANAGEMENT AND OUTCOME

Empiric antimicrobial therapy was initiated with metronidazole and ertapenem, and image-guided percutaneous drainage was performed. Intraoperatively, thick, grayish, blood-tinged pus was aspirated from honeycomb-like, multiseptated abscesses. Culture of the drained fluid yielded *Burkholderia pseudomallei*, prompting a shift to meropenem, followed by intravenous ceftazidime for two weeks. The patient was discharged on oral cotrimoxazole for 12 weeks.

Serial liver ultrasound studies performed on November 5, November 18, 2024, and February 8, 2025, showed progressive resolution of the hepatic abscesses, with eventual transformation into small, avascular hypoechoic foci. The patient completed the antibiotic regimen without complications and recovered clinically and biochemically, with normalization of liver enzymes and inflammatory markers.

E-POSTER ABSTRACTS

CONCLUSION:

This case underscores the importance of considering melioidosis in the differential diagnosis of hepatic abscesses, particularly in diabetic patients—even in the absence of classical exposure risks. A high index of suspicion, culture confirmation, and timely initiation of targeted antimicrobial therapy are critical for favorable outcomes. The presence of solid, multiseptated liver abscesses should raise suspicion for melioidosis over common pyogenic etiologies. Prolonged antibiotic therapy, combined with percutaneous drainage and close radiologic monitoring, remains the cornerstone of treatment. Awareness of this rare manifestation is essential for early diagnosis and prevention of complications in endemic settings.

Keyword(s) : Hepatic melioidosis Burkholderia pseudomallei Liver abscess Diabetes mellitus

1865 - Biliary Mass Mimicking Cholangiocarcinoma as a presentation of Hepatobiliary Tuberculosis in a Young and Immunocompetent patient.

Bettyna Rose Rustia¹

University Of The Philippines - Philippine General Hospital, Internal Medicine, Division Of Gastroenterology, Manila-Philippines ¹

Biliary involvement in tuberculosis is uncommon and, like its other manifestations, it may closely resemble malignant processes, posing significant diagnostic challenges for physicians. Obstructive jaundice from tuberculosis usually results from extrinsic compression by enlarged lymph nodes or strictures caused by infection of the biliary epithelium. In rare cases, it can appear as mass-like lesions.

We present the case of a 30-year-old male who developed obstructive jaundice and was initially misdiagnosed with cholangiocarcinoma based on a triphasic liver CT scan showing intrahepatic ductal ectasia with a heterogeneously enhancing mass in the right posterior ductal branch. A multidisciplinary team of hepatobiliary surgeons, hepatologists, and radiologists met to determine the best management strategy. To confirm tuberculosis, the patient underwent several diagnostic tests, including a bile duct biopsy and PCR testing; however, neither test confirmed tuberculosis, so the patient was empirically treated. Given the clinical presentation and imaging findings suggestive of tuberculosis, the patient began a 9-month course of antituberculous therapy. Following antituberculous therapy, the patient demonstrated clinical recovery, and imaging showed

regression of the pseudotumor. This case highlights the necessity of including tuberculosis in the differential diagnosis of obstructive jaundice, especially in regions where tuberculosis is endemic.

Keyword(s) : Hepatobiliary Tuberculosis, Biliary Tract Mass, Obstructive Jaundice, Anti-tuberculous therapy

1866 - Real world evidence on albumin use in the management of patients with cirrhosis and ascites during paracentesis in Taiwan

Cristina Coll-ortega¹, Kai-cheng Chang², Wei-ting Chen³, Liu Yang⁴, Cristina Fuster¹, Eli Viayna¹, Kuan-lin Lin⁵, Hung-wei Lin⁵, David Gomez¹
Instituto Grifols, Heor & Rwe, Sant Cugat Del Valles-Spain ¹ Linkou Chang Gung Memorial Hospital, Department Of Pharmacy, Taoyuan-Taiwan ² Linkou Chang Gung Memorial Hospital, Department Of Gastroenterology And Hepatology, Taoyuan-Taiwan ³ Grifols Pharmaceutical Technology, Medical Affairs, Shanghai-China ⁴ Iqvia Solutions, Real World Solutions, Taipei-Taiwan ⁵

Background / Hypothesis:

Administration of human albumin (HA) at a dose of 6–8 g per liter of ascitic fluid removed is recommended following paracentesis by the APASL international clinical guidelines. Moreover, in cases of large-volume paracentesis (LVP), HA is strongly advised to prevent paracentesis-induced circulatory dysfunction (PICD). This study aims to examine current treatment practices for patients with cirrhosis and ascites undergoing paracentesis in Taiwan.

Materials and Methods:

Adult patients with a catastrophic illness certificate for liver cirrhosis between January 2018 and August 2023, with at least one valid paracentesis record were identified from the Chang Gung Research Database (CGRD). A valid record was defined as one containing volume data, and the first paracentesis event was defined as the index date. Patients with one of the following coexisting diseases during the 1-year baseline were excluded for the analysis: hepatocellular carcinoma, liver transplantation and heart failure. Patient demographics, clinical characteristics and patterns of albumin utilization were analyzed.

Results:

E-POSTER ABSTRACTS

Among 1,492 adult patients with catastrophic illness certificate for liver cirrhosis, 188 patients were excluded due to the following exclusion criteria: N=148 due to hepatocellular carcinoma, N=1 due to liver transplantation and N=43 due to heart failure. A total of 184 patients with a total of 535 valid paracentesis events were identified among 1,304 eligible cirrhosis patients. 75.5% of patients were male, with a median age of 57.7 years. Mean and median time from cirrhosis diagnosis to first paracentesis was 11.0 and 4.5 months respectively (Table 1). Mean and median serum albumin levels were lower than 3 g/dL in both the albumin and non-albumin cohorts (Table 2). Overall, HA was not administered in most paracentesis procedures (Table 3). Notably, in LVP involving removal of more than 5 liters of ascitic fluid, most patients did not receive albumin, despite strong recommendations for its use in clinical guidelines.

Conclusions:

HA was significantly underutilized in Taiwan, even in guideline-recommended indications such as paracentesis exceeding 5 liters.

Keyword(s) : cirrhosis, RWE, LVP, albumin, paracentesis, human albumin, Taiwan

1868 - Phenobarbital Induced DRESS with Acute Liver Injury A Hepatology Focused Approach Using Early Immunosuppression and Hepatoprotective Support

Christine Velasquez¹, Shelomith Hope Lozada², Angelo Lozada¹
Makati Medical Center, Gastroenterology, Makati-Philippines¹ Makati Medical Center, Internal Medicine, Makati-Philippines²

BACKGROUND:

Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) is a rare but potentially life-threatening, drug-induced hypersensitivity reaction characterized by rash, fever, eosinophilia, and multiorgan involvement. Among the affected systems, hepatic injury is most common—seen in up to 80% of cases—and significantly influences clinical outcomes. Liver damage may range from asymptomatic transaminitis to fulminant hepatic failure. Early recognition and timely intervention are critical in preventing progression and ensuring full recovery.

CASE PRESENTATION:

We report a case of a 21-year-old Filipino male with

seizure disorder who developed DRESS syndrome two weeks after initiating phenobarbital. He initially presented with fever, morbilliform rash, leukocytosis, and marked eosinophilia (5278/uL). Liver enzymes were normal on admission, but on hospital day 12, he developed acute liver injury with abrupt elevations in AST (1458 U/L), ALT (1111 U/L), and total bilirubin (3.71 mg/dL), with a mixed hepatocellular-cholestatic pattern. Extensive workup ruled out viral hepatitis, CMV, EBV, and HHV. Despite absence of hepatic encephalopathy or coagulopathy, the rapid biochemical deterioration prompted early immunosuppressive therapy.

MANAGEMENT AND OUTCOME:

The patient was initiated on intravenous methylprednisolone (60 mg/day for 4 days) and cyclosporine (150 mg every 12 hours). Glycyrrhizic acid, S-adenosylmethionine, and ursodeoxycholic acid were concurrently administered as hepatoprotective agents. Empiric antibiotics (aztreonam and clindamycin) were given due to elevated procalcitonin and pulmonary symptoms, selected for their minimal hepatic metabolism. Within 48 hours, eosinophilia resolved and liver enzymes began to decline. By day 4, transaminases were halved, and bilirubin stabilized. Corticosteroids were tapered, and cyclosporine was continued for two weeks without adverse effects. The patient achieved complete biochemical recovery with no recurrence on follow-up.

CONCLUSION

This case highlights the pivotal role of liver-focused, timely intervention in DRESS-related hepatotoxicity. Early immunosuppression with short-course corticosteroids and cyclosporine—augmented by hepatoprotective therapies—facilitated rapid reversal of liver injury. Cyclosporine showed excellent tolerability and may serve as a valuable steroid-sparing agent. A multidisciplinary approach grounded in hepatology principles is essential to optimize outcomes and prevent long-term hepatic sequelae in DRESS syndrome.

Keyword(s) : DRESS syndrome; Drug-induced liver injury; Cyclosporine therapy; Immunosuppressive Therapy

1869 - Societal impact of cholestatic pruritus in patients diagnosed with primary biliary cholangitis A cross sectional survey in Japan

Atsushi Tanaka¹, Zsafia Kiss², Joanna De Courcy³, Laura Mirams³, Morgan Fox³, Caz Canavan⁴, Ai

E-POSTER ABSTRACTS

Hayashi ⁵, Megumi Koyano ⁵, Atsumasa Komori ⁶
Teikyo University School Of Medicine, Department Of
Medicine, Tokyo-Japan ¹ Gsk, Munich, , -Germany ²
Adelphi Real World, , Bollington-United Kingdom ³ Gsk,
London, , -United Kingdom ⁴ Gsk, , Tokyo-Japan ⁵ Nho
Nagasaki Medical Center, , Nagasaki-Japan ⁶

Background / Hypothesis:

Cholestatic pruritus has been described as a deep, intense itch with a profound impact on quality of life. It affects 55–89% of people with primary biliary cholangitis (PBC) during the course of their disease and up to 53% report clinically significant pruritus. Furthermore, 51% of patients with PBC from Japan reported experiencing pruritus. There is a lack of evidence describing the broader societal and economic burden of pruritus in PBC, particularly regarding work productivity. This study aimed to address these gaps by assessing the societal impact of pruritus in patients with PBC and their partners/close family members in Japan.

Materials and Methods:

This study is a non-interventional, cross-sectional online survey in Japan of patients experiencing pruritus as a symptom of PBC and their partners/family members. Patients were ≥ 18 years of age and had experienced itch due to PBC in the week before completing the survey. A separate survey captured insights from partners/close family members (≥ 18 years of age) of patients with PBC pruritus.

Results:

In total, 70 patients were enrolled in the study (female: 66%, n=46; median age: 55 years), most of whom received prescription medication for pruritus (69%, n=48). Among all respondents, 66% (n=46) were employed full- or part-time. The majority of patients reported moderate-to-severe sleep disturbance (56%, n=39) and financial worries due to PBC-related itch (86%, n=60); 37% (n=26) reported a moderate-to-severe impact of itch on their ability to focus at work and on everyday activities.

Overall mean work impairment (reported on the Work Productivity and Activity Index) was 37% in the total population and 47% in patients with severe itch. Patients with moderate-to-severe sleep disturbance due to itch reported 47% work impairment. In addition, 29 partners/close family members were enrolled (female: 28%, n=8; median age: 55 years). The majority worked full time (79%, n=23) and 90% (n=26) reported

providing help due to the patient's itching. Based on responses from 24 partners/close family members, an average of 34% overall work impairment due to problems associated with their partner's/family member's itching was reported.

Conclusions:

In patients with PBC, itch and sleep disturbance had a broad impact on work/employment and everyday activities and carried a financial burden. Itch experienced by patients also negatively impacted the work of their partners/close family. Improving management of pruritus in PBC, including more effective treatment options, would reduce the burden for patients and their partners/family members, and subsequently, the broader societal impact of pruritus in Japan.

Funding: GSK (221129).

1870 - SILENT STONES SERIOUS INFECTION THE ROLE OF ASYMPTOMATIC CHOLELITHIASIS IN PYOGENIC LIVER ABSCESS

Desiree Jane Lacuin ¹, Carlo Cornejo ¹

Makati Medical Center, Gastroenterology, Makati City-Philippines ¹

Background:

A liver abscess is defined as a pus-filled mass in the liver that can develop from injury to the liver or an intraabdominal infection disseminated from the portal circulation. The majority of these abscesses are categorized into pyogenic or amoebic, although a minority is caused by parasites and fungi. *Klebsiella pneumoniae* is a prominent etiology of pyogenic abscess in Southeast Asia and presents as more severe than other forms of bacterial abscesses, possibly because of enhanced virulence factors of the bacteria. The usual pathophysiology for pyogenic liver abscesses is bowel content leakage and peritonitis where the bacteria travels to the liver via the portal vein and resides there. Infection can also originate in the biliary system due to the proximity of the liver to the gall bladder. Notably, 50–60% of hepatic abscesses are of biliary origin, commonly associated with cholecystitis or choledocholithiasis. However, there is limited literature documenting pyogenic liver abscess arising from isolated asymptomatic cholelithiasis without

E-POSTER ABSTRACTS

evidence of inflammation or biliary obstruction, making such presentations particularly uncommon.

CASE:

This is the case of a 37-year-old male with no known comorbidities who presented with a 5-day history of fever associated with watery stools and abdominal cramps. Routine fecalysis and urinalysis were unremarkable, with no ova or parasites detected. Laboratory evaluation showed leukocytosis. Whole abdominal ultrasound revealed a 7 × 7 cm liver abscess in the left lobe, along with multiple gallstones (largest measuring 1 cm) without evidence of cholecystitis or CBD stones. Ultrasound-guided drainage of the hepatic abscess was performed, yielding purulent material. Culture grew *Klebsiella pneumoniae*, confirming a pyogenic liver abscess. Tests for amoebic, tuberculous, and fungal etiologies were negative. The patient was started on intravenous Ceftriaxone, with defervescence on third hospital day. Repeat ultrasound showed significant interval reduction in abscess size. He was subsequently discharged in improved condition with oral antibiotics for completion at home. Patient decided to have elective Cholecystectomy on separate admission.

Conclusion:

This case highlights that pyogenic liver abscess may rarely arise from asymptomatic cholelithiasis in the absence of biliary inflammation or obstruction. Early imaging, prompt drainage, and appropriate antibiotic therapy remain essential for favorable outcomes. Clinicians should consider biliary pathology in atypical presentations to facilitate early intervention and optimize patient outcomes.

1871 - ORAL SEMAGLUTIDE FOR WEIGHT MANAGEMENT AND GASTROINTESTINAL SAFETY IN METABOLIC DISEASE; A META ANALYSIS AND NARRATIVE LIVER OUTCOME SYNTHESIS

Christine Velasquez¹, Sharlene Nicole Chan², Oscar Cabahug¹, Gerardo Pedregosa¹

Makati Medical Center, Gastroenterology, Makati-Philippines¹ Makati Medical Center, Internal Medicine, Makati-Philippines²

BACKGROUND:

Oral semaglutide is the first and only oral glucagon-like peptide-1 receptor agonist (GLP-1 RA), offering a non-injectable therapeutic option for type 2 diabetes (T2D), obesity, and metabolic dysfunction associated

steatotic liver disease (MASLD). Although individual trials have demonstrated its efficacy and safety, existing reviews have combined oral and subcutaneous (SC) formulations, limiting formulation-specific insights. To date, no meta-analysis has focused exclusively on oral semaglutide. A dedicated synthesis is needed to clarify its weight-loss efficacy, gastrointestinal (GI) tolerability, and potential hepatic benefits, particularly as oral GLP-1 therapies gain prominence in metabolic care.

OBJECTIVE:

To evaluate the efficacy of oral semaglutide for achieving clinically meaningful weight reduction and to assess its GI safety profile through meta-analysis, complemented by a narrative review of liver-related outcomes.

METHODS:

Following PRISMA 2020 guidelines, a comprehensive search of PubMed, Embase, Cochrane CENTRAL, Web of Science, Scopus, ClinicalTrials.gov, and WHO ICTRP was conducted up to 20 August 2025. Eligible studies included randomized controlled trials (RCTs) and prospective interventional studies in adults (≥18 years) with T2D, obesity, or MASLD who received oral semaglutide 14–50 mg daily for at least 12 weeks. The primary endpoint was achievement of ≥5% weight loss. Secondary endpoints included GI adverse events and treatment discontinuation. Hepatic outcomes—changes in aminotransferases, controlled attenuation parameter (CAP), fibrosis scores, and elastography—were narratively synthesized. Random-effects models generated pooled risk ratios (RRs) with corresponding 95% confidence intervals (CIs).

RESULTS:

Five studies met inclusion criteria (four RCTs and one pilot study), enrolling over 2,000 participants. Meta-analysis of OASIS-1, OASIS-2, and PIONEER-1 demonstrated that oral semaglutide markedly increased the likelihood of achieving ≥5% weight loss (RR 5.46, 95% CI 4.37–6.83; $I^2 = 0\%$). However, GI adverse events were significantly more frequent with oral semaglutide (RR 1.95, 95% CI 1.66–2.28), and treatment discontinuations were higher (RR 3.00, 95% CI 1.59–5.67), though overall rates remained modest. The MASLD pilot trial showed improvements in ALT, AST, CAP, and FIB-4, but no meaningful reduction in liver stiffness, suggesting potential but still inconclusive hepatic benefits.

CONCLUSION:

E-POSTER ABSTRACTS

Oral semaglutide produces substantial and clinically meaningful weight loss, accompanied by increased but generally manageable GI adverse events. Its discontinuation rate remains acceptable within the context of GLP-1 RA therapy. Preliminary evidence suggests metabolic and hepatic improvements, but larger, dedicated RCTs are needed to validate liver-specific outcomes. As the first meta-analysis focused exclusively on oral semaglutide, this study provides timely and formulation-specific evidence to guide clinical decisions in metabolic disease management.

1872 - Circulating C1Q+ monocytes associate with lower HBsAg level in chronic HBV infection

Fengge Zhu¹, Man-fung Yuen¹, Lung-yi Mak¹
The University Of Hong Kong, Department Of Medicine, Hong Kong-Hong Kong SAR, China¹

Background / Hypothesis:

Peripheral myeloid cells, including monocytes, dendritic cells, and macrophages, are key innate immune effectors in viral infections, migrating to infected tissues to phagocytose viruses and secrete pro-inflammatory cytokines like TNF- α . However, they can also serve as viral reservoirs, promoting immune evasion or chronic persistence in chronic HBV infection. Low serum HBsAg levels predict functional cure, but the association with circulating monocyte subsets remains unknown.

Materials and Methods:

We analyzed single-cell transcriptomics from PBMC of 20 chronic HBV patients (9 high HBsAg [920-12447 IU/mL], 11 low HBsAg [1-100 IU/mL]) and paired liver FNA from 8. Data (GSE247322) were integrated with Seurat3, clustered using Louvain (resolution 0.5, top 2000 HVGs, 30 PCs), and annotated manually. DEGs were identified by Wilcoxon test (FDR <0.001, |log2FC| >1). CellPhoneDB and SCIPAC assessed communication and phenotype association. Bulk RNA-seq (GSE173897) validated findings using Fisher's exact test (reference 20,000 genes).

Results:

To elucidate the transcriptional signatures linked to HBsAg-mediated immune modulation in chronic HBV infection, we first quantified upregulated and downregulated differentially expressed genes (up-DEGs) in peripheral blood mononuclear cells and liver

fine-needle aspiration biopsies, contrasting high versus low serum HBsAg levels. Blood up-DEGs (2935, high vs low HBsAg) and liver up-DEGs (849) overlapped in 513 genes ($p = 6.64 \times 10^{-213}$, OR 9.94, 59% liver overlap); down-DEGs overlapped in 137 ($p = 2.02 \times 10^{-34}$, OR 4.22, 32% liver overlap). The overlapping up-DEGs were predominantly enriched in CD33+ myeloid subsets, including IL-1 β + monocytes, SLC8A1+ monocytes, ISG+ monocytes (IFI27, IFI30, SIGLEC1), C1Q+ monocytes (C1QA, VMO1), CD302+ monocytes, cDCs (CD1c, FCER1A), and pDCs (IL3RA). AUC score of overlapping genes was highest in C1Q+ monocytes (mean AUC 0.177; high HBsAg group 0.186, low 0.168). SCIPAC analysis on GSE173897 (97 patients) showed SLC8A1+ monocytes correlated with viral inactive phenotype (HBV DNA <2,000 IU/mL; $p = 6.98 \times 10^{-4}$, $\lambda = -2.19$). CellPhoneDB analysis revealed C1Q+ monocytes interact with ISG+ monocytes via HLA-E-VSIR (enhanced in low HBsAg group), cDCs, CD302+ monocytes, and other C1Q+ monocytes via CD44-TYROBP, CD52-SIGLEC10, CD55-ADGRE5 interaction pairs. Among the 51 DEGs in C1Q+ monocytes, 7 complement-linked (FCN1, CLEC7A, NAIP, CASP3, CD36, NFKBIA, MYH9) genes were significantly upregulated in low HBsAg group.

Conclusions:

Circulating C1Q+ monocytes associate with lower HBsAg in chronic HBV infection, potentially mediated by upregulated membrane-bound complement regulators CD55 and CD97, the exact mechanism of which requires further study.

Keyword(s) : monocytes, HBsAg, HBV

1873 - The Clinical Epidemiology and Treatment of Acute Hepatitis C Caused by Unsafe Clinical Practices

Qing-lei Zeng¹, Ru-yue Chen¹, Yan-qin Ai², Ya-jie Pan¹, Yue-hang Wang¹, Zhuang-zhuang Zhai¹, Xue-jing Yu¹

The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases And Hepatology, Zhengzhou-China¹ Xu Chang Central Hospital, Department Of Infectious Diseases, Xuchang-China²

Background / Hypothesis:

Compared to chronic hepatitis C, acute hepatitis C (AHC) is more difficult to detect and therefore less likely to be treated in a timely manner. This study reports the clinical epidemiological characteristics, treatment, and outcomes of AHC caused by unsafe clinical practices.

E-POSTER ABSTRACTS

Materials and Methods:

From 2023 to 2024, an outbreak of hepatitis C caused by unsafe clinical practices occurred at a clinic in Xuchang City, Henan Province, China. The local government and Center for Disease Control and Prevention screened 630 individuals. Through comprehensive epidemiological and virological assessments, 72 adolescents and adults aged 5 years and older were identified as having AHC. Among them, 47 AHC patients agreed to receive a 12-week course of direct-acting antiviral (DAA) therapy. The criterion for evaluating treatment efficacy was sustained virological response (SVR) 12, defined as undetectable hepatitis C virus (HCV) RNA 12 weeks after completion of therapy, meanwhile, the safety profiles were closely monitored. Results:

Among the 72 patients with detectable HCV RNA, 38 (52.8%) patients were male, 71 (98.6%) patients tested positive for HCV antibodies. The mean age was 62.5 (54.0, 72.0) years, with 4 (5.6%) patients aged 5-12 years, 4 (5.6%) patients aged 13-18 years, and 64 (88.8%) patients aged over 18 years. The mean HCV RNA level was $5.60 \pm 1.64 \log_{10}$ IU/mL, genotype 1b accounted for 87.5% (63/72). Among the 37 patients with alanine aminotransferase (ALT) results, the mean ALT level was 143.0 (61.8, 378.7) U/L. 58 (80.6%) patients reported history of Injection or dental treatment within the last 6 months (Table 1). Among the 47 patients who received DAA therapy, the regimens used were as follows: Sofosbuvir/Velpatasvir in 24 patients (33.3%), Emitasvir/Sofosbuvir in 20 patients (27.8%), Ledipasvir/Sofosbuvir in 2 patients (2.8%), and Cobloipasvir/Sofosbuvir in 1 patient (1.4%). Notably, 100% (47/47) of DAA-treated patients achieved SVR 12. For the 25 untreated patients, reasons for non-treatment included financial constraints, advanced age with impaired mobility, and unspecified refusal. Within one year, 9 patients were successfully recalled. Among them, 3 patients achieved spontaneous clearance, 2 patients reached SVR12 after antiviral therapy, and 4 patients are currently undergoing antiviral treatment. The remaining patients are undergoing continued follow-up.

Conclusions:

This outbreak highlights the risks of unsafe clinical practices and the importance of early detection and treatment of AHC. DAA therapy was highly effective, with all treated patients achieving SVR12. Strengthened infection control and timely intervention are crucial to preventing similar events.

clinical practices ; Sustained Virological Response (SVR12)

1874 - Research on the Mechanism of LSEC Functional Abnormalities Induced by TMAO in porto sinusoidal vascular disease

Yadi Li¹, Huiguo Ding¹

Beijing You'an Hospital, Affiliated With Capital Medical University, Department Of Gastroenterology And Hepatology, Beijing-China¹

Background / Hypothesis:

Porto-sinusoidal vascular disease (PSVD) is a hepatic vascular disorder characterized by non-cirrhotic portal hypertension. The underlying pathophysiological mechanism primarily involves dysfunction of liver sinusoidal endothelial cells (LSECs) and disruption of the hepatic sinusoidal microenvironmental homeostasis. To date, the precise etiology of PSVD remains poorly understood. In our clinical cohort study on PSVD, trimethylamine N-oxide (TMAO) was identified as having significant clinical relevance. Multi-omics sequencing analyses combined with in vitro experimental validation demonstrated that TMAO induces the expression of serine hydroxymethyltransferase 1 (SHMT1), thereby contributing to LSEC injury. Notably, such an association has not been previously reported. This study aims to investigate the role and molecular mechanisms through which TMAO-induced SHMT1 expression contributes to the pathogenesis of PSVD.

Materials and Methods:

ELISA was used to confirm the elevated level of TMAO in PSVD patients. Subsequently, transcriptome and metabolome sequencing analysis identified SHMT1 as a key biomarker for TMAO-induced LSEC injury. In vitro validation was conducted using techniques such as PCR, WB, IHC, and LC-MS/MS. Functional experiments included migration, invasion, and angiogenesis assays. To explore the mechanism, SHMT1 gene silencing technology was employed to verify that TMAO induces LSEC injury by inducing SHMT1 and altering the one-carbon metabolic flux (SAM/SAH ratio increases, serine consumption rises).

Results:

1. Under electron microscopy of liver tissue in patients with PSVD, damage to the hepatic sinusoidal microenvironment can be observed: the window pores of hepatic sinusoidal endothelial cells disappear and fuse. Hepatic stellate cells are activated and collagen

E-POSTER ABSTRACTS

fibers increase in the Dlls space.

2. In vitro experiments have verified that TMAO can lead to LSEC damage accompanied by functional impairment. Multi-omics joint analysis (Transcriptome and Metabolome) has confirmed that SHMT1 is a key biomarker for the function of TMAO.

3. When TMAO continuously stimulated for 24 hours, the expression of SHMT1 reached its peak. Silencing SHMT1 could lead to a decrease in the SAM/SAH ratio and a weakening of folate one-carbon metabolic flux, and SHMT1 can be replenished after stimulation with TMAO.

Conclusions:

This study reveals that TMAO is involved in the injury and dysfunction of LSEC in PSVD, and verifies that this process is caused by inducing the expression of SHMT1 to activate the one-carbon metabolic pathway by folate, thereby having a certain promoting effect on the liver sinusoidal vascular injury in PSVD.

Keyword(s) : Porto-sinusoidal vascular disease (PSVD); liver sinusoidal endothelial cells (LSECs); trimethylamine N-oxide (TMAO); injury; hydroxymethyltransferase 1 (SHMT1)

1875 - Circulating NCAN as a protective biomarker and causal modifier of multistage liver disease

Tianyi Xia¹, Yaoyao Yu¹, Lingling Gao², Shenghong Ju¹

Zhongda Hospital Southeast University, Radiology, Nanjing-China¹ School Of Instrumentation And Optoelectronic Engineering, Beihang University, Bioengineering, Beijing-China²

Background / Hypothesis: Multistage liver diseases, from steatosis to cirrhosis and hepatocellular carcinoma (HCC), require biomarkers that capture progression and enable risk stratification. This study systematically evaluated circulating proteins to identify causal drivers across liver disease stages, with a focus on Neurocan (NCAN) as a potential cross-stage protective factor.

Materials and Methods: We integrated cis-pQTLs from eight large proteomic datasets with genome-wide association data from 13 cohorts covering alcoholic liver disease (ALD), non-alcoholic fatty liver disease (NAFLD), cirrhosis, and HCC. Mendelian randomization (MR) assessed causal effects, and cross-validation identified proteins consistently associated across stages. Bulk and single-cell RNA-seq characterized tissue distribution. NCAN dynamics and pathology

correlations were examined in a NASH-HCC mouse model. Clinical relevance was evaluated using 51,966 UK Biobank participants with proteomic profiling and a multi-center Chinese cohort (n = 202). Predictive performance was assessed alone and combined with established scores (FIB-4, LiverRisk, aMAP, mPAGE-B).

Results: MR identified 20 robust protein-disease associations, highlighting 17 circulating proteins. NCAN consistently emerged as a protective protein across NAFLD, cirrhosis, and HCC, with no evidence of reverse causation or pleiotropy. Transcriptomic analyses showed negligible hepatic expression and predominant extrahepatic origin, supporting a circulating rather than liver-derived role. In the NASH-HCC model, NCAN levels progressively decreased from steatosis to carcinoma and were strongly inversely correlated with steatosis grade, lobular inflammation, and fibrosis severity. In UK Biobank, higher circulating NCAN was associated with lower liver disease burden, reduced incident liver disease (HR = 0.82, 95% CI, 0.74-0.91, P = 2.76×10⁻⁴), and improved liver-related survival after multivariable adjustment. Addition of NCAN improved long-term prediction for both liver disease onset and mortality compared with standard clinical models. In the Chinese cohort, NCAN levels declined stepwise from healthy controls to steatotic liver disease, cirrhosis, and HCC. NCAN independently predicted significant fibrosis and HCC (AUC = 0.92 and 0.89, respectively), and integration with FIB-4 or LiverRisk further improved diagnostic performance.

Conclusions: This comprehensive proteogenomic evaluation identifies NCAN as a consistent, cross-stage protective biomarker in liver disease progression. Evidence from genetic analyses, transcriptomics, animal models, and cross-ethnic human cohorts demonstrates that circulating NCAN reflects key pathological processes and enhances prediction of fibrosis, liver disease incidence, and clinical outcomes. Incorporating NCAN into existing clinical scores substantially improves diagnostic and prognostic accuracy, underscoring its potential utility in personalized liver disease surveillance and risk assessment.

1876 - Beyond the Usual Course Prolonged Cholestatic Hepatitis A in a 36 Year Old Female

John Paul Dela Peña¹, Gerardo Mendoza¹, Ian Homer Cua¹

E-POSTER ABSTRACTS

St. Luke's Medical Center - Global City, Institute Of Digestive And Liver Diseases, Taguig-Philippines ¹

Hepatitis A virus (HAV) infection typically manifests as a self-limited, acute viral hepatitis with resolution within weeks. However, a subset of patients may present with a prolonged cholestatic course, posing diagnostic and therapeutic challenges. We report the case of a 36-year-old female with no prior comorbidities, who presented with fever, epigastric pain, postprandial vomiting, malaise, and jaundice. Laboratory evaluation revealed markedly elevated transaminases and progressive hyperbilirubinemia with cholestatic predominance. Serology confirmed acute HAV infection, while autoimmune and viral hepatitis panels were negative. Imaging studies demonstrated hepatomegaly with fatty infiltration, splenomegaly, reactive lymphadenopathy, and findings consistent with acalculous cholecystitis. Despite initial conservative management, her cholestatic symptoms and bilirubin levels persisted, necessitating corticosteroid therapy. Gradual tapering of prednisone led to clinical and biochemical improvement.

This case highlights the uncommon presentation of prolonged cholestatic hepatitis A, which may mimic other hepatobiliary disorders and complicate management, particularly when associated with reactive acalculous cholecystitis. Key diagnostic considerations include exclusion of autoimmune hepatitis, biliary obstruction, and other viral hepatitis. Early recognition of this variant can guide appropriate supportive care, timely use of ursodeoxycholic acid, and judicious corticosteroid therapy in selected patients. Clinicians should maintain vigilance for prolonged cholestasis in adults with HAV, as delayed resolution may impact quality of life and prolong hospitalization. This report underscores the importance of a comprehensive, multidisciplinary approach in managing atypical HAV presentations and contributes to the limited literature on prolonged cholestatic hepatitis A in adults.

Keyword(s) : Prolonged cholestatic hepatitis A; Acalculous cholecystitis; Corticosteroid therapy

1877 - Dynamic Increase in HBsAg during Long Term Antiviral Therapy The Role of HBV Integration and Clonal Hepatocyte Expansion

Luqi Tang ¹, Bingqiong Wang ¹, Guiwen Guan ², Yameng Sun ¹, Shuyan Chen ¹, Jialing Zhou ¹, Xiaojuan Ou ¹, Jidong Jia ¹, Xiaoning Wu ¹, Hong You ¹

Capital Medical University, Liver Research Center, Beijing Friendship Hospital, Beijing-China ¹ Northwest A&F University, College Of Veterinary Medicine, Shaanxi-China ²

Background / Hypothesis:The longitudinal association between dynamic changes in hepatitis B virus (HBV) integration expression and serum hepatitis B surface antigen (HBsAg) during long-term antiviral therapy remain poorly characterized.

Materials and Methods:Patients with liver biopsy-proven HBV-related fibrosis/cirrhosis who had at least one liver biopsy at baseline, week 78, or week 260 were enrolled from a multicenter cohort study. The HBsAg increase was defined by either an increase in HBsAg level ($\Delta > 0$ IU/mL) from baseline to year 4 or at least two increases between consecutive annual visits. Integrated clinical data, RNA sequencing, and histopathological profiling of a subgroup of ten patients with three serial biopsies elucidated the mechanisms driving HBsAg increase. Transcriptionally active HBV integration was identified using ChimericSeq and verified by BLAST, while intrahepatic HBsAg expression was assessed by immunohistochemistry.

Results:Overall, 37.0% (115/311) of patients met the criteria for HBsAg increase, the other were classified into HBsAg stable/decrease group. Among the patients with three serial liver biopsies, overall increasing trend in transcriptionally active integration was observed at week 260 compared with week 78. Patients in the HBsAg increase group (4/10, 40.0%) exhibited a rise in transcriptionally active HBV integration by week 260 relative to week 78, while no such increase was observed in the stable/decrease group.

Correspondingly, intrahepatic HBsAg staining displayed marginal positivity with a clustered distribution pattern that emerged at treatment baseline and persisted during anti-viral treatment. Transcriptomic analyses revealed an attenuated antiviral immune response in the increase group. **Conclusions:**HBsAg increase is linked to rising transcriptionally active integration and clustered, marginally positive HBsAg hepatocytes, suggesting that long-term treatment and immune pressure may preserve hepatocyte clones with integrated HBV.

Keyword(s) : HBV, CHB, HBV integration, HBsAg, antiviral therapy

1878 - Association between the alkaline phosphatase to albumin ratio and all cause mortality in critically ill patients with cirrhosis and

E-POSTER ABSTRACTS

sepsis a retrospective study

Xuanxuan Niu¹, Jinmin Zhao¹

Beijing Ditan Hospital, Capital Medical University,
Center Of Liver Diseases Division 3, Beijing-China¹

Background / Hypothesis: Mortality rates among critically ill patients with cirrhosis are high, particularly among those with sepsis. The alkaline phosphatase-to-albumin ratio (APAR) is an emerging biomarker associated with prognostic risk across multiple diseases. We aimed to evaluate the predictive value of APAR for mortality risk in patients with cirrhosis and sepsis.

Materials and Methods: The MIMIC-IV (version 3.0) database used in this study included adult patients (≥ 18 years) with cirrhosis who were admitted to the intensive care unit. The primary endpoint was 365-day all-cause mortality, and the secondary endpoints were 90-day and 28-day mortality after admission. The hazard ratios (HRs) and 95% confidence intervals (CIs) for the association between APAR and mortality outcomes were estimated using Cox proportional hazards models. Different predictive models were applied to assess the association between APAR and mortality in patients with cirrhosis and sepsis. In addition, subgroup analyses were conducted to evaluate the predictive value of the APAR index across different cirrhosis subpopulations.

Results: A total of 2,186 patients with cirrhosis were included from the MIMIC-IV database. These patients were divided into four groups based on their APAR values. When APAR was analyzed as a continuous variable, higher APAR levels were associated with increased 28-day (HR 1.307, 95% CI 1.226–1.393, $p < 0.001$), 90-day (HR 1.377, 95% CI 1.265–1.414, $p < 0.001$), and 365-day mortality (HR 1.355, 95% CI 1.289–1.424, $p < 0.001$). When assessed as a categorical variable, patients in the highest APAR quartile (Q4) had significantly higher 28-day (HR 2.197, 95% CI 1.796–2.687), 90-day (HR 2.368, 95% CI 1.988–2.820), and 365-day mortality (HR 2.527, 95% CI 2.155–2.963) compared with those in the lowest quartile (Q1). APAR demonstrated a linear association with all-cause mortality at 28, 90, and 365 days after admission (nonlinearity $p = 0.296, 0.740$, and 0.077 , respectively). Subgroup analyses showed that among patients with cirrhosis and comorbid hypertension, portal hypertension, malignancy, or hepatorenal syndrome, higher APAR levels were significantly associated with increased short-term mortality. Furthermore, among those with cirrhosis who had malignancy, hepatorenal syndrome, or higher SOFA and MELD scores, elevated APAR levels were significantly associated with

increased long-term mortality.

Conclusions: A higher APAR index was significantly associated with an increased risk of all-cause mortality in patients with cirrhosis. APAR may serve as a potential biomarker for assessing both short-term and long-term prognoses in critically ill patients with cirrhosis.

1879 - PRIMARY MYELOFIBROSIS PRESENTING WITH VARICEAL BLEEDING A RARE CAUSE OF NON CIRRHOTIC PORTAL HYPERTENSION

Desiree Jane Lacuin¹, Suzette Kho-herman¹, Patricia Cabral-prodigalidad¹

Makati Medical Center, Gastroenterology, Makati City-Philippines¹

Background:

Primary myelofibrosis (PMF) is a chronic myeloproliferative neoplasm characterized by bone marrow fibrosis, splenomegaly, and anemia with nucleated and teardrop-shaped red blood cells. Portal hypertension is a rare but significant complication of myelofibrosis, which is characterized by increased pressure in the portal vein system. In primary myelofibrosis, portal hypertension can arise from increased portal flow due to splenomegaly and intrahepatic obstruction resulting from thrombotic obliteration of small portal veins. The development of portal hypertension can lead to the formation of varices (swollen veins) in the esophagus and stomach, which can rupture and cause bleeding.

CASE:

This is a case of a 57-year old male with known primary myelofibrosis who presented with melena. Esophagogastroduodenoscopy revealed esophageal varices Grade III. Rubber band ligation (x5) were done for the noted esophageal varices. Liver blood tests revealed alanine aminotransferase 28.46 U/L, aspartate aminotransferase 35.93 U/L, alkaline phosphatase 155 U/L, bilirubin 0.65 mg/dL, albumin 2.93g/dL, and international normalized ratio (INR) 1.37. Work-up for chronic liver disease were negative for Hepatitis serologies for past and present infection as well as for presence of hemochromatosis. CT scan of the abdomen revealed splenomegaly with prominent splenic vessels but with smooth liver margins. Abdominal ultrasound noted moderate ascites. The portal vein (1.83cm) and splenic vein (1.8cm) are both

E-POSTER ABSTRACTS

prominent in size on Ultrasound with color doppler with no evidence of portal or hepatic vein thrombus with noted hepatopetal portal flow. Paracentesis done revealed serum to ascites albumin gradient of 2.57 and total protein of 1g/dL. He was started on Ruxolitinib and was eventually discharged

Conclusions:

Non-cirrhotic portal hypertension is a rare but severe complication of advanced primary myelofibrosis. Its pathogenesis may involve increased splanchnic inflow and intrahepatic vascular obstruction, but the mechanisms remain poorly defined. This case highlights the need for heightened clinical awareness and further prospective studies to better characterize the prevalence, screening strategies, and management of portal hypertension in patients with myelofibrosis.

1880 - The predictive value of different attenuation assessment tools for clinical adverse outcomes in patients with cirrhosis

Yuyu Li¹, Guzainuer Yiliyae², Qian Li¹, Chao Ma¹, Litifu Abulimiti³, Yan Guo³, Wang Xiao Zhong³, Feng Guo³
Xinjiang Medical University, Department Of Hepatology, Affiliated Hospital Of Traditional Chinese Medicine, Urumqi-China¹ Affiliated Hospital Of Chengdu University Of Traditional Chinese Medicine, Affiliated Hospital Of Chengdu University Of Traditional Chinese Medicine, Chengdu-China² Xinjiang Uygur Autonomous Region Traditional Chinese Medicine Hospital, Depaxinjiang Uygur Autonomous Region Traditional Chinese Medicine Hospitalrtment Of Hepatology, Affiliated Hospital Of Traditional Chinese Medicine, Urumqi-China³

Background / Hypothesis:

We compared the predictive power of multiple frailty assessment tools in predicting adverse clinical outcomes in cirrhosis patients within one year, and provided reference for clinical prognosis assessment.

Materials and Methods:

This retrospective study analyzed 260 cirrhosis patients admitted to the Hepatology Department of Xinjiang Autonomous Region Hospital of Traditional Chinese Medicine between October 2023 and October 2024. Four frailty assessment tools—Fried Frailty Phenotype (FFP), FRAIL, Liver Frailty Index (LFI), and Clinical Frailty Scale (CFS)—were used for baseline frailty evaluation.

Patients underwent 12-month prospective follow-up to document adverse clinical outcomes. The predictive value of these scales, CTP score, and MELD score for hepatic composite adverse events was assessed using the area under the receiver operating characteristic (ROC) curve.

Results:

(1) This study enrolled 231 patients with liver cirrhosis, including 126 males (54.55%) with an average age of 56.29 ± 11.82 years and 105 females (45.45%) with an average age of 63.86 ± 11.53 years. The prevalence rates of frailty on the Fried, Frail, LFI, and CFS scales were 33.34%, 33.2%, 25.97%, and 23.2%, respectively. During the 12-month follow-up, 29 patients (12.55%) died from liver-related causes, and 94 patients (29.83%) experienced decompensation events.

(2) The Area Under the Curve (AUC) values for mortality prediction by the four scales—LFI, CFS, Frail, and Fried—were 0.771 (95% CI: 0.711, 0.832), 0.739 (95% CI: 0.675, 0.802), 0.729 (95% CI: 0.664, 0.793), and 0.704 (95% CI: 0.636, 0.772), respectively. The Delong test revealed statistically significant differences between the Fried frailty phenotype and LFI (AUC difference: 0.058; 95% CI: 0.012, 0.105; $Z=2.428$; $P=0.0152$), while no significant differences were found among the other scales (all $P>0.05$). ROC curves were plotted for the CTP score and MELD score to predict adverse clinical outcomes, with areas under the curve of 0.781 and 0.708, respectively. The CTP score demonstrated superior predictive performance due to its higher AUC value.

(3) The combined prediction performance of CTP score and LFI was the best (AUC=0.825).

Conclusions:

All four scales can predict the risk of death in 12 months in patients with cirrhosis, and LFI scale has the best predictive power.

Keyword(s) : cirrhosis; frailty assessment tools; correlation;

1881 - Serum free T3 free T4 ratio as a predisposing factor for the development of metabolic dysfunction associated steatotic liver disease a large scaled cohort study of euthyroid state

Hyunwoo Oh¹, Won Sohn¹, Yong Kyun Cho¹, Byung Ik Kim¹

E-POSTER ABSTRACTS

Kangbuk Samsung Hospital, Sungkyunkwan University School Of Medicine, Department Of Internal Medicine, Seoul-South Korea ¹

Background / Hypothesis:

Thyroid hormones are key regulators of hepatic lipid metabolism, and recent evidence highlights the potential role of thyroid hormone sensitivity, particularly the free triiodothyronine to free thyroxine (FT3/FT4) ratio, in the pathogenesis of metabolic dysfunction-associated steatotic liver disease (MASLD) among euthyroid individuals. However, most prior studies have been cross-sectional, limiting insight into temporal or causal associations.

Materials and Methods:

A cohort of 209,729 apparently healthy men and women who were free from ultrasound-based MASLD at baseline were followed for a median of 5.7 years annually or biennially, from January 1, 2011 to December 31, 2021. Serum FT3, FT4 and thyroid stimulating hormone (TSH) were measured and FT3/FT4 ratios were calculated. Incident MASLD was defined by liver ultrasound findings and metabolic dysfunction criteria. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for MASLD incidence by quintiles of the FT3/FT4 ratio, adjusting for potential confounders.

Results:

Mean age of 209,729 participants was 35.7 years. During a mean follow-up of 5.98 years, Over 1,254,033.5 person-years of follow-up, 51,205 incident MASLD cases were identified. Higher FT3/FT4 ratios were significantly associated with increased MASLD risk in both men and women, with stronger associations in time-dependent models. In time-dependent models, multivariable-adjusted HRs (95% CIs) for MASLD incidence across increasing FT3/FT4 quintiles (Q2-Q5 vs. Q1) were 1.10 (1.06-1.15), 1.17 (1.13-1.22), 1.24 (1.19-1.28) and 1.29 (1.25-1.34), respectively, among men and 1.08 (1.02-1.14), 1.20 (1.14-1.26), 1.30 (1.24-1.37) and 1.44 (1.37-1.51) among women.

Conclusions:

In a large cohort of euthyroid men and women, higher FT3/FT4 ratios within the normal thyroid function range are independently associated with increased risk of

developing MASLD in a dose-dependent manner. The FT3/FT4 ratio may serve as a valuable biomarker for identifying individuals at higher risk of MASLD development, suggesting that thyroid hormone metabolism plays an important role in hepatic steatosis pathogenesis even in euthyroid populations.

1882 - Safety and Effectiveness of Peginterferon Alfa 2b Combined with Tenofovir Amibufenamide in Patients with Chronic Hepatitis B

Qing-lei Zeng ¹, Ru-yue Chen ¹, Sheng-li Ma ², Yu-meng Zhu ³, Yue-hang Wang ¹, Zhuang-zhuang Zhai ¹, Xue-jing Yu ¹

The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases And Hepatology, Zhengzhou-China ¹ Xu Chang Central Hospital, Department Of Infectious Diseases, Xuchang-China ² The Luoyang Central Hospital, Department Of Infectious Diseases, Luoyang-China ³

Background / Hypothesis: Data on the combination of Peg-IFN α -2b and tenofovir amibufenamide (TMF) remain limited. This study aims to evaluate the safety and effectiveness of Peg-IFN α -2b combined with TMF in patients with CHB.

Materials and Methods: Patients treated with TMF (25mg/day) and Peg-IFN α -2b (180 μ g/week) from January 2022 to May 2025 were retrospectively enrolled from three hospitals in Henan, China. This study included two groups: the switch combination group, consisting of patients who transitioned from nucleos(t)ide analog (NA) monotherapy to a combination of TMF and Peg-IFN α -2b; and the treatment-naïve combination group, comprising patients who received TMF plus Peg-IFN α -2b as initial therapy. The primary endpoint of this study was the rate of hepatitis B surface antigen (HBsAg) loss at 48 weeks of treatment, the secondary endpoints were the rate HBV DNA undetectable (<25 IU/mL) and safety profiles during treatment.

Results: A total of 180 patients were enrolled, with 120 patients in the switch group and 60 patients in the treatment-naïve group. The treatment period of NA monotherapy in switch group was 67.45 $\pm$ 35.36 months. At baseline, the age, HBV DNA, hepatitis B e antigen (HBeAg), HBsAg, alanine aminotransferase (ALT) levels of the patients in the switch group and treatment-naïve group were 38.48 $\pm$ 0.89 vs. 37.20 $\pm$ 1.28 years ($p=0.413$), 4.1 (2.6, 6.5) vs. 4.9 (3.1, 7.8) log₁₀

E-POSTER ABSTRACTS

IU/mL ($p=0.169$), 255.0 (11.0, 406.6) vs. 304.9 (12.1, 459.7) PEIU/mL ($p=0.536$), 2.63 ± 1.14 vs. 2.79 ± 1.18 log₁₀ IU/mL ($p=0.370$), 34.10 ± 4.31 vs. 50.14 ± 6.62 U/L ($p=0.037$), respectively; At 48 weeks of treatment (Figure 1), the HBV DNA undetectable rates were 99.17% vs. 96.67% ($p=0.537$), the HBeAg clearance rates were 76.67% vs. 42.86% ($p=0.026$), the HBsAg loss rates were 44.16% vs 28.33% ($p=0.040$), in the switch group and treatment-naïve group, respectively. Regarding laboratory abnormalities, the main adverse events during treatment were the ALT elevation (57.50% vs. 33.33%, $p=0.002$), leukopenia (46.67% vs. 31.67%, $p=0.054$), neutropenia (45.83% vs. 28.33%, $p=0.024$), thrombocytopenia (65.83% vs. 40.00%, $p=0.001$), in the switch combination group and treatment-naïve combination group, respectively. Only one patient presented with elevated total bilirubin (39.2 μ mol/L). No serious adverse events occurred. Conclusions: At week 48 of treatment, the switch combination group exhibited significantly higher rates of HBsAg loss and HBeAg seroconversion compared to the treatment-naïve combination group. Both groups maintained a favorable overall safety profile throughout the treatment period. These findings suggest that initiating therapy with nucleos(t)ide analogs followed by combination with Peg-IFN α may be a reasonable and promising strategy to promote HBsAg loss.

1884 - Variceal bleeding in toddlers Is the endoscopic outcome in extrahepatic portal hypertension worse than chronic liver disease

Ajay Aravind¹, Moinak Sen Sarma¹, Anshu Srivastava¹, Ujjal Poddar¹
Sanjay Gandhi Postgraduate Institute Of Medical Sciences, Pediatric Gastroenterology, Lucknow-India¹

Background / Hypothesis:

Toddler with extrahepatic portal venous obstruction (EHPVO) may exhibit pronounced degree of portal hypertension because of abrupt and complete interruption of portal venous flow causing early and marked development of portosystemic collaterals and large varices. In contrast, chronic liver disease causes portal hypertension more gradually, in parallel with progressive fibrosis and intrahepatic resistance. Hence we aimed to assess the endoscopic outcome of bleeding toddlers with extrahepatic portovenous

obstruction (EHPVO) and Chronic liver disease (CLD).

Materials and Methods:

Endoscopic outcome of toddlers with extrahepatic portal venous obstruction (EHPVO) were compared with chronic liver disease (CLD). As a standard protocol, all bleeders underwent endoscopic sclerotherapy at 2-3 weekly sessions till primary eradication of esophageal varices (EV) followed by 3-6 monthly sessions for endoscopic surveillance. Outcome was noted at follow-up.

Results:

Of the 152 patients, 79 (n=59 EHPVO, n=20 CLD) underwent secondary prophylaxis. Etiology of CLD were operated biliary atresia (n=15), sclerosing cholangitis (n=2) and autoimmune hepatitis (n=3). Figure 1 shows the study flow diagram and comparison of endoscopic outcomes between two groups. As compared to CLD, EHPVO had earlier onset of bleeding [8(4-36) months vs. 20(8-30) months, $p=0.01$], more hypersplenism [61% vs. 25%, $p=0.007$], endoscopic sessions [9(4-15) vs. 5(4-8), $p=0.03$], total volume of sclerosant [17.5(8-53) vs. 10(4-63), $p=0.03$], recurrence of EV [34% vs. 15%, $p=0.04$] and portal hypertensive gastropathy (PHG). 6% had sclerotherapy complications (bleeding ulcers and stricture). Duration of follow-up was 36(12-120) months. 22% EHPVO required secondary eradication of EV. Overall interval bleeding from varices during primary eradication occurred in 20% within 11(7-16) days from last endoscopic session. None of the patients developed bleed from gastric varices or PHG. Using multivariate analysis, the independent predictors of recurrence of EV and secondary eradication were age of onset <9mo (OR:4.8, 95% CI:2.6-13.3, $p<0.01$), hypersplenism (OR:3.6, 95% CI:1.6-15.9, $p<0.01$) and primary gastric varices (OR:5.4, 95% CI:4.5-8.8, $p=0.03$). Non-favorable vascular anatomy for portosystemic shunting was observed (100% for Meso-Rex bypass; 64% for non-selective shunts) in EHPVO. 38% BA were referred for liver transplantation.

Conclusions:

Toddlers with EHPVO have larger varices, recurrent bleeding, and greater degree of portal hypertension, as compared to CLD. Endoscopic therapy is the mainstay since majority may not have favorable anatomy for portosystemic shunting.

E-POSTER ABSTRACTS

Keyword(s) : Extrahepatic portal hypertension, Chronic liver disease, Endoscopic outcome

1885 - The sweet protein brazzein in ice cream suppresses postprandial glucose elevation in patients with metabolic dysfunction associated steatotic liver disease (MASLD) and diabetes mellitus (DM).

Alexey Goncharov ¹, Armida Sasunova ¹, Vladimir Bessonov ², Vasily Isakov ¹

Federal Research Center Of Nutrition And Biotechnology, Department Of Gastroenterology, Hepatology And Diet Therapy, Moscow-Russia ¹
Federal Research Center Of Nutrition And Biotechnology, Food Chemistry Laboratory, Moscow-Russia ²

Introduction: MASLD and DM remain highly prevalent worldwide, and excess intake of added sucrose is a key modifiable contributor to postprandial hyperglycaemia. Rapid glycaemic excursions following sucrose-rich foods intake exacerbate metabolic stress and accelerate progression of comorbid conditions, including MASLD. Objective: To evaluate the differences in postprandial glycemia after consumption of ice cream "a"(containing brazzein, maltitol, oligofructose), ice cream "b" (containing brazzein, maltitol, erythritol, inulin) and ice cream "c" (containing sucrose) in patients with MASLD and DM.

Materials and methods: This double-blind, randomized, crossover clinical study was conducted under a registered protocol (ClinicalTrials.gov: NCT06724913). Interstitial glucose was measured using a continuous glucose monitoring system at 15-min intervals over 150 min following ingestion. Glycaemic trajectories were analysed with linear mixed-effects models including patient-specific random intercepts and adjustment for baseline glucose (time 0). Time was modelled using a cubic B-spline (df = 5) with spline(time)×ice-cream×group interactions; fixed effects included ice-cream type, patient group, period and sequence. Model-derived curves with 95% confidence intervals (CI) were generated, and pairwise time-point contrasts were FDR-corrected using the Benjamini–Hochberg procedure.

Results: A total of 101 participants were analysed (MASLD, n=57; MASLD+DM, n=44). In both groups, sucrose ice cream (type "c") produced marked postprandial glucose rises, peaking at approximately 45–65 min in the MASLD group and 80–95 min in the MASLD+DM group, followed by a decline toward

baseline by 120–140 min. By contrast, both brazzein-based products elicited substantially flatter profiles, with minimal elevation and a gradual decrease over time. In the MASLD group, glucose levels after ice cream "c" were significantly higher than after types "a" and "b" across nearly the entire 20–120-min interval, whereas glucose levels after intakes of ice cream "a" and "b" did not differ significantly. In the MASLD+DM group, differences between ice creams "c" and "a" remained significant from 45 to 145 min, and between "c" and "b" from 60 to 150 min. A modest but significant mid-phase separation between "b" and "a" (30–85 min) suggested a slightly higher blood glucose response to "b", while both remained clearly superior to ice cream "c".

Conclusion: substituting sucrose with brazzein-based sweetening systems in ice cream yields a significantly more favourable postprandial glucose profile in patients with MASLD, including those with concomitant diabetes. These findings support sweet proteins as a potential dietary strategy to reduce postprandial glycaemic load in DM with MASLD comorbidity.

Keyword(s) : brazzein, metabolic dysfunction-associated steatotic liver disease, MASLD, protein sweetener, sucrose

1887 - Dynamic changes of serum lipids metabolism in hepatitis B virus related acute on chronic liver failure

Jing Lai ¹, Hong Deng ¹, Zhebin Wu ¹, Xiaoan Yang ¹, Hong Shi ¹

Third Affiliated Hospital, Sun Yat-sen University, Department Of Infectious Diseases, Guangzhou-China ¹

Background / Hypothesis:

At present, the relationship between lipids metabolism and the prognosis of liver failure is a hotspot. The purpose of this study was to explore the dynamic changes of serum lipids parameters in hepatitis B virus related acute-on-chronic liver failure (HBV-ACLF).

Materials and Methods:

For patients with HBV-ACLF, to describe the dynamic changes in serum lipids parameters pretreatment and after four weeks of treatment in survival group, and that of four weeks before death. The diagnostic criteria were in accord with American Association for the study of Liver Diseases practice guidance on acute-on-chronic liver failure and the management of critically ill patients with cirrhosis in 2023. Differences between groups were made by the t-test. And $P < 0.05$ is considered statistically significant.

E-POSTER ABSTRACTS

Results:

From June 1, 2020 to March 1, 2025, 70 patients with HBV ACLF had enrolled in Third Affiliated Hospital of Sun Yat-sen University, including 40 patients had survived more than 12 weeks and 30 cases died within 5 weeks. Their ages were 43.38 ± 11.69 years and 46.38 ± 13.23 years respectively, and no significant difference was between the two groups ($t = -0.914$ $P = 0.364$). The parameters values and the comparisons were shown in Table 1 and 2.

HBV-ACLF could cause fluctuations and decreases in serum lipids. After 4 weeks of treatment, lipid parameters gradually recovered in survival groups. Furthermore, except for HDL-C and Lipoprotein- α , the other parameters of four weeks before death were significantly lower than those of survival group (all $P < 0.05$) (table 2).

Conclusions:

Hypolipidemia may worsen HBV-ACLF. To improve it could contribute to the recovery and prognosis of HBV-ACLF.

Keyword(s) : Lipids metabolism; Hepatitis B virus related acute-on-chronic liver failure (HBV-ACLF); dynamic changes

1888 - An Optimized In Hospital Management Model Enhances Linkage to Care for Non Hepatology HBV Infected Patients Interim Analysis of Hot Wave Project 2.0

Jia Chen ¹, Fangfang Wei ², Qiumin Luo ¹, Xin Song ¹, Zhongsi Hong ³, Liang Peng ¹
Third Affiliated Hospital Of Sun Yat-sen University, Department Of Infectious Diseases, Guangzhou-China ¹
Sixth Affiliated Hospital Of Sun Yat-sen University, Department Of Infectious Diseases, Guangzhou-China ²
Fifth Affiliated Hospital Of Sun Yat-sen University, Department Of Infectious Diseases, Zhuhai-China ³

Background / Hypothesis:

A significant proportion of HBV-infected individuals in China remain undiagnosed or untreated. We aimed to evaluate whether an optimized in-hospital management model, emphasizing multi-disciplinary collaboration and patient education, improves linkage-to-care (LTC) and antiviral treatment (AVT) rates for HBsAg-positive patients identified in Non-hepatology departments.

Materials and Methods:

The "Hot Wave Project," initiated in 2022 at the Third

Affiliated Hospital of Sun Yat-sen University (SYSU-3AH). Key interventions included collaboration between the Department of Hepatology and various clinical and administrative departments. The measures implemented were automated lab report alerts, establishment of dedicated HBV health clinics, varied patient education programs, and big data monitoring to facilitate professional consultation and treatment for HBV-infected patients. In April 2025, the model expanded to the Fifth Affiliated Hospital of SYSU (SYSU-5AH) and the Sixth Affiliated Hospital of SYSU (SYSU-6AH) as "Hot Wave Project 2.0", featuring enhanced education plans, and call-back mechanisms. We compared data of HBsAg-positive patients from Non-hepatology departments between 2024 and January–September 2025 across these three centers.

Results:

At SYSU-3AH, 15,201 HBsAg-positive patients were identified in 2024, with 9,065 receiving AVT (59.63%) and 2,716 referred to Hepatology (17.88%). From Jan–Sep 2025, among 13,686 identified patients, the AVT rate increased to 61.38% (8,140/13,686, $p = 0.002$), and the referral rate rose significantly to 27.72% (3,797/13,686, $p < 0.0001$). At SYSU-5AH, 6,044 and 4,311 patients were screened in 2024 and Jan–Sep 2025, respectively. The AVT rate improved from 20.14% (1,217/6,044) to 22.67% (978/4,311, $p = 0.002$), while the referral rate remained stable at 16.78% (1,014/6,044) versus 17.26% (744/4,311) ($p = 0.52$). At SYSU-6AH, the AVT rate increased significantly from 21.97% (1,121/5,103) to 35.40% (1,944/5,492) ($p < 0.0001$), and the referral rate improved from 2.12% (108/5,103) to 7.28% (400/5,492) ($p < 0.0001$).

Conclusions:

The implementation of the Hot Wave Project 2.0 was associated with improved antiviral treatment uptake and referral rates for HBV patients in non-hepatology settings across multiple centers. The optimized referral system and education strategies demonstrate potential feasibility for expanding in-hospital HBV management coverage.

1891 - Research progress on the association between metabolic dysfunction associated fatty liver disease and gallstones

Shihao Guo ¹

Chengde Medical College Affiliated Xingtai People's Hospital, Hepatological Surgery Department, Xingtai

E-POSTER ABSTRACTS

City,hebei Province-China ¹

Background:

Metabolic dysfunction-associated fatty liver disease (MAFLD) and gallstones diseases (GSD) are common liver and gallbladder diseases, with highly overlapping epidemiological features and risk factors, confirming a certain correlation between the two, but with different conclusions. With the update of diagnostic criteria for MAFLD, the research dimensions of the correlation between the two continue to expand. This review integrates recent clinical evidence and mechanism research, providing reference for clinical diagnosis and future research.

Materials and Methods:

Search Pubmed and CNKI databases to include research papers on the association between MAFLD and gallstones. Exclude review literature.

Results:

Firstly, the summarized research results indicate that compared with non MAFLD patients, the incidence of GD in NAFLD patients is almost twice that of non MAFLD patients (incidence rates of 47% and 26%, respectively, $p < 0.0001$); Compared with patients without GSD, 56% of patients with gallstones had MAFLD ($p < 0.0001$). Secondly, the research mechanism suggests that the two share three core pathways: lipid metabolism disorders, insulin resistance, and chronic inflammation. The accumulation of free fatty acids leading to bile cholesterol supersaturation is a key link. Insulin resistance serves as a crucial bridge between GSD and MAFLD. The relationship between abnormal glucose metabolism and fatty liver disease is highly recognized, and fasting blood glucose levels are fully correlated with the presence of GSD in MAFLD patients. Finally, in terms of influencing factors, age increase, sex, diabetes, ALP increase, HDL decrease and FBS increase are the only predictors of biliary node in MAFLD patients. Lifestyle interventions can reduce risks. Other studies have shown that asymptomatic patients with MAFLD and non obese individuals also exhibit an increased risk of gallstones. Therefore, in clinical practice, caution should be exercised in treatment and comprehensive screening should be conducted to prevent the occurrence of the disease.

Conclusions:

There is a clear epidemiological association and common pathophysiological basis between MAFLD and gallstones. Clinical attention should be paid to

screening for gallstones in MAFLD patients, especially in high-risk subgroups. Future research should focus more on the molecular mechanisms associated with the two and explore targeted intervention measures, providing favorable references for clinical diagnosis and treatment management.

Keyword(s) : gallstone disease,nonalcoholic fatty liver disease,insulin resistance

1892 - Reactive Pericarditis Secondary to Cholangitic Abscess from a Neglected Biliary Stent A Case Report

Bettyna Rose Rustia ¹, Romel John Sazon ¹, Ashraf Tawasil ¹, Mark Anthony De Lusong ¹

University Of The Philippines - Philippine General Hospital, Internal Medicine, Division Of Gastroenterology, Manila-Philippines ¹

Endoscopic biliary stent insertion is a life-saving procedure for severe cholangitis, often due to choledocholithiasis. In resource-limited settings, high costs and limited follow-up can lead to neglected stents and increased health risks. Patients may present months or years later with severe infections, such as hepatic or cholangitic abscesses from stent failure, or with perforation from stent migration, both of which are life-threatening. Pericarditis is a rare and often fatal complication of cholangitis, typically resulting from direct penetration or abscess extension. We present a rare case of subdiaphragmatic cholangitic abscess from a neglected stent causing reactive pericarditis in an immunocompetent man.

A 45-year-old male with no comorbidities, who had previously undergone endoscopic retrograde cholangiopancreatography (ERCP) with stent insertion for large choledocholithiasis two years prior, presented with right upper quadrant pain, fever, and jaundice. Ultrasound demonstrated left intrahepatic bile duct ectasia. Clinical assessment on admission indicated cholangitis secondary to stent failure. Urgent ERCP confirmed the neglected biliary stent, prompting stent removal and reinsertion, as well as initiation of empiric broad-spectrum antibiotics. Cholangiography revealed a markedly dilated common bile duct with multiple ovoid filling defects. Bile cultures grew *Escherichia coli*. Despite these interventions and one week of antibiotic therapy, the patient developed progressive dyspnea and chest pain. Electrocardiogram and echocardiography confirmed pericarditis. Magnetic resonance cholangiopancreatography (MRCP) identified a subdiaphragmatic abscess adjacent to the

E-POSTER ABSTRACTS

pericardium. Percutaneous drainage of the abscess and targeted antibiotic therapy resulted in resolution of pericarditis. The patient achieved full recovery and was discharged after six weeks.

This case highlights the need for patient education and consistent post-procedural follow-up to ensure timely stent removal. Prompt source control is essential for optimal outcomes. Clinicians should remain alert to extra-biliary complications of cholangitis, such as pericarditis, particularly in patients with cardiopulmonary symptoms.

Keyword(s) : Pericarditis, Cholangitis, Neglected Biliary Stent

1894 - AI Driven Pathomics Transforming Precision Medicine Across the Chronic Liver Disease Hepatocellular Carcinoma Spectrum

Huiyang Fan ¹

Xingtai People's Hospital, Surgery, Xingtai-China ¹

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide, often arising from a progressive chronic liver disease (CLD) continuum that includes inflammation, fibrosis, and malignant transformation. Conventional histopathology, while the diagnostic gold standard, is limited by subjective interpretation, inter-observer variability, and an inability to quantitatively analyze dynamic tissue changes. The emergence of digital pathology and artificial intelligence (AI) has given rise to pathomics—a field that integrates whole-slide imaging (WSI) with deep learning to decode subvisual morphological, spatial, and molecular patterns(Fig.1).

Materials and Methods:This study systematically investigated the core methodologies and applications of AI-driven liver pathomics through a comprehensive literature review based on the PubMed database.

Results:AI-powered pathomics has demonstrated significant breakthroughs in both CLD and HCC management. In CLD, it enables automated quantitative assessment of hepatic fibrosis inflammatory activity grading in non-alcoholic steatohepatitis, and accurate identification of premalignant lesions. In HCC, AI models assist in differential diagnosis, molecular subtyping, microvascular invasion prediction , and recurrence risk stratification post-resection or transplantation. Multimodal integration further improves prognostic

accuracy and immunotherapy response prediction.

Conclusions: Despite persistent challenges related to data standardization, model transparency, and clinical translation, emerging technologies—such as spatial transcriptomics, quantum-accelerated computing, and federated learning—offer promising pathways forward. Through continued interdisciplinary collaboration and advances in explainable AI, multimodal fusion, and global data governance, AI pathomics is poised to enable proactive risk prediction, early interception, and precision therapy throughout the liver disease continuum.

Keyword(s) : artificial intelligence, pathomics, chronic liver disease, hepatocellular carcinoma, digital pathology

1896 - Xinjiang Uygur Autonomous Region Traditional Chinese Medicine Hospital

Menyao He ¹, Hong Yu ², Yuyan Kuang ³, Qian Li ¹, Jieensinuer Sayilaxi ⁴, Zhuanguo Wang ⁴, Zhonghui Ning ⁴, Xiaozhong Wang ⁵, Feng Phd ⁵

Background / Hypothesis:

To evaluate the correlation between the severity of esophageal varices (EV) and ocular fundus indicators in patients with liver cirrhosis based on fundus images, aiming to provide a non-invasive and convenient clinical method to reduce reliance on invasive examinations.

Materials and Methods:

A total of 86 inpatients with liver cirrhosis from the Department of Liver Diseases, Traditional Chinese Medicine Hospital of Xinjiang Uygur Autonomous Region (December 2024 to September 2025) were

E-POSTER ABSTRACTS

enrolled. Based on endoscopic findings, patients were divided into three groups: no EV group (n=19), mild EV group (n=24), and moderate-to-severe EV group (n=43). Patients with no or mild EV were defined as the low-risk group (n=43), and those with moderate or severe EV as the high-risk group (n=43). Scanning laser ophthalmoscopy (SLO) fundus images were collected and analyzed using the EvisionAI intelligent fundus image analysis system to extract indicators (e.g., area of fundus hemorrhage, number of hemorrhages). Pearson and Spearman correlation analyses were used to assess the correlation between EV severity/risk level and fundus image indicators.

Results:

- (1) The grading of EV severity showed negative correlations with total leopard spot density, leopard spot density in the optic disc area, average vessel tortuosity in the inferior nasal region within the 6mm-9mm annular zone, the number of peripheral microaneurysms, and leopard spot density within the 10mm-15mm annular zone of the macula.
- (2) Spearman correlation analysis revealed that the high-risk EV group was positively correlated with the AVR ($p=0.21$, $P<0.05$), and negatively correlated with the average vessel tortuosity in the inferior nasal region within the 6mm-9mm annular zone ($p=-0.33$, $P<0.05$), average vessel diameter in the inferior temporal region within the 3-photoreceptor-disc-diameter (3PD) circular zone ($p=-0.22$, $P<0.05$), vessel density in the inferior nasal region within the 6mm-9mm annular zone ($p=-0.23$, $P<0.05$), number of vessels within 1cm of the optic disc ($p=-0.22$, $P<0.05$), leopard spot density within the 10mm-15mm annular zone of the macula ($p=-0.25$, $P<0.05$), and leopard spot density in the superior sector of the 10mm-15mm annular radius circle of the macula ($p=-0.28$, $P<0.05$).

Conclusions:

The high-risk group for esophageal varices in patients with liver cirrhosis is positively correlated with the arteriole-to-venule diameter ratio, suggesting that fundus images can, to some extent, reflect the risk level of esophageal varices in these patients.

Keyword(s) : Liver cirrhosis; Esophageal varices; Fundus images; Correlation ;

1898 - Successful Management of Hepatitis B Virus Reactivation Induced Acute on Chronic Liver Failure with Integrated Traditional Chinese and Western

Medicine A Case Report

Lu Ziman Lu¹, Zheng Chao Zheng¹, Sun Xuehua Sun¹
Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Department Of Hepatology, Shanghai-China¹

Background: Self-discontinuation of nucleos(t)ide analogue therapy is a critical risk factor for HBV reactivation and progression to acute-on-chronic liver failure (ACLF) in chronic hepatitis B patients. Despite standard supportive care, ACLF mortality remains high. This report demonstrates successful management through integrated Traditional Chinese and Western medicine.

Case Presentation: A 43-year-old male with chronic hepatitis B presented with worsening jaundice 75 days after discontinuing entecavir. Examination showed profound icterus. Laboratories revealed total bilirubin 295.2 $\mu\text{mol/L}$, PTA 17.5%, INR 2.75. Imaging demonstrated cirrhosis with ascites. Diagnosed as ACLF Grade 2 (COSSH criteria) with AARC score 7 (ACLF Grade 1), indicating poor prognosis.

Therapeutic Intervention: Western treatment included tenofovir reinstatement, comprehensive liver protection, infection control, and coagulation support. Traditional Chinese Medicine was initiated in the second month using syndrome differentiation. The treatment strategy followed the disease progression: initial stage employed modified Yinchenhao Tang (with 100g *Artemisia capillaris*) to clear dampness-heat; middle stage utilized Xijiao Dihuang Tang (with water buffalo horn) to resolve heat-toxins; advanced stage incorporated cultured cattle gallstone and bear bile powder to enhance blood-cooling and detoxification effects. This phased approach addressed the evolving pathogenesis patterns throughout the disease course. Outcome: After three months, symptoms resolved completely. Laboratories showed total bilirubin 69.7 $\mu\text{mol/L}$, PTA 42.6%, INR 1.65. The patient no longer met ACLF criteria (COSSH), with AARC score improving from 7 to 4 (non-ACLF). Notably, a significant clinical turning point occurred following the introduction of TCM decoctions, with accelerated improvement in biochemical markers and symptom resolution. This temporal association suggests that the therapeutic effect of TCM intervention extended beyond mere adjunctive support, pointing to a synergistic "1+1>2" interaction with conventional Western treatment.

Conclusion: This case highlights the crucial importance of antiviral adherence and demonstrates the substantial benefits of integrated medicine for HBV-ACLF. The sequential TCM application, meticulously guided by syndrome differentiation, provided targeted

E-POSTER ABSTRACTS

therapy at different disease stages. This integrative approach likely contributed to effective inflammation control and enhanced hepatic recovery through multi-targeted mechanisms, demonstrating a synergistic effect that warrants further clinical validation and protocol standardization.

1900 - Prevalence of Hepatitis B and C among Adolescents and Young Adults in Sindh Pakistan A Substudy of a Provincial Population Based Survey

Om Parkash ¹, Mahrukh Ali ¹, [Abhishek Lal](#) ¹, Saeed Hamid ¹

Aga Khan University, Medicine, Karachi-Pakistan ¹

Background / Hypothesis:

Globally, hepatitis B and C virus infections are recognized as the leading cause of liver-related morbidities and mortalities. Sustainable Development Goal 2030s has targeted the elimination of hepatitis B and C. Understanding early-age prevalence and coexisting metabolic risk factors is essential for designing integrated prevention and control strategies to mitigate the rising prevalence of hepatitis B and C. This analysis represents a substudy of a larger provincial population-based survey aimed to determine the prevalence of hepatitis B and C among adolescents and young adults in Sindh, Pakistan.

Materials and Methods:

This provincial cross-sectional, multistage household survey was conducted across all districts of Sindh, Pakistan. Participants included adolescents (10–19 years) and young adults (20–24 years) were enrolled. Data were collected on sociodemographic factors, diet, and physical activity, alongside anthropometric and blood pressure measurements. Each participant underwent laboratory testing for complete blood count, liver function, lipid profile, fasting glucose, and hepatitis B surface antigen (HBsAg) and hepatitis C antibody (anti-HCV). Hepatic steatosis was assessed utilizing FibroTouch elastography.

Results:

A total of 2,136 participants were surveyed, comprising 1,651 adolescents and 485 young adults from both urban and rural areas of Sindh. The sero-prevalence of hepatitis B was 1.4%, while hepatitis C was 0%. Co-

occurrence with elevated liver enzymes and metabolic abnormalities was observed, suggesting an overlapping burden of infectious and metabolic liver disease in this young population.

Conclusions:

Findings of this study highlight a measurable burden of viral hepatitis B and reassuringly low prevalence of Hep C in adolescents and young adults. The coexistence of metabolic disorders exposes new dual threats. Strengthening integrated screening, immunization, and early linkage-to-care programs is critical to maintaining progress toward national and global hepatitis eradication targets.

1901 - A Modular Assembly of Urine Derived Stem Cells and Hydrogel into a Therapeutic Ectopic Mini Liver for Wilson's Disease

[Jiaqi Li](#) ¹, Pengfei Yu ¹, Jiateng Zhang ¹, Huaibin Zou ¹, Yuanyuan Zhang ², Yu Chen ¹, Zhongping Duan ¹
Beijing You'an Hospital, Capital Medical University, Beijing Key Laboratory Of Liver Regeneration And Artificial Liver Transformation Research, Beijing-China ¹
Wake Forest School Of Medicine, Wake Forest Institute For Regeneration Medicine, Winston-salem-United States ²

Background / Hypothesis: Wilson's disease (WD) is a disorder of copper metabolism caused by ATP7B gene mutations. Urine-derived stem cells (USCs) offer a novel cell source for therapy, but their therapeutic potential is limited by poor survival after transplantation. This study explores a strategy using a hydrogel system to form an ectopic mini-liver, leveraging the hydrogel's 3D microenvironment to boost USC viability and efficacy for the treatment of WD.

Materials and Methods: USCs were isolated from a WD patient with a homozygous ATP7B R778L mutation and a healthy donor using repeated centrifugation. Cells were cultured in an optimized medium and characterized by flow cytometry for surface markers (CD44, CD73, CD90, CD105 positive; CD19, CD34, CD45, CD11b, HLA-DR negative) and immunofluorescence for ATP7B. For the therapeutic experiment, ATP7B knockout WD model mice were

E-POSTER ABSTRACTS

randomized into three groups: normal control, disease model, and USC-treated group. The treatment group received four intraperitoneal injections of WD-USCs (2×10^6 cells per injection in 200 μ L volume, pre-mixed with hydrogel at a 1:1 ratio) over 14 days.

Comprehensive endpoint assessments included serum copper and ceruloplasmin levels, liver function and antioxidant assays, histopathological evaluation (H&E, Oil Red O, Masson, Sirius Red), transmission electron microscopy (TEM), and integrated transcriptomic and targeted metabolomic analyses.

Results: WD-USCs exhibited enhanced proliferative capacity and higher expression of mesenchymal markers (CD44, CD73, CD90, CD105) compared to healthy USCs. Transplantation of hydrogel-encapsulated WD-USCs significantly ameliorated systemic copper metabolism, evidenced by decreased serum copper and increased ceruloplasmin activity. Liver function tests and antioxidant capacity were markedly improved. Histologically, the treatment led to a substantial reduction in hepatic steatosis, inflammatory infiltration, and collagen deposition. Ultrastructural analysis by TEM confirmed the mitigation of critical cellular injuries, including mitochondrial swelling, nuclear fragmentation, and endoplasmic reticulum stress. Integrated transcriptomic and targeted metabolomic analyses further identified that these therapeutic benefits were linked to the regulation of key pathways related to mitochondrial function and metabolism.

Conclusions: This study provides compelling proof-of-concept for a novel regenerative strategy against WD, wherein a bioengineered ectopic liver created from patient-specific USCs and hydrogel corrects core metabolic defects and mitigates hepatotoxicity. Integrated multi-omics analysis reveals that the restoration of mitochondrial homeostasis serves as a fundamental mechanism mediating these therapeutic benefits, positioning the USC-hydrogel platform as a promising and clinically translatable therapeutic avenue for WD.

Keyword(s) : Wilson disease, Urine-derived stem cells, Hydrogel, Mitochondrial homeostasis, Cell therapy

Indeterminate Phase Chronic Hepatitis B with Normal ALT

Mengya Liu¹, Hong Tang¹

West China Hospital Of Sichuan University, Center Of Infectious Diseases, Chengdu-China¹

Background:

In chronic hepatitis B (CHB), an indeterminate phase exists outside the typical predefined phases. Among patients with CHB in the indeterminate phase, approximately 40% are treatment-naïve. Clinical outcomes and the effect of antiviral therapy on the indeterminate phase remain unclear. Our study investigates the efficacy and clinical benefits of antiviral therapy in indeterminate-phase CHB (IHC) patients with normal alanine aminotransferase (ALT) levels.

Materials and Methods:

In this prospective study, we identified all treatment-naïve IHC patients with normal ALT. Patients were assigned to receive TAF monotherapy or Peg-IFN plus TAF therapy based on the patients' own discretion. They were monitored closely for 52 weeks with liver function tests, complete blood counts, virological markers, and imaging examinations.

Results:

To date, a total of 129 patients have completed 52 weeks of antiviral therapy, including 106 in Peg-IFN- α plus TAF group and 23 in TAF monotherapy group. During the 52-week therapy, hepatitis B virus (HBV) DNA decreased over time in both groups ($P < 0.05$). At week 52, 87.6% (113/129) patients achieved undetectable HBV DNA, with 86.8% (92/106) in the combination group and 91.3% (21/23) in the monotherapy group reaching this outcome. Baseline HBsAg level [2.7 (1.9 - 3.1) vs. 3.3 (3.1 - 3.5) log₁₀ IU/mL, $P < 0.001$], HBV RNA [2.2 (2.0 - 3.0) vs. 3.1 (2.7 - 3.7) log₁₀ copies/mL, $P = 0.001$] and HBcrAg [2.8 (2.0 - 3.3) vs. 4.2 (3.2 - 5.3) log₁₀ U/mL, $P < 0.001$] were significantly lower in the HBV DNA-negative group compared to the HBV DNA-positive group at week 52. The combination group demonstrated significantly greater reductions from baseline at each point compared to the monotherapy group ($P < 0.001$). The HBsAg seroclearance rate in the combination group was 14.7% (18/129) at week 52, and no patient in the monotherapy group achieved HBsAg seroclearance at week 52. Baseline HBsAg level [1.4 (0.7 - 2.1) vs. 2.9 (2.2 - 3.3) log₁₀ IU/mL, $P < 0.001$], HBV RNA [2.0 (2.0 - 2.0) vs. 2.4 (2.0 - 3.2) log₁₀ copies/mL, $P = 0.002$] and HBcrAg [2.4 (2.0 - 3.0) vs. 3.0 (2.5 - 3.6) log₁₀ U/mL, $P = 0.006$] were significantly lower in the HBsAg-seroclearance group compared to the Non-seroclearance group at week 52.

1902 - Antiviral Therapy Leads to Virological Response and Functional Cure in Treatment Naïve

E-POSTER ABSTRACTS

Conclusions: This study demonstrates that treatment-naïve IHC patients with normal ALT exhibited a favorable response to antiviral therapy, with Peg-IFN- α combination therapy is effective in achieving clinical cure.

Keyword(s) : Chronic hepatitis B, HBV DNA, Indeterminate phase, antiviral therapy,

1904 - High prevalence of Hepatic Steatosis in adolescence and Young Adults A crosssectional survey from Sindh Pakistan

Om Parkash ¹, Aysha Almas ¹, Suneel Piryani ², Arjumand Rizvi ³, Abhishek Lal ¹, Areesha Ikram ², Jai Das ³

Aga Khan University, Medicine, Karachi-Pakistan ¹ Aga Khan University, Institute Of Global Health And Development, Karachi-Pakistan ² Aga Khan University, Institute Of Global Health And Development And Department Of Paediatrics & Child Health, Karachi-Pakistan ³

Background / Hypothesis:

Hepatic Steatosis and its Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) are emerging as a global concern and have a major impact on health. The overall aim of the study was to estimate the prevalence of Hepatic Steatosis and MASLD in adolescents and young adults in the province of Sindh, Pakistan and report associated metabolic factors including obesity, central obesity, dyslipidemia and Prediabetes/Diabetes with Hepatic Steatosis

Materials and Methods:

It was a cross-sectional study using a multistage complex household sampling strategy conducted in all (31) districts of Sindh, Pakistan, in 2023-2024.

Adolescents (10-19 years) and young adults (20-24 years) were included and those who were hepatitis B or C positive were excluded. The primary outcome 1 was Hepatic Steatosis and Primary outcome 2 was MASLD. Hepatic Steatosis was defined as ultrasound attenuation parameter UAP > 244 dB/m using a Fibro touch: Shear-wave Elastography System. MASLD was defined as Hepatic Steatosis and any one of the cardiometabolic criteria (Obesity, hypertension, triglyceride > 150 mg/dl, HDL < 40 mg/dl, Fasting blood sugar > 100 mg/dl,)

Results:

A total of 2,200 participants were invited to participate, of whom 2,136 (97.1%) agreed. Among these, 1,651 (77.3%) were adolescents aged 10–19 years and 485 (22.7%) were young adults aged 20–24 years, with a mean (SD) age of 15.8 ± 4.0 years. Overall, 997 (43.7%) participants were from rural, 1,053 (47.6%) were males. Of the total 456 (21.1%) were underweight, 162 (8.6%) were overweight, and 87 (4.3%) were obese, 519 (26.0%) had impaired fasting glucose, and 93 (8.8%) had diabetes.

Overall, 1,053 (53.3%) participants had hepatic steatosis, including 802 (52.1%) adolescents and 251 (57.6%) young adults. Among adolescents with Hepatic steatosis 444 (55.08%) and 358 (44.92%) were in early (10–14) and Mid-Late Adolescence (15–19). On multivariate regression, overweight or Obesity (OR 2.52 (95 % CI 1.19-5.31), central obesity (OR 3.37 (95 % CI 1.38-8.26) was associated with hepatic steatosis, while being in middle (OR 0.80 (0.59-1.08) or rich (OR 0.87 (0.58-1.30) socio economic index was protective for Hepatic steatosis. The prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD) was 717 (36.3%) overall, comprising 525 (34.9%) adolescents and 192 (41.4%) young adults

Conclusions:

High prevalence of hepatic steatosis and MASLD in adolescents and adults from Sindh, Pakistan indicating that the occurrence happens much early in life. Further studies are required to look at mechanisms that lead to hepatic Steatosis early

Keyword(s) :

1905 - Partial Splenic Embolization in a Cirrhotic Patient with Refractory Variceal Bleeding and Portal Venous Thrombosis

Rafael Emmanuel Mendoza ¹, Federico Peralta ¹, Jasmin Gundayao ¹, Ryan Clifford Uy ², David Nagtalon ², Suzette Grace Kho-herman ¹, Ramon Santos Ocampo ² St. Luke's Medical Center - Global City, Institute Of Digestive And Liver Diseases, Taguig City-Philippines ¹ St. Luke's Medical Center - Global City, Institute Of Radiology, Taguig City-Philippines ²

Significance: Variceal bleeding remains a major cause of mortality among cirrhotic patients. Compared to esophageal varices, gastric varices are less common but more challenging to manage. This case report highlights the use of partial splenic embolization (PSE) as an alternative option in a cirrhotic patient with portal vein thrombus (PVT).

E-POSTER ABSTRACTS

Case Presentation: A 68-year-old male with cirrhosis from chronic hepatitis B and hepatocellular carcinoma was admitted due to hematemesis. Initial management carried out with antibiotics, octreotide, and supportive blood transfusions. Esophagogastroduodenoscopy showed gastroesophageal varices GOV-1. Beta blockers started, with intent to do rubber band ligation late once the varices are smaller. Dynamic CT of the liver demonstrated tumor thrombi in the proximal main portal vein, immediately after the splenic and superior mesenteric veins. On the 4th hospital day, patient had hematemesis hence on repeat gastroscopy, histoacryl glue was injected into the GOV-1. PSE was planned but family consented only on the 7th hospital day. He underwent PSE using polyvinyl alcohol particles and 500-700 micron microspheres, showing devascularization of 70% of the spleen. After two days, the patient again had hematemesis, hence he opted for palliative care and expired.

Recommendation: In our patient, PSE was done to reduce splenic venous inflow into the portal vein. If done early, PSE might have significantly reduced portal pressure, as demonstrated in other case reports. However, given our patient's overall poor prognosis, PSE was used as a salvage therapy to control his refractory variceal bleeding.

Keyword(s) : Refractory Variceal Bleeding, Cirrhosis, Partial Splenic Embolization

1907 - Delayed diagnosis of intrahepatic cholestasis of pregnancy in North India Uncovering health system gaps through a mixed methods approach

Tushar Prabhakar¹, Bronica Saini², Sarika V², Satya Vir Singh¹

Amrita School Of Medicine, Community Medicine, New Delhi-India¹ Esic Hospital Rohini, Obstetrics And Gynaecology, Delhi-India²

Background/Hypothesis:

Intrahepatic cholestasis of pregnancy (ICP) is linked to preterm birth, stillbirth and neonatal morbidity, with risks increasing at higher bile acid levels. Evidence on health-system contributors to delayed recognition in rural South Asia is scarce. We quantified diagnostic delays among women with ICP presenting to a rural secondary-care public hospital in North India and examined multi-level barriers to timely diagnosis and management.

Materials and Methods:

We conducted a convergent mixed-methods study in a government hospital serving a predominantly rural population. The quantitative component was a retrospective cohort of pregnant women with ICP. Data were extracted on timing of pruritus onset, first facility contact, bile acid testing, diagnosis and delivery, and fetomaternal outcomes. "Health-system diagnostic delay" was defined a priori as ≥ 7 days from first documented presentation for pruritus to confirmed diagnosis.

The qualitative component included 22 in-depth interviews with women experiencing delay, frontline providers and ASHA workers. Data were analysed thematically using the three-delays framework.

Results:

We included 214 women (mean age 26.9 ± 4.3 years; 61.7% multigravida). Median gestational age at pruritus onset was 30 weeks (IQR 28–32). The median interval from first facility contact to confirmed ICP diagnosis was 9 days (IQR 5–16); 58.4% ($n=125$) met criteria for health-system diagnostic delay. Delay was more frequent among women first seen at sub-centres/primary health centres versus those presenting directly to the hospital ANC clinic (adjusted odds ratio [aOR] 2.11, 95% CI 1.19–3.74) and among those without jaundice (aOR 1.86, 95% CI 1.03–3.37). After adjustment for bile acid levels, gestational age at diagnosis and ICP severity, diagnostic delay was independently associated with the composite adverse perinatal outcome (aOR 1.72, 95% CI 1.01–2.94). The odds of preterm birth (<37 weeks) were also higher in the delayed group (aOR 1.94, 95% CI 1.06–3.55). Qualitative analysis identified four themes: (1) pruritus widely perceived as normal in pregnancy, delaying attention; (2) fragmented referral pathways and limited access to bile acid testing; (3) low prioritisation of liver disease within routine ANC; and (4) structural barriers including laboratory constraints, costs and after-hours access. Theme saturation was reached by the 20th interview.

Conclusion:

More than half of women with ICP experienced health-system diagnostic delay, which remained associated with adverse perinatal outcomes. Improving recognition of pruritus, strengthening referral pathways and ensuring timely bile acid testing could reduce preventable complications in similar rural settings.

1910 - A Bibliometric Analysis of the Diagnosis and Treatment of Portal Hypertension Based on the Web of Science Database

Hezhao Wang¹, Jitao Wang², Dengxiang Liu³

Xingtai People's Hospital Affiliated To Hebei Medical University, Hepatological Surgery, Xingtai City, Hebei Province, China-China¹ Tsinghua University Affiliated Changgeng Hospital, Hepatological Surgery, Beijing City, China-China² Hebei Provincial Key Laboratory Of Portal Hypertension And Cirrhosis, Administrative, Xingtai City, Hebei Province, China-China³

Background / Hypothesis: Portal hypertension refers to a clinical syndrome characterized by abnormally elevated pressure within the portal venous system due to various causes. It imposes a significant global disease burden, with severe and potentially fatal complications. With deepening understanding of the pathophysiological mechanisms underlying portal hypertension, diagnostic and therapeutic techniques have made substantial progress in recent years. Diagnostic and therapeutic strategies for portal hypertension have evolved significantly, yet numerous challenges persist. Therefore, timely and accurate diagnosis coupled with effective treatment are crucial for improving patient outcomes and reducing mortality rates.

Materials and Methods: A retrospective collection of studies related to the diagnosis and treatment of portal hypertension from the Web of Science Core Collection (WOSCC) database was conducted. Bibliometric methods were employed to analyze the number of publications, countries, journals, authors, keywords, and other relevant factors.

Results: A total of 1,200 English-language publications were included in the analysis, showing an overall upward trend in annual output. China ranked highest in co-occurrence frequency (341 instances), demonstrating absolute dominance in research output within this field. The United States exhibited the highest centrality (0.16), occupying a core hub position within the research network. The University of Barcelona (Univ Barcelona) led with 55 co-occurrence frequencies and the highest centrality (0.14),

establishing itself as a core research hub. The most frequently co-occurring author was Thomas Reiberger from the United States (32 times), a key driving force in the current field. Research hotspots in portal hypertension demonstrate vertical deepening from therapeutic techniques toward mechanism analysis and risk assessment, while simultaneously expanding horizontally into specialized studies of specific subtypes and complications.

Conclusions: Research on portal hypertension exhibits thematic differentiation and convergence over time, with technological breakthroughs and clinical needs serving as dual core drivers of its evolution. Future studies should prioritize precision-integrated therapies, prognostic assessment, and molecular target validation, while strengthening the integration of mechanism elucidation with clinical practice.

1913 - Impact of of air pollution to liver diseases

Bolor Beejin¹, Enkhjargal Altangerel¹, Suvd Batbaatar², Burmaajav Badrakh³

National Center For Public Health, Department For Environmental Health And Impact Assessment, Ulaanbaatar-Mongolia¹ Ach Medical University, Public Health, Ulaanbaatar-Mongolia² Mongolian Academy Of Science, Public Health, Ulaanbaatar-Mongolia³

Background / Hypothesis:

Liver disease accounts for approximately 2 million deaths per year worldwide and is responsible for 4% of all deaths. Mongolia is one of the most polluted countries in the world. Exposure to PM2.5 is linked to the development of inflammation, which may be a major risk factor in the advancement of non-alcoholic fatty liver disease. Many epidemiological and ecological studies were done in Mongolia on air pollution and health. However, it is still not clear how much ambient air pollution can cause cirrhosis and non-alcoholic fatty liver disease incidence in Mongolia.

Materials and Methods:

This study employed a cross-sectional study design using data from the nationwide health screening program to assess the prevalence and healthy Mongolian population. The nationwide health screening program was conducted by the Ministry of

E-POSTER ABSTRACTS

Health in Mongolia between 2022 to 2024. The health screen program included 209,055 adults aged over 18 years. Participants with missing data, outliers in key variables, and those had any kind of hepatitis virus infection who live in rural area were excluded, resulting in a final sample of 173,762 adults. Because of only Ulaanbaatar city air pollution data is available, we used only Ulaanbaatar city resident's screening data. We used 16 air quality monitoring stations to measure air pollutant including PM_{2.5} µg/m³, and PM₁₀ mg/m³.

Results:

The study found that the mean age of respondents was 44.01±15.35 years, with females being slightly older on average. Liver enzyme levels were higher among males for both ALT (2.42±12.32) and AST (1.97±9.04). Weight emerged as the strongest predictor of ALT, with age, PM_{2.5}, and PM₁₀ contributing smaller yet statistically significant effects; similar patterns were observed for AST. The combined model of age, weight, and particulate matter (PM_{2.5} and PM₁₀) explained 10.3% of the variance in blood ALT levels and 3.0% of the variance in AST levels. Overall, both liver enzymes showed only weak but direct correlations with particulate air pollution.

Conclusions:

This large population-based analysis indicates that ambient particulate air pollution has only a weak but direct association with liver enzyme levels among healthy adults in Ulaanbaatar.

Keyword(s) : liver enzyme, air pollution, Ulaanbaatar, Mongolia

1914 - Research progress on the association between metabolic dysfunction associated fatty liver disease and gallstones

Shihao Guo¹, Jitao Wang², Dengxiang Liu³
Chengde Medical College Affiliated Xingtai People's Hospital, Hepatological Surgery Department, Xingtai City, Hebei Province-China¹ Tsinghua University Affiliated Changgeng Hospital, Hepatological Surgery Department, Beijing-China² Hebei Provincial Key Laboratory Of Portal Hypertension And Cirrhosis, Administrative, Xingtai City, Hebei Province-China³

Background:

Metabolic dysfunction-associated fatty liver disease (MAFLD) and gallstones diseases (GSD) are common liver and gallbladder diseases, with highly overlapping

epidemiological features and risk factors, confirming a certain correlation between the two, but with different conclusions. With the update of diagnostic criteria for MAFLD, the research dimensions of the correlation between the two continue to expand. This review integrates recent clinical evidence and mechanism research, providing reference for clinical diagnosis and future research.

Materials and Methods:

Search Pubmed and CNKI databases to include research papers on the association between MAFLD and gallstones. Exclude review literature.

Results:

Firstly, the summarized research results indicate that compared with non MAFLD patients, the incidence of GD in NAFLD patients is almost twice that of non MAFLD patients (incidence rates of 47% and 26%, respectively, $p < 0.0001$); Compared with patients without GSD, 56% of patients with gallstones had MAFLD ($p < 0.0001$). Secondly, the research mechanism suggests that the two share three core pathways: lipid metabolism disorders, insulin resistance, and chronic inflammation. The accumulation of free fatty acids leading to bile cholesterol supersaturation is a key link. Insulin resistance serves as a crucial bridge between GSD and MAFLD. The relationship between abnormal glucose metabolism and fatty liver disease is highly recognized, and fasting blood glucose levels are fully correlated with the presence of GSD in MAFLD patients. Finally, in terms of influencing factors, age increase, sex, diabetes, ALP increase, HDL decrease and FBS increase are the only predictors of biliary node in MAFLD patients. Lifestyle interventions can reduce risks. Other studies have shown that asymptomatic patients with MAFLD and non obese individuals also exhibit an increased risk of gallstones. Therefore, in clinical practice, caution should be exercised in treatment and comprehensive screening should be conducted to prevent the occurrence of the disease.

Conclusions:

There is a clear epidemiological association and common pathophysiological basis between MAFLD and gallstones. Clinical attention should be paid to screening for gallstones in MAFLD patients, especially in high-risk subgroups. Future research should focus more on the molecular mechanisms associated with the two and explore targeted intervention measures, providing favorable references for clinical diagnosis and treatment management.

1915 - Ibrutinib Associated HBV Reactivation in Hematologic Malignancies Clinical Experience From Our Center

Berna Yoldas ¹, Selma Tosun ¹

Izmir City Hospital, Infectious Diseases And Clinical Microbiology, Izmir-Türkiye ¹

Background / Hypothesis: Ibrutinib is widely used for chronic lymphocytic leukemia (CLL) and other hematologic malignancies, but its immunosuppressive effects raise concerns about hepatitis B virus (HBV) reactivation in previously exposed patients. This study evaluated HBV serologic status, the frequency and timing of reactivation, and related clinical outcomes in patients receiving ibrutinib at our center.

Materials and Methods: A retrospective analysis was conducted on 29 patients with hematologic malignancies who received ibrutinib therapy between 2013 and 2023. Demographic characteristics, concomitant immunosuppressive treatment, HBV serology, use of antiviral prophylaxis, and laboratory data during treatment were reviewed. HBV reactivation was defined as newly detected HBV DNA positivity in patients previously HBV DNA-negative, a ≥ 1 log increase in HBV DNA level, or HBsAg seroreversion in HBsAg-negative/anti-HBc IgG-positive individuals. Clinical course, prophylaxis, and treatment approaches for patients who experienced reactivation were documented.

Results: Of the 29 patients, 23 received ibrutinib for CLL and 6 for lymphoma. Evidence of past natural HBV infection was present in 18 patients (62%). HBV reactivation occurred in 8 of these 18 patients (44.4%) during ibrutinib therapy. Two of the affected patients were also receiving rituximab. In 6 patients (33.3%), reactivation was attributed solely to ibrutinib. All reactivated patients had baseline resolved immunity (anti-HBc IgG-positive, anti-HBs-positive). One patient experienced reactivation 7 months after discontinuation of ibrutinib, while the remaining five reactivated during therapy at months 26, 20, 12, 7, and 3, respectively. Reactivation manifested as HBV DNA increase in three patients, newly detectable HBV DNA in two patients, and isolated HBsAg seroreversion in one patient. HBV reactivation was more common in patients with anti-HBs < 100 IU/L, although this was not statistically significant ($p = 0.553$). The risk of reactivation was nearly four times higher in this group. All patients were treated with entecavir or tenofovir, resulting in complete virological suppression; no liver

failure or HBV-related mortality occurred.

Conclusions: In our series, patients with hematologic malignancies receiving ibrutinib who had prior HBV exposure exhibited a notably high reactivation rate. Since reactivation may occur at various stages of treatment—even after therapy discontinuation—close virological monitoring is essential in this population. Although ibrutinib is classified as an uncertain-risk agent in some guidelines, our findings indicate that greater vigilance is warranted during prolonged oral ibrutinib therapy. Considering baseline HBV serologic profile and individual risk factors, prophylactic antiviral therapy may be appropriate in selected patients. Larger, prospective studies are needed to determine the optimal preventive and management strategies.

Keyword(s) : HBV reactivation, immunosuppression, hematologic malignancy, ibrutinib

1917 - Association between the platelet high density lipoprotein cholesterol ratio and metabolic dysfunction associated steatotic liver disease A corhot study

Weihua Cao ¹, Yao Xie ¹, Minghui Li ¹

Beijing Ditan Hospital, Capital Medical University, Hepatology Division 2, Beijing-China ¹

Background / Hypothesis:

The platelet/high-density lipoprotein cholesterol ratio (PHR) is a novel marker of inflammation and hypercoagulability, representing the severity of metabolic syndrome. Hepatic metabolic syndrome manifests as metabolic dysfunction-associated steatotic liver disease (MASLD), which is associated with inflammation and hypercoagulability. This study aims to determine the relationship between PHR and MASLD diagnosed by liver biopsy.

Materials and Methods:

This retrospective study included patients who underwent liver biopsy were diagnosed with MASLD at Beijing Ditan Hospital as shown in Figure 1. The PHR was calculated as the ratio of platelets to high-density lipoprotein cholesterol. According to PHR quartiles, to compare the differences in various clinical indicators at the Q1-Q4 levels, and the relationships between PHR and clinical parameters. The differences in CAP and LSM among the quartiles of PHR, and the differences between MASLD and hepatic fibrosis according to the quartiles of PHR were analyzed.

Results:

E-POSTER ABSTRACTS

A total of 527 patients diagnosed with MASLD by liver biopsy were enrolled. After adjusting for other clinical variables, patients in the highest PHR quartile had 3.02 times higher odds and 95% CI (1.89-3.78) of having NAFLD compared to those in the lowest quartile. This result was statistically significant ($P=0.003$). While increased PHR was initially associated with fibrosis, this association became not statistically significant ($P=0.093$) after adjusting for other variables.

Conclusions:

PHR is an effective and promising marker for identifying MASLD. The study suggests that interventions aimed at improving a patient's PHR could help reduce the incidence of MASLD.

1919 - Trends of Chronic Liver Disease and Cirrhosis Mortality in Medically Underserved Areas of Taiwan 2015–2022

Kuo-chih Tseng¹, Sheng-nan Lu², Chih-hsun Yi³, Chih-ming Lin⁴, Kuan-fu Liao⁵, Wei-yu Chan⁶, Tou-yuan Tsai⁷, Yi-ting He He⁸

Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation; School Of Medicine, Tzuchi University, Department Of Internal Medicine, Chiayi-Taiwan¹ Kaohsiung Chang Gung Memorial Hospital, Division Of Hepato-gastroenterology, Department Of Internal Medicine, Kaohsiung-Taiwan² Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation; School Of Medicine, Tzu Chi University, Department Of Medicine, Hualien-Taiwan³ Taichung Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Division Of Gastroenterology, Department Of Internal Medicine, Taichung-Taiwan⁴ Taichung Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation; School Of Medicine, Tzu Chi University, Division Of Gastroenterology, Department Of Internal Medicine, Taichung-Taiwan⁵ Taipei Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Division Of Gastroenterology, Department Of Internal Medicine, Taipei-Taiwan⁶ Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation; School Of Medicine, Tzuchi University, Emergency Department; Center For Health Data & Advanced Translational Analytics, Dalin Tzu Chi Hospital, Chiayi-Taiwan⁷ Dalin Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Center For Health Data & Advanced Translational Analytics, Dalin Tzu Chi Hospital, Chiayi-Taiwan⁸

Background / Hypothesis:

The World Health Organization (WHO) aims to eliminate viral hepatitis by 2030, and Taiwan is on track to achieve hepatitis C (HCV) elimination as early as 2025 following nationwide reimbursement of direct-acting antivirals (DAAs) beginning in 2017. Despite these advances, national mortality databases do not document viral etiologies for deaths from chronic liver disease and liver cirrhosis (CLD/LC). Sentinel hospital data are therefore essential to provide HBV/HCV-specific mortality estimates and to evaluate progress among high-risk subpopulations, particularly medically underserved areas (MUAs), where healthcare access and screening remain limited.

Materials and Methods:

This analysis included individuals who died from CLD/LC (ICD-10 K70, K73–K74) between 2015 and 2022 across two major Taiwanese healthcare systems (Chang Gung and Tzu Chi). Deaths due to primary liver cancer were excluded. In addition to HBV and HCV data, the analysis also linked administrative, laboratory, and imaging datasets. MUAs were defined based on the National Health Insurance Administration's 2024 classification. Viral-specific mortality proportions change was calculated.

Results:

Among 6,619 decedents with complete viral testing, overall HCV-related mortality declined markedly from 22.4% in 2015 to 12.8% in 2022. In contrast, HBV-related mortality showed minimal change, and Non-BC mortality increased steadily, suggesting a rising burden of metabolic or lifestyle-related liver disease. Within MUAs, the decline in HCV mortality was even more pronounced, decreasing from 28.1% to 11.6%, while HBV mortality declined modestly from 17.7% to 14.3%. Women experienced a larger reduction in HCV-related deaths (–75%) than men (–49%). MUAs also exhibited disproportionately high smoking and alcohol use among men, coupled with unexpectedly low detection of diabetes and fatty liver disease, indicating under-screening and healthcare access gaps.

Conclusions:

Taiwan has achieved substantial reductions in HCV-related CLD/LC mortality both nationally and within MUAs, reflecting the broad impact of DAA therapy. However, HBV-related mortality remains largely unchanged, and Non-BC mortality continues to rise, highlighting increasing contributions from metabolic and lifestyle-associated liver disease. MUAs represent a

E-POSTER ABSTRACTS

vulnerable subpopulation characterized by high behavioral risks, limited diagnostic detection, and unequal healthcare access. Strengthening HBV management, improving screening coverage, and enhancing access to antiviral therapy in MUAs will be essential to ensure equitable progress toward Taiwan's 2025 HCV elimination milestone and WHO's 2030 viral hepatitis elimination targets.

1921 - Clinical spectrum and long term adverse outcome of Infantile onset Extrahepatic Portal Vein Obstruction

Ajay Aravind¹, Ujjal Poddar¹, Anshu Srivastava¹, Moinak Sen Sarma¹
Sanjay Gandhi Postgraduate Institute Of Medical Sciences, Pediatric Gastroenterology, Lucknow-India¹

Background / Hypothesis:

Extrahepatic portal vein obstruction (EHPVO) is one of the leading causes of portal hypertension in children. Apart from variceal bleeding, significant morbidity occurs due to massive splenomegaly, hypersplenism, portal biliopathy and growth retardation. This study aims to assess the clinical features and outcomes of infantile onset EHPVO and to compare with onset in older children providing insights into how age at presentation influences disease progression, complications and management.

Materials and Methods:

Data from a prospectively maintained database of 1,050 children with EHPVO, spanning from 1993 to 2024, were analysed. Patients were categorized by age at onset: infancy, 1–5 years, 6–10 years, and 11–18 years, and these groups were compared with respect to growth, hypersplenism, and the development of complications such as portal biliopathy and portal colopathy.

Results:

Total 1050 children were diagnosed with EHPVO during the study period. Mean age of onset of symptoms were 6(2.75-9)years and mean age at diagnosis were 9(6-13 years). Presentation in infancy (n=88), between 1-5years (n=268), between 6-10 years (n=430) and between 11-18 years (n=213) with slight male predominance across all groups. Presentation as

variceal bleeding was significantly higher in infancy as compared to older children (89.7% vs. 86.07%, $p=0.043$). Median follow-up of these children were available for 96 (36-144) months. Symptomatic portal biliopathy was seen in significantly higher proportion in infantile onset group (7.95%) as compared to all other groups. Portal colopathy was significantly higher in infantile onset group (17%) compared to children with onset after 6 years of age. Growth failure was significantly higher in children with onset 1-5 years compared to infantile onset and 6-10 years group. Spleen size was significantly large and hemoglobin was significantly low in infantile onset group. No difference was seen with respect to presence of hypersplenism, liver function tests, platelet count and total leukocyte count. Porto-systemic shunt surgery was done in 307 (29.23%) children. Incidence of shunt block was seen in significantly higher proportion in infantile onset group (11.5%) as compared to other groups.

Conclusions:

This large study on EHPVO demonstrates that complications are significantly more severe in patients with disease onset during infancy. This heightened severity is likely due to the prolonged duration of disease, which allows for the progressive consequences of portal hypertension to become more pronounced over time. These findings underscore the critical importance of early detection and proactive management in at-risk populations to minimize long-term complications and improve clinical outcomes.

Dr. Matei Balș" National Institute For Infectious Diseases, Adults 3 Infectious Diseases Department, Bucharest-Romania² "Carol Davila" University Of Medicine And Pharmacy, "prof. Dr. Matei Balș" National Institute For Infectious Diseases, Pathophysiology And Immunology

E-POSTER ABSTRACTS

Department, Bucharest-Romania ³

Background / Hypothesis:

Hepatitis B and D viruses (HBV and HDV) contribute to high liver disease burden, despite effective vaccination available for almost 30 years. Recent evaluation of HBV prevalence among European countries sets Romania the second highest (6.2%), after Cyprus. Regarding HDV global epidemiology, the assessed prevalence was 4.5% in people with chronic HBV infection, yet insufficient data for an accurate estimation in Romania. In 2024, Bulevirtide has been approved in Romania, preliminary results showing positive effects on slowing disease progression and increasing survival.

Objective: Analysis of the clinical characteristics, complications and treatment of HBV and HDV infection

Materials and Methods:

We conducted a retrospective study on HBV and HDV infection cases among adults evaluated in our department of National Institute for Infectious Diseases "Prof. Dr. Matei Balș" between September 2010 and November 2025. Clinical, biological and treatment-related data were collected and analyzed using SPSS Statistics (version 26).

Results:

We included 110 patients, the median age was 51.25 years (IQR: 48.45-54, age range 21-79 years old) and sex ratio M:F = 1:1. Positive HDV load was found in 67 of 88 patients tested (76.13%), with a median value of 19.876 UI/mL. Cirrhosis was identified in 44 patients and hepatocellular carcinoma in 6 cases. HIV co-infection was diagnosed in 8 patients, with a lower median age than the seronegative group (33.1 years, $p < 0.001$). Median Charlson comorbidity index was 3.65 (IQR: 3.20-4.11). Cirrhosis was associated with higher monocyte-to-lymphocyte ratio than non-cirrhotic patients (mean 0.25 versus 0.41, $p = 0.037$). HBV and HDV reactivation in patients with hematological malignancies receiving chemotherapy occurred in 4 cases. Between 2003 and 2024, Interferon therapy was administered to 46 patients, maximum number of cycles was 4, without successful suppression of HDV. Bulevirtide 2 mg monotherapy or co-administered with nucleoside/nucleotide analogues has been initiated in 21 patients since January 2025, 5 of them with history of IFN treatment, with a decrease in the alanine aminotransferase (ALT) levels (mean 123.85 U/L before treatment to 42.14 U/L after 6 months of treatment) and without adverse events.

Conclusions:

Bulevirtide currently represents the only therapeutic option available for chronic HBV and HDV hepatitis, improving the liver function after 6 months of administration. More eligible patients need to be enrolled in treatment with Bulevirtide and further studies must assess the long-term evolution.

Keyword(s) : hepatitis B virus, hepatitis D virus, bulevirtide

1924 - Safety and feasibility of next generation extracorporeal albumin detoxification dialysis for long term bridging to liver transplantation in secondary sclerosing cholangitis

Jan Stange ¹, Sebastian Koball ¹, Michael Hinz ¹, Sitne Koball ¹, Adrian Dominik ¹, Steffen Mitzner ¹
University Of Rostock, Internal Medicine, Rostock-Germany ¹

Background / Hypothesis:

Secondary sclerosing cholangitis in critically ill patients (SSC-CIP) is a highly lethal condition, with approximately 50% mortality within the first year. We report the course of a 35-year-old male who developed severe necrotizing bacterial pneumonia following RSV pneumonia. His only known comorbidity was IgA nephropathy treated with antihypertensives; he was not immunosuppressed. Right lower-lobe lobectomy was followed by septic shock, hemorrhagic complications, vasopressor-dependent circulatory failure, and acute kidney injury requiring continuous renal replacement therapy (CRRT). Progressive cholestasis and liver injury evolved into critical-illness cholangiopathy, confirmed by ERCP and liver biopsy, with bilirubin exceeding 15 mg/dL.

Materials and Methods:

As bilirubin and bile acids continued to rise—accompanied by severe pruritus—we escalated CRRT to extracorporeal albumin dialysis (ECAD) using the MaxiCycler system, which has been shown to provide enhanced bile-acid clearance compared with MARS, CytoSorb, plasma perfusion over BR350, or plasma exchange (Stange et al., NDT 2024).

Results:

Over the first month of ECAD therapy, multiorgan failure resolved sufficiently for transfer out of the ICU and subsequently home. Because bile excretory function did not recover over more than six months, outpatient ECAD was continued three times weekly. Serial imaging and ERCP confirmed persistent impairment of biliary excretion, although the patient

E-POSTER ABSTRACTS

exhibited no clinical signs of cirrhosis after one year and 170 ECAD sessions. Each session consistently removed >540 mg of bile acids. The patient maintained weight, remained free of pruritus, and had stable functional status. Liver biopsy later showed progressive fibrosis; the patient was subsequently listed for transplantation and received a liver graft 18 months after initiation of ECAD, following >200 sessions.

Conclusions:

MARS-based ECAD has been shown to ameliorate hepatic encephalopathy, hemodynamic instability, and renal dysfunction in controlled studies, though effects on overall survival remain under investigation. Limitations of earlier systems included restricted adsorption capacity and complex workflows. This case illustrates that next-generation ECAD platforms provide higher detoxification efficiency and are more compatible with routine critical care practice. To our knowledge, this represents the longest continuous outpatient ECAD treatment reported to date.

1925 - Burden of metabolic dysfunction associated steatotic liver disease in Saudi Arabia Evidence from the first nationwide population based cohort study

Saleh A. Alqahtani ¹, Faisal M. Sanai ², Haifa F. Alotaibi ³, Shadan Almuhaideb ⁴, Basmah Khoja ⁴, Layan A. Alsubki ⁴, Samar A. Alqussayer ³, Dalal Sharbini ⁵, Rawan Aseeri ⁶, Waleed Alhazzani ³

King Faisal Specialist Hospital & Research Center, Liver, Digestive, And Lifestyle Health Research Section, And Organ Transplant Center Of Excellence, Riyadh-Saudi Arabia ¹ King Abdulaziz Medical City, King Abdullah International Medical Research Center, Gastroenterology Section, Department Of Medicine, Jeddah-Saudi Arabia ² Ministry Of Defense Health Services, Health Research Center, Riyadh-Saudi Arabia ³ King Faisal Specialist Hospital & Research Center, Liver, Digestive, & Lifestyle Health Research Section, And Biostatistics, Epidemiology, And Scientific Computing Department, Riyadh-Saudi Arabia ⁴ King Fahad Military Medical Complex, Medical Laboratory Department, Dhahran-Saudi Arabia ⁵ Armed Forces Hospital, Department Of Family Medicine, Dhahran-Saudi Arabia ⁶

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of chronic liver disease and is strongly linked to obesity and diabetes, all of which are increasing globally and in Saudi Arabia. However, robust national-level data on MASLD prevalence and associated risk factors are still needed. We aimed to estimate MASLD prevalence among Saudi adults using clinical, biochemical, and imaging assessments.

Materials and Methods:

GENESIS is the first large-scale, prospective, population-based cohort study designed to assess the prevalence and severity of MASLD in Saudi Arabia. Adults without prior liver disease, except MASLD, were recruited from primary healthcare centers across three major regions between March 2024 and June 2025. All participants underwent standardized clinical evaluation, laboratory testing, and vibration-controlled transient elastography. MASLD was defined as a controlled attenuation parameter (CAP) ≥ 268 dB/m together with ≥ 1 cardiometabolic risk factor (CMRF) (e.g., BMI ≥ 25 kg/m², elevated HbA1c, hypertension, or dyslipidemia). Sensitivity analyses used alternative definitions (CAP ≥ 220 dB/m and MASLD liver fat score [MASLD-LFS]). Significant fibrosis (F2–F4) was defined as a liver stiffness ≥ 7.1 kPa.

Results:

Among 2,983 participants, the MASLD prevalence was 37.2% (age-adjusted: 34.1%), with higher prevalence in males (43.6% vs. 30.9%). Hepatic steatosis was present in 68.8% of participants, and 20.7% had severe steatosis (CAP ≥ 300 dB/m). Using alternative definitions, steatosis prevalence was 66.1% with CAP ≥ 220 dB/m and 58.6% with MASLD-LFS. Significant fibrosis was observed in 2.9% of participants.

Participants with MASLD were more often male (58.4% vs. 44.8%) and older (mean age: 46.1 vs. 39.5 years) (all $p < 0.001$). No differences were observed in smoking or coffee consumption between MASLD and non-MASLD groups.

Participants with MASLD had higher BMI (median: 31.6 vs. 27.0 kg/m²), higher waist-to-hip ratio (mean: 0.91 vs. 0.86), and greater CMRF burden (diabetes: 33.4% vs. 12.9%; hypertension: 23.0% vs. 10.1%; dyslipidemia: 36.5% vs. 20.6%) (all $p < 0.001$). Despite similar liver enzyme levels, participants with MASLD had higher

E-POSTER ABSTRACTS

median insulin (13.0 vs. 8.1 μ U/mL) and C-reactive protein (3.5 vs. 2.1 mg/L) (all $p < 0.001$).

Conclusions:

MASLD was present in 37.2% of this nationwide cohort, with hepatic steatosis in two-thirds of participants. Individuals with MASLD were more often male, older, and more likely to have greater CMRF burden. These findings reflect a substantial and growing public health burden and highlight the need for targeted prevention and management strategies. The findings can support future national initiatives for MASLD and broader noncommunicable disease control in Saudi Arabia.

Background / Hypothesis:

Diabetes mellitus (DM) is a major metabolic disorder increasingly linked to liver disease progression. However, the full phenotypic burden of DM on liver health and cardiometabolic risk in the Middle East region insufficiently characterized. We hypothesized that DM is associated with more pronounced metabolic liver disease and multidimensional comorbidities.

Materials and Methods:

We analyzed data from 2,983 adults enrolled in the Genomics and Environmental Noninvasive Evaluation for Saudi Intrahepatic Steatosis (GENESIS), a large-scale, population-based, liver health screening project in Saudi Arabia. Between March 2024 and June 2025, adults from the general population without pre-existing liver disease other than metabolic-associated steatotic liver disease (MASLD) were recruited through primary healthcare centers across three major regions to assess the prevalence of MASLD and its associated morbidities. These participants were categorized based on their DM status, which was determined by self-reported DM or current use of antidiabetic medications. Collected data included sociodemographic characteristics, comorbidities, and transient elastography findings (controlled attenuation parameter [CAP] and liver stiffness measurement [LSM]). MASLD was defined as moderate-to-severe hepatic steatosis ($\text{CAP} \geq 268$ dB/m) in the presence of at least one cardiometabolic risk factor. Significant fibrosis (F2–F4) was defined as $\text{LSM} \geq 7.1$ kPa.

Results:

The cohort included 630 participants with DM (21.1%) and 2,353 without DM (78.9%). Participants with DM were older (mean age: 53.7 vs 38.8 years, $P < 0.001$), while sex distribution was similar between groups (males: 50.2% vs 49.8%, $P = 0.91$). DM was associated with a substantially higher prevalence of metabolic syndrome traits, including dyslipidemia (66.5% vs 15.8%), hypertension (41.9% vs 7.6%), and higher BMI (median: 31.0 vs 28.2 kg/m^2) (all $P < 0.001$).

Liver disease severity was significantly elevated among participants with DM, with MASLD prevalence of 60.6% vs 31.0%, severe steatosis ($\text{CAP} \geq 300$ dB/m) at 38.4% vs 15.9%, and advanced fibrosis at 8.1% vs 1.5% (all $P < 0.001$).

Conclusions:

In one of the largest Middle Eastern screening cohorts, DM was strongly associated with higher MASLD prevalence, more severe hepatic steatosis, and increased rates of advanced fibrosis, alongside a markedly higher cardiometabolic burden. These findings highlight the urgent need for integrated MASLD care pathways and support prioritizing individuals with DM for early screening, lifestyle

E-POSTER ABSTRACTS

interventions, and fibrosis assessment to prevent progression to advanced liver disease and improve long-term outcomes.

1928 - Beyond the usual suspects" uncovering autoimmune hepatitis overlap with Wilson disease

Basavaraj Patil¹

Madras Medical College, Hepatology, Chennai-India¹

Background / Hypothesis:

Autoimmune hepatitis with Wilson disease is a rare overlap and potentially life threatening condition if presents with ALF. We report 3 cases to highlight diagnostic challenges and treatment outcomes in such overlap.

This series aim to describe autoimmune hepatitis and Wilson disease and there clinical presentations and management outcomes.

Case series :

Three patients (2 female & 1 male) aged between 10 to 30 years.

Case 1 & case 2- Two female patients (13 years & 15 years) presented with ALF , (jaundice& hepatic encephalopathy) , both patient had transaminitis , elevated INR, normal ceruloplasmin levels, urine cu 24 hours was more than 100mcg/24hrs, autoimmune hepatitis serology positive ,liver biopsy suggestive of AIH with copper deposits and genetic testing revealed presence of ATP7B gene mutation . Both patient according to AIH simplified & revised international score suggestive of definite AIH. Patients were started on steroids ,chelation and plasma exchange in view of ALF and blood parameters improved with improvement of hepatic encephalopathy, then patients were referred for liver donor liver transplant .

Case 3- male (28 years) patient with alcohol use disorder , presented with jaundice and ascites .transaminitis revealed of ethanol pattern with reduced platelets and reduced ALP initially.then ceruloplasmin normal with elevated urine 24 hrs and liver biopsy suggestive of ?Wilson disease? Cholestatic diseases, gene studies revealed ATP 7B gene mutation

,autoimmune hepatitis serology is positive and AIH simplified & revised international score suggestive of definite AIH.CECT - suggestive of cld with PHTN and ascites.

Diagnosis - ACLF(APASL) , patients was started on steroids and chelation and now patient on waiting list for liver transplant.

Conclusions: case series underscores the importance for early diagnosis of autoimmune hepatitis with wilson disease, for effective management of these overlaps.

In case of ALF in these overlaps plasma exchange is a bridging therapy before liver transplant.

1929 - hUC MSC Derived Exosomal miR 22 3p Attenuates Liver Fibrosis via Inhibition of the NLRP3 Inflammasome

Wei Huang¹, Yonghong Wang¹, Hong Tang¹

West China Hospital Of Sichuan University, Center Of Infectious Diseases, Chengdu-China¹

Background / Hypothesis:

Liver fibrosis features excessive extracellular matrix deposition and tissue remodeling in response to chronic injury and can progress to cirrhosis or hepatocellular carcinoma. Effective antifibrotic drugs are lacking, partly due to poor translation from animal models. Mesenchymal stem cells (MSCs) show immunomodulatory and regenerative potential, but direct transplantation is limited by low survival, immunogenicity and tumorigenicity. Exosomes from MSCs provide a safer, cell-free alternative that delivers bioactive cargos such as miRNAs. This study investigated the therapeutic effect and mechanism of human umbilical cord-derived MSC (hUC-MSC) exosomes on liver fibrosis, focusing on miR-22-3p-mediated regulation of the NLRP3 inflammasome.

Materials and Methods:

hUC-MSCs were isolated and identified by morphology, surface markers and tri-lineage differentiation. Exosomes were obtained by ultracentrifugation and characterized by NTA, TEM and Western blot (CD63, CD81, TSG101). Uptake and antifibrotic effects of PKH67-labeled exosomes were evaluated in LX2 hepatic stellate cells and a carbon tetrachloride (CCl₄)-induced mouse model. LX2 cells were activated by LPS/ATP and treated with hUC-MSC exosomes. Fibrosis markers (Col1A1, α -SMA) and

E-POSTER ABSTRACTS

NLRP3 inflammasome components (NLRP3, Caspase-1, ASC, GSDMD, IL-1 β , IL-18) were assessed by qPCR, Western blot, IHC and ELISA. Public datasets GSE151098 and GSE153752, bioinformatic analysis and dual-luciferase assays were used to identify miR-22-3p targeting NLRP3. Exosomes enriched or depleted in miR-22-3p via agomir/antagomir transfection were used to verify its function in vitro and in vivo.

Results:

hUC-MSC exosomes were successfully characterized and efficiently internalized by LX2 cells. Exosome treatment reduced Col1A1 and α -SMA expression in activated LX2 cells, preferentially accumulated in the liver, and alleviated CCl₄-induced fibrosis, as shown by improved histology and decreased serum ALT, AST, HA and Hyp. Exosomes inhibited NLRP3 inflammasome activation and lowered IL-1 β and IL-18 production. miRNA profiling and functional validation identified miR-22-3p as a key exosomal miRNA directly targeting NLRP3. Overexpression of miR-22-3p strengthened, whereas its inhibition weakened, the antifibrotic and anti-inflammatory effects of exosomes.

Conclusions:

hUC-MSC-derived exosomes exert potent antifibrotic effects by targeting hepatic stellate cells and suppressing NLRP3 inflammasome activation. miR-22-3p is a critical exosomal cargo mediating these actions, supporting hUC-MSC exosomal miR-22-3p as a promising cell-free strategy for liver fibrosis therapy.

Keyword(s) : Liver fibrosis; hUC-MSC; Exosome; NLRP3; miR-22-3p

1930 - Outcomes of Percutaneous Interventions in Liver Abscess in children 15 year experience from a tertiary care center

Ajay Aravind¹, Ujjal Poddar¹, Anshu Srivastava¹, Moinak Sen Sarma¹, Rajanikant Yadav², Anil Kumar Singh²

Sanjay Gandhi Postgraduate Institute Of Medical Sciences, Pediatric Gastroenterology, Lucknow-India¹
Sanjay Gandhi Postgraduate Institute Of Medical Sciences, Radiodiagnosis, Lucknow-India²

Background / Hypothesis:

Adult studies have demonstrated the safety and effectiveness of percutaneous interventions in liver abscess. However, literature is scarce in children. The aim of our study was to compare the effectiveness of percutaneous needle aspiration (PNA) and

percutaneous catheter drainage (PCD) in the management of liver abscess in children

Materials and Methods:

Prospectively kept database of children (<18 years) diagnosed with liver abscess between 2011 and 2025 were analysed. Diagnosis of liver abscess was based on the clinical symptoms and confirmation by abdominal imaging showing liver abscess. Percutaneous needle aspiration is preferred in cases of solitary abscess, less than 5cm, thin pus, unilocular and non-toxic patients. Percutaneous catheter drainage was preferred in multiloculated abscess, size >5cm, failure of ≥ 1 aspirations, toxic or septic patients. Outcomes assessed were success of intervention, volume of abscess, duration of hospital stay, timing of clinical improvement and radiological resolution and complications related to the procedure performed.

Results:

A total of 145 children with liver abscess were included. Median age was 8 (IQR: 6-14) years with a slight male preponderance (M:F 1.4:1). Most common presentation was fever and abdominal pain (n=108, 74.5%) followed by fever, abdominal pain and breathlessness (n=21, 14.7%), fever, abdominal pain and jaundice (n=3, 1.9% and isolated fever (n=13, 8.8%). The majority of cases had a single abscess (74, 80.4%), with a predilection for the right lobe (70%). Median volume of the abscess was significantly higher in PCD group compared to PNA group; 100 (63.5-200) ml vs. 39 (13.75-67) ml, p=0.008. The success rate in patients treated with PCD were similar to that of PNA (93.8% vs. 91.1%, p=0.256). Time to achieve clinical improvement was similar in both groups [PCD: 18.5 (15.5-22) days vs. PNA 17 (14.5-20) days, p=0.389] and time to achieve radiological resolution of abscess was similar in both groups [PCD: 45 (30-60) days vs. PNA: 45 (40-60) days, p=0.295]. No significant differences were found in the duration of hospitalization [PCD: 21 (16.25-24.75) days vs. PNA: 20.5 (15.5-25) days, p=0.380] or procedure-related complications [PCD: 3.09% vs. PNA: 2.94%, P=0.763].

Conclusions:

Both percutaneous needle aspiration and catheter drainage are safe methods of draining liver abscess in children. Both PCD and PNA has a similar success rate, time to achieve clinical and radiological resolution and hospital stay. Percutaneous needle aspiration can be

E-POSTER ABSTRACTS

preferred in cases of small (<5cm), unilocular, solitary abscess, in non-toxic patients.

Çam Sakura Education And Research Hospital, Department Of Infectious Diseases, Istanbul-Türkiye⁸

Background: In patients with chronic hepatitis B (CHB), hepatitis B surface antigen (HBsAg) seroclearance is the primary target of treatment and is rarely observed. This study aimed to investigate the factors affecting HBsAg loss.

Methods: This multicenter study was conducted in hospitals in eight provinces in different regions of Türkiye. This study was designed to retrospectively evaluate HBsAg status and clinical and laboratory findings in patients with CHB. A total of 8983 chronic hepatitis B (HB) infection patients who were treated or followed between 2014 and 2024 were evaluated retrospectively. 71 CHB patients were examined based on exclusion criteria, and 71 patients without HBsAg loss were matched as controls. A total of 142 patients were included in the study. Patient data and laboratory findings were retrieved from patient files. Statistical analysis was performed using SPSS version 25.0. The chisquare test was used for categorical variables.

Results: The basal mean hepatitis B virus (HBV) DNA level was significantly lower in the HBsAg loss group ($p < 0.001$). There were no significant differences between the sexes. Hepatosteatorsis was detected in 52% of patients in the group with HBsAg loss and in 39% of

patients in the group without HBsAg loss ($p > 0.05$). The prevalence of hyperlipidemia comorbidity ($p = 0.001$) was significantly higher in the HBsAg loss group compared to the non-HBsAg loss group.

Conclusions: In conclusion, our study identified several factors associated with HBsAg seroclearance in CHB patients, including low baseline HBVDNA levels, hyperlipidemia.

1932 - Parkin perturbs Hepatocyte Mitochondria associated Endoplasmic Reticulum Membranes Dynamics

Zhong Wen Wang¹, Chuanmiao Liu¹, Dongdong Li¹
First Affiliated Hospital Of Bengbu Medical University, Department Of Infectious Disease And Hepatology, Bengbu-China¹

Background / Hypothesis:

Mitochondrial-associated Endoplasmic Reticulum Membranes (MAM) plays an important intracellular function in facilitating the synergistic interactions and communication between endoplasmic reticulum and mitochondria. The study of MAM contributes to an in-depth understanding of the communication and regulatory mechanisms between intracellular organs, which is of great significance in revealing the pathogenesis and treatment of related diseases.

Materials and Methods:

Animal models were developed in liver-specific HO-1 knockout (HO-1HepKO) and wild-type (WT) mice. Ultrastructure changes in MAM were observed under TEM. Immunofluorescence double labeling was used to determine the co-localization of important proteins on MAM.

Results:

Deletion of HO-1 in mice exacerbated ultrastructural MAM damage as evidenced by the increased MAM length and reduced the number of MAM which were observed under TEM when compared to the WT mice. Deletion of HO-1 up-regulated Parkin and down-regulated MFN2, resulting in a decrease in Mito [Ca²⁺]/Cyto [Ca²⁺] ratio in vitro. However, HO-1 overexpression showed opposite results. Overexpression of Parkin by pcDNA3.1 plasmid in vitro leads to MAM abnormalities similar to those observed in Liver-specific HO-1 knockout mice, and knockdown of Parkin by siRNA plasmid in vitro has the opposite

E-POSTER ABSTRACTS

results. Moreover, immunofluorescence co-localization showed increased co-localization of Parkin and MFN2 in the MAM region in HO-1HepKO mice, and their interaction may lead to MAM injury.

Conclusions:

We used CRISPR/Cas9 technology to construct a liver-specific knockout HO-1 mice to investigate the role of HO-1 in the structure of r MAM in liver tissue and its regulation of calcium ion transport.

1933 - Advancing Fibrosis Assessment in Chronic Hepatitis C Through Non Invasive Approaches

Ikram Aluahabi¹, Mohamed Borahma¹, Fatima Zahra Chabib¹, Nawal Lagdali¹, Selma Sebbah¹, Fatima Zohra Ajana¹, Maryeme Kadiri¹
Ibn Sina University Hospital, Faculty Of Medicine And Pharmacy Of Rabat. Mohammed V University Rabat., Medecine C Hepatogastroenterology Departement,, Rabat-Morocco¹

Background

Chronic hepatitis C(CHC) remains a major cause of chronic liver disease worldwide. Early identification of advanced fibrosis is crucial to guide management and prevent complications. Non-invasive fibrosis scores, such as FIB-4 and the Gamma-Glutamyl Transpeptidase-to-Platelet Ratio (GPR), are increasingly used as alternatives to liver biopsy. This study aimed to evaluate the diagnostic performance, sensitivity, specificity, and discriminative ability of FIB-4 and GPR for detecting significant fibrosis in CHC patients.

Methods

We conducted a retrospective descriptive study including CHC patients followed in a gastroenterology department over several years. Clinical, biological, imaging, and fibrosis assessment data were collected from medical records. Fibrosis was evaluated using liver biopsy, FibroScan, or FibroTest. Continuous variables were tested for normality using the Shapiro-Wilk test. The diagnostic performance of FIB-4 and GPR for significant fibrosis (>F3) was assessed using receiver operating characteristic (ROC) curve analysis.

Results

167 patients were included, The mean age was 59.4 ± 14.9 years, with a M/F ratio of 0.8. Comorbidities included hypertension in 47 individuals (28%) and

diabetes in 32 (19.1%), and 21 (12.5%) were tobacco users. CHC was incidentally diagnosed in 75 cases (44.9%). Genotype 1b was the most frequent, found in 97 cases (57.9%). Signs of chronic liver disease were present in 40 (23.7%), and portal hypertension in 31 (18.3%).

Fibrosis assessment showed that 125 (75.1%) had baseline fibrosis: F4 in 43 (26%), F3 in 32 (19%), F2 in 41 (24.6%), and F0-F1 in 49 (29.4%). Median FIB-4 was 3.25 [1.49-4.40], and median GPR was 0.87 [0.46-2.12]. A total of 150 (90%) received direct-acting antivirals, achieving sustained virological response in 136 (81.5%). FIB-4 demonstrated an AUROC of 0.874, with 90.1% sensitivity and 77.6% specificity for detecting significant fibrosis(F3-F4). GPR showed superior performance, with an AUROC of 0.913, 91.4% sensitivity, and 81.1% specificity.

Conclusion

In this cohort of CHC patients, both FIB-4 and GPR demonstrated excellent diagnostic accuracy for predicting significant fibrosis(F3-F4), with GPR outperforming FIB-4 across all metrics. These findings support the use of simple, accessible non-invasive scores in routine clinical practice, particularly in resource-limited settings, to improve early detection and management of advanced fibrosis.

1936 - Generalized Anxiety Among the patients of Fatty Liver Disease A Cross Sectional Study

Imteaz Mahbub¹, Akm Jubaere², Yasir Arafat²
National Gastroliver Institute And Hospital, Medical Gastroenterology, Dhaka-Bangladesh¹ National Gastroliver Institute & Hospital, Medical Gastroenterology, Dhaka-Bangladesh²

Background / Hypothesis: Metabolic Dysfunction Associated Steatotic Fatty liver disease (MASLD) is one of the most common morbidities worldwide, and most patients may suffer from anxiety due to uncertainty of future disease progression. This cross-sectional study aimed to investigate the prevalence and correlates of anxiety among patients with MASLD, examining the relationship between demographic factors, disease severity, and anxiety levels.

Materials and Methods: This cross-sectional study was conducted in the National Gastroliver Institute and

E-POSTER ABSTRACTS

Hospital, Dhaka, from January 2025 to December 2025. A total of 128 patients diagnosed with MASLD based on ultrasound were evaluated for Generalized anxiety by the validated Bengali Generalized Anxiety Disorder-7 (GAD-7) questionnaire. Anxiety levels were assessed using standardized measures and categorized into minimal, mild, moderate, and severe categories. Fatty liver severity was graded using ultrasonography (Grade I-III).

Results: The prevalence of anxiety among fatty liver disease patients was substantial, with 59.4% experiencing some degree of anxiety: minimal anxiety (40.6%), mild anxiety (37.5%), moderate anxiety (12.5%), and severe anxiety (9.4%). The mean anxiety score was 6.25 ± 4.896 (range: 0-18). Age emerged as the most significant predictor of anxiety levels, showing a strong positive correlation ($r = 0.377$, $p = 0.002$) and remaining statistically significant in multivariate regression analysis ($p = 0.001$). The regression model explained 24.7% of the variance in anxiety levels. A trend toward increased anxiety was observed with higher grades of fatty liver severity, but this relationship did not reach statistical significance ($p = 0.074$). Other demographic factors, including sex, occupation, residential location, and monthly family income, showed no significant associations with anxiety levels.

Conclusions: This study reveals that anxiety is highly prevalent among patients with MASLD, affecting nearly 60% of the study population. Age represents the primary demographic risk factor for increased anxiety, with older patients experiencing significantly higher anxiety levels. Healthcare providers should consider routine anxiety screening, particularly for older patients with MASLD, and implement appropriate mental health interventions as part of comprehensive disease management.

1937 - Evaluating Baveno VII Recompensation in Children with Autoimmune Decompensated Cirrhosis Clinical Predictors and Immune Axis Modulation

Anmol Anmol ¹, Vikrant Sood ², Rajeev Khanna ¹, Seema Alam ¹, Bikrant Biharilal ¹, Sukriti Baweja ³, Guresh Kumar ⁴

Institute Of Liver And Biliary Sciences, Pediatric Hepatology, Delhi-India ¹ Institute Of Liver And Biliary Sciences, Pediatric Hepatology, Delhi-India ² Institute Of Liver And Biliary Sciences, Molecular Medicine, Delhi-India ³ Institute Of Liver And Biliary Sciences, Biostatistics, Delhi-India ⁴

Background / Hypothesis:

With immunosuppression, cirrhosis reversal ("recompensation") is increasingly observed in autoimmune hepatitis (AIH), but pediatric insights are limited. We characterized incidence, predictors, cytokine patterns, and clinical outcomes of Baveno-VII-defined recompensation in children with AIH-related decompensated cirrhosis.

Materials and Methods:

Children <18 years with AIH and decompensated cirrhosis (2014–2024) with ≥ 1 -year follow-up were assessed. Recompensation required disease control, ≥ 12 months' absence of decompensating events without supportive therapies, and normalized bilirubin/albumin/INR. Longitudinal liver health, survival, re-decompensation and predictive factors were analyzed. A subset underwent stool-plasma cytokine studies.

Results:

Seventy-eight children (median age 11 years) were included. 69.2% achieved recompensation, with stepwise resolution: INR/HE $\rightarrow$ ascites $\rightarrow$ jaundice $\rightarrow$ albumin, reflecting synthetic recovery lag. Re-decompensation occurred in 12.9%, linked to flare or adherence issues.

Recompensation conferred significant benefit: higher native liver survival (96.6% vs 70.1%, $p=0.003$) and markedly reduced transplantation (1.8% vs 16.6%). On multivariable analysis, spleen size independently predicted recompensation (AOR 1.36 per cm). Smaller spleen signaled lesser portal hypertension and higher reversibility potential.

Cytokine profiling ($n=20$) revealed higher stool IL-10 and IL-1 β alongside lower plasma IL-6 in recompensators. Stool cytokines suggest local immune repair, improved epithelial integrity, and microbiota-mediated tolerance restoration — key to resolving immune-driven hepatic injury. Conversely, lower systemic IL-6 reflects reduced chronic inflammatory burden, a state favoring hepatic regeneration rather than ongoing necroinflammation. These findings collectively support a dual-compartment immune recovery model underpinning recompensation.

E-POSTER ABSTRACTS

Conclusions:

Recompensation occurs in nearly 70% of children with decompensated AIH, with major gains in survival and reduced transplant requirement. Spleen size is a strong, readily measurable predictor. Cytokine signatures highlight the importance of gut-immune recalibration as a mechanism of liver repair. Future multi-center, biomarker-driven studies should refine prediction and therapeutic targeting

1939 - Transient elastography versus the fibrosis 4 index for fibrosis detection in metabolic dysfunction associated steatotic liver disease and metabolic dysfunction associated steatohepatitis

Shadan Almuhaideb ¹, Faisal Abaalkhail ², Basmah Khoja ¹, Mohammed Alghamdi ³, Nasser Al Masri ⁴, Majd Alsayb ⁵, Mushabbab Asseri ⁶, Zobair M. Younossi ⁷, Waleed Alhazzani ⁸, Saleh A. Alqahtani ⁹

King Faisal Specialist Hospital & Research Center, Liver, Digestive, & Lifestyle Health Research Section, And Biostatistics, Epidemiology, And Scientific Computing Department, Riyadh-Saudi Arabia ¹ King Faisal Specialist Hospital & Research Center, Gastroenterology Section, Department Of Medicine, Riyadh-Saudi Arabia ² King Fahad Military Medical Complex, Gastroenterology Unit, Internal Medicine Department, Dhahran-Saudi Arabia ³ Prince Sultan Military Medical City, Hepatology, Riyadh-Saudi Arabia ⁴ King Fahad Armed Forces Hospital, Hepatology, Jeddah-Saudi Arabia ⁵ Prince Sultan Medical Military City, Department Of Endocrine & Diabetes, Riyadh-Saudi Arabia ⁶ Center For Outcomes Research In Liver Disease, The Global Nash/mash Council, Washington, Dc-United States ⁷ Ministry Of Defense Health Services, Health Research Center, Riyadh-Saudi Arabia ⁸ King Faisal Specialist Hospital & Research Center, Liver, Digestive, And Lifestyle Health Research Section, And Organ Transplant Center Of Excellence, Riyadh-Saudi Arabia ⁹

Background / Hypothesis:

The prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic dysfunction-associated steatohepatitis (MASH) is increasing in Saudi Arabia. Although fibrosis-4 index (FIB-4) is included among first-line non-invasive tests (NITs) for MASLD risk stratification, its diagnostic accuracy compared with transient elastography (TE)

liver stiffness measurement (LSM) in this population is unclear. We aimed to evaluate performance of FIB-4 overall and across age- and diabetes-defined subgroups.

Materials and Methods:

We analyzed 622 adults with MASLD/MASH from the Saudi Arabia Global Liver Registry who had TE data. Participants were stratified by LSM ≥ 8 kPa (n=53) versus < 8 kPa (n=569). Data on demographics, body mass index (BMI), comorbidities, and liver enzyme levels were collected. FIB-4 was calculated for 525 participants with complete aspartate aminotransferase (AST), alanine aminotransferase (ALT), platelet count, and age data; a cut-off of ≥ 1.30 defined patients at risk. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated overall and stratified by age category and diabetes status.

Results:

Participants with significant fibrosis (LSM ≥ 8 kPa) were older (median 51 vs 47 y) and had higher BMI (32.0 vs 30.5 kg/m²) compared with those with LSM < 8 kPa. Type 2 diabetes (54.7% vs 39.2%), hypertension (41.5% vs 26.7%), and hyperlipidemia (66.0% vs 52.2%) were more frequent in the elevated LSM group. Median AST and ALT levels were higher (28.0 vs 21.0 U/L; 34.0 vs 23.0 U/L), and median FIB-4 was 0.9 versus 0.7, with FIB-4 ≥ 1.30 observed in 20.4% versus 9.7%. Overall, FIB-4 ≥ 1.30 had 20.4% sensitivity, 90.3% specificity, 17.9% PPV, and 91.7% NPV for detecting significant fibrosis.

Age-stratified analysis showed increasing sensitivity with age: < 35 y had 14.3% sensitivity, 96.3% specificity, 25.0% PPV, and 92.8% NPV; 35–64 y had 17.1%, 91.2%, 15.8%, and 91.9%; while ≥ 65 y had 42.9%, 66.7%, 21.4%, and 84.6%. Diabetes-stratified performance was similarly low. Participants with diabetes had 19.2% sensitivity, 89.5% specificity, 19.2% PPV, and 89.5% NPV, whereas participants without diabetes had 21.7%, 90.9%, 16.7%, and 93.3%.

Conclusions:

FIB-4 ≥ 1.30 demonstrates low sensitivity but high specificity for detecting significant fibrosis in MASLD/MASH, with sensitivity increasing and specificity decreasing with age. Low sensitivity across diabetes-defined subgroups indicates that many

E-POSTER ABSTRACTS

individuals with elevated LSM are missed by FIB-4, suggesting that FIB-4 underestimates the at-risk population, particularly younger adults, and highlight the need for TE-based imaging or biomarker-based approaches to improve fibrosis detection.

Keyword(s) : MASLD, MASH, NAFLD, NASH, TE, FIB-4, Liver Fibrosis, Saudi Arabia, Diabetes, Cardiometabolic risk

1942 - Long term outcomes of chronic hepatitis B Effect of metabolic risk factors on liver stiffness measurement by vibration controlled transient elastography

Bengu Tatar¹, Seda Buyukcam², Sevim Selen Karabulut², Melda Turken¹, Suheyla Serin Senger¹
University Of Health Sciences, Izmir Faculty Of Medicine, Izmir City Hospital, Department Of Infectious Diseases And Clinical Microbiology, Izmir, Turkey, Izmir-Türkiye¹ Ministry Of Health, Izmir City Hospital, Department Of Infectious Diseases And Clinical Microbiology, Izmir, Turkey, Izmir-Türkiye²

Background / Hypothesis: The coexistence of chronic hepatitis B(CHB)and metabolic dysfunction-associated steatotic liver disease (MASLD)is common in clinical practice.This condition,referred to as "dual- etiology liver disease" leads to higher complication rates and increased management complexity. This relationship suggests a model called the "two-hit hypothesis". According to this hypothesis, MASLD-associated insulin resistance,oxidative stress and chronic inflammation may accelerate fibrosis progression by triggering HBV-induced liver injury. Vibration-Controlled Transient Elastography (VCTE)is a non-invasive, rapid and reproducible method that measures liver steatosis (Controlled Attenuation Parameter-CAP) and stiffness (fibrosis, kPa value). The aim of this study was to determine the effects of metabolic risk factors and hepatic steatosis detected by VCTE on liver fibrosis in patients with CHB.

Materials and Methods:The study included 103 CHB patients who were followed at our clinic. Patients with HDV, HCV, or HIV co-infection, those with daily alcohol consumption, and those with missing data were excluded.

Patients were divided into two groups: Metabolic risk factors (MRF) group (patients with a diagnosis of DM, HT, or HL, or those with a BMI $\geq$ 25 kg/m²) and control group (patients who did not have any of these risk factors). Additionally, patients were compared based on their VCTE steatosis grades (Significant steatosis:

S2-S3 vs. Minimal/No steatosis: S0-S1). Liver stiffness measured by VCTE(kPa, rates of advanced fibrosis ($\geq$ F3)

Results:The mean age of the 103 patients was 51.2 $\pm$ 13.4 years, and 65% were male, 42% had a metabolic risk factor and 38% had significant steatosis (S2-S3. The mean VCTE kPa value was significantly higher in patients with MRF (7.9 $\pm$ 4.1) compared with the control group (5.2 $\pm$ 2.3). The rate of advanced fibrosis was also significantly higher in the MRF group (25.4%) compared with the control group (8.9%)(Table1). Similarly, in patients with significant steatosis (S2-S3), the mean kPa value (9.1 $\pm$ 4.5) was higher than in those with minimal steatosis (5.8 $\pm$ 2.7). A significant positive correlation was found between body mass index (BMI) and VCTE kPa value as well as between waist circumference and VCTE kPa value (Table 2).

Conclusions: In conclusion, this study demonstrates that the coexistence of metabolic syndrome and MASLD in patients with HBV is a significant and modifiable risk factor for the progression of liver fibrosis. This suggests that metabolic status should be central to clinical follow-up. Therefore, to improve the long-term health of patients, the clinical approach should focus on optimizing the patient's metabolic profiles in addition to achieving viral suppression.

Keyword(s) : Vibration-Controlled Transient Elastography, Liver stiffness, Metabolic risk factors

1944 - Baveno VII-Defined Hepatic Recompensation in Children with Decompensated Cirrhosis Frequency and Determinants

Anmol Anmol¹, Vikrant Sood², Rajeev Khanna¹, Seema Alam¹, Bikrant Biharilal¹, Sukriti Baweja³, Guresh Kumar⁴

Institute Of Liver And Biliary Sciences, Pediatric Hepatology, Delhi-India¹ Institute Of Liver And Biliary Sciencesinstitute Of Liver And Biliary Sciences, Pediatric Hepatology, Delhi-India² Institute Of Liver And Biliary Sciences, Molecular Medicine, Delhi-India³ Institute Of Liver And Biliary Sciences, Biostatistics, Delhi-India⁴

Background / Hypothesis:

Decompensated cirrhosis has long been considered irreversible phenomenon. With effective etiological treatment, however, some may achieve "recompensation"—sustained reversal of decompensation with functional recovery. Currently, literature in pediatrics is limited. We aimed to assess

E-POSTER ABSTRACTS

incidence, predictors, and outcomes of recompensation in children as per Baveno-VII definition.

Materials and Methods:

An ambispective cohort study was conducted in children <18 years with decompensated Wilson disease and autoimmune hepatitis (AIH). Recompensation was defined using modified Baveno VII criteria: aetiological disease control, sustained remission of decompensating events with restored liver function.

Results:

Of 79 Wilson disease and 78 AIH decompensated children with ≥ 1 -year follow-up, recompensation occurred in 88.6% and 69.2%, respectively. In both cohorts, recompensation conferred superior native liver survival ($p < 0.05$). Smaller spleen size, higher platelet/total leukocyte counts, lower alanine aminotransferase levels and lower liver stiffness predicted recompensation in Wilson disease; spleen size was independently predictive of recompensation in AIH. Re-decompensation was infrequent (≈ 11 –13%), largely due to non-adherence. Recovery typically followed the trend: ascites $\rightarrow$ jaundice $\rightarrow$ international normalised ratio $\rightarrow$ serum albumin normalization. Baseline exploratory cytokine profiling suggested higher levels of plasma IL-10 and higher stool IL-6 in Wilson cohort and elevated stool IL-1 β /IL-10 and lower plasma IL-6 in AIH cohort recompensators.

Conclusions:

Recompensation is achievable and durable in pediatric Wilson disease and AIH with appropriate aetiology-directed therapy. Non-invasive markers of portal hypertension (spleen size, platelets, and liver stiffness) may stratify likelihood of reversal and also track recovery. Paired stool–plasma cytokines further merit validation as adjunctive biomarkers.

Keyword(s) : recompensation; Wilson disease; autoimmune hepatitis; pediatric cirrhosis; portal hypertension; elastography

1946 - Comprehensive Assessment of HBV Reactivation in Immunosuppressed Hematology Patients Serological and Clinical Perspectives

Berna Yoldaş¹, Selma Tosun¹, Hande Tuğba Karayel²
Izmir City Hospital, Infectious Diseases And Clinical Microbiology, Izmir-Türkiye¹ Balıkesir Atatürk City Hospital, Hematology, Balıkesir-Türkiye²

Background / Hypothesis: The aim of this study is to determine the risk of hepatitis B virus (HBV) reactivation in hematology patients receiving immunosuppressive therapy, to evaluate the clinical outcomes of patients who developed reactivation, and to assess the effectiveness of preemptive and prophylactic treatment practices

Materials and Methods: Patients ≥ 18 years receiving immunosuppressive therapy at a tertiary center in İzmir (2013–2023). Data on demographics, diagnosis, treatments, labs (HBsAg, anti-HBc, anti-HBs, HBV DNA, anti-HBe, HBeAg, ALT), antiviral prophylaxis/treatment, HBV reactivation, and outcomes were obtained from hospital records.

Results: A total of 804 patients (mean age 57.14 ± 15.34 years; 53.4% male) were included. HBV exposure was identified in 282 patients (35%): 9 HBsAg positive, 5 isolated anti-HBc IgG positive, and 9 with past immunity (HBsAg negative, anti-HBc IgG and anti-HBs positive). HBV reactivation occurred in 23 patients, 8 during and 15 after immunosuppressive therapy. The timing of post-treatment reactivation was observed in the 3rd, 4th, 5th, 6th, 7th ($n=4$), 10th, 14th, 22nd, 23rd, 24th, 36th, and 60th months after cessation of therapy. Six of these 15 patients had not received antiviral therapy. Four patients were under antiviral treatment; however, one of them did not regularly use tenofovir disoproxil fumarate (TDF), while the others were on lamivudine therapy. In five patients, antiviral therapy was initiated but discontinued before the completion of immunosuppressive therapy or not continued for an adequate period after treatment cessation.

Reactivation was most frequent with rituximab (14/23, 60.8%) and ibrutinib (5/23, 21.7%), followed by doxorubicin (2/23, 8.6%), high-dose corticosteroids (1/23, 4.3%), and ruxolitinib (1/23, 4.3%). Eighteen patients showed increased HBV DNA, four developed HBsAg seroreversion, and one was diagnosed via liver biopsy.

Among those with past immunity, six patients had anti-HBs titers between 10–99 IU/mL, two between 100–299 IU/mL, and only one patient had a titer above 300 IU/mL. During follow-up, 10 of the 23 patients (43.5%) who developed HBV reactivation died; three deaths (13.0%) were associated with hepatic failure and fulminant hepatitis.

Conclusions: The prevention of hepatitis B virus reactivation in hematology patients receiving immunosuppressive therapy relies on regular monitoring, appropriate antiviral prophylaxis, and a multidisciplinary approach. In our study, no reactivation occurred in patients who received

E-POSTER ABSTRACTS

tenofovir or entecavir correctly for the appropriate duration, highlighting the effectiveness of proper antiviral management. These findings emphasize the importance of collaboration for patient safety and treatment success, and are expected to guide future large-scale, prospective research and strengthen standardized clinical practices.

1947 - Hepatocellular Carcinoma A Seven Year Cohort Revealing Large Tumor Size and Advanced Fibrosis Despite Early BCLC Staging

Samia M'rabet¹, Mohammed Borahma², Fatima Zahra Chabib¹, Naoual Lagdali¹, Salma Sebbah¹, Fatima Zohra Ajana¹, Maryeme Kadiri¹
Ibn Sina University Hospital Rabat,
Hepatogastroenterology-medicine C, Kenitra-Morocco
¹ Ibn Sina University Hospital-medicine C,
Hepatogastroenterology-medicine C, Rabat-Morocco²

Background / Hypothesis:

Hepatocellular carcinoma (HCC) remains a major cause of cancer-related mortality, mainly occurring in patients with advanced fibrosis or cirrhosis. In our region, viral hepatitis continues to be the predominant etiology. This study aimed to describe the demographic, hepatic, and tumor characteristics of patients diagnosed with HCC in our center and to analyze associations between fibrosis severity and tumor/clinical presentation.

Materials and Methods:

A retrospective descriptive study was conducted including all patients diagnosed with HCC between 2019 and 2025. Collected data included demographics, risk factors, fibrosis stage, Child-Pugh and MELD scores, clinical presentation, AFP, MRI characteristics (LI-RADS), number and size of nodules, and BCLC classification. Comparative analysis between severe fibrosis (F3-F4) and mild/no fibrosis (F0-F2) was performed.

Results:

Twenty-three patients were included (mean age 64 years; M/F ratio = 1.3). At least one toxic risk factor (smoking or alcohol) was present in 48% of cases. Severe fibrosis (F3-F4) was observed in 60.7% of patients. Viral hepatitis accounted for 69.6%

of etiologies (HCV 52.2%, HBV 17.4%).

Portal hypertension signs were present in 60% of patients. Among those with F3-F4 fibrosis, 64.3% were Child-Pugh B-C, compared to none in F0-F2. The median MELD score was 11.

AFP levels were less than 20 ng/mL in 34.8%, 20-200 in 30.4%, and > 200 in 17.4%.

MRI identified LI-RADS 5 lesions in 95.4% of evaluated patients. A single nodule was observed in 69.6% of cases, yet tumors were large (median size 58 mm [15-100]), with 82% exceeding 20 mm.

Segment VIII was the most common localization.

Multifocal involvement was present in 34.8%.

According to BCLC staging, stage A was the most prevalent.

Comparative analysis showed:

- Nodules <20 mm were more frequent in F3-F4 (91%) than F0-F2 (67%).
- Child-Pugh B-C occurred exclusively in F3-F4 (64.3% vs. 0%).
- AFP >200 ng/mL was more common in F3-F4 (22% vs. 11%).

Conclusions:

HCC in our cohort was predominantly related to chronic viral hepatitis and frequently associated with severe fibrosis at diagnosis. Patients with advanced fibrosis presented significantly larger tumors and more impaired liver function. Despite large tumor size, many patients remained within early BCLC stages. These findings highlight gaps in surveillance programs and emphasize the need for strengthened screening strategies in high-risk populations to promote earlier detection and improve therapeutic outcomes.

E-POSTER ABSTRACTS

King Faisal Specialist Hospital & Research Center, Gastroenterology Section, Department Of Medicine, Riyadh-Saudi Arabia ³ King Faisal Specialist Hospital & Research Center, Organ Transplant Center Of Excellence, Riyadh-Saudi Arabia ⁴ Ministry Of Defense Health Services, Health Research Center, Riyadh-Saudi Arabia ⁵ King Faisal Specialist Hospital & Research Center, Liver, Digestive, And Lifestyle Health Research Section, And Organ Transplant Center Of Excellence, Riyadh-Saudi Arabia ⁶

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is highly prevalent across the Middle East, yet the genetic determinants of susceptibility in this population remain poorly characterized. Although several MASLD-associated variants have been established in Western populations, their relevance in Middle Eastern cohorts is unclear. We hypothesized that a pilot subset of the Genomics and Environmental Noninvasive Evaluation for Saudi Intrahepatic Steatosis (GENESIS) cohort would demonstrate genotype-phenotype patterns consistent with established MASLD biology

Materials and Methods:

GENESIS is a nationwide population-based cohort of 2,983 Saudi adults evaluating MASLD prevalence and determinants. We analyzed a pilot subset of 91 participants with available transient elastography (FibroScan®) and targeted genotyping data. MASLD was defined as controlled attenuation parameter ≥ 268 dB/m plus at least one cardiometabolic risk factor. Clinical, biochemical, and genetic characteristics were compared between MASLD (n=46) and non-MASLD (n=45) participants. Variants assessed included PNPLA3 p.I148M, TM6SF2 p.E167K, GCKR p.Leu446Pro, HSD17B13 rs72613567, and MARC1 p.A165T.

Results:

Participants in the MASLD group were older than those without MASLD (mean age: 48.5 vs 41.0 years, $p=0.005$), and gender distribution was comparable (male: 47.8% vs 31.1%, $p=0.134$). The MASLD group had a higher mean body mass index (32.6 vs 27.9 kg/m², $p<0.001$), higher prevalence of dyslipidemia (43.5% vs 11.1%, $p<0.001$) and diabetes (37.0% vs 8.9%, $p=0.001$), higher median triglycerides (1.9 vs 1.0 mmol/L, $p<0.001$) and higher median insulin levels (18.1 vs 9.9 μ U/mL, $p<0.001$).

Genotype distributions showed observed differences between groups. For PNPLA3 p.I148M, wild-type genotypes were more common in MASLD (23.9% vs 11.1%), whereas heterozygous (32.6% vs 35.6%) and homozygous variants (43.5% vs 53.3%) were more frequent in non-MASLD ($p=0.268$). For GCKR p.Leu446Pro, homozygous variant carriers were more prevalent in MASLD (30.4% vs 13.3%), while heterozygous carriers were more common in non-MASLD (44.4% vs 32.6%) ($p=0.134$). TM6SF2 p.E167K heterozygosity was similar between groups (15.2% vs 11.1%, $p=0.758$). The protective HSD17B13 variant remained predominantly homozygous in both groups (71.7% vs 73.3%, $p=0.561$). For MARC1 p.A165T, Wild-type carriers were more common in MASLD (50.0% vs 31.1%), heterozygous variants were more frequent in non-MASLD (60.0% vs 37.0%), and homozygous variants were slightly higher in MASLD (13.0% vs 8.9%) ($p=0.088$).

Conclusions:

This pilot analysis demonstrates distinct metabolic and genetic patterns associated with MASLD within the Saudi population. While limited by sample size, the distribution of risk and protective alleles aligns with established biological pathways and supports expanding genomic and multi-omics analyses across the full GENESIS cohort

1951 - Clinical Laboratory and Microbiological Profile of Post-ERCP Infections A Retrospective Study from a Single Tertiary Referral Center

Sibel Yildiz ¹, Bülent Durdu ¹, Yasemin Akkoyunlu ¹, Gülay Okay ¹, Sercan Kiremitçi ², Özge Pasin ³, Turan Aslan ¹, Yasemin Durdu ⁴, Hakan Şentürk ²
Bezmialem Vakif University, Infectious Diseases And Clinical Microbiology, Istanbul-Türkiye ¹ Bezmialem Vakif University, Gastroenterology, Istanbul-Türkiye ² Universtiy Of Health Sciences, Hamidiye Medical Faculty, Biostatistic Department, Istanbul-Türkiye ³ Universtiy Of Health Sciences, Hamidiye Medical Faculty, Infectious Diseases And Clinical Microbiology, Istanbul-Türkiye ⁴

Background / Hypothesis:

Endoscopic retrograde cholangiopancreatography(ERCP) is an invasive

E-POSTER ABSTRACTS

procedure widely used for the diagnosis and treatment of biliary and pancreatic diseases. Infectious complications following ERCP can lead to significant morbidity and mortality. In this study, we compared the clinical, laboratory, and microbiological characteristics of patients who developed post-ERCP infections with mild versus severe clinical courses.

Materials and Methods:

A total of 1092 patients who underwent ERCP at Bezmialem Vakıf University Hospital between January 1, 2023, and October 1, 2025, were retrospectively reviewed. Sixty-two patients (5.67%) who developed ERCP-associated infections were included in the study. Patients were categorized into two groups based on clinical course: Mild and severe infections. Severe infection was defined as the development of sepsis, the need for intensive care, or infection-related mortality. Demographic data, comorbidities, ERCP indications, procedural characteristics, laboratory values, microbiological findings, and clinical outcomes were retrospectively collected from patient records.

Results:

Of the 62 patients who developed post-ERCP infection, 75.8% were female (n=47) and 24.2% were male (n=15). The mean age was 63.63 ± 16.04 years (27–94), and the mean BMI was 25.54 ± 3.75 kg/m². The most common ERCP indication was choledocholithiasis (33.9%; n=21), followed by malignant biliary stricture (22.6%; n=14), benign biliary stricture (17.7%; n=11), pancreatic causes (8.1%; n=5), and other indications (17.7%; n=11). Post-ERCP complications included sepsis in 51.6% (n=32), bacteremia in 48.4% (n=30), pancreatitis in 16.1% (n=10), perforation in 12.9% (n=8), and cholangitis in 9.7% (n=6). Blood cultures were obtained from 96.8% of patients (n=60), with growth in 48.3% (n=30). Among positive cultures, *Escherichia coli* (E.coli) accounted for 46.7% (n=14), *Klebsiella pneumoniae* for 20.0% (n=6), *Pseudomonas aeruginosa* for 16.7% (n=5), and other organisms for 16.7%. Extended spectrum beta-lactamase (ESBL) positivity was 85.7% in E. coli isolates (n=12). In *Klebsiella pneumoniae* ESBL positivity was 16.7% (n=1), multidrug-resistance (MDR) 33.3% (n=2), and extensively drug-resistant 16.7% (n=1). The 30-day mortality rate was 6.5% (n=4). There were no significant differences between mild and severe infection groups regarding ASA score, Charlson comorbidity index, number of procedures, or hospital stay (all p>0.05). Immunosuppressive therapy, higher GGT, elevated procalcitonin, and positive blood cultures were significantly more common in severe infections (p<0.05) while post-ERCP pancreatitis was

more frequent in mild cases (p<0.05).

Conclusions: In post-ERCP infections, severe clinical course is more closely linked to host-related factors, systemic inflammatory burden, and resistant pathogens rather than procedural characteristics. High antimicrobial resistance rates highlight the need for individualized empirical antibiotic selection based on local resistance patterns and patient risk.

Keyword(s) : Endoscopic retrograde cholangiopancreatography (ERCP), pancreatitis, sepsis, cholangitis

1952 - Performance of anti HCV screening and identification of false positive results in a real life cohort

Sena Nur Doğan¹, Gülay Okay¹, Bülent Durdu¹, Bilge Sümbül², Turan Aslan¹, Yasemin Akkoyunlu¹
Bezmialem Vakıf University Hospital, Infectious Diseases And Clinical Microbiology, Istanbul-Türkiye¹
Bezmialem Vakıf University Hospital, Medical Microbiology, Istanbul-Türkiye²

Background / Hypothesis: The prevalence of hepatitis C virus (HCV) infection is determined by the rate of positivity of anti-HCV antibody. Anti-HCV is a widely used first-line screening test; however, false-positive reactivity remains a major diagnostic challenge, particularly in low-prevalence settings. Differentiating true infections, previously treated infections, and false-positive serology is essential to avoid unnecessary follow-up and antiviral therapy. We hypothesized that the proportion of false-positive anti-HCV results is substantial in real-life practice and that anti-HCV signal-to-cut-off ratio (s/co) levels may aid in distinguishing confirmed infection from false positivity.

Materials and Methods: This retrospective study included 1222 anti-HCV-positive adults tested between January 2020 and December 2023 at a tertiary care university hospital. During the study period, a total of 117,059 anti-HCV tests were performed, of which 1,222 were positive, yielding an overall seropositivity prevalence of 1.04%. HCV RNA results and antiviral treatment information were obtained from the hospital's electronic database. Anti-HCV testing was performed using a chemiluminescent microparticle immunoassay (CMIA) on the Abbott Alinity i platform. Quantitative HCV RNA testing was conducted using a real-time PCR-based assay on the Abbott m2000 system (m2000sp/m2000rt). False-positive anti-HCV was defined as anti-HCV-positive, HCV RNA-negative

E-POSTER ABSTRACTS

individuals with no history of antiviral therapy. Among the 1,222 anti-HCV-positive patients, 694 (56.8%) were female and 528 (43.2%) were male. Anti-HCV S/CO distributions, categorical S/CO bands, and ROC analysis (AUC and optimal threshold using the Youden index) were performed.

Results: Among 1222 anti-HCV-positive patients, HCV RNA, was not performed in 394 (32.2%), while 828 (67.8%) underwent RNA testing. Active HCV infection was confirmed in 110 patients (13.3%); the remaining 718 (86.7%) were RNA negative. A total of 536 RNA-negative patients without treatment history met criteria for false-positive results, representing 74.6% of all RNA-negative cases and 43.9% of all anti-HCV-positive patients. Median s/co was 17.4 in RNA-positive cases, compared with 3.1 in RNA-negative and 2.0 in false-positive cases. Among false-positive patients, 65.1% had s/co <3 and 92.9% had s/co <10. ROC analysis demonstrated an AUC of 0.86, with the optimal s/co cut-off at 7.34 (sensitivity 96.3%, specificity 69.8%).

Conclusions: In this real-life cohort from 2020–2023, nearly half of all anti-HCV-positive results were false positive. Anti-HCV s/co values showed strong discriminative capacity, and low s/co levels—particularly <3 and <10—were highly indicative of false positivity. Incorporating s/co interpretation into routine screening workflows may reduce unnecessary RNA testing and prevent misclassification, improving diagnostic accuracy and resource utilization.

1953 - Chronic Dexamethasone Drives Selective SNAT Remodeling to Fuel HNF4 Alpha Mediated Gluconeogenesis

Yusuf Anil Ay ¹, Emir Enis Yurdgulu ¹, Pelin Aydin ², Zekai Halici ³, Halime Nur Deveci ³, Fatih Albayrak ⁴, Elif Cadirci ³

Atatürk University, Biochemistry, Erzurum-Türkiye ¹
Erzurum City Hospital, Anesthesiology And Reanimation, Erzurum-Türkiye ²
Atatürk University, Pharmacology, Erzurum-Türkiye ³
Atatürk University, Gastroenterology, Erzurum-Türkiye ⁴

Background / Hypothesis: Following their synthetic development, glucocorticoids have become life-saving agents used across a wide range of clinical indications. However, despite their broad therapeutic utility, they are associated with numerous adverse effects that require careful consideration. Among these, one of the most significant is hyperglycemia resulting from increased hepatic gluconeogenesis. Glucocorticoids are

master regulators of hepatic gluconeogenesis, a critical survival pathway largely orchestrated by the transcription factor Hepatocyte Nuclear Factor 4 alpha (HNF4- α). To sustain the high rate of glucose production induced by glucocorticoids, the liver requires a continuous supply of key gluconeogenic precursors, specifically alanine and glutamine. This uptake is mediated by Sodium-coupled Neutral Amino Acid Transporters (SNATs). However, it remains unclear whether chronic glucocorticoid exposure actively remodels the hepatic transporter profile to meet this metabolic demand. We hypothesized that chronic glucocorticoid exposure establishes a coordinated transcriptional axis where the upregulation of HNF4- α drives the activation of specific SNAT subtypes, thereby ensuring the necessary amino acid influx to fuel enhanced hepatic gluconeogenesis.

Materials and Methods: Male rats were divided into four groups (n=7): one control and three receiving dexamethasone (1, 2, or 4 mg/kg/day, intraperitoneal, 21 days). Liver tissues were collected, and mRNA expression of HNF4- α and SNAT2, SNAT3, SNAT4, SNAT7, SNAT9, and SNAT10 was quantified by Real-Time PCR. Treated groups were statistically compared with the control.

Results: Dexamethasone produced marked, dose-dependent transcriptional remodeling. HNF4- α expression increased progressively, indicating activation of the gluconeogenic program. In parallel, SNAT2, SNAT3, and SNAT4—key transporters of alanine and glutamine—were significantly upregulated in a dose-dependent manner, peaking at 4 mg/kg (p<0.05). Conversely, SNAT7 and SNAT9 were significantly suppressed with increasing doses, while SNAT10 showed no change across groups.

Conclusions: The study demonstrates that chronic dexamethasone exposure orchestrates a selective metabolic remodeling in the liver. The upregulation of SNAT2, 3, and 4 parallels the rise in HNF4- α , suggesting that the liver adaptively increases transport capacity to ensure sufficient alanine and glutamine availability for enhanced gluconeogenesis. Conversely, the concurrent downregulation of SNAT7 and 9 likely reflects a strategic metabolic trade-off, where the liver suppresses non-essential transport pathways to conserve energy and prioritize gluconeogenic flux. Therefore, therapeutic interventions targeting these upregulated transporters could offer a potential strategy to mitigate the metabolic side effects, particularly hyperglycemia, associated with glucocorticoid therapy.

1955 - The overlooked Threat on the Path to Hepatitis B Eradication Delta Hepatitis

Alper Gündüz¹, Ekrem Arslantaş¹, Nuran Karabulut², Sema Alaçam², Ramazan Korkusuz¹, Meliha Meriç Koç¹, Özlem Altuntaş Aydın¹
Başakşehir Çam Ve Sakura City Hospital, Infectious Diseases And Clinical Microbiology, Istanbul-Türkiye¹
Başakşehir Çam Ve Sakura City Hospital, Medical Virology, Istanbul-Türkiye²

Background / Hypothesis:

Globally, the prevalence of Hepatitis B has decreased significantly as a result of the elimination programs conducted by the World Health Organization (WHO). Delta co-infection tends to be overlooked in Hepatitis B infections and is anticipated to give a considerable health burden due to probable consequences in the forthcoming years. Therefore, it is critical for those diagnosed with Hepatitis D infection to receive a diagnosis promptly, and our study aims to evaluate the level and rate of screening for Delta co-infection in individuals infected with Hepatitis B.

Materials and Methods:

This retrospective analysis evaluated all individuals who underwent HBsAg testing at our hospital from May 27, 2020, to September 30, 2025. Duplicate tests were omitted, and each participant was evaluated solely once. No age limitations were imposed. Results of the Anti-HDV test were evaluated in HBsAg-positive patients, and HDV RNA testing was conducted in those identified as anti-HDV positive. Results for HBsAg, anti-HDV, and HDV RNA were retrieved from the laboratory information management system.

Results:

A total of 885,150 individuals underwent HBsAg testing, with a positive rate of 1.78%. Among the HBsAg-positive individuals, 9,139 (57.87%) were male and 6,652 (42.13%) were female ($p < 0.001$). The positivity rate for HBsAg tests was 2.4% in individuals aged 28 and older, compared to 0.4% in those aged 27 and younger ($p < 0.001$). Anti-HDV testing was conducted in 46.1% of HBsAg-positive patients, with an anti-HDV positivity rate of 4.33% (315 cases). HDV RNA positivity was identified in 91 (29%) of the 315 patients who tested positive for anti-HDV. Of the HDV RNA-positive patients, 58 were male and 33 were female, and this gender difference was statistically significant ($p < 0.01$).

Conclusions:

Our analysis indicates that about 1% of Turkey's population of 85 million has been tested for HBsAg, signifying the attainment of extensive community-wide screening coverage. The study's findings indicate that HBsAg positivity rates among individuals aged 27 and younger are statistically significantly low. This scenario is believed to demonstrate the enduring protective impact of the national hepatitis B vaccination program established in 1998.

Although annual anti-HDV screening is recommended in current guidelines for HBsAg-positive patients, the absence of delta antibody level measurements in over half of the patients indicates that delta infection is being neglected in clinical practice. We believe that this issue could be resolved with the integration of "double reflex test" (automated testing for anti-HDV and, if warranted, HDV RNA in individuals identified as HBsAg-positive).

Keyword(s) : Delta Hepatitis, hepatitis B

1956 - Comparative Evaluation of Serological Virological and Biochemical Outcomes in Chronic Hepatitis B Patients Receiving Tenofovir or Entecavir

Kamil Mert¹, Bengu Tatar², Yasemin Nadir³
University Of Istanbul Medipol, Department Of Infectious Diseases And Clinical Microbiology, Izmir, Turkey, Istanbul-Türkiye¹ University Of Health Sciences, Izmir Faculty Of Medicine, Izmir City Hospital, Department Of Infectious Diseases And Clinical Microbiology, Izmir, Turkey, Izmir-Türkiye² Ministry Of Health, Izmir Tepecik Education And Research Hospital, Department Of Infectious Diseases And Clinical Microbiology, Izmir, Turkey, Izmir-Türkiye³

Background / Hypothesis: This study aimed to evaluate changes in HBeAg loss, HBV-DNA suppression, ALT normalization, and other biochemical parameters in chronic hepatitis B (CHB) patients receiving long-term potent antiviral therapy with tenofovir or entecavir.

Materials and Methods: This retrospective study was conducted in tertiary care hospital located in Izmir, Turkey and included patients diagnosed with CHB who initiated treatment between January 2008 and January 2018. Patients who were received potent antiviral treatment (either tenofovir or entecavir (ETV) for a

E-POSTER ABSTRACTS

minimum of five years were enrolled and grouped. Long-term treatment responses—including HBeAg loss, HBV DNA suppression, ALT normalization, and biochemical parameter changes were compared between the two treatment groups.

Results: A total of 218 non-sirotic CHB patients who underwent treatment (tenofovir group (n=90) and ETV group (n=128)) for a minimum of five years were included. Long-term potent antiviral therapy resulted in significant reductions in HBV DNA levels and improvements in ALT and AST values. There were no significant differences between tenofovir and entecavir groups regarding HBeAg loss or anti-HBe seroconversion. Virological and biochemical response rates were similar in both treatment groups (Table).

Conclusions: Long-term potent antiviral therapy yields favorable virological, biochemical, and serological outcomes in patients with CHB. The findings indicate that tenofovir and ETV demonstrate comparable efficacy in long-term treatment.

Keyword(s) : Chronic hepatitis B; Tenofovir; Entecavir; Long-term potent antiviral therapy

1557 - HBx Upregulates the Interferon Negative Regulator IFITM2 via Activating the JAK STAT Pathway and Impairing Lysosomal Function

Jiayi Wang¹, Lingyao Du¹, Duoduo Lv¹, Mengya Liu¹, Libo Yan¹, Hong Tang¹

West China Hospital Of Sichuan University, Center Of Infectious Diseases, Chengdu-China¹

Background / Hypothesis:

Interferon-induced transmembrane protein 2 (IFITM2) is a key negative regulator in Peg-IFN α therapy. HBV has been shown to increase IFITM2 expression and therefore suppress endogenous IFN production. This study aimed to elucidate the mechanisms by which HBV regulates IFITM2, thereby providing insights for optimizing Peg-IFN α efficacy.

Materials and Methods:

Plasmid containing 1.3 copies of the full-length HBV genome or encoding HBx, HBc, or HBs were transfected into Huh7 cells. The STAT1 inhibitor

Fludarabine was applied to block JAK-STAT pathway signaling. IFITM2 expression and JAK-STAT pathway components were assessed by RT-qPCR and western blotting. Nuclear expression and translocation of interferon-stimulated gene factor 3 (ISGF3) were assessed by immunofluorescence and quantified using the Opera Phenix Plus High-Content Screening System. IFITM2 protein stability was evaluated using cycloheximide (CHX) chase assays. Colocalization of IFITM2 with the endo-lysosomal system was analyzed via confocal microscopy. Lysosomal acidity and membrane stability were evaluated using pH-dependent lysosomal probes and acridine orange (AO) staining, respectively.

Results:

HBV and HBx markedly increased IFITM2 transcription and translation. HBV and HBx also induced STAT1, STAT2, IRF9, and major ISGs (ISG15, USP18, MxA), along with increased phosphorylation of STAT1 (S727, Y701) and STAT2 (Y690). Fludarabine suppressed HBV/HBx-induced STAT1 activation, and IFITM2 expression changed in parallel with STAT1 phosphorylation. HBV and HBx enhanced nuclear translocation of pSTAT1, while pSTAT2 and IRF9 showed no significant differences. IFITM2 protein exhibited a half-life of 11.04h, and its degradation after 24 h of CHX treatment was limited to 10.8% and 13.3% in the HBV or HBx expressing groups, respectively. Both proteasome and lysosome inhibition prevented IFITM2 degradation, with lysosomal suppression exerting the predominant effect. IFITM2 protein colocalized with early endosomal marker Rab5, late endosomal marker Rab7 and lysosomes. HBV and HBx impaired lysosomal proteolysis by reducing lysosomal accumulation and acidification, and destabilizing lysosomal membranes, as shown by reductions in AO red fluorescence of $39.38 \pm 5.59\%$ (control), $54.37 \pm 3.46\%$ (HBV), and $49.88 \pm 6.96\%$ (HBx) at 140 min.

Conclusions:

HBx upregulated IFITM2 by activating the JAK-STAT pathway and inhibiting lysosomal degradation. HBx promotes ISGF3 nuclear expression and pSTAT1 nuclear translocation, while also prolonging IFITM2 protein half-life through impaired lysosomal acidification and membrane stability. These findings identify dual mechanisms by which HBx sustains IFITM2 elevation and suggest potential strategies to enhance Peg-IFN α therapeutic responses.

1958 - Optimizing operator competency in transient elastography for metabolic dysfunction associated steatotic liver disease screening in a multicenter study

Faisal Abaalkhail¹, Shadan Almuheidib², Duna Barakeh², Felialyn Cruz³, Marwah Abusawadah⁴, Maha Mhdi⁵, Mariam Seria⁶, Mohammed Alghamdi⁶, Waleed Alhazzani⁷, Saleh A. Alqahtani⁸

King Faisal Specialist Hospital & Research Center, Gastroenterology Section, Department Of Medicine, Riyadh-Saudi Arabia¹ King Faisal Specialist Hospital & Research Center, Liver, Digestive, & Lifestyle Health Research Section, And Biostatistics, Epidemiology, And Scientific Computing Department, Riyadh-Saudi Arabia² King Salman Armed Forces Hospital, Radiology Department, Tabuk-Saudi Arabia³ King Fahad Armed Forces Hospital, Family Medicine Department, Jeddah-Saudi Arabia⁴ King Fahad Armed Forces Hospital, Medical Laboratory Department, Jeddah-Saudi Arabia⁵ King Fahad Military Medical Complex, Gastroenterology Unit, Internal Medicine Department, Dhahran-Saudi Arabia⁶ Ministry Of Defense Health Services, Health Research Center, Riyadh-Saudi Arabia⁷ King Faisal Specialist Hospital And Research Center, Liver, Digestive, And Lifestyle Health Research Section, And Organ Transplant Center Of Excellence, Riyadh-Saudi Arabia⁸

Background / Hypothesis:

Accurate non-invasive assessment of liver steatosis and fibrosis is essential for effective screening of metabolic dysfunction-associated steatotic liver disease (MASLD). Transient elastography (TE) is widely adopted, yet its diagnostic reliability highly depends on operator competency. This study aimed to develop and validate a structured, reproducible TE training protocol for non-expert healthcare workers across multiple centers.

Materials and Methods:

A prospective multicenter study was conducted from March 2024 to May 2025 across six centers in three major regions in Saudi Arabia. A hepatology-led expert committee developed a standardized TE training protocol using FibroScan®. Nine healthcare workers with no prior TE experience (research coordinators) underwent structured, hands-on training delivered by nine certified supervisors. Training included 100 supervised and 10 unsupervised TE examinations with

real-time feedback. Supervisors, blinded to unsupervised trainee results, performed parallel assessments on the same individuals during the validation phase. Measurements included controlled attenuation parameter (CAP), liver stiffness measurements (LSM), and the interquartile range (IQR). LSM reliability was defined as an IQR-to-median ratio <30%. Inter-operator reproducibility was assessed using intraclass correlation coefficients (ICCs), with >0.80 indicating strong reliability.

Results:

Trainees (55.6% female) had a median age of 28 years (range: 23–38) and four years of clinical experience (range: 0–13). Their professional backgrounds included nursing (44.4%), radiology (22.2%), genomics (22.2%), and pharmacy (11.1%). Supervisors (88.9% female) were from diverse professional backgrounds: pharmacists (33.3%), hepatologist/gastroenterologists (22.2%), ultrasound technologist (11.1%), biochemist (11.1%), and genomics specialist (11.1%). The median training duration was 20 days (range: 14–22), with a median of six hours/day (range: 4–8). Each trainee was supervised by a median of two supervisors (range: 1–3). Seven trainees (77.8%) achieved competency on first attempt. Inter-operator agreement was excellent, with a median ICC for CAP was 0.95 (IQR: 0.92–0.98) and 0.96 (0.82–0.99) for LSM. Median IQR-to-median ratios were comparable between trainees (13.5%) and supervisors (14.0%), indicating high measurement reliability.

Conclusions:

A structured, short-duration TE training protocol involving 100 supervised TE assessments over 20 days can effectively train non-expert operators to achieve expert-level proficiency. This standardized protocol enhances reliability of TE measurements and provides a scalable model for MASLD screening programs in diverse healthcare settings.

1959 - Investigation of the Effects of Nintedanib in Liver Damage Induced by CCl4 in Rats

Gihad Ozcelik¹, Zekai Halici¹, Elif Cadirci¹, Erdem Toktay²

Ataturk University Faculty Of Medicine, Medical Pharmacology, Erzurum-Türkiye¹ Kafkas University

E-POSTER ABSTRACTS

Faculty Of Medicine, Histology And Embryology, Kars-Türkiye ²

Background / Hypothesis: This study aims to evaluate the potential effect of administering Nintedanib, a multiple tyrosine kinase inhibitor with drug-induced liver side effects, at three different times in a carbon tetrachloride (CCl₄)-induced liver damage model.

Materials and Methods: Seventy-two rats were randomly assigned to six groups, each consisting of 12 animals. The healthy group received 1 ml of olive oil intraperitoneally, while the Nintedanib group received 100 mg/kg nintedanib orally. A liver injury model was created in the other four groups using 1 mg/kg CCl₄. Three of these groups received a single dose of 100 mg/kg nintedanib 12 hours before, 30 minutes before, and 12 hours after CCl₄ administration. Half of the rats in each group (n=6) were sacrificed 24 hours after CCl₄ administration, and the other half (n=6) were sacrificed 1 week later. Blood and liver samples were collected after sacrifice. Serum ALT and AST levels were measured; TNF- α and IL-6 were measured in liver tissue by ELISA, and TGF- β and α -SMA gene expression was measured by RT-PCR. In addition, histopathological and immunohistochemical examinations were performed, and TGF- β staining was carried out.

Results: On day 1, in the CCl₄ group where liver injury was induced in sacrificed rats, serum ALT and AST levels, tissue IL-6 and TNF- α levels, and TGF- β and α -SMA gene expression were increased compared to the healthy group. In the group administered Nintedanib 12 hours prior to CCl₄ administration, these parameters increased compared to both the healthy group and the CCl₄ group. These findings are also supported by histopathological evaluation. In rats sacrificed one week after liver damage was induced, these parameters were measured at values similar to those in the healthy group.

Conclusions: Liver injury in rats sacrificed on day 1 was increased in the group given nintedanib 12 hours prior to CCl₄ administration compared to the group treated with CCl₄ alone. The increased injury was resolved in the rats sacrificed at the end of the first week.

Nintedanib should be used with caution when administered with hepatotoxic agents due to the risk of drug-induced liver injury, or in individuals with underlying liver disease.

Keyword(s) : Nintedanib, Drug Induced Liver Injury, CCl₄, TGF- β , inflammation

1960 - High risk of obstructive sleep apnea among adults with metabolic dysfunction associated steatotic liver disease based on findings from a national population study

Waleed Alhazzani ¹, Haifa F. Alotaibi ¹, Shadan Almuhaideb ², Basmah Khoja ², Habeeb I.a. Razack ³, Fares Alharbi ⁴, Khaled Alshehri ⁴, Hani Tamim ⁵, Bandar Al-judaibi ⁶, Saleh A. Alqahtani ⁷
Ministry Of Defense Health Services, Health Research Center, Riyadh-Saudi Arabia ¹ King Faisal Specialist Hospital & Research Center, Liver, Digestive, & Lifestyle Health Research Section, And Biostatistics, Epidemiology, And Scientific Computing Department, Riyadh-Saudi Arabia ² King Saud University, College Of Medicine, Riyadh-Saudi Arabia ³ King Fahad Armed Forces Hospital, Medical Laboratory Department, Jeddah-Saudi Arabia ⁴ Alfaisal University, College Of Medicine, Riyadh-Saudi Arabia ⁵ King Faisal Specialist Hospital & Research Center, Organ Transplant Center Of Excellence, Riyadh-Saudi Arabia ⁶ King Faisal Specialist Hospital & Research Center, Liver, Digestive, And Lifestyle Health Research Section, And Organ Transplant Center Of Excellence, Riyadh-Saudi Arabia ⁷

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is strongly linked with obesity, diabetes, and metabolic syndrome. Sleep disturbances, particularly obstructive sleep apnea (OSA), are increasingly recognized as contributing to the pathogenesis of metabolic diseases, including MASLD. This study aimed to evaluate the prevalence of high OSA risk among adults with and without MASLD in a large, population-based Saudi cohort using the validated Berlin Questionnaire.

Materials and Methods:

Data were drawn from the GENESIS study, a prospective, population-based cohort conducted across three major regions of Saudi Arabia. MASLD was defined using transient elastography with a controlled attenuation parameter (CAP) ≥ 268 dB/m plus ≥ 1 cardiometabolic risk factor. Between March 2024 and

E-POSTER ABSTRACTS

June 2025, participants underwent clinical assessment for MASLD and completed the Berlin Questionnaire, which categorizes OSA risk into three domains: snoring/apnea (Category 1), fatigue/sleepiness (Category 2), and body mass index (BMI) $>30 \text{ kg/m}^2$ or hypertension (Category 3). BMI was measured through direct clinical measurement; all other questionnaire items were self-reported. High OSA risk was defined as positive scores in ≥ 2 categories.

Results:

Among 2,983 adults included, 1,111 (37.2%) had MASLD and 1,872 (62.8%) did not. High OSA risk was significantly more prevalent in the MASLD group (37.0% vs. 17.0%, $p<0.001$). Among Berlin Questionnaire categories, participants with MASLD showed higher rates in Category 1 (snoring/apnea: 29.8% vs. 16.0%; $p<0.001$) and Category 3 (BMI/hypertension: 71.6% vs. 36.9%; $p<0.001$), while Category 2 (fatigue/sleepiness) did not differ significantly (24.9% vs. 23.3%; $p=0.35$). Self-reported OSA diagnosis was low and comparable between groups (3.6% vs. 3.0%, $p=0.42$).

Conclusions:

Adults with MASLD have a substantially higher Berlin Questionnaire-defined OSA risk, mainly driven by elevated BMI/hypertension and snoring/apnea. The low rate of self-reported OSA highlights its under-recognition in this population. These results support incorporating sleep disorder screening into MASLD management, enabling early identification and intervention to potentially prevent disease progression.

1961 - HBV Reactivation in Rheumatology Patients With Resolved Hepatitis B Infection Receiving DMARD Therapy

Ebru Taşpınar Şen¹, Sabahat Çeken¹, İrem Karakaya¹, Ali Karakaya¹, Göknur Yapar Toros¹, Ebru Oruç¹, Burcu Altunay¹, Melih Pamukçu², Sevinç Can Sandıkçı², Emin Ediz Tütüncü¹

Etlik City Hospital, Infectious Diseases And Clinical Microbiology, Ankara-Türkiye¹ Etlik City Hospital, Rheumatology, Ankara-Türkiye²

Background / Hypothesis: Hepatitis B virus reactivation (HBVr) remains an important clinical concern in patients with rheumatologic diseases receiving

immunosuppressive therapy. The risk of HBVr varies depending on the potency and duration of immunosuppression, the underlying rheumatologic condition, and the patient's baseline virological profile. This study aimed to evaluate the risk of HBVr in rheumatology patients treated with disease-modifying antirheumatic drugs (DMARDs).

Materials and Methods: A retrospective review was conducted at Etlik City Hospital between October 2022 and 2025. Patients receiving any form of DMARD therapy who had resolved HBV infection (HBcAb-positive, HBsAg-negative) were included. HBV reactivation was defined as either an increase in HBV DNA levels or HBsAg seroreversion. Risk stratification was performed according to current international guideline recommendations.

Results: A total of 1094 patients with documented rheumatologic diseases, treatments, and baseline HBV status were screened. HBsAg was positive in 2.6% ($n = 29$) of patients, while 23 % ($n = 253$) had anti-HBc IgG positivity. Among the 253 patients 224 patients with resolved infection were included in the study. The mean age was 57 years and 135 (60%) of them were female. The number of patients with anti HBs positivity was 186 (83%). No detectable HBV DNA was observed in patients with resolved HBV infection. Antiviral prophylaxis was administered to 92 of the patients (41%) and 132 (59%) of them were monitored without prophylaxis. No cases of HBVr were observed during the immunosuppressive therapy in any group (mean follow-up: 16 months, min 6-max36). Among the therapies administered, bDMARDs included TNF inhibitors ($n=135$), cytokine/integrin inhibitors ($n=13$), anti-IL-1 agents ($n=6$), a T-cell costimulation inhibitor ($n=6$), and an anti-IL-6 agent ($n=5$); tsDMARDs consisted of Janus kinase inhibitors ($n=10$); csDMARDs encompassed conventional synthetic agents ($n=36$); and B-cell-depleting therapy with rituximab ($n=13$) was also utilized. HBV DNA testing at month 3 and month 6 was performed in 57% (75/132) and 54% (71/132) of these patients, respectively.

Conclusions: Immunosuppressive regimens used in rheumatologic diseases continue to pose a clinically relevant risk for HBVr. No reactivation occurred in resolved HBV patients regardless of prophylaxis status during the study period. The present data encompass a 16-month observation period, and it was observed that a portion of the patients who were not receiving

E-POSTER ABSTRACTS

prophylaxis did not attend regular follow-up visits. For such patients, prophylaxis may represent a more appropriate management option.

Keyword(s) : HBV reactivation, immunosuppressive therapy, rheumatology, DMARDs, antiviral prophylaxis

1962 - Native liver survival in pediatric hyperacute liver failure Is standard medical therapy effective

Akash Nair¹, Moinak Sen Sarma¹, Ujjal Poddar¹, Anshu Srivastava¹

Sgpgi Lucknow, Pediatric Gastroenterology, Lucknow-India¹

Background / Hypothesis:

There is a paucity of outcome data on Hyperacute liver failure (HALF), a unique subset of pediatric fulminant hepatic failure. We aimed to study the effect of standard medical therapy and risk factors related to outcome in HALF

Materials and Methods:

Clinical data (January 2017 – November 2022) were retrieved from a prospectively maintained database.. HALF,) Acute liver failure (ALF) and subacute liver failure (SALF) were classified as per Pediatric Acute Liver Failure Study Group (PALFSG) criteria (jaundice and coagulopathy of ≤ 7 , 8–28 and ≥ 29 days of presentation). Pediatric End Stage Liver Disease (PELD) score and King's College Hospital Criteria (KCHC) were compared between the subgroups. Outcomes were survival with native liver (SNL) or need for liver transplantation or death.

Results:

Of the 119 patients with paediatric fulminant hepatic failure (Table 1), SNL was seen in 53 (44.5 %) with a complete resolution of liver functions over a median follow up 9 (IQR 5 – 12) months. In HALF group (n=20), univariate regression analysis showed presence of shrunken liver span, hypoalbuminemia and acute kidney injury were predictive of poor outcome. A PELD score of >27 in HALF predicted poor outcome (sensitivity 80 %; specificity 74.6 % [p=0.023, AUC=0.847]) (fig 1). PELD score did not predict prognosis in ALF and SALF subgroups. KCHC had a 90% sensitivity 71.6 % specificity, 80% positive predictive value and 14% negative predictive value overall in determining poor outcome in the HALF group.

Conclusions:

Three-fourth of HALF will survive with native liver on

standard medical therapy. Indicators for poor outcome are shrunken liver span, acute kidney injury and hypoalbuminemia. A PELD score >27 can be used to optimize the listing for liver transplantation.

Keyword(s) : Pediatric Acute liver failure , Native liver survival, Viral hepatitis

1963 - Hepatitis B Screening Prior to Immunosuppressive Therapy in Patients with Multiple Myeloma

Sabahat Çeken¹, Selenay Kiliç¹, Kadir Acar², Gökür Yapar Toros¹, Ebru Oruç¹

Etlik City Hospital, Infectious Diseases And Clinical Microbiology, Ankara-Türkiye¹ Etlik City Hospital, Hematology, Ankara-Türkiye²

Background / Hypothesis:

Hepatitis B infection remains an important public health concern worldwide, including in Türkiye, which is considered a region of intermediate endemicity for Hepatitis B virus (HBV). Multiple myeloma (MM) is a B-cell malignancy characterized by the clonal proliferation of plasma cells within the bone marrow and accounts for approximately 13% of all hematologic cancers. The use of proteasome inhibitors, immunomodulatory drugs (IMiDs), and monoclonal antibodies in MM therapy has been associated with an increased risk of HBV reactivation. Therefore, as recommended in current clinical guidelines, patients should be evaluated for prior exposure to HBV before initiating treatment. In this study, we examined whether patients diagnosed with MM in the Hematology Department of Etlik City Hospital were appropriately screened for HBV infection.

Materials and Methods:

Newly diagnosed MM patients were retrospectively evaluated between October 2022 and August 2025. Results of HBsAg, anti-HBs, and anti-HBc IgG tests were obtained from the hospital electronic medical record system.

Results:

A total of 193 patients aged 18 years or older who had been diagnosed with MM were included in the study. The mean age was 63.9 ± 11.97 years, and 117 patients (60.6%) were male. Among these patients, HBsAg testing had been performed in 184 individuals, of whom 11 (5.9%) were positive. Anti-HBc IgG was tested in 144 patients, and 44 (30.5%) were positive. Anti-HBs testing was performed in 159 patients, with 40 (25%) testing positive. Eighty-four patients (43.5%) were

E-POSTER ABSTRACTS

screened with both HBsAg and anti-HBc IgG. The proportion of patients who underwent all three recommended tests (HBsAg, anti-HBc IgG, and anti-HBs) was 41.4%.

Conclusions:

According to the findings of this study, approximately one-third of patients diagnosed with MM had evidence of prior HBV exposure, and 5.9% had chronic HBV infection. The rate of prior HBV exposure was comparable to that reported in other studies conducted in Türkiye. The fact that fewer than half of the patients underwent the complete recommended screening panel highlights the need to increase awareness and adherence to HBV screening guidelines in this population.

1964 - Nephropathy Following Portosystemic Shunt Surgery in Children with Extrahepatic Portal Venous Obstruction A hitherto undescribed entity

Akash Nair¹, Moinak Sen Sarma¹, Ankur Mandelia², Anupama Kaul³, Dharmendra Bhaduria³, Anshu Srivastava¹, Ujjal Poddar¹, Surender Yachha¹, Richa Lal², Anu Behari⁴

Sgpgi, Pediatric Gastroenterology, Lucknow-India¹
Sgpgi, Pediatric Surgery, Lucknow-India² Sgpgi, Nephrology, Lucknow-India³ Sgpgi, Surgical Gastroenterology, Lucknow-India⁴

Background / Hypothesis:

Porto-systemic shunt (PSS) surgery is well established for managing portal hypertension and associated complications of extrahepatic portal venous obstruction (EHPVO) in children. However, the long-term renal effects have not been systematically studied. We aimed to evaluate the prevalence, clinical spectrum, histopathology, treatment response, and outcomes of nephropathy developing after PSS in children with EHPVO.

Materials and Methods:

We conducted an ambispective observational cohort study of 315 EHPVO children undergoing non-selective PSS (August 1993-December 2024). Patients were followed with periodic renal monitoring (serum creatinine, blood urea nitrogen, urine protein:creatinine ratio), liver function tests, and Doppler ultrasonography for shunt patency. Renal biopsy was performed if proteinuria was persistent. The clinical, biochemical, and histologic findings, treatment, and outcomes were systematically recorded

Results:

Twelve of 315 children (4%) developed post-shunt nephropathy in a span of 36 months (IQR: 18.5–24) from PSS. Renal biopsies were suggestive of membranoproliferative glomerulonephritis (n=6), IgA nephropathy (n=4), focal segmental glomerulosclerosis (n=1) and diffuse proliferative (n=1) Treatment included angiotensin receptor blockers (n=11) immunosuppressive (n=7), and renal replacement therapy (n=1). Partial remission occurred in 7; two children progressed to end-stage renal disease and died. One patient experienced recurrence of nephropathy in the renal graft.

Conclusions: Post-shunt nephropathy is an underrecognized but serious complication following PSS in EHPVO. Renal surveillance, early biopsy, and timely therapy are critical.

1966 - Investigating hepatitis B virus recurrence in post liver transplant patients a single center retrospective cohort study

Iftahar Köksal¹, Tonguç Utku Yılmaz², Alara Apa³, Serhat Özfistikçi³, İkbāl Karabal³, Ece Cilli³, Ufuk Canözer³, Ömer Şaka³, İman Cihan³, Sevan Dağlıyan³, Dença Silahlı³

Acibadem Mehmet Ali Aydınlar University, School Of Medicine, And Acibadem Atakent Hospital, Department Of Infectious Diseases And Clinical Microbiology, Istanbul-Türkiye¹ Acibadem Mehmet Ali Aydınlar University, School Of Medicine, And Acibadem Atakent Hospital, General Surgery, Division Of Transplantation, Istanbul-Türkiye² Acibadem Mehmet Ali Aydınlar University, School Of Medicine, Istanbul-Türkiye³

Background / Hypothesis:

Hepatitis B virus (HBV) infection is a primary indication for liver transplantation globally and in Türkiye, despite effective post-transplant prophylaxis (Hepatitis B immunoglobulin (HBIG) and nucleos(t)ide analogues (NUCs)). HBV recurrence still affects approximately 10% of recipients. High pre-transplant viral load, HBeAg positivity, and poor adherence to immunosuppression are known recurrence determinants. A comprehensive assessment of recurrence risk factors is essential to optimize post-transplant prophylaxis and improve long-term outcomes in high-risk patients. The present

E-POSTER ABSTRACTS

study aims to investigate the incidence and associated risk factors of HBV recurrence among Turkish patients who underwent living donor liver transplantation (LDLT) for HBV-related disease at Acibadem Atakent Hospital in Türkiye.

Materials and Methods:

This retrospective, single-center cohort study includes records of all adult Turkish patients who underwent LDLT for HBV-related disease at Acibadem Atakent Hospital between 2012 and 2025. Collected data include demographic, clinical, biochemical, virological, and pre-transplant tumor parameters, alongside specific HBV prophylactic and immunosuppressive protocols. Patient characteristics and HBV recurrence incidence will be summarized using descriptive statistics. Univariate and multivariate Cox regression analyses are planned to identify independent risk factors associated with HBV recurrence. Results will be presented with a 95% confidence interval (CI), and a p-value of <0.05 will be considered statistically significant.

Results:

This study encompasses a single-center cohort of Turkish LDLT recipients with HBV-related disease, including patients through 2025. Anticipated results include a detailed incidence rate of HBV recurrence and the identification of independent risk factors, such as high pre-transplant HBV DNA levels and specific immunosuppressive drug use, which will be strongly correlated with recurrence risk. The findings are expected to highlight the critical role of standardized viral and immunological monitoring in preventing late recurrence, which has not been comprehensively addressed in this specific population.

Conclusions:

The successful completion of this study will provide crucial, high-impact data on the long-term management of HBV-related LDLT in a significant regional cohort. By pinpointing key pre- and post-transplant risk factors through robust multivariate analysis, our findings will offer actionable, evidence-based recommendations for optimizing prophylactic regimens and improving surveillance protocols. The derived risk stratification model will serve as an essential tool for clinicians in Türkiye and other regions with similar demographics, thereby leading to reduced HBV recurrence rates and significantly enhanced graft and patient survival in high-risk transplant recipients.

1969 - Patients with Hepatocellular Carcinoma Undergoing Transarterial Therapies Have Higher Risk of Hepatic Decompensation With Transarterial Radioembolization and Are Linked to Worse Prognosis

Faisal M Sanai ¹, Saad Dosari ¹, Adnan Alzanbagi ², Khalid I Bzeizi ³, Faisal Abaalkhail ⁴, Ahmed Saati ¹, Bandar Aljudaibi ³, Ali Albenmoussa ³, Hamdan Alghamdi ⁵, Saleh A Alqahtani ⁶

King Abdulaziz Medical City, King Abdullah International Medical Research Center, Ministry Of National Guard - Health Affairs, Gastroenterology Section, Department Of Medicine, Jeddah-Saudi Arabia ¹ King Abdallah Medical City, Gastroenterology Department, Makkah-Saudi Arabia ² King Faisal Specialist Hospital And Research Center, Organ Transplant Centre Of Excellence, Riyadh-Saudi Arabia ³ King Faisal Specialist Hospital And Research Center, Department Of Medicine, Section Of Gastroenterology, Riyadh-Saudi Arabia ⁴ King Abdulaziz Medical City, Ministry Of National Guard Health Affairs, Hepatology Section, Department Of Hepatobiliary Sciences And Organ Transplantation, Riyadh-Saudi Arabia ⁵ King Faisal Specialist Hospital And Research Center, Liver, Digestive, And Lifestyle Health Research Section, And Organ Transplant Centre Of Excellence, Riyadh-Saudi Arabia ⁶

Background: Transarterial radioembolization (TARE) with Yttrium-90 resin microspheres and transarterial chemoembolization (TACE) are widely recognized locoregional treatments (LRTs) for patients with unresectable hepatocellular carcinoma (uHCC). In this study, we aimed to identify the predictors of hepatic decompensation (HD) and evaluate its impact on overall survival (OS) in patients with uHCC undergoing TACE or TARE.

Methods: We retrospectively analyzed consecutive patients with uHCC treated with TARE (n=135, 43.3%) or TACE (n=177, 56.7%) across four academic centers. Exclusion criteria included extrahepatic metastases, Child-Pugh (CP) class C disease, and bland embolization. HD was defined as the occurrence of ascites, variceal bleeding, or portosystemic encephalopathy at baseline or ≤6 months post LRT. Median OS (mOS) and objective response (per mRECIST) were assessed.

E-POSTER ABSTRACTS

Results: The cohort comprised 312 patients, predominantly male (73.9%), with a mean age of 66.8 ± 10.5 years. Most patients had intermediate-stage disease (BCLC B, 54.5%), followed by early-stage (BCLC 0/A, 34.0%) and locally advanced-stage disease (BCLC C, 11.5%). HD was present at baseline in 36 patients (11.5%) and occurred after LRT in 48 patients (15.4%). Patients with post-LRT HD showed lower complete response rates (10.9%) than those without HD (31.4%; $P=0.002$). The mOS in patients without HD (41.0 months [95% CI: 33.0-46.0]) was significantly longer than in those with HD at presentation (15.0 months, 95% CI: 12.0-22.0; HR 2.35, 95% CI: 1.37-4.01) or after LRT (14.0 months, 95% CI: 12.0-21.0; HR 2.66, 95% CI: 1.68-4.26). Multivariable analyses revealed hepatitis C etiology (OR 0.35, 95% CI: 0.15-0.78), CP score (OR 2.28, 95% CI: 1.12-4.65), ALBI score (OR 1.69, 95% CI: 1.14-2.14), and intervention with TARE (OR 2.32; 95% CI: 1.15-4.76) as independent predictors of post-LRT HD.

Conclusions: Post-LRT HD is associated with significantly reduced OS in patients with uHCC. Baseline hepatic reserve and intervention with TARE are key predictors of post-intervention HD. These results highlight the need for individualized, biology-driven treatment planning in uHCC.

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is a major contributor to chronic liver disease globally. Despite growing research interest, population-level data on MASLD and its impact on health-related quality of life (HRQoL) in Saudi Arabia remain limited. The Genomics and Environmental Noninvasive Evaluation for Saudi Intrahepatic Steatosis (GENESIS) study, a prospective, population-based cohort, was designed to provide comprehensive national data on MASLD prevalence and outcomes. This analysis aimed to assess HRQoL differences between adults with and without MASLD using the RAND 36-Item Health Survey (SF-36).

Materials and Methods:

Adults aged ≥ 18 years were recruited between March 2024 and June 2025 from three major regions in Saudi Arabia using a multistage stratified sampling approach. MASLD was defined using transient elastography with a controlled attenuation parameter (CAP) ≥ 268 dB/m plus ≥ 1 cardiometabolic risk factor. HRQoL was measured using SF-36, covering eight domains: physical functioning, role limitations due to physical health (role-physical), bodily pain, general health, vitality/energy-fatigue, social functioning, role limitations due to emotional problems (role-emotional), and mental health/emotional well-being. Composite scores included physical component summary (PCS), mental component summary (MCS), and overall SF-36 score.

Results:

Of 2,983 participants evaluated, 1,111 (37.2%) had MASLD. Those with MASLD were older (mean age: 46.1 vs. 39.5 years), more often male (58.4% vs. 44.8%), and had higher body mass index (median: 31.6 vs. 27.0 kg/m^2) (all $p < 0.001$). MASLD participants had lower mean scores in physical functioning (82.0 vs. 88.1), role-physical (83.0 vs. 86.7), bodily pain (82.2 vs. 85.7), and general health (71.4 vs. 74.4) (all $p < 0.001$). No significant differences were observed in vitality/energy-fatigue, social functioning, role-emotional, or mental health/emotional well-being. PCS scores were lower in the MASLD group (79.7 vs. 83.8, $p < 0.001$), while MCS scores were similar (79.1 vs. 79.7, $p = 0.37$). Overall SF-36 score was modestly lower in the MASLD group (79.4 vs. 81.7, $p < 0.001$).

E-POSTER ABSTRACTS

Conclusions:

In this nationally representative cohort, MASLD was linked to lower HRQoL, primarily affecting physical and general health domains. These findings emphasize the need for integrated, patient-centered care strategies to address MASLD-related HRQoL impacts and align with Saudi Vision 2030 priorities for improving population health.

1971 - Evaluation of HBV screening status and test results for mothers fathers siblings spouses and children of individuals who are HBsAg positive

Selma Tosun¹

University Of Health Sciences Turkey, Izmir Faculty Of Medicine, Izmir City Hospital, Infectious Diseases And Clinical Microbiology, Izmir-Türkiye¹

Background / Hypothesis: It is crucial to screen the mothers, fathers, siblings, spouses, and children of HBsAg-positive individuals for HBV markers; to vaccinate seronegative individuals; and to follow up on those found to be seropositive. However, worldwide, the rate of people knowing whether they are infected with HBV is quite low, and individuals' awareness of this issue is around 5-10%. Our study aimed to evaluate the exposure to HBV among family members of HBsAg-positive individuals.

Materials and Methods: Study data collection began in 2021 following ethical committee approval. Face-to-face interviews were conducted with patients attending routine follow-up appointments to inquire about HBV testing and/or vaccination status among family members. Responses, along with existing test results for patients and data obtained from the automation system, were entered into an Excel spreadsheet for analysis.

Results: A total of 1083 HBsAg-positive individuals, 683 of whom were women, aged 18-67, participated in the study. The rate of HBV screening among the mothers of index cases was 41.7% (452/1083); the rate of HBV screening among fathers was 23.8% (239/1005); the rate of HBV testing among siblings was 31.2% (1524/4890); the rate of HBV testing among spouses was 65.9% (581/882); the rate of HBV testing among children was 51.3% (1245/2424) (Table 1).

97.3% of mothers are infected with HBV, and 77.6% are HBsAg positive; 94.6% of fathers are infected with HBV, and 69.3% are HBsAg positive; 97.8% of siblings are

infected with HBV, and 94.5% are HBsAg positive. The rate of children infected with HBV is 27.8%, the rate of HBsAg positive is 22.3% (Table 2). As can be seen, vertical transmission is quite significant in our country, and due to transmission from mother to child, there is a high rate of HBsAg positivity in both the mothers and siblings of index cases. In our country, since HBsAg testing has been performed before marriage since 2007, the rates of HBV testing among spouses have been found to be higher. Similarly, the implementation of HBsAg testing during marriage and pregnancy has also ensured higher rates of HBV testing among children. These rates are still insufficient.

Conclusions: In conclusion, although mother-to-child transmission has decreased significantly since the start of the national HBV vaccination program in 1998, there are still many people who were infected in previous years and are currently unaware of their status. Therefore, all index cases should be informed about HBV testing for their family members.

1972 - Comparative Inpatient Outcomes and Comorbidity Profiles in Patients with Alcohol Associated Liver Disease With and Without Metabolic Syndrome Insights from a Nationally Representative US Database

Talal Khurshid Bhatti¹, Carla Barberan Parraga², Madeha Irfan³, Sanjay Satapathy¹

Northwell Health, Hepatology, Ny-United States¹
Maimondees Health, Hepatology, Ny-United States²
Uhs,lahore, Medicine, Lahore-Pakistan³

Background / Hypothesis:

The intersection of metabolic syndrome and alcohol-associated liver disease (ALD) is increasingly recognized as a unique phenotype termed MetALD. However, data comparing clinical characteristics and inpatient outcomes between ALD patients with and without metabolic syndrome remain limited.

Materials and Methods:

We identified adult patients (≥18 years) hospitalized with a principal diagnosis of ALD between 2016 and 2021 using the National Inpatient Sample (NIS) and ICD-10 codes. Patients were stratified into two groups based on the presence or absence of metabolic syndrome, defined by ≥ 3 components out of obesity (BMI ≥30), diabetes, hypertension, and hyperlipidemia.

E-POSTER ABSTRACTS

Weighted analyses were performed to account for the complex survey design. Baseline characteristics were compared using Rao-Scott chi-square and Student's t-tests. Multivariate regression models were developed to assess the impact of Metabolic Syndrome associated ALD (MetS +ALD) on in-hospital outcomes, adjusting for variables with $p < 0.1$ in univariate analysis

Results:

A total of 936,645 weighted hospitalizations were included (ALD: 759,680 [81.1%]; MetS + ALD: 6,965 [18.9%]). Met S+ ALD patients were older (57.8 vs. 52.2 years, $p < 0.001$) and more likely male (80.1% vs. 67.4%, $p < 0.001$). MetS + ALD was significantly associated with higher prevalence of diabetes (91.7% vs. 17.9%), hypertension (96.1% vs. 44.6%), hyperlipidemia (91.7% vs. 12.2%), and chronic kidney disease (25.0% vs. 10.0%; all $p < 0.001$). Despite a higher burden of comorbidities, MetALD patients had lower in-hospital mortality (3.0% vs. 4.9%, $p = 0.0024$) and reduced need for mechanical ventilation (4.2% vs. 5.8%, $p = 0.0125$). No significant differences were noted in length of stay or total hospital charges.

Conclusions:

Patients with MetS + ALD represent a distinct clinical subgroup of ALD with greater metabolic comorbidity burden but paradoxically lower inpatient mortality and respiratory support needs. These findings support further investigation into the natural history and tailored management strategies for MetS + ALD.

Background / Hypothesis:

Diabetes is a complex metabolic disorder that causes

profound impairments in hepatic energy metabolism, insulin signaling, and amino acid utilization. Sodium-dependent neutral amino acid transporters (SNAT; SLC38 family), which play key roles in these processes, are essential regulators of amino acid uptake and metabolic adaptation in hepatocytes. Diabetes-associated metabolic stress may lead to marked alterations in the expression of SNAT transporters. This study aims to provide new insights into the pathophysiology of the diabetic liver by evaluating SNAT gene and protein levels in an experimental diabetes model. Furthermore, the experimental findings were supported by bioinformatic analyses, through which potential molecular mechanisms were examined in greater detail.

Materials and Methods:

Male Wistar rats obtained from Atatürk University were used in this study. The animals were divided into two groups: a control group and a diabetes group induced with streptozotocin (STZ, 200 mg/kg, IP). To reduce the risk of hypoglycemia after STZ administration, 5% glucose was added to the drinking water for 24 hours, and fluid support was maintained until 60 hours. Rats with fasting glucose levels ≥ 300 mg/dL on day 3 were considered diabetic. At the end of the experiment, liver tissues were preserved under appropriate conditions for subsequent analyses. mRNA levels of the SLC38 family transporters (SNAT1–SNAT10) were assessed by RT-qPCR, and their tissue localization was evaluated through immunohistochemistry. Additionally, bioinformatic analyses were performed based on gene expression and pharmacology databases, including differential gene expression analysis, weighted gene co-expression network analysis, and protein–protein interaction assessment through molecular docking.

Results:

In the diabetic group, notable expression alterations were observed in several members of the SNAT transporter family compared with the control group. RT-qPCR results indicated that diabetes induced adaptive responses across SNAT1–SNAT11 subtypes. Immunohistochemical analyses revealed shifts in the cellular localization and regional density of SNAT transporters in diabetic hepatocytes. These alterations are considered to be associated with diabetes-related metabolic stress, impaired insulin signaling, and adaptive regulation of amino acid utilization. Bioinformatic analysis demonstrated the presence of protein–protein interaction networks.

E-POSTER ABSTRACTS

Conclusions:

This study demonstrates that diabetes induces notable molecular alterations in hepatic amino acid transport systems, particularly those involving SNAT transporters. The adaptive responses observed within the SNAT family may influence amino acid utilization, cellular energy balance, and metabolic stress regulation in the diabetic liver. The findings shed light on the mechanistic significance of the SLC38 family in the pathophysiology of diabetes.

Keyword(s) : SNAT transporters, SLC38 family, diabetes, liver, hepatic metabolic adaptation

1975 - NTCP S267F (rs2296651) in HBV Infection Among Asian Populations A Systematic Review and Meta analysis

Alfiyyah Rizqy¹, Jason Phowira¹, Salsabila Rezkia

Andini¹, Ariestiana Ayu Ananda Latifa¹, Najila

Ramadhina¹, Juferdy Kurniawan¹

Faculty Of Medicine, Universitas Indonesia, Department Of Internal Medicine, Jakarta Pusat-Indonesia¹

Background:

Chronic hepatitis B virus (HBV) infection poses a significant health burden in Asian populations. The sodium taurocholate co-transporting polypeptide (NTCP) encoded by the SLC10A1 gene is the primary receptor mediating HBV entry into hepatocytes. The S267F variant (rs2296651) produces a loss of function effect that reduces bile acid transport and limits viral entry into hepatocytes, contributing to reduced susceptibility to chronic hepatitis B (CHB). This systematic review and meta-analysis aimed to quantitatively evaluate the association between NTCP S267F polymorphism and CHB risk in Asian populations.

Methods:

A systematic review and meta-analysis were performed in databases including Pubmed, Scopus, Cochrane, Proquest, ScienceDirect, and manual searches following PRISMA guidelines. Eligible studies included case-controls evaluating the S267F genotype in CHB. Study quality was assessed using the Newcastle-Ottawa Scale. RevMan 5.4 was used for analysis under various genetic models. Pooled odds ratios (ORs) were generated using fixed or random effect models based on heterogeneity assessed by I² statistics.

Result:

Sixteen studies were included, consisting of 28,028 individuals with CHB and 111,704 controls across East

and Southeast Asian populations. The dominant model (GG vs GA+AA) showed significantly reduced susceptibility of chronic hepatitis B among variant carriers (OR 0.57; 95% CI 0.44–0.73; $p < 0.0001$). The heterozygous model (GG vs GA) also showed reduced susceptibility (OR 0.58; 95% CI 0.45–0.75; $p < 0.0001$). Similarly, the allelic model (G vs A) demonstrated a significant reduced risk of CHB (OR 0.54; 95% CI 0.40–0.72; $p < 0.0001$). Meanwhile, the homozygous model (AA vs GG) (OR 0.26; 95% CI 0.05–1.44; $p = 0.12$) and the recessive model (AA vs GA+GG), reduced susceptibility remained non-significant (OR 0.27; 95% CI 0.04–1.74; $p = 0.17$). Limitations include overrepresentation of Chinese cohorts, potentially restricting external generalizability, and minimal AA genotype frequency, requiring larger studies to confirm homozygous and recessive model effects.

Conclusion:

The SLC10A1 S267F loss of function variant was significantly associated with reduced susceptibility to CHB among Asian populations, supporting the relevance of host receptor genetic factors in CHB pathogenesis. These findings support clinical implications of NTCP genotyping for risk stratification, screening and NTCP targeting entry inhibitors as potential therapeutic strategies in endemic regions. However, overrepresentation of Chinese cohorts and the rare AA genotype limit generalizability, highlighting the need for larger, multiethnic studies to clarify these findings.

1976 - Advanced liver fibrosis in patients with metabolic dysfunction associated steatotic liver disease (MASLD) impairs sensory perception of ice cream with the protein sweetener brazzein

Vasily Isakov¹, Vladimir Pilipenko¹, Alla Kochetkova², Alexey Goncharov¹

Federal Research Center Of Nutrition And Biotechnology, Department Of Gastroenterology, Hepatology And Diet Therapy, Moscow-Russia¹

Federal Research Center Of Nutrition And Biotechnology, Laboratory Of Food Biotechnology And Foods For Special Uses, Moscow-Russia²

Introduction: In individuals with MASLD, the progression of hepatic fibrosis may be accompanied by alterations in sensory perception, including changes in taste responsiveness. Such effects may have important implications for the acceptability of sugar-reduced or

E-POSTER ABSTRACTS

sugar-free dietary products. The objective of this study was to evaluate the association between fibrosis severity and the sensory perception of ice cream sweetened with brazzein, a natural sweet protein, and sucrose.

Materials and methods: This clinical investigation was conducted under a protocol registered at ClinicalTrials.gov (NCT06724913). The study employed a double-blind, randomized, two-period crossover design with two treatment sequences (AB and BA), where treatment A consisted of brazzein-sweetened ice cream and treatment B consisted of sucrose-sweetened ice cream. Fibrosis staging was determined using liver stiffness measurement (LSM) by vibration-controlled transient elastography. Sensory perception was assessed using a standardized 5-point hedonic scale evaluating overall impression, flavour, texture, aroma, appearance, and color. The study was supported by the Russian Science Foundation (Project No. 19-76-30014-P).

Results: A total of 103 participants with MASLD were enrolled. Fibrosis staging was as follows: F0–F1 (71.8%), F2 (15.5%), F3 (8.7%), F4 (3.9%). Texture ratings demonstrated a clear, fibrosis-dependent divergence between the two ice creams. Among participants with F0–F1 fibrosis, texture ratings for brazzein- and sucrose-sweetened samples were nearly identical (difference = -0.04 points). In F2–F3 stages, brazzein elicited moderately lower texture ratings (-0.25 и -0.11 points), whereas in F4 the decline exceeded 1 point relative to sucrose, representing a clinically meaningful difference. Sensitivity analyses across various LSM thresholds confirmed the robustness of the sweetener type×fibrosis interaction: no significant interaction was observed at 8 kPa, whereas thresholds ≥ 9 kPa produced statistically significant effects, which strengthened at LSM values of 10–12 kPa. Effect size analyses (Cohen's d) further supported a fibrosis-dependent pattern. In the LSM < 9.6 kPa subgroup, effect sizes were uniformly small (d -0.05 to -0.25), indicating practical equivalence between sweeteners. In contrast, participants with LSM ≥ 9.6 kPa demonstrated medium to large effect sizes (texture d = -0.69; taste d = -0.84; overall impression d = -0.99), indicating substantial degradation of sensory perception specific to brazzein.

Conclusion: Advancing hepatic fibrosis in MASLD is associated with significant impairment in the sensory perception of brazzein-sweetened ice cream, while perception of sucrose-sweetened ice cream remains largely preserved. These findings carry clinical relevance: individuals with advanced fibrosis are among those who most require dietary sugar

reduction, yet diminished acceptability of sweetener-based products may hinder adherence to sugar-restriction strategies.

1977 - PREVALENCE OF LIVER FIBROSIS AMONG A COHORT OF PATIENTS WITH METABOLICALLY ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) FOLLEWED AT AN URBAN SETTING IMPACT OF UTILIZATION OF FIBROSCAN.

Jumshaid Qureshi ¹, Elkhatab Magdy ², Abdullah Qureshi ³, Ilya Abedi ², Jillian Ho ², Katarina Kangranga ², Mariantha Masri ², Gabriel Bishara ², Iftikhar Khan ³, Marzena Magnes ¹

Toronto Liver Center, Research, Toronto-Canada ¹
Toronto Liver Centre, Research, Toronto-Canada ²
Fatima Memorial Hospital College Of Medicine And Dentistry, Research, Lahore-Pakistan ³

Background / Hypothesis:

Metabolically Associated Steatotic Liver disease is widely recognized as a major cause of progressive liver disease. MASLD can lead to advanced fibrosis and cirrhosis, particularly in patients with more than one component of the metabolic syndrome. Transient elastography (FibroScan®) non-invasively quantifies liver stiffness kPa (fibrosis) and steatosis (CAP™). This study aims to describe the distribution of liver fibrosis and steatosis severity in a large, real-world cohort of patients with MASLD.

Materials and Methods:

We conducted a retrospective analysis of 11,214 patients who underwent FibroScan® at the Toronto Liver Centre between 2020 and 2025. Among them, 8,149 patients (72.7%) were identified with MASLD and formed our study cohort. Liver stiffness (kPa) and CAP (dB/m) values were used to stage fibrosis (F0-F4) and grade steatosis (S0-S3).

Results:

Statistical analysis was performed. The median liver stiffness was 6.6 kPa, and the median CAP was 287 dB/m. Fibrosis was distributed as: F0: n=2705(33%) F0-

E-POSTER ABSTRACTS

F1: n= 2977(37%), , F1:(n=501, 6.2%), F1-F2: n=907(11%), F2: n=303,(3.7%), F2-F3: n =242(3%), F3:n=113 (1.3%), F3-F4:n=133(1.6%),and F4 (cirrhosis): n=267(3.2%).Steatosis was distributed as: S0:n=1285(15%),S0-S1:n=221(2.7%), S1:n=1521(18.6%), S1-S2:n=115 (1.4%), S2:n=1618(19.9%), S2-3:n=1209(14.8%), S3:n=2176 (26.7%). The majority of scans (70.4%) were performed using the M probe, and 29.6% were performed using the XL probe.

Conclusions:

In one of the largest reported MASLD cohorts assessed by transient elastography, severe steatosis was present in 45%, Mild liver fibrosis was present in about 70% while moderate to advanced liver Fibrosis and Cirrhosis was present in 25%. Fibrocan's widespread use is essential to identify the minority of patients with advanced fibrosis who are at high risk for progression to decompensated liver disease, enabling targeted intervention and resource allocation. This study highlights the importance of Fibroscan as a screening tool for stratification of liver steatosis and fibrosis.

1978 - Clinical characteristics and one year survival of patients with hepatocellular carcinoma linked to metabolic dysfunction associated steatotic liver disease findings from a comprehensive institutional registry

Saleh A Alqahtani¹, Faisal Abaalkhail², Waleed K Al-hamoudi³, Abeer Abdullah⁴, Amwaj I Alanazi⁴, Mohammad Mansour³, Mussadique Ali Jhatial⁵, Mehwish Hussain⁵, Fahad Almugbel⁵, Saad Alghamdi³
King Faisal Specialist Hospital And Research Center, Liver, Digestive, And Lifestyle Health Research Section And Organ Transplant Center Of Excellence, Riyadh-Saudi Arabia¹ King Faisal Specialist Hospital And Research Center, Department Of Medicine, Gastroenterology Section, Riyadh-Saudi Arabia² King Faisal Specialist Hospital And Research Center, Organ Transplant Center Of Excellence, Riyadh-Saudi Arabia³ King Faisal Specialist Hospital And Research Center, Liver, Digestive, And Lifestyle Health Research Section, Riyadh-Saudi Arabia⁴ King Faisal Specialist Hospital And Research Center, Department Of Medical Oncology, Riyadh-Saudi Arabia⁵

Background: Hepatocellular carcinoma (HCC) is the most common type of primary liver cancer globally

and a leading cause of cancer-related mortality in Saudi Arabia. With the control of viral hepatitis, there is a worldwide trend in the etiology of HCC shifting towards MASLD. In Saudi Arabia, research on the clinical characteristics and outcomes of HCC linked to metabolic dysfunction-associated steatotic liver disease (MASLD) is still evolving. We compare patient characteristics, disease presentation, and clinical outcomes between individuals with HCC related to MASLD and those with HCC from other etiologies (non-MASLD-related HCC).

Methods: We conducted a retrospective analysis of a prospectively maintained registry for HCC at King Faisal Specialist Hospital and Research Center in Riyadh, which comprised patients diagnosed with HCC (either through histological or radiological methods) from August 2020 to May 2025. We then compared demographic, clinical, and tumor characteristics, as well as treatment modalities, between patients with MASLD-related and non-MASLD-related HCC. One-year survival was also estimated using Kaplan-Meier analysis, with censoring at the date of last follow-up for patients who did not die within the first year. All patients, including those with less than one year of follow-up, were included in the analysis.

Results: Among the 427 patients diagnosed with HCC, 152 cases (35.6%) were associated with MASLD. Most of the patients were male, accounting for 69.5%, and there was no significant difference in gender distribution between those with MASLD-related HCC and those without ($p=0.971$). Patients with MASLD were slightly older at diagnosis (median age 66 vs. 63 years, $p<0.001$) and more likely to have diabetes (67.8% vs. 46.9%, $p<0.001$). There were no significant differences between the groups in ECOG performance status, BCLC stage, Milan criteria, or Child-Pugh class at the time of diagnosis. Locoregional therapies were the most common first-line treatments in both groups (53.3% in MASLD vs. 57.1% in others, $p=0.913$). One-year survival was similar across groups (log-rank $p=0.44$), with comparable Kaplan-Meier survival estimates.

Conclusions: MASLD has become the predominant etiology of HCC in Saudi Arabia, accounting for over one-third of the cases. Despite presenting at an older age and having a higher diabetes prevalence, patients with MASLD-related HCC had similar tumor burden, treatment approaches, and one-year survival outcomes compared to non-MASLD-related HCC. The findings underscore the need for increased surveillance efforts

E-POSTER ABSTRACTS

and earlier risk stratification for MASLD. Future research should focus on long-term outcomes and tailoring therapies to the distinct metabolic profile of MASLD-related HCC.

1979 - Squamous cell carcinoma of the gallbladder A case report

Houda Chehboune¹, Lagdali Nawal¹, Kadiri Maryeme¹, Ajana Fatima Zohra¹, Borahma Mohamed¹
Ibn Sina University Hospital, Rabat, Morocco,
Department Of Gastroenterology "c", Rabat-Morocco ¹

Squamous cell carcinoma of the gallbladder is a rare malignant tumor, representing less than 3% of gallbladder cancers.

We report the case of a 70 year old man with a history of focal segmental glomerulosclerosis for which he was on ace inhibitors, a history of tobacco and cannabis use and risk factors for hepatotoxicity such as traditional cauterization and unsafe dental procedures. One month prior his admission, he presented epigastric pain with cholestatic jaundice that resolved spontaneously, associated with fever, asthenia, anorexia and a 7.6% weight loss in one month. On clinical examination he was vitally stable with a moderate epigastric tenderness and 14 cm hepatomegaly. Laboratory findings revealed cholestasis and an inflammatory syndrome.

The patient was first evaluated by abdominal ultrasound which revealed a hyperechoic mass in hepatic segment V in close contact with the gallbladder fundus, showing focal wall thickening and microlithiasis. Then a computed tomography scan of the chest, abdomen and pelvis was done which revealed a gallbladder mass measuring 55 × 57 × 65 mm infiltrating segments V and VI of the liver, extending to the gallbladder bed, in close contact with the second portion of the duodenum. Deep lymph nodes were present (coeliac, mesenteric and retroperitoneal). The mass was radiologically staged T3 pN2 Mx.

An ultrasound guided biopsy was performed for histological confirmation which identified a well differentiated, keratinizing, infiltrating squamous cell carcinoma of the gallbladder.

The patient was discharged in good condition and referred to the medical oncology department, where he was started on adjuvant chemotherapy.

Gallbladder squamous cell carcinoma is a rare, aggressive tumor often discovered late due to nonspecific symptoms. Diagnosis relies on histopathology, as imaging is frequently inconclusive. Clinicians should keep this entity in mind when evaluating gallbladder or biliary lesions, as each case adds valuable insight into this uncommon malignancy

Keyword(s) : Gallbladder carcinoma, Biliary tract malignancy, Ultrasound-guided biopsy

1980 - SPLEEN STIFFNESS MEASUREMENT AS A FAVORABLE PREDICTOR OF PORTAL HYPERTENSION IN A COHORT OF PATIENTS WITH CHRONIC LIVER DISEASE FOLLOWED AT AN URBAN LIVER CENTRE IN TORONTO (TLC).

Jumshaid Qureshi¹, Elkhashab Magdy², Shahzaib Ahmed³, Abdullah Qureshi³, Nada El-zahabi², Mehrdad Modaressi², Marzena Magnes², Furkan Hassan²

Toronto Liver Centre, Research, Scarborough-Canada ²
Fatima Memorial Hospital College Of Medicine And Dentistry, Research, Lahore-Pakistan ³

Background / Hypothesis:

Portal hypertension, the primary driver of complications in advanced liver disease, is best measured by the invasive hepatic venous pressure gradient (HVPG). While liver stiffness (LSM by VCTE) correlates with HVPG in early disease, its accuracy plateaus in significant portal hypertension (≥ 10 mmHg), limiting its predictive value for critical outcomes like varices.

As the spleen undergoes consistent morphological changes in response to portal hypertension, SSM has emerged as a more reliable, non-invasive surrogate for HVPG, offering an alternative for stratifying the risk of varices and clinically significant portal hypertension.

We sought to evaluate the liver and spleen stiffness in a cohort of patients who underwent Fibroscan and spleen stiffness at TLC. Clinically significant portal hypertension (CSPH) is defined as one or more of the following: ascites, varices, splenomegaly, encephalopathy, recanalized umbilical vein, collaterals, dilated portal vein, or history of GI bleed. Data on 112 patients who met these criteria were collected and analyzed.

Materials and Methods:

E-POSTER ABSTRACTS

We conducted a retrospective cohort analysis on patients who underwent a spleen stiffness and FibroScan at an urban Toronto Liver Centre. Fibroscan and spleen stiffness measurements, past medical history, ultrasound findings, endoscopic findings and physical examination findings were analyzed.

Results: The cohort comprised 46% females, 54% males, and an age range of 17 to 87 (median age 63.5). The spleen stiffness score ranged from 11.4 to 100 kPa with a median stiffness of 43.5 kPa.

Fibroscan® readings revealed a liver stiffness range of 3.5 to 75 with a median stiffness of 18.5, and 83 % of patients had advanced fibrosis or cirrhosis (defined as a liver stiffness of ≥ 13 kPa). Controlled attenuation parameter (CAP) ranged from 121 to 400, with a median CAP score of 266. Ascites was present (5.4%), esophageal varices (28.6%), splenomegaly (29.5%), dilated portal veins (4.5%), and variceal bleeding (6.25%).

The underlying liver diseases were: MASLD 41.3%, MASH 3.7%, Hepatitis B 12.8%, Hepatitis C 11.9%, ALD 21 %, AIH 5.5%, PBC 1.8%, and elevated liver enzymes NYD 2.7%. BMI range of 18.2- 59.1 (median BMI 28.4) There was a strong correlation between patients with ascites (0.417) and patients with GI bleed (0.466), and spleen stiffness and liver stiffness measurements.

Conclusion: Based on the medians of the spleen stiffness and Fibroscan measurements, a cut-off of 69.8 kPa for spleen stiffness and 24.5 kPa for liver stiffness was predictive for the presence of CSPH. A prospective study is underway in our centre to further elucidate these findings.

Keyword(s) : MASLD, Spleen Stiffness, Fibroscans, Chronic liver disease

1981 - Improving Elimination in Albumin Dialysis Liver Support Different Responses of Water Soluble and Albumin Bound Toxins

Stine Koball¹, Adrian Dominik¹, Sebastian Koball¹, Jan Stange¹
University Of Rostock, Nephrology, Rostock-Germany¹

Background / Hypothesis:

Extracorporeal Albumin Detoxification-Dialysis (ECAD) is the leading procedure to support failing livers by detoxification, it has been used in over 150.000 therapies. Past Meta-Analysis concluded dose of treatment would be an important cofactor determining a good outcome. The introduction of a new generation of adsorbents to maintain dialysate albumin's purity

has increased the bile acid removal compared to MARS and Cytosorb. However, since next generation adsorbents may have moved the set points for optimal blood and dialysate flow rates, the aim of this investigation was to elucidate the role of blood- and dialysate flow on the removal of water soluble toxins, albumin bound toxins and improvement of albumin binding.

Materials and Methods:

Eight Albunique treatments were performed using two blood flow rates (100 and 140 mL/min) and stepwise dialysate flow rates (2–4 L/h). Pre- and post-dialyzer blood samples were collected.

Photometric analysis was used to quantify albumin-bound toxins (bilirubin and bile acids) and water-soluble toxins (creatinine and urea). Albumin binding function at Sudlow site II was assessed by Dansylsarcosine titration, yielding K_d values (concentration at which half of the available binding sites are occupied). Instantaneous filter clearance was calculated and compared across the different flow conditions.

Results:

Instantaneous filter clearance during the eight Albunique treatments was analyzed for albumin-bound toxins (bilirubin and bile acids) and water-soluble toxins (creatinine) under two blood flow rates (100 and 130 mL/min) and stepwise increasing dialysate flow rates (2, 3, and 4 L/h).

Significantly higher clearance was observed for water-soluble toxins, particularly creatinine, with increasing dialysate flow. In contrast, no advantage was demonstrated for albumin-bound toxins; a trend toward reduced clearance was noted at higher dialysate and blood flow rates. Furthermore, K_d values at Sudlow site II did not improve with increased flow rates. These findings indicate a differential response of toxin classes to dialysate flow rate adjustments.

Conclusions:

The present data demonstrate that increasing dialysate and blood flow rates significantly enhance the clearance of water-soluble toxins. In contrast, no beneficial effect was observed for albumin-bound toxins; higher flow rates were not associated with a trend toward improved clearance of bilirubin and bile acids. Similarly, albumin binding function did not improve under higher flow conditions. These findings suggest that aggressive flow escalation does not confer an advantage for the removal of albumin-bound toxins. Instead, lower or moderate flow settings may

E-POSTER ABSTRACTS

provide more favourable conditions for albumin-mediated detoxification.

1983 - Unmasking Cryptogenic Cirrhosis Extreme Low LDL C as a Critical Clue for Adult Onset Familial Hypobetalipoproteinemia

Yusuf Bünyamin Ketenci¹, Hakan Demiröz¹, Mehmet Akca¹, Ufuk Avcioğlu¹, Ibrahim Gören¹, Müge Ustaoglu Dede¹, Talat Ayyildiz¹, Ahmet Bektaş¹
Ondokuz Mayıs University, Gastroenterology, Atakum-Türkiye¹

Background/Aims: Familial hypobetalipoproteinemia (FHBL) is a rare genetic disorder primarily caused by mutations in the APOB gene, resulting in impaired hepatic secretion of VLDL and LDL. While often diagnosed asymptotically in childhood through incidental low lipid findings, FHBL can lead to progressive hepatic steatosis and, rarely, cirrhosis in adulthood due to intrahepatic triglyceride accumulation. We present a Turkish father and son diagnosed with FHBL-related cirrhosis in adulthood.

Case Presentation: The index case, a 41-year-old male without comorbidities, was evaluated for severe incidental thrombocytopenia. Abdominal ultrasound revealed findings consistent with liver cirrhosis, including a lobulated liver, splenomegaly (210 mm), and dilated portal/splenic veins. Standard etiological screenings for chronic liver disease (viral, autoimmune, metabolic, Wilson's) were negative. Notably, his lipid profile showed profoundly low LDL-C levels (confirmed on repeat: 14 mg/dL and 8 mg/dL). Genetic analysis identified a heterozygous variant in the APOB gene (c.333-2A>T). This diagnosis prompted a re-evaluation of his 68-year-old father, who had undergone liver transplantation 20 years prior for presumed alcoholic cirrhosis and hepatocellular carcinoma. Retrospective analysis of the father's pre-transplant records revealed extremely low LDL-C levels (6-10 mg/dL), which had normalized (80-100 mg/dL) immediately following transplantation. Genetic testing confirmed the identical APOB mutation in the father.

Conclusions: This family cluster highlights FHBL as an important, yet often overlooked, differential diagnosis in adult patients presenting with cryptogenic cirrhosis. The dramatic normalization of lipid profiles following liver transplantation in the father provides strong

clinical evidence supporting the hepatic origin of the metabolic defect. Clinicians should maintain a high index of suspicion for hypolipoproteinemias when evaluating unexplained liver disease, regardless of patient age, as early identification may guide management and family screening.

Background / Hypothesis:

Hepatocellular carcinoma (HCC) has a poor prognosis and ranks as the fourth leading cause of cancer-related mortality worldwide. MicroRNA-221 plays a key role in regulating the cell cycle.

This study investigated the potential therapeutic effect of polymeric nanoparticles as a delivery system for miR-221 in an experimental HCC model.

Materials and Methods:

PLGA nanoparticles were synthesized, characterized, and conjugated with a miR-221 mimic. The nanocomposite was evaluated in vitro against HepG2 cells using the MTT assay, and in vivo in a DEN-induced HCC model in Balb/C mice treated either with PLGA nanoparticles alone or with miR-221-loaded nanoparticles.

Results:

The miR-221 nanocomposite exhibited significant cytotoxic activity toward HepG2 cells, with an IC50 value of 97.12. In vivo findings demonstrated marked improvement in the miR-221 nanocomposite-treated mice compared with the pathological control group, as

E-POSTER ABSTRACTS

evidenced by histopathological recovery and downregulation of caspase-3, caspase-9, cyclin D1, α -SMA, CD44, Bcl-2, and Ki67. Tumor-associated biomarkers including AFP, VEGF, PDGF, and TNF- α were also significantly reduced compared with the DEN group.

Conclusions: MiR-221-loaded polymeric nanoparticles represent a promising and innovative therapeutic strategy for hepatocellular carcinoma.

Background: Liver cancer is emerging as a leading cause of morbidity and mortality, particularly among men, due to late-stage diagnoses and low survival rates. We aimed to quantify the public health and economic burden of liver cancer in Saudi Arabia in 2022 and to assess the potential economic impact for future early detection scenarios.

Methods: A cohort-based static model was developed to estimate the disease burden in terms of years of life lost (YLL) and economic costs, including both medical

expenses and productivity losses. The model inputs were based on local real-world data, including the population-based Saudi Cancer Registry, statistics from the General Authority for Statistics, and liver cancer incidence and mortality estimates from GLOBOCAN 2022. Medical costs were assessed over a 5-year treatment period, with adjustments made to the baseline year of 2022. Productivity losses were estimated for both patients and caregivers during the treatment phase, whereas productivity loss due to premature death was calculated up to the age of 65 using the human capital approach, considering employment rates. A scenario analysis simulated the impact of shifts in the stage distribution compared to the current state.

Results: Liver cancer caused an estimated 13,800 YLL among men and 4,600 YLL among women in 2022. The total economic burden was approximately USD 219 million, comprising USD 126 million in medical costs. Productivity losses accounted for USD 93 million, 88% of which were incurred by men, for whom treatment and productivity costs were nearly equal. In contrast, productivity losses accounted for approximately 25% of total costs for women, primarily due to lower workforce participation. Scenario analyses showed that shifting late-stage diagnoses to earlier stages reduced YLL and productivity losses mainly through decreased mortality. Although annual per-patient medical costs are lower in earlier stages, total medical costs increased due to prolonged survival and continued healthcare utilization.

Conclusions: Liver cancer imposes a substantial health and economic burden in Saudi Arabia, with productivity losses, particularly among men, constituting a major share of the economic impact. Effective early detection strategies are needed to improve survival, reduce YLL, mitigate productivity losses, and potentially offset increased medical costs.

Chongqing Medical University, The Second Affiliated Hospital, Chongqing-China ¹

Background / Hypothesis: Hepatocellular carcinoma is one of the most prevalent

E-POSTER ABSTRACTS

and fatal cancers. With the application of systemic therapy, especially combination therapies based on immune checkpoint inhibitors (ICIs), significant therapeutic benefits have been achieved in advanced hepatocellular carcinoma. However, Whether chemotherapeutic drugs, targeted drugs, or ICIs, can cause tissue damage, known as treatment-related adverse events (trAEs). Early identification and assessment of adverse events have significant clinical significance. This study aims to characterize the signatures of adverse events by integrating proteomics and metabolomics.

Materials and Methods:

A total of 40 patients were enrolled in the study. Plasma samples were collected after the first five treatments. 27 patients had various types of adverse events, including 7 cases of liver injury. The plasma samples were analyzed by proteomics and metabolomics, and the adverse event-related proteins and metabolites were characterized by differential abundance analysis, Gene Ontology (GO) enrichment, Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis. Candidate biomarkers were screened using a machine learning model, and the discriminant performance was evaluated by receiver operating characteristic (ROC) curve.

Results:

By comparing the liver injury group with the non-injury group, 102 differentially expressed proteins and 57 differentially expressed metabolites were found. Through functional enrichment and network analysis, it was found that the liver injury is mainly related to metabolic reprogramming in vivo, affecting multiple amino acid and bile acid metabolic pathways to form a synergistic injury network. Four candidate markers (COL12A1, CEACAM1, PRG2 and C4BPB) were screened out through machine learning, and the regions under the ROC curves were 0.875, 0.813, 0.75 and 0.843, respectively.

Conclusions: Through the combined analysis of proteomics and metabolomics, we have selected several potential markers related to liver injury in the combined treatment of aHCC, which need to be further verified in large-scale prospective studies in the future

Keyword(s) : ICIs, biomarker, HCC, Liver Injury

1990 - Description of a Cohort of patients with chronic Liver disease of various etiologies characterized by TEE (Fibroscan) Toronto Liver Centre (TLC) Real world experience. HIGH PREVELECE OF MASLD

Elkhashab Magdy ¹, Jumshaid Qureshi ², Marzena Magnes ¹, Abdullah Qureshi ³, Jillian Ho ², Katarina Kangraga ², Mariantha Masri ², Gabriel Bishara ⁴, Ilya Abedi ², Michelle Guerreri ¹

Toronto Liver Center, Research, Toronto-Canada ¹
Toronto Liver Centre, Research, Toronto-Canada ²
Fatima Memorial Hospital College Of Medicine And Dentistry, Research, Lahore-Pakistan ³
Toronto Liver Centre, Research, Toronto-Canada ⁴

Background / Hypothesis:

Transient elastography (FibroScan) is increasingly recognized as a non-invasive diagnostic tool which measures liver stiffness (Fibrosis) and Controlled Attenuation Parameter (CAP) (steatosis). Real-world data etiological-based patterns remain limited in the diverse population of the Greater Toronto Area (GTA). Understanding these patterns is critical for identifying high-risk groups and guiding public health and screening initiatives tailored to the etiologies. To examine fibrosis (kPa) and steatosis (CAP) distribution across patients with chronic liver disease of different etiologies in a cohort of patients who underwent FibroScan examination in the GTA between 2020 and 2025.

Materials and Methods:

A retrospective analysis was performed on more than 11,214 FibroScan examinations conducted across multiple TLC FibroScan sites in the GTA. Variables included age, sex, ethnicity, etiology, liver stiffness (E median, kPa), hepatic steatosis (CAP median, dB/m), and probe type (M vs XL). Subgroup analyses were conducted across etiologies to highlight clinical variability within the cohort.

Results:

Of the 11,214 patients, the median age of the cohort was 56.3 ± 14.2 years. The cohort was equally distributed by gender (51.8 % male, 48.2 % female). The mean liver stiffness was 6.7 kPa. With a mean CAP value of 275 dB/m. MASLD was the predominant etiology (n=8149, 72.8%), demonstrating the highest

E-POSTER ABSTRACTS

steatosis levels (median CAP 285 dB/m) with modest stiffness (6.6 kPa). Viral hepatitis B (n=1856, 16.6%) showed the lowest stiffness (5.4 kPa) and relatively low CAP values (246.5db/m), while hepatitis C demonstrated slightly higher stiffness (7.1 kPa) and CAP of (251 dB/m). Alcohol-related liver disease (n=180, 1.6%) with a mean stiffness of 12.4 kPa and a median CAP value of 259 db/m. PBC and PSC accounted for (n=35, 0.3%), with a median stiffness of 6.8 kPa and a CAP of 233 dB/m. Autoimmune hepatitis represented (n=99 0.9%), with median liver stiffness of (7.2 kPa) and CAP of (261 dB/m). Patients on Methotrexate (N=32,0.29%), Mean stiffness (5.0 kPa), and CAP of (273 dB/m). Other etiologies comprised (n=622,5.5%) with a mean liver stiffness of (8.5kpa) and a CAP value of (249 dB/m). Overall, fibrosis and steatosis patterns varied across etiologies, with MASLD dominating steatosis and ALD showing the highest stiffness(Fibrosis)values.

Conclusions:The high prevalence of MASLD highlights the growing impact of steatotic liver disease and the urgent need for public-health strategies focused on metabolic liver disease prevention and screening protocols for early identification and prevention of chronic liver disease.

Excellence, Riyadh-Saudi Arabia ⁷

Background:

Hepatocellular carcinoma (HCC) remains a major global health burden, with rising incidence and mortality. Novel diagnostic approaches may improve early detection and streamline diagnostic pathways, crucial for improving survival. We aimed to systematically review novel HCC detection approaches reporting diagnostic accuracy measures

Methods:

A systematic review was conducted using PRISMA guidelines by searching PubMed, EMBASE, Scopus, and the Cochrane Library on Dec 11, 2024. Eligible studies were cohort or randomized controlled trials in design, in English or Arabic, reported a novel diagnostic approach for HCC in any clinical setting, enrolled ≥ 300 participants, and reported diagnostic accuracy measures. Studies identifying incident HCC were included. Two reviewers independently screened studies and assessed risk of bias using the QUADAS-2 tool. Due to heterogeneity in index tests, populations, and outcome measures, meta-analysis was not performed.

Results:

Four studies (n = 50,363) met the inclusion criteria, each evaluating a distinct approach . Three studies focused on patients with existing liver conditions (hepatitis B and cirrhosis); two studies in hepatitis B cohorts reported predictive algorithms aimed at improving HCC detection above usual care. The methylation, mutation, and protein-HCC (M2P-HCC) clinical prediction model for patients with hepatitis B had an AUC of 0.88 (95% CI 0.81-0.95), outperforming standard care (0.76 [0.69-0.84]), with low risk of bias. Another model for patients with hepatitis B that included circulating tumor DNA had an AUC of 0.93 (0.90-0.97); however, CIs overlapped with those of standard care, limiting the strength of the comparative claim. The ALARM model, based on radiomics and deep learning techniques, achieved an AUC of 0.92 (0.90-0.96) in a cohort of patients with cirrhosis. The fourth study identified novel hepatitis B-specific AFP cut-off for screening in a high-prevalence area, reporting an AUC of 0.999 at a pre-specified cut-off of ≥ 8.1 ng/ml, though concerns remain about overfitting and generalizability.

E-POSTER ABSTRACTS

Conclusions:

This review highlights four novel approaches to HCC diagnosis, encouraging diagnostic performance, particularly in the M2P-HCC and ALARM models. Prospective validation in broader populations is crucial to assess clinical and health economic impacts, alongside regulatory, interpretability, and implementation challenges. The limited number of eligible studies highlights the need for further high-quality, real-world evaluations.

Keyword(s) : Early detection , HCC , Hepatocellular Carcinoma

1992 - Sustained Virologic Response After Only One Week of Glecaprevir Pibrentasvir A Rare Ultra Short Treatment Success

Hatun Öztürk Çerik¹, Arzu Altunçekiç Yildirim¹, Celali Kurt¹

Ordu University School Of Medicine, Department Of Infectious Disease And Clinical Microbiology, Ordu-Türkiye¹

Background / Hypothesis:

Direct-acting antivirals (DAAs) have revolutionized chronic hepatitis C (CHC) treatment, achieving >95% cure rates with short-duration regimens. Glecaprevir/pibrentasvir (G/P) is a pangenotypic, highly effective regimen with standard treatment durations of 8–12 weeks. Data on ultra-short G/P therapy (≤ 2 weeks) remain extremely limited. We report a rare case in which only one week of G/P therapy resulted in a sustained virologic response (SVR) in a kidney transplant recipient.

Materials and Methods:

A retrospective evaluation was conducted of a kidney-transplanted, treatment-naïve, non-cirrhotic patient diagnosed with genotype 1b CHC. Clinical, laboratory, and viral kinetics data from 2017 to 2025 were reviewed. Therapy duration was confirmed through direct pill count and patient interview.

Results:

A female patient with a history of living-donor kidney transplantation (2008), diabetes mellitus, hypertension, and chronic renal failure presented in 2021. Although diagnosed with CHC in 2017, she remained untreated until presentation. The 2021 work-up revealed an HCV RNA load of 1,020,000 IU/mL (Genotype 1b). Laboratory results showed ALT 140 U/L, AST 121 U/L, and platelets 141,000/ μ L; bilirubin and albumin levels were within normal limits. The patient initiated G/P

therapy but self-discontinued after seven days and was lost to follow-up. Upon reassessment two years later, HCV RNA was undetectable. Medication reconciliation confirmed the ingestion of only one week's dosage. Serial virologic monitoring demonstrated persistent aviremia throughout 2023, 2024, and 2025, confirming durable SVR.

Conclusions:

This case demonstrates a notable achievement of SVR after only one week of glecaprevir/pibrentasvir in a complex post-transplant patient with multiple comorbidities. To date, only two similar cases of success with such ultra-short G/P exposure have been reported. These findings underscore the rapid potency of G/P, suggesting that viral clearance may occur significantly earlier than established treatment guidelines in specific individuals.

Keyword(s) : Hepatitis C; glecaprevir/pibrentasvir; direct-acting antivirals; sustained virologic response.

1994 - Effects of biological agents on hepatitis B virus reactivation in patients who are negative for hepatitis B surface antigen and positive for antibodies against hepatitis B core antigen

Atiye Ayrik Demir¹, Orhan Yildiz², Bilgehan Aygen²
Kayseri City Hospital, Department Of Infectious Diseases And Clinical Microbiology, Kayseri-Türkiye¹
Erciyes University Faculty Of Medicine, Department Of Infectious Diseases And Clinical Microbiology, Kayseri-Türkiye²

Background / Hypothesis:

In HBsAg-negative, anti-HBc IgG-positive individuals, the risk of hepatitis B virus reactivation (HBVr) associated with immunosuppressive therapy varies depending on the immunosuppressive potency of the biological agent used. This study aimed to evaluate the development of HBVr in HBsAg-negative, anti-HBc IgG-positive patients receiving medium- or high-risk biological agents.

Materials and Methods:

A total of 172 patients identified as HBsAg-negative and anti-HBc IgG-positive were retrospectively evaluated. Patients were classified into moderate- and high-risk groups according to the HBVr risk associated with the biological agents used. Rituximab and ocrelizumab were categorized as high-risk agents, while anti-TNF- α agents (adalimumab, infliximab, golimumab, certolizumab, etanercept), the IL-6 inhibitor tocilizumab, and the IL-12/23 inhibitor

E-POSTER ABSTRACTS

ustekinumab were considered moderate-risk agents. Demographic and clinical characteristics, treatment details, concomitant immunosuppressive medications, and antiviral prophylaxis status were recorded. Virological and serological data obtained during follow-up were reviewed, and the occurrence of HBVr was assessed.

Results:

The mean age of the study population was 52.3 ± 11.0 years. The most common indications for biological agent therapy were ankylosing spondylitis (30.2%) and rheumatoid arthritis (29.7%). While 20.9% (n=36) of patients received high-risk agents, 79.1% (n=136) received moderate-risk agents. The median follow-up duration was 28.5 months (12–60 months) in the high-risk group and 36 months (12–96 months) in the moderate-risk group. All patients in the high-risk group received antiviral prophylaxis at treatment initiation, and no HBVr events were observed. In contrast, only 33.1% (n=45) of patients in the moderate-risk group received prophylaxis, while 66.9% (n=91) were monitored without prophylaxis. Among those not receiving prophylaxis, only one patient experienced virological reactivation without clinical or biochemical hepatitis. This patient had an initial anti-HBs level of ≥ 1000 IU/L, which remained stable during follow-up.

Conclusions:

Antiviral prophylaxis is effective in preventing HBV reactivation in HBsAg-negative, anti-HBc IgG-positive individuals receiving moderate- or high-risk biological agents. For patients treated with moderate-risk agents, regular virological monitoring may serve as a safe alternative to universal prophylaxis, allowing timely identification and management of the rare reactivation events that occur.

1995 - Ethnic Variation in FibroScan Detected Fibrosis and Steatosis in a Large Multi Ethnic Canadian Cohort Implications for Targeted MASLD Screening

Ilya Abedi¹, Jillian Ho², Jumshaid Qureshi¹, Magdy Elkhatab², Michelle Guerrero², Katarina Kangraba², Mariantha Masri², Gabriel Bishara², Marzena Magnes¹
Toronto Liver Center, Research, Toronto-Canada¹
Toronto Liver Centre, Research, Toronto-Canada²

Background / Hypothesis:

FibroScan enables non-invasive assessment of fibrosis and steatosis through liver stiffness measurement (LSM) and controlled attenuation parameter (CAP). It is established that genetic factors play a role in the pathogenesis of MASLD. While international Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD) guidelines acknowledge that metabolic risk factors and disease burden vary across ethnic groups, there is limited real-world Canadian evidence describing these ethnic-specific patterns.

To evaluate the distribution of FibroScan-derived fibrosis and steatosis stages across ethnic groups in a large, diverse Canadian cohort.

Materials and Methods:

A retrospective analysis was conducted on adult patients with chronic liver disease who underwent FibroScan examination at participating Greater Toronto Area liver clinics between January 2020 and May 2025. Variables include ethnicity, and fibrosis and steatosis stages, which were classified using validated cut-offs. Statistics were stratified by ethnicity.

Results:

Ethnic variation was observed in the distribution of advanced fibrosis (F3-F4), cirrhosis (F4), and advanced steatosis (S3). The highest proportions of advanced fibrosis within ethnic groups were Northern European (7.4%), Jewish (5.2%), and Southern European (3.4%) populations. Cirrhosis was most prevalent among Caribbean (8.6%), Southern European (6.3%), and Western European (6.3%) groups.

Advanced Steatosis (S3) was greatest in Northern European (37.0%), Caribbean (29.3%), Iberian (27.5%), and Southern European (27.1%) populations. Elevated S3 levels were also observed in other European sub-groups, as well as Hispanic, South Asian, and MENA groups, reflecting broader metabolic susceptibility.

Conclusion:

In this large, diverse Canadian cohort, FibroScan detected fibrosis and steatosis patterns that varied significantly by ethnicity. These real-world findings highlight ethnic variability in liver disease severity that extends beyond traditional risk factors. Understanding

E-POSTER ABSTRACTS

ethnicity-related patterns may refine FibroScan® interpretation and optimize MASLD screening for diverse populations. Further prospective studies are underway to elucidate these findings.

1996 - Triple Threat A Rare Case of Drug Induced Liver Injury Triggering Autoimmune Hepatitis and Overlapping Systemic Lupus Erythematosus

Yrah Damiene Fernandez¹, Paolo Cervantes², Jose Guillain Cataluna¹

Institute Of Digestive And Liver Diseases, St. Luke's Medical Center Quezon City, Medicine, Quezon City-Philippines¹ St. Luke's Medical Center Quezon City, Medicine, Quezon City-Philippines²

Background / Hypothesis:

Autoimmune Hepatitis (AIH) is an uncommon chronic inflammatory liver disease, with a prevalence of 16–18 per 100,000 individuals in Europe. AIH–Lupus Hepatitis overlap syndrome (AIH-L) presents a diagnostic challenge due to shared clinical, serologic, and immunologic features, and is typically considered when a patient meets both the American College of Rheumatology (ACR) criteria for Systemic Lupus Erythematosus (SLE) and the International Autoimmune Hepatitis Group (IAIHG) scoring system. Meanwhile, anti-tuberculosis (TB) medications are recognized causes of drug-induced liver injury (DILI), sometimes displaying autoimmune features that mimic AIH. Differentiating DILI with autoimmune manifestations from true AIH or overlap syndromes is difficult, especially when patients present with acute liver failure. This case highlights a complex diagnostic and therapeutic dilemma in a patient treated with anti-TB drugs who presented with seropositive autoantibodies and rapidly progressive hepatic dysfunction.

Materials and Methods:

We present a 69-year-old female who developed progressive jaundice, abdominal pain, and hepatic dysfunction six weeks after initiating anti-TB therapy for pulmonary tuberculosis. Magnetic resonance cholangiopancreatography (MRCP), autoimmune serologies, immunoglobulin profiling, and viral hepatitis studies were performed. The clinical trajectory, interpretation of autoimmune markers, and therapeutic decisions—including steroid initiation and subsequent complications—were analyzed in the context of available diagnostic frameworks for AIH, SLE,

and DILI.

Results:

Initial evaluation revealed non-dilated bile ducts and absence of structural obstruction on MRCP, supporting DILI as the principal working diagnosis. However, progressive hepatic decompensation prompted reassessment for underlying chronic liver disease. Autoimmune testing showed high-titer ANA positivity, elevated IgG, positive anti-smooth muscle antibody (SMA), and anti-dsDNA, fulfilling both ACR criteria for SLE and IAIHG scoring parameters suggestive of AIH. These findings raised strong suspicion for AIH–SLE overlap syndrome precipitated or unmasked by anti-TB therapy. Steroid therapy was initiated but complicated by pneumonia and worsening thrombocytopenia, which precluded liver biopsy. The patient subsequently developed acute liver failure with superimposed sepsis and succumbed to multiorgan dysfunction despite supportive care.

Conclusions:

AIH–SLE overlap is a rare entity with significant diagnostic complexity, especially when concurrent DILI from anti-TB therapy is present. Overlapping serologies and clinical features make differentiation difficult, and biopsy—often essential—may be unsafe in acute liver failure. Early recognition, prompt cessation of offending drugs, initiation of corticosteroids, and aggressive monitoring for infectious and hematologic complications are critical. This case underscores the importance of high clinical suspicion and multidisciplinary management to optimize outcomes in rapidly deteriorating autoimmune and drug-induced hepatic injury.

1997 - Hepatic resection versus stereotactic body radiation therapy as first line treatment for BCLC stage 0 hepatocellular carcinoma a propensity score weighted analysis

Sang Min Yoon¹, Hye In Lee¹, Jinhong Jung¹, Gi-won Song²

Asan Medical Center, Radiation Oncology, Seoul-South Korea¹ Asan Medical Center, Surgery, Seoul-South Korea²

Background / Hypothesis:

Stereotactic body radiation therapy (SBRT) has emerged as a promising curative treatment for

E-POSTER ABSTRACTS

hepatocellular carcinoma (HCC); however, robust comparative data with surgical resection remain limited. This study aimed to evaluate long-term outcomes of surgical resection versus SBRT in patients with Barcelona Clinic Liver Cancer (BCLC) stage 0 HCC.

Materials and Methods:

In this single-institution retrospective study, 537 patients with treatment-naïve, single HCC ≤ 2 cm who underwent surgical resection (n=450) or SBRT (n=87) between 2015 and 2023 were analyzed. Inverse probability of treatment weighting (IPTW) was applied to balance baseline characteristics. Overall survival (OS), disease-free survival (DFS), recurrence patterns, and treatment-related toxicities were compared between groups.

Results:

Over a median follow-up of 55.8 months (range, 8.3–117.0), unweighted 5-year OS rates were 95.6% for resection and 83.9% for SBRT (hazard ratio [HR] 4.14; 95% confidence interval [CI], 1.96–8.71; $P < 0.001$). The 5-year DFS rates were 68.1% and 58.6%, respectively (HR 1.76; 95% CI, 1.17–2.64; $P = 0.006$). However, IPTW-weighted analysis showed comparable survival outcomes, with 5-year OS rates of 93.8% versus 96.0% (HR 1.16; 95% CI, 0.44–3.02; $P = 0.766$) and 5-year DFS rates of 64.7% versus 75.2% (HR 1.18; 95% CI, 0.67–2.08; $P = 0.562$) in the resection and SBRT groups, respectively. Grade ≥ 3 complications occurred in 31 (6.9%) patients after resection, whereas no severe toxicities were reported after SBRT.

Conclusions:

After adjusting for baseline imbalances, SBRT demonstrated comparable survival outcomes to surgical resection. These findings support SBRT as a viable alternative for patients with BCLC stage 0 HCC who are suboptimal surgical candidates. Further prospective studies are warranted to optimize treatment strategies in this patient population.

Keyword(s) : very early stage; treatment-naïve patients; overall survival; disease-free survival; adverse events; inverse probability of treatment weighting.

1998 - The Efficacy of Atezolizumab and Bevacizumab Combination in real world for Advanced Hepatocellular Carcinoma

Ji Hoon Kim ¹, Eunho Choi ¹

Korea University Guro Hospital, Internal Medicine, Seoul-South Korea ¹

Background / Hypothesis:

Atezolizumab-bevacizumab combination therapy has been approved for first-line systemic chemotherapy in advanced hepatocellular carcinoma. Real-world retrospective analysis was performed to evaluate the effectiveness and safety of the chemotherapy.

Materials and Methods:

A single-center, retrospective cohort study was performed. Between January 2020 and July 2023, patients with advanced hepatocellular carcinoma who received atezolizumab-bevacizumab systemic therapy were enrolled. Response to the therapy was assessed with mRECIST criteria. Evaluation of first radiologic response, best overall response, progression-free survival, and overall survival was done. Safety data were collected. Also, prognostic factors for first radiologic response, progression-free survival, and overall survival were also assessed.

Results:

A total of 70 patients were investigated. Baseline characteristics showed a median age of 63 years, male dominance (89%), and viral etiology (84%). Four patients achieved complete response and 19 reached partial response when evaluated by best overall response. Response duration was 4.7 months (range 1.5–25.5). Median progression-free survival was 4.1 months (95% CI, 3.7–6.7), and median overall survival was 24.6 months (95% CI, 11.6–). Age and tumor extent of over 50% of the liver was predictive of progression-free survival ($p = 0.009$ and $p = 0.007$, respectively). Tumor extent of over 50% of the liver and ALBI score were predictive of overall survival ($p = 0.025$ and $p = 0.004$, respectively).

Conclusions: Atezolizumab-bevacizumab therapy showed valuable outcomes and tolerable safety profiles in real-world advanced HCC patients. The outcome and safety results were comparable to previous studies.

1999 - Malnutrition and its association with mortality in liver cirrhosis a prospective nutritional assessment in northern Iran

Fariba Yadollahi ¹, Shiva Hosseini ²

Zahedan University Of Medical Sciences, Rehabilitation, Zahedan-Iran ¹ Sbmu, Medicine, Tehran-Iran ²

E-POSTER ABSTRACTS

Background / Hypothesis:

Today chronic liver disease is developing and liver cirrhosis mortality is increasing in Iran. Malnutrition is a complication of liver cirrhosis and is associated with poor outcomes. This study aimed to determine the association between malnutrition and mortality in patients with liver cirrhosis in northern Iran.

Materials and Methods:

This prospective cross-sectional study was conducted on individuals with liver cirrhosis who lived in northern Iran. Patient information, including demographics (age, gender, etiology of cirrhosis, alcohol and smoking history), as well as triceps skinfold (TSF), mid-arm circumference (MAC), Child-Pugh score, and Model for End-Stage Liver Disease (MELD) score, was recorded for all patients. Patients were classified A, B, and C based on the Subjective Global Assessment (SGA) questionnaire.

Results:

A total 984 participants with the mean age 51.38 were recruited in this study. Viral infections were the most common etiology and 61.7% of participants were in the classification A of Child-Pugh Score. TSF ($P < 0.01$) and MAC ($P < 0.001$) were significantly lower in SGA class C. The survival rate in SGA class C was significantly lower than other groups ($P < 0.01$; log-rank test). The risk of mortality in patients with SGA class A and B was 87% (HR value: 0.21; 95% CI: 0.04-0.78; $P < 0.05$) and 72% (HR value: 0.31; 95% CI: 0.07-0.79; $P < 0.02$) lower than those with SGA class C.

Conclusions:

Our findings showed that SGA measure is easy and accessible methods for assessing malnutrition and mortality in individuals with liver cirrhosis.

Keyword(s) :

2001 - Retrospective Analysis of Clinical and Genetic Characteristics in 68 Adult Patients with Gilbert Syndrome from a Tertiary Hospital in Southwest China

Ning Han¹, Libo Yan¹, Hong Tang¹
West China Hospital, Sichuan University, Center Of Infectious Diseases, Chengdu-China¹

Background / Hypothesis:

Gilbert syndrome (GS) is a benign hereditary condition caused by reduced UGT1A1 activity, leading to intermittent unconjugated hyperbilirubinemia. Data on

adult GS patients in China remain limited, especially in the Southwest region. This study aimed to investigate the clinical features and UGT1A1 variant spectrum in adult GS patients from a tertiary hospital in Southwest China.

Materials and Methods:

This retrospective study included 68 adult patients diagnosed with GS between 2019 and 2022. Demographic characteristics, symptoms, bilirubin profiles, liver biochemical tests, and UGT1A1 sequencing results were analyzed.

Results:

Among the 68 patients, the median age was 30 years (IQR 21.0–42.5), and 41 (60.3%) were male. All patients exhibited elevated bilirubin, and 18 (26.5%) presented with jaundice. The mean total bilirubin was 86.9 ± 45.2 $\mu\text{mol/L}$, with a median indirect bilirubin of 70.0 $\mu\text{mol/L}$ (IQR 50.43–98.73).

UGT1A1 analysis revealed that 56 patients carried a single variant, 11 carried two variants, and 1 carried three variants. The most frequent variants were UGT1A1*28 (41 cases) and UGT1A1*6 (21 cases). Seven patients harbored rare variants, including five PBREM enhancer region variants, one exon 1 missense mutation (c.668G>A), and one UGT1A1*7 mutation (c.1456T>G).

Conclusions:

UGT1A1*28 and UGT1A1*6 were the predominant variants among adult GS patients in Southwest China. Rare promoter, enhancer, and exonic mutations also contributed to the genetic heterogeneity of GS. Genetic testing is valuable for adults presenting with isolated indirect hyperbilirubinemia and may reduce unnecessary diagnostic investigations.

Keyword(s) : Gilbert syndrome, UGT1A1 variants, Unconjugated hyperbilirubinemia

2003 - Mechanism Based Efficacy and Advantage of Traditional Chinese Medicine in Treating Anemia Associated with HBV Related Hepatocellular Carcinoma from an Inflammatory Perspective

Wanxin Shi¹, Huiwen Yan¹, Zhibo Dang², Mengge Li², Xiaoli Liu¹, Lihua Yu¹, Songwei Li³, Xinhui Wang⁴, Zhiyun Yang¹

Beijing Ditan Hospital, Capital Medical University, Center Of Integrative Medicine, Beijing-China¹ Henan Province Hospital Of Traditional Chinese Medicine, Department Of Hepatobiliary Diseases, Zhengzhou-China² The First Affiliated Hospital Of Henan University Of Chinese Medicine, Endocrinology Department, Zhengzhou-China³ Beijing Children's Hospital, Capital Medical University, Center Of Integrative Medicine,

E-POSTER ABSTRACTS

Beijing-China ⁴

Background / Hypothesis:

This study aimed to identify independent prognostic factors for patients with concurrent hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC) and cancer-related anemia (CRA), and to investigate the impact of traditional Chinese medicine (TCM) on patient outcomes. Furthermore, the objective was to determine the patient subset most likely to benefit from TCM intervention for guiding clinical practice.

Materials and Methods:

A total of 532 patients diagnosed with coexisting HBV-related hepatocellular carcinoma and cancer-related anemia at Beijing Ditan Hospital between June 2008 and June 2017 were included. The cohort comprised 318 patients who received TCM treatment and 214 patients who underwent exclusive modern medical therapy. To evaluate the association between TCM intervention and patient survival, multivariable Cox regression analysis was employed to estimate hazard ratios (HRs) while adjusting for potential confounding factors. Kaplan-Meier survival curves were generated to visualize survival distributions, and dendrograms were utilized to explore hierarchical relationships among prognostic factors and stratify mortality risks in this patient population. Building upon the observed synergistic interaction between C-reactive protein (CRP) and alpha-fetoprotein (AFP) in predicting clinical outcomes, this study further developed a decision tree model.

Results:

Patients who received TCM treatment for more than six months demonstrated a significantly higher survival rate compared to those treated with TCM for less than six months. AFP and CRP were identified as independent risk factors for 1-year survival within the TCM treatment group. The subgroup characterized by low levels of both AFP (≤ 350 ng/mL) and CRP (≤ 5 mg/L)—designated as the LALC subgroup—exhibited the most favorable survival outcomes. A decision tree model constructed based on CRP, AFP, platelet count (PLT), and hemoglobin (HGB) provided an intuitive tool for prognostic prediction. Among these variables, CRP level demonstrated a particularly strong association with patient outcomes: patients with CRP ≤ 5 mg/L achieved a 1-year survival rate of 87%, constituting 47% of the study population. Additional indicators positively influencing prognosis in patients with HCC

complicated by anemia included AFP ≤ 350 ng/mL, PLT $\leq 100 \times 10^9$ /L, and HGB < 90 g/L. Patients meeting all these criteria collectively achieved a 1-year survival rate of 60%, representing 11% of the study cohort.

Conclusion: TCM demonstrated protective effects in patients with HBV-related HCC and CRA, and survival was positively associated with the duration of TCM use. Patients with low CRP and AFP levels represent the optimal population for TCM treatment to enhance prognosis. Observing the levels of CRP, AFP, platelets, and hemoglobin can help predict the prognosis.

2005 - The positive impact of the national HBV vaccination program implemented in Turkey on the prevalence of HBV among health school students

Selma Tosun ¹

University Of Health Sciences Turkey, Izmir Faculty Of Medicine, Izmir City Hospital, Infectious Diseases And Clinical Microbiology, Izmir-Türkiye ¹

Background / Hypothesis: This study aimed to determine hepatitis B virus (HBV) exposure among students enrolled in health-related schools who were attending internships at a training and research hospital in Izmir.

Material and methods: After receiving ethics committee approval, students' HBsAg, anti-HBcIgG, and anti-HBs results were obtained either from the hospital automation system or from the students' personal reports. Türkiye's national HBV vaccination program began in 1998, followed by a catch-up program in schools between 2005 and 2009; thus, individuals born between 1991 and 1997 were also theoretically included in the vaccination cohort. Study data were evaluated based on birth years corresponding to these vaccination periods.

Results: A total of 1,174 students born between 1991 and 2007 were included; 898 were female and 276 were male. HBsAg positivity was detected in five students: two females (born in 1997 and 2003) and three males (born in 1991, 1992, and 2006). Of the nine students who had natural immunity due to past HBV exposure, three were born in 1997, two in 1991, and one each in 1992, 2003, 2005, and 2006. Among the 1,160 students who were not exposed to HBV and were anti-HBcIgG negative, 81% had protective anti-HBs levels ≥ 10 IU/mL.

E-POSTER ABSTRACTS

A decline in anti-HBs titers over time after infant vaccination is expected. In this study, students born in 2000 or later—who received only the three-dose infant series without subsequent boosters—had significantly higher rates of non-protective antibody titers. To identify when titers began to decline, students with low anti-HBs levels (10–50 IU/mL) were analyzed. Low titers were found in 29.3% of students born between 2000 and 2002, 23.2% of those born in 2003–2004, and 13.6% of those born between 2003 and 2007. All students with negative titers showed an anamnestic response following a booster dose, confirming preserved immune memory.

Conclusion: Overall, the national HBV vaccination program has been highly effective for students preparing for healthcare professions. Among those born after the vaccination program began, 98.8% (1160/1174) were protected through vaccination. Of the five students found to be HBsAg positive, three were born before the vaccination program and two after; in all cases, their mothers were HBsAg positive, suggesting perinatal transmission. The findings highlight both the success of the vaccination program and the importance of monitoring anti-HBs levels in individuals vaccinated only in infancy, as their antibody titers may fall below protective levels over time despite preserved immune memory.

2007 - A Survey on Awareness of Antiviral Therapy Among CHB Patients

Yinyan Yu ¹, Yongfeng Chen ¹, Hua Wang ¹, Hongyan Yuan ¹, Min Liao ¹, Zixin Chen ¹, Min Li ¹, Yanqin Du ¹, Xin Zheng ¹

Union Hospital, Tongji Medical College, Huazhong University Of Science And Technology, Department Of Infectious Diseases, Wuhan-China ¹

Background / Hypothesis: The overall treatment rate for CHB in China is currently only 27%. This study aimed to evaluate, from the patient perspective, the reasons for not initiating antiviral therapy and the level of awareness regarding antiviral treatment.

Materials and Methods: From August 2025 to November 2025, a self-administered electronic questionnaire was used to collect data from 502 CHB patients attending the Department of Infectious

Diseases in our hospital. The questionnaire contained 16 items covering three domains: awareness of antiviral therapy, reasons for not receiving treatment, and clinical care needs.

Results: Among the 502 surveyed CHB patients, 336 were currently receiving antiviral therapy, yielding an overall treatment rate of 67%; the proportion of patients who had not initiated antiviral therapy remained as high as 33%. A total of 449 patients (89.4%) were over 30 years of age, of whom 132 (29.4%) had not started antiviral therapy (Baseline characteristics shown in Table 1). The results indicated that age, educational level, occupation, medical insurance coverage, economic status, time since CHB diagnosis, and frequency of medical visits were significantly associated with treatment uptake ($P < 0.05$). Sex was not significantly associated with antiviral treatment ($P > 0.05$). Analysis of reasons for not initiating antiviral therapy showed that: 74.7% were unwilling to take long-term medication, 62% were concerned about drug side effects, and 54.8% reported that their physicians had not recommended treatment (Figure 1). Regarding awareness of antiviral therapy, the Likert 5-point scale revealed high scores for “I clearly understand that antiviral therapy reduces the risk of hepatocellular carcinoma” and “I trust my physician’s treatment recommendations,” with scores of 4.39 ± 0.72 and 4.39 ± 0.73 , respectively (one-sample t tests, $P < 0.05$), indicating positive perceptions. In contrast, “I worry that treatment will affect my work or daily life” scored 2.41 ± 1.03 ($P < 0.05$), reflecting negative perceptions that require enhanced patient education. Additionally, 62.5% of patients reported that receiving clear explanations from physicians regarding long-term medication use, drug safety, and other treatment-related concerns would encourage them to initiate therapy. Moreover, 80.3% expressed a desire for a dedicated communication platform for physician–patient interaction

Conclusions: The treatment rate for CHB requires further improvement. Patients who have not initiated antiviral therapy show notable gaps and misconceptions regarding treatment. Targeted and standardized management strategies in clinical practice are needed to promote early antiviral treatment

2009 - A research on gastroesophageal varices in patients with liver cirrhosis of different etiologies

Yuerong Zhang¹, Yuhui Jiang¹

University-town Hospital Of Chongqing Medical University, Department Of Gastroenterology, Chongqing-China¹

Background / Hypothesis: To explore the differences in the manifestations of gastroesophageal varices in patients with liver cirrhosis of different etiologies.

Materials and Methods: A retrospective analysis was conducted on 101 patients with viral hepatitis, alcoholic hepatitis, and cirrhosis after autoimmune liver disease who were randomly admitted to the medical institution where the researcher worked. The bleeding, degree, location, maximum diameter, red sign, and risk factors of gastroesophageal varices were observed and compared.

Results: In terms of the degree of varicose veins, the proportion of mild varicose veins in the viral hepatitis group (3.03%) was lower than that in alcoholic liver disease (22.73%), and the difference was statistically significant ($P < 0.05$). At the same time, the proportion of mild varicose veins in the viral hepatitis group was lower than that in the autoimmune liver disease group (23.08%), and the difference was statistically significant ($P < 0.05$); The positive rate of RC in the viral hepatitis group (59.09%) was higher than that in the alcoholic liver disease group (27.27%), and the difference was statistically significant ($P < 0.05$); In terms of the maximum inner diameter (mm) of the portal vein in patients with viral hepatitis, it was 15.00 (14.00, 16.00) higher than that in the alcoholic liver disease group, which was 13.50 (11.00, 14.75), and the difference was statistically significant ($P < 0.05$). At the same time, the portal vein inner diameter in the viral hepatitis group was larger than that in the autoimmune liver disease group, which was 12.00 (11.00, 14.00), and the difference was statistically significant ($P < 0.05$).

Conclusions: The maximum diameter of the portal vein and the condition of gastroesophageal varices vary in patients with different etiologies of liver cirrhosis. Patients with viral hepatitis and liver cirrhosis have thicker portal veins, a higher proportion of mild to severe gastroesophageal varices, and a higher positive rate of red signs. Therefore, it is even more important to be vigilant about the rupture and bleeding of

gastroesophageal varices. Active antiviral treatment should be given to patients with viral hepatitis who have indications for antiviral therapy to reduce the likelihood of developing cirrhosis and complications such as esophagogastric variceal bleeding.

2011 - Integrated Multi omics Liquid Biopsy Advancing Early Detection and Precision Management of HCC

Xinhao Gao¹, Jitao Wang², Dengxiang Liu³, Juan Liu⁴, Hezhao Wang¹

Xingtai People's Hospital, Hepatobiliary Surgery, Xingtai-China¹ Tsinghua University, Hepatobiliary Surgery, Beijing-China² Xingtai, Xingtai People's Hospital, Xingtai-China³ Beijing, Tsinghua University, Beijing-China⁴

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide, often diagnosed at late stages due to the limited sensitivity and specificity of current surveillance methods such as ultrasound and alpha-fetoprotein (AFP) testing. Liquid biopsy, which non-invasively analyzes circulating biomarkers, offers a promising alternative (Fig 1). However, single-omics approaches often lack the robustness required for early detection. Multi-omics integration presents a transformative strategy to enhance diagnostic accuracy and enable precision oncology in HCC.

Materials and Methods:

This review synthesizes recent advances in multi-omics liquid biopsy for HCC, incorporating genomic (e.g., TERT, TP53 mutations), epigenomic (e.g., RASSF1A methylation), proteomic/glycomic (e.g., AFP-L3, GP73, exosomal glycans), fragmentomic (cfDNA fragmentation patterns), and cellular biomarkers (CTCs, EVs) (Fig 2). Cross-omics integration strategies—such as cSMART, HIFI, and ASDAm-H1—were evaluated alongside emerging technologies including nanopore sequencing, SERS-based single-exosome analysis, and machine learning models (e.g., XAI, GNNs, Bayesian Networks) (Fig 3).

Results:

The integration of multi-omics biomarkers has demonstrated transformative diagnostic performance for early HCC (Table 1). Cross-omics models consistently outperformed single-modality approaches:

E-POSTER ABSTRACTS

combined genomic-epigenomic assays achieved sensitivities of 80–90% for early-stage detection, while the fragmentomic-epigenomic HIFI model distinguished HCC from cirrhosis with exceptional accuracy (AUC 0.996, sensitivity 95.42%, specificity 97.83%). Integrated protein-epigenetic panels, such as the ASDAm-H1 index, reached an AUC of 0.96, and longitudinal application of multi-parametric scores like GALAD significantly improved sensitivity to 69.2% for early HCC compared to single measurements (53.8%). Fragmentomics-based models enabled early screening with sensitivities exceeding 96%, and metabolomic panels detected preclinical HCC up to one year before clinical diagnosis with 80% sensitivity. Beyond detection, multi-omics liquid biopsy proved vital for precision management: ctDNA mutation profiling enabled dynamic monitoring of targeted therapy response, PD-L1⁺ CTCs and cfDNA copy number variations predicted outcomes to immune checkpoint inhibitors, and machine learning-driven deconvolution of single-exosome SERS fingerprints or cfDNA methylation data provided unprecedented molecular resolution. These approaches not only identified AFP-negative HCC cases but also facilitated early recurrence prediction and molecular subtyping, effectively transitioning liquid biopsy from a passive detection tool to an active component in the dynamic, personalized management of HCC.

Conclusions:

Multi-omics liquid biopsy represents a paradigm shift in HCC management, enabling high-accuracy early detection and dynamic monitoring of disease progression and treatment response. Despite challenges in data integration, standardization, and clinical validation, future directions—including explainable AI, single-cell multi-omics, and closed-loop precision oncology systems—hold great promise (Fig 4). With continued interdisciplinary collaboration and standardization efforts, multi-omics liquid biopsy is poised to become the cornerstone of next-generation HCC care.

2013 - Projected health and economic impact of physical activity on metabolic dysfunction associated steatotic liver disease in Saudi Arabia A

Markov modeling study

Carolyn Wallace ¹, Saleh Alessy ², Saad Alghamdi ³, Abdulrahman Alkabbani ⁴, Alwaleed Almojel ², Tagreed A Mazi ⁵, Waleed K Al-hamoudi ⁶, Brandon Eurich ¹, Homie Razavi ¹, Saleh A Alqahtani ⁷
Center Of Disease Analysis Foundation, Epidemiology, Riyadh-Saudi Arabia ¹ King Faisal Specialist Hospital And Research Center, Liver, Digestive, And Lifestyle Health Research Section, And And Biostatistics, Epidemiology, And Scientific Computing Department, Riyadh-Saudi Arabia ² King Faisal Specialist Hospital And Research Center, Organ Transplant Center Of Excellence, Riyadh-Saudi Arabia ³ King Faisal Specialist Hospital And Research Center, Endocrinology, Riyadh-Saudi Arabia ⁴ King Saud University, Community Health Sciences – Clinical Nutrition, Riyadh-Saudi Arabia ⁵ King Faisal Specialist Hospital And Research Center, Organ Transplant Centre Of Excellence, Riyadh-Saudi Arabia ⁶ King Faisal Specialist Hospital And Research Center, Liver, Digestive, And Lifestyle Health Research Section, And Organ Transplant Centre Of Excellence, Riyadh-Saudi Arabia ⁷

Background:

Inadequate physical activity (PA) remains a global health concern, linked to various chronic conditions, including metabolic dysfunction-associated steatotic liver disease (MASLD). In Saudi Arabia, MASLD affects over 30% of the population. Increasing PA has been shown to reduce hepatic fat and improve liver outcomes. This study aimed to project the future health and economic burden of MASLD under varying PA scenarios in Saudi Arabia.

Methods:

A Markov model was used to simulate disease progression from 2025 to 2045, stratified by age and gender. The model incorporated MASLD prevalence, natural history, and mortality, and was validated using national datasets from the Ministry of Health and General Authority for Statistics, including data on hepatocellular carcinoma (HCC). Three intervention scenarios were modeled to assess the impact of PA on MASLD, assuming 10%, 20%, and 30% of individuals with MASLD achieved a 30% relative reduction in hepatic fat, based on clinical trial evidence associated with histological improvement. Health and economic impacts were analyzed using U.S.-based cost data, adjusted for medical inflation, and expressed in disability-adjusted life years (DALYs). Economic inputs were held constant across scenarios to ensure consistency and isolate the effect of PA on the economic burden of MASLD.

E-POSTER ABSTRACTS

Results:

In scenarios where 10%, 20%, and 30% of individuals with MASLD achieved a 30% hepatic fat reduction, cumulative liver-related deaths declined by 4.0%, 7.9%, and 11.6%, respectively. Cumulative HCC cases were reduced by 4.7%, 9.3%, and 13.5%. Decompensated cirrhosis cases dropped by up to 13.3%, and total MASLD prevalence declined by approximately 4.6% in the highest scenario. A 30% PA scenario could prevent over 27,800 liver-related deaths and 5,300 HCC cases by 2045. Direct healthcare costs averted by 3.8%, 7.5%, and 11.1% across the scenarios, and DALYs averted ranged from 8.3% to 23.6%.

Conclusions:

Inadequate PA contributes to the increasing burden of MASLD in Saudi Arabia. Promoting PA can significantly reduce the health and economic impacts. The impact of MASLD should be included in national PA promotion campaigns and non-communicable disease advocacy efforts. These findings support the implementation of national PA promotion strategies under Saudi Vision 2030. While the model is based on Saudi data, the framework and findings may be applicable to other countries with high MASLD prevalence and inadequate PA.

Keyword(s) : MASLD, Physical Activity, Metabolic Dysfunction-associated Steatotic Liver Disease, Saudi Arabia, Economic Impact

2014 - Longitudinal Changes in Non Invasive Fibrosis Markers and Risk Factors for Fibrosis Progression in People with HIV and Metabolic Dysfunction Associated Steatotic Liver Disease

Wei Xu ¹, Li Liu ¹, Meiyun Sun ¹, Jiangrong Wang ¹, Wei Song ¹, Yang Tang ¹, Tangkai Qi ¹, Youming Chen ¹, Jia Tang ¹, Zhenyan Wang ¹, Renfang Zhang ¹, Jun Chen ¹, Yinzhong Shen ¹

Shanghai Public Health Clinical Center, Department Of Infection And Immunity, Shanghai-China ¹

Background / Hypothesis:

Longitudinal monitoring with the fibrosis-4 index (FIB-4) is valuable for tracking fibrosis progression and predicting outcomes in metabolic dysfunction-associated steatotic liver disease (MASLD). This study aimed to evaluate dynamic changes in FIB-4 and metabolic parameters in PWH during antiretroviral therapy and to identify risk factors for liver fibrosis progression (LFP).

Materials and Methods:

MASLD was diagnosed after excluding excessive alcohol consumption and other known causes of liver disease, based on the presence of hepatic steatosis along with at least one cardiometabolic risk factor. LFP was defined based on serial FIB-4 measurements. Participants were stratified by baseline FIB-4: those with a low level (<1.3) were considered to have progression if their FIB-4 increased by $\geq 20\%$ and reached ≥ 1.3 ; those with a high level (≥ 1.3) were considered to have progression with a $\geq 20\%$ increase. Metabolic parameters, including body weight, blood glucose, and lipid profiles, were assessed at baseline and the end of follow-up.

Results:

From March 25, 2024, to December 10, 2024, 2,003 people with HIV (PWH) were screened. After exclusions, 683 with MASLD were enrolled. After a median follow-up of one year, 28 (4.1%) participants were lost to follow-up. Among the remaining 655 participants, 59 (9.0%) exhibited fibrosis progression, and 596 (91.0%) remained stable. In multivariable logistic regression, both baseline age (OR = 1.10; 95% CI: 1.06–1.14; $P < 0.001$) and weight gain (OR = 1.29; 95% CI: 1.21–1.38; $P < 0.001$) were independently associated with LFP. Transition to obesity was also independently associated with LFP (OR = 6.56; 95% CI: 2.95–14.56; $P < 0.001$).

Conclusions: Liver fibrosis progression occurs in a non-negligible proportion of PWH with MASLD, even within a relatively short period. Weight gain and transition to obesity are significant risk factors for LFP in this population.

2016 - Comparing Protein Induced by Vitamin K Absence II and Alpha Fetoprotein in Hepatocellular Carcinoma Clinical and Tumor Related Correlations in a Filipino Cohort

Matthew Joseph Po¹, Jenny Limquiaco¹, Jan Catherine Carrera¹, Aaron Lemuel Ong¹
Chong Hua Hospital, Internal Medicine - Gastroenterology, Cebu City-Philippines¹

Background / Hypothesis:

AFP is the most widely used serum biomarker for HCC with increased levels linked to early recurrence, advanced stage, and unfavorable prognosis. PIVKA-II, a newer biomarker, has been shown to be more sensitive in detecting HCC. Some studies show that PIVKA-II levels also correlate with tumor size and Barcelona Clinic Liver Cancer (BCLC) Stage. This study aims to determine how these biomarkers correlate with the clinicopathologic features of HCC.

Materials and Methods:

This cross-sectional study reviewed records of adult HCC patients in a tertiary hospital. PIVKA-II and AFP levels, demographics, liver function tests, tumor characteristics, presence of portal vein thrombosis and metastases were recorded. Comparative analyses used the Kruskal-Wallis test and Dunn's post hoc comparisons. Receiver Operating Characteristic (ROC) analyses were conducted to assess the diagnostic performance of AFP and PIVKA-II as markers for portal vein thrombosis (PVT), lymphatic, and distant metastasis.

Results:

Among the 92 patients in this study, viral hepatitis-related HCC had significantly higher AFP ($p = 0.010$), not observed with PIVKA-II ($p = 0.071$). Increased levels of both biomarkers correlated with increased tumor size ($p = 0.009$ for AFP, $p = 0.002$ for PIVKA-II) and increased tumor number ($p = 0.010$ for AFP, $p < 0.001$ for PIVKA-II). Both biomarkers rose with advancing BCLC stages ($p = 0.010$ for AFP and $p = 0.002$ for PIVKA-II). The areas under the ROC curve (AUC) of lymph node metastasis in HCC were 0.711 (95% CI, 0.596-0.826, $p < 0.001$) for PIVKA-II, and 0.622 (95% CI 0.622-0.066, $p = 0.063$) for AFP, underscoring PIVKA-II as a superior predictor for lymph node metastasis. At a threshold of 2,960.50 mAU/mL, PIVKA-II showed 72% sensitivity for detecting lymph node metastasis, with a negative predictive value of 86% at lower levels. Neither biomarker showed strong predictive power for PVT or distant metastasis.

Conclusions:

AFP and PIVKA-II correlate with tumor burden and advanced HCC stages. Elevated PIVKA-II levels showed moderate predictive power for lymph node metastasis

2017 - The Cost Changes in Hepatitis C Patients Before and After the Introduction of Direct Acting Antivirals in Korea

Hwa Young Choi¹, Moran Ki¹

National Cancer Center, Public Health & Ai, Goyang-si-South Korea¹

Background / Hypothesis:

This study evaluates the economic impact of this treatment paradigm shift by analyzing changes in patient population and healthcare costs before and after Direct-Acting Antivirals (DAAs) introduction in Korea.

Materials and Methods:

Total costs were calculated by summing direct and indirect costs. Direct costs included medical costs and non-medical costs (time, transportation, and caregiving expenses). Indirect costs included productivity losses due to premature mortality from HCV-related liver disease, estimated using data from the Korean Statistical Information Service. Direct costs for acute and chronic HCV patients were analyzed using National Health Insurance Service data from 2012 to 2023. The prevalence method was employed for cost calculation. All costs were converted to US dollars (USD, \$1=1,388 KRW).

Results:

Over the 12-year period, 167,534 HCV patients were identified. Total costs rose from \$146 million (2012) to a peak of \$224 million (2016) after DAA introduction, then decreased by 51.8% to \$108 million by 2023. Per-patient costs peaked at \$4,425 in 2016 and declined to \$3,401 by 2020, but increased again to \$3,649 by 2023. Healthcare costs surged from \$31 million to \$120 million in 2016 with DAA introduction, but declined dramatically to \$35 million by 2023, while premature mortality costs decreased consistently from \$96 million to \$66 million over the study period.

Medication costs dominated healthcare expenditure, peaking at \$102.3 million in 2016 with DAA introduction but declining to \$26.8 million by 2023. Injection costs plummeted by 98% from \$12.0 million (2012) to \$0.2 million (2023), reflecting the shift from

interferon-based to DAA therapy. The introduction of pan-genotypic DAAs in 2018 further reduced diagnostic burden, with HCV RNA testing proportion dropping from 27.8% (2012) to 7.6% (2018) of laboratory costs.

During the 12-year period, 64,926 patients received antiviral treatment, with total medication costs of \$494.04 million. Treatment paradigm shifted dramatically from peginterferon-based therapy (\$12.69 million in 2012) to DAA (\$97.49 million in 2016), with peginterferon use virtually eliminated by 2018. DAA costs peaked in 2016 and subsequently declined by 75% to \$24.75 million by 2023.

Conclusions:

Over the 12-year study period spanning pre- and post-DAA eras, Korea experienced initial cost increases with DAA introduction in 2016, followed by continuous declines in both HCV patient numbers and healthcare costs. This likely stems from reduced drug prices, pan-genotypic treatment availability, and improved treatment efficiency. These findings suggest innovative treatments can reduce long-term disease burden, providing evidence for future infectious disease policy development.

2020 - FOXK1 aggravates acute liver failure through HIF 1 α mediated histone lactylation at H4K16

Chengcheng Li¹, Hong Li²

Guizhou Medical University, Infectious Diseases Department, Guiyang-China¹ Guizhou Provincial People's Hospital, Infectious Diseases Department, Guiyang-China²

Background / Hypothesis: Acute liver failure (ALF) is a severe clinical syndrome characterized by rapid onset, rapid progression, and poor prognosis. Recent studies have highlighted the role of epigenetic modifications in the pathogenesis of ALF, particularly histone lactylation, a novel post-translational modification involved in inflammation and metabolic disorders. FOXK1, a transcription factor implicated in hepatic metabolism and stress response, has not been fully explored in the context of histone lactylation and ALF. This study aimed to investigate whether FOXK1 aggravates ALF by promoting H4K16 histone lactylation through the HIF-1 α signaling pathway.

Materials and Methods: An LPS/D-GalN-induced mouse model of ALF was established. FOXK1 expression was knocked down using adenoviral vectors. Serum

E-POSTER ABSTRACTS

biochemical indices (ALT, AST) and lactate levels were measured. Liver pathology was assessed by H&E staining. Immunohistochemistry and Western blot were used to detect HIF-1 α and H4K16la expression. Chromatin immunoprecipitation (ChIP) was performed to analyze the interaction between FOXK1 and HIF-1 α . Results: In ALF mice, FOXK1 expression was significantly upregulated, accompanied by elevated levels of HIF-1 α and H4K16la. Knockdown of FOXK1 markedly attenuated liver injury, reduced serum ALT/AST and lactate levels. Mechanistic studies revealed that FOXK1 enhanced the stability and transcriptional activity of HIF-1 α , thereby promoting the expression of enzymes involved in lactate metabolism and driving H4K16 histone lactylation. Conclusions: This study reveals for the first time that FOXK1 aggravates acute liver failure by activating the HIF-1 α pathway and inducing H4K16 histone lactylation. The FOXK1-HIF-1 α -H4K16la axis may represent a potential therapeutic target for ALF intervention.

2021 - Sex related differences in clinical and immunologic phenotype of male primary biliary cholangitis a retrospective cohort study

Xia Liu¹, Xiao Lin², Xue Yang², Wen Gao², Chunyang Huang², Bin Xu²

Yuncheng Yanhu People's Hospital, 1 department Of Gastroenterology, Yuncheng-China¹ Beijing Youan Hospital, Liver Disease Center, Beijing-China²

Background / Hypothesis:

Primary biliary cholangitis is a chronic autoimmune cholestatic liver disease that predominantly affects women. However, the specific clinical and immunologic features of male disease and potential sex-related differences in phenotype remain incompletely defined.

Materials and Methods:

We conducted a retrospective cohort study of adults with primary biliary cholangitis at Beijing Youan Hospital, Capital Medical University. Clinical data, liver biochemistry, immunoglobulins, autoantibodies, and indices of disease severity were collected at diagnosis. The albumin-bilirubin score and imaging-based assessment were used to evaluate cirrhosis and portal hypertension. Patients were stratified by sex, and between-group comparisons were performed using independent-samples t tests or chi-square tests.

Results:

A total of 964 patients were included, of whom 114 were men and 850 were women. Men accounted for 11.8% of all cases and were older at diagnosis than women (59.55 vs 56.06 years, $P < 0.01$). Men had higher gamma-glutamyltransferase levels (402.07 vs 238.49 units per liter, $P < 0.001$), whereas other liver tests, immunoglobulins, blood counts, and prothrombin time were similar between sexes. Male patients showed a distinct autoantibody pattern, with a lower prevalence of anticentromere antibodies (14.0% vs 27.5%, $P = 0.002$) but a higher prevalence of anti-gp210 antibodies (46.5% vs 33.3%, $P = 0.005$); antimitochondrial and anti-sp100 antibody positivity rates were comparable (95.6% vs 92.4%, $P = 0.208$; 13.2% vs 10.7%, $P = 0.432$, respectively). The prevalence of cirrhosis, portal hypertension, and esophageal varices did not differ between men and women.

Conclusions:

In this large real-world cohort, male primary biliary cholangitis was characterized by later age at diagnosis, more pronounced cholestasis, and an autoantibody profile with higher anti-gp210 and lower anticentromere antibody positivity, while advanced disease manifestations were similar between sexes. These sex-related differences may reflect divergent disease biology and support consideration of male-specific serologic and cholestatic features when tailoring risk assessment and clinical management.

2022 - Xiaozhi Huaxian Formula Ameliorates Type 2 Diabetes Associated Metabolic Dysfunction Associated Steatohepatitis via the Gut Derived Acetate-Hepatic GPR43 Axis

Xin Wang¹, Wei Wei², Ying Su¹, Yan Su¹, Feng-xiang Fang¹, Ya-juan Geng², Ning Yao^{* 2}

Gansu University Of Chinese Medicine, College Of Integrated Traditional Chinese And Western Medicine, Lanzhou City-China¹ Gansu University Of Chinese Medicine, First School Of Clinical Medicine, Lanzhou City-China²

Background/Hypothesis:

The global increase in the incidence of type 2 diabetes

E-POSTER ABSTRACTS

mellitus-associated metabolic dysfunction-associated steatohepatitis (T2DM-associated MASH) poses a significant clinical challenge, as affected patients are at heightened risk for progressive liver injury, including fibrosis, cirrhosis, and hepatocellular carcinoma. The pathogenesis of T2DM-associated MASH is characterized by a complex interplay of metabolic dysregulation and aberrant immune activation. Xiaozhi Huaxian Formula (XHF), a patented Chinese herbal formulation based on a modified classical prescription (Patent No. ZL202310099104.1), has shown promising efficacy in alleviating T2DM-associated MASH in clinical observations. However, the precise molecular mechanisms underlying its hepatoprotective effects remain incompletely understood. Growing evidence underscores the critical role of the gut microbial metabolites in the pathogenesis of metabolic disorders. Therefore, this study aims to elucidate the therapeutic mechanism of XHF from the perspective of gut microbiota-immune system interactions.

Methods:

Male C57BL/6J pups at two days of age received a single subcutaneous injection of streptozotocin (200 µg/20 µL per mouse). Following weaning at 4 weeks, the mice were maintained on a high-fat diet until the end of week 9 to establish a T2DM-associated MASH model. For the in vivo arm of the study, mice were administered the XHF decoction via oral gavage daily for four consecutive weeks, beginning at week 5. Concurrently, hepatocytes were isolated from mice to analyze the mRNA expressions of GPR43, and liver tissue homogenate were prepared to examine pro-inflammatory cytokines levels. Following, hepatocytes were isolated from T2DM-associated MASH mice and subjected to in vitro treatment with 10% XHF-containing serum derived from XHF-fed healthy male C57BL/6J mice for subsequent cellular-level analyses.

Results:

Relative to normal controls, T2DM associated MASH mice exhibited a significant reduction in plasma acetate levels within the portal vein and in hepatocyte GPR43 mRNA expression, alongside a marked elevation of IL 6 and TNF α levels in liver tissue homogenates. XHF treatment dose-dependently ameliorated both gut microbial dysmetabolism and hepatic immune dysregulation in T2DM-associated MASH mice (all $p < 0.005$, respectively). In vitro, treatment with XHF containing serum significantly up regulated GPR43 mRNA expression in primary

hepatocytes from T2DM associated MASH mice compared with control serum, and concurrently suppressed acetate induced secretion of IL 6 and TNF α (all $p < 0.001$, respectively).

Conclusions:

XHF conferred protection against T2DM-associated MASH by enhancing the production of the anti-inflammatory gut microbial metabolite acetate and upregulating hepatic GPR43 signaling, thereby suppressing the production of pro-inflammatory cytokines in the liver.

2024 - Coronary heart disease is an independent risk factor for liver fibrosis progression in patients with MAFLD

Yuging Zhao¹, Xinyu Zhao², Weiping Li³, Ying Wang¹, Jinjin Liu¹, Jingjie Zhao⁴, Hong You¹
Beijing Friendship Hospital, Capital Medical University, Liver Research Center, Beijing-China¹ Beijing Clinical Research Institute, Clinical Epidemiology & EBM Unit, Beijing-China² Beijing Friendship Hospital, Capital Medical University, Department Of Cardiology, Cardiovascular Center, Beijing-China³ Capital Medical University, Clinical Center For Metabolic Associated Fatty Liver Disease, Beijing-China⁴

Background / Hypothesis: Coronary Heart Disease (CHD) and metabolic dysfunction-associated fatty liver disease (MAFLD) share lots of overlapping pathogenic mechanisms, and the population with both MAFLD and CHD is quite large. However, there are few clinical data on whether CHD is an independent risk factor for the progression of liver fibrosis in patients with MAFLD.

Materials and Methods: We retrospectively analyzed 270 MAFLD patients with CHD diagnosed by coronary angiography and 854 MAFLD patients undergoing health check-up in Beijing Friendship Hospital, Capital Medical University (Beijing, China). Propensity score matching (PSM) were employed to mitigate confounding effects, including age, gender, BMI and diabetes. Multivariate logistic regression analyses were used to examine the association between CHD and the

E-POSTER ABSTRACTS

progression of liver fibrosis (defined as FIB-4 increased by $\geq 30\%$) after a 2-year follow-up. Sensitivity analysis were conducted to test the robustness of the results.

Results:After PSM, among the 348 included patients with MAFLD, 174 cases (50%) were complicated with CHD, who had a median age of 53 years, a median BMI of 26.9 kg/m², and 86.2% were male. The number of cases with progression of liver fibrosis after a 2-year follow-up was 56 (32.2%) and 19 (10.9%) in the MAFLD with CHD group and the MAFLD group respectively. Multivariate logistic regression analysis revealed that after adjusting for age, gender, BMI, hypertension, diabetes, TG, HDL, AST and baseline FIB-4, CHD was a significant risk factor for the progression of liver fibrosis (OR = 3.43, 95% CI: 1.66 - 7.09). In sensitivity analysis, the endpoint was defined as FIB-4 increasing by $\geq$ one grade (FIB-4 was classified into three grades based on 1.3 and 2.67) after 2-year follow-up and the association remained significant after adjusting for confounding factors (OR = 2.42, 95% CI: 1.06 - 5.54).

Conclusions:In a retrospective cohort study of patients with MAFLD, CHD was a strong independent risk factor for the progression of liver fibrosis, indicating that prevention and treatment of CHD may reduce the risk of liver fibrosis.

Keyword(s) : MAFLD, CHD, liver fibrosis

2025 - Targeting the Gut Liver Axis Novel Strategies for Liver Cirrhosis Intervention

Fan'e Cheng¹, Wenying Qi²

Beijing University Of Chinese Med, Dongzhimen Hospital, Beijing-China¹ Beijing University Of Chinese Medicine, Dongzhimen Hospital, Beijing-China²

Background / Hypothesis:Liver cirrhosis is a chronic disease characterized by fibrosis and structural damage, primarily caused by hepatitis B and alcohol in China. Current treatments are limited to symptom management. Recent gut-liver axis research offers new therapeutic insights.

Materials and Methods: This research involved systematically searching and reviewing relevant literature from databases including Web of Science, PubMed, and Google Scholar, integrating theoretical analysis with cutting-edge empirical studies. It first elucidates the core components (including gut microbiota, intestinal barrier, bile acid metabolism; and

immune crosstalk) and functions of the gut-liver axis. It then focuses on discussing how gut-liver axis disruption drives the inflammatory and fibrotic processes in cirrhosis through core pathways such as "gut microbiota dysbiosis - intestinal barrier damage - endotoxemia." Finally, it systematically summarizes the efficacy and molecular mechanisms of intervention strategies targeting the gut-liver axis (e.g., probiotics, fecal microbiota transplantation, bile acid receptor agonists) as demonstrated in preclinical and clinical studies.

Results:Analysis indicates that the gut-liver axis is a highly promising new target for the prevention and treatment of liver cirrhosis. Specifically:**Mechanistic Level:** Patients with liver cirrhosis exhibit significant gut microbiota dysbiosis and increased intestinal permeability. This leads to the translocation of gut bacteria and their metabolites to the liver via the portal vein, activating hepatic immune cells and triggering/sustaining chronic inflammation and hepatic stellate cell activation through signaling pathways such as TLR4, thereby exacerbating liver fibrosis.

Intervention Level: Strategies targeting the regulation of the gut-liver axis have been proven effective in ameliorating the progression of cirrhosis.

Conclusion : Targeting the gut-liver axis presents a promising therapeutic strategy for cirrhosis, warranting further mechanistic and clinical investigation.

Keyword(s) : Gut-liver axis; Liver cirrhosis; Gut microbiota; Microbiota-host interactions; Intestinal barrier; Pathogenesis.

2026 - A Bibliometric Analysis of Medicinal Food in Chronic Liver Disease Research

Fan'e Cheng¹, Wenying Qi²

Beijing University Of Chinese Med, Dongzhimen Hospital, Beijing-China¹ Beijing University Of Chinese Medicine, Dongzhimen Hospital, Beijing-China²

Background / Hypothesis:Chronic liver disease (CLD) has a high global prevalence, and existing treatment options have limitations. Medicinal food, a key concept in traditional Chinese medicine (TCM), has demonstrated great potential in the prevention and management of CLD due to its safety profile and multi-target advantages. Consequently, related research is rapidly expanding. However, the current research landscape in this field is complex and fragmented, lacking a systematic review from a macro perspective. Therefore, this study employs bibliometric methods to visually analyze the research hotspots and development trends in this field, aiming to provide

E-POSTER ABSTRACTS

direction for future investigations.

Materials and Methods:Based on bibliometric methods, we systematically retrieved relevant research literature on medicinal food and CLD from the Web of Science Core Collection database (covering the period from January 1, 2005, to November 29, 2025). Using visualization software such as CiteSpace and VOSviewer, we conducted quantitative statistics and visual mapping analysis on annual publication volume, country/institutional collaboration networks, author co-occurrence, keyword co-occurrence, keyword clustering, and burst detection.

Results:A total of 832 publications were included. The analysis results show:The annual publication volume in this field shows a rapid growth trend, particularly over the past decade, indicating strong research vitality.China holds an absolute dominant position in this field, but international collaboration remains limited. Several core research teams have formed, yet inter-institutional collaboration networks need strengthening.Keyword cluster analysis revealed four core knowledge groups: 1) pharmacological mechanism research on specific herbs (e.g., Bupleurum, Salvia miltiorrhiza, Glycyrrhiza) and their active components (e.g., glycyrrhizic acid, curcumin); 2) the prevention and treatment of non-alcoholic fatty liver disease (NAFLD) as the current absolute focus; 3) molecular mechanisms such as "oxidative stress, insulin resistance, apoptosis" being core pathways for in-depth exploration; and 4) "hepatoprotective effects, safety, clinical efficacy" as common themes spanning basic to clinical research.Burst detection of keywords indicates that the research frontier is dynamically shifting from traditional "anti-hepatic fibrosis" towards emerging interdisciplinary fields such as "gut microbiota," "immunomodulation," "network pharmacology," and "multi-omics integration."

Conclusions: This study visually elucidates the research panorama of medicinal food in the CLD field through knowledge mapping. Current research hotspots focus on the modern pharmacological interpretation of core herbs, while future trends will place greater emphasis on holistic mechanism exploration based on systems biology concepts and the translation of high-quality clinical evidence. This field holds broad prospects for development.

Background / Hypothesis:

İrritabl bağırsak sendromu (İBS) toplumda sık görülen bir hastalıktır. Bu çalışmada reprodüktif dönemdeki kadın İBS hastalarının yaşam kalitesi, İBS olmayan sağlıklı kontrollerle karşılaştırılması amaçlanmıştır.

Materials and Methods:

Çalışmaya Roma IV kriterlerine göre İBS tanısı alan 18-55 yaş arası ardışık 50 kadın hasta ve benzer demografik özelliklere sahip malign ve kronik bir hastalığı, İBS'si olmayan 50 sağlıklı kontrol alınmıştır. Her iki grubun demografik verileri, sağlık anksiyete ölçeği, BECK anksiyete ölçeği, yaşam kalite ölçeği anketleri doldurulmuş ve gruplar karşılaştırılmıştır.

Results:

İBS tanısı alan 50 hastanın yaş ortalaması 34.84 ± 11.44 (yaş dağılımı 18-54), kontrol grubun yaş ortalaması 28.18 ± 9.39 (dağılım18-53) idi. Her iki grubun demografik özellikleri benzer idi. İBS hastalarının 9'unda (%18) psikiyatrik hastalık vardı, kontrol grubunda 4 (%8) ($p<0.05$). İBS hastalarının 11'i (%22) sigara içiyordu, kontrol grubunda 6 (%12) ($p<0.05$). İBS hastalarında kontrol grubuna göre sağlık anksiyete ortalaması benzerken, BECK anksiyete ölçeği ve İBS yaşam kalite ölçeği kontrol grubuna göre anlamlı yüksek bulunmuştur (35.44 ± 8.8 vs 33.36 ± 8.8 $p>0.05$, 25.06 ± 9.4 vs 13.26 ± 10.8 $p<0.05$, 98.3 ± 22.3 vs 37.8 ± 6.6 $p<0.05$).

Conclusions:

Reprodüktif dönemdeki İBS hastalarında benzer yaş ve

E-POSTER ABSTRACTS

demografik sağlıklı kontrol grubuna göre sağlık anksiyete ölçeği benzerken, BECK puanı yaklaşık iki kat, İBS yaşam kalite ölçeği puanı yaklaşık 3 kat yüksek çıkmıştır.

2031 - Global Burden and Trends of Primary Liver Cancer Attributable to Comorbid Type 2 Diabetes Mellitus Among People Living with NASH An Observational Trend Study from 1990 to 2021

Xinyu Zhao¹

Beijing University Of Chinese Medicine, Dongzhimen Hospital, Beijing-China¹

Background / Hypothesis:The synergistic interaction between non-alcoholic steatohepatitis (NASH) and type 2 diabetes mellitus (T2DM) is an emerging driver of hepatocellular carcinoma (HCC). However, a comprehensive global assessment of the liver cancer burden specifically attributable to this comorbidity is lacking. This study aimed to quantify the global burden and temporal trends of primary liver cancer due to NASH-T2DM comorbidity from 1990 to 2021.

Materials and Methods:Using Global Burden of Disease (GBD) 2021 data from 204 countries (1990-2021), we estimated liver cancer burden attributable to NASH-T2DM comorbidity. Population attributable fractions (PAFs) were calculated using Levin's formula. We analyzed age-standardized prevalence, disability-adjusted life years (DALYs), and mortality rates, stratified by region, sociodemographic index (SDI), sex, and age. Temporal trends were assessed using estimated annual percentage change (EAPC).

Results:In 2021, the global age-standardized prevalence and DALY rates were 13.6 (95% Uncertainty Interval [UI]: 2.2–36.4) and 257.1 (95% UI: 42.9–688.6) per 10,000,000 individuals, respectively. The highest burdens were observed in high-SDI regions, particularly High-income Asia Pacific and North America. The disease burden was approximately five-fold higher in individuals aged ≥60 years, and males exhibited a higher burden across most age groups. While EAPC point estimates were positive across all

regions, wide uncertainty intervals precluded statistical significance, indicating substantial uncertainty in temporal trends.

Conclusions:The comorbidity of NASH and T2DM represents a substantial and growing driver of the global liver cancer burden, disproportionately affecting high-income nations and older adults. The observed statistical uncertainty highlights critical gaps in global surveillance and diagnosis of metabolic-associated liver cancer. These findings highlight the need for integrated metabolic health strategies, region-specific prevention, and targeted surveillance for high-risk populations.

2032 - The Therapeutic Potential of Traditional Chinese Medicine in the Management of Chronic Hepatitis B

Fan'e Cheng¹, Wenying Qi²

Beijing University Of Chinese Med, Dongzhimen Hospital, Beijing-China¹ Beijing University Of Chinese Medicine, Dongzhimen Hospital, Beijing-China²

Background / Hypothesis:The pathogenesis of chronic hepatitis B (CHB) involves complex mechanisms, with hepatitis B virus-induced immune responses playing a central role in hepatocyte injury and inflammatory necrosis. This condition is not only a driver of liver pathology but also demonstrates significant associations with various extrahepatic manifestations, including depression, cognitive dysfunction, diabetes mellitus, insomnia, non-alcoholic fatty liver disease, and thrombocytopenia. Conventional antiviral therapy faces limitations such as low hepatitis B surface antigen clearance rates and frequent adverse drug reactions.

Materials and Methods:By reviewing and analyzing relevant studies on representative TCM formulations (e.g., Yinchenhao Decoction, Xiaochaihu Decoction, and Fuzheng Huayu Tablet), their modes of action were summarized. These involve multi-ingredient, multi-target approaches to modulate immune pathways and intervene in key stages of the HBV lifecycle. **Results:**TCM achieves a tripartite therapeutic synergy in CHB management, encompassing immune reconstitution, viral suppression, and hepatic repair. It demonstrates distinct immunomodulatory effects and

E-POSTER ABSTRACTS

therapeutic advantages.

Conclusions: Traditional Chinese Medicine holds significant value in the comprehensive management of chronic hepatitis B. Future research should employ modern technologies to further elucidate its mechanisms, facilitating the development of standardized and optimized treatment protocols with considerable potential for clinical translation.

Keyword(s) : Chronic Hepatitis B; Traditional Chinese Medicine; Immunomodulation; Multi-target Therapy; Integrated Chinese and Western Medicine

2033 - Risk stratification of chronic kidney disease using noninvasive tests in metabolic dysfunction associated steatotic liver disease

Chan-young Jung ¹, Hye Won Lee ², Jung Il Lee ³, Han Ah Lee ⁴, Seung Up Kim ², Beom Seok Kim ⁵
Asan Medical Center, Division Of Nephrology, Department Of Internal Medicine, Seoul-South Korea ¹

Chung Ang University Hospital, Division Of Gastroenterology, Department Of Internal Medicine, Seoul-South Korea ⁴
Severance Hospital, Division Of Nephrology, Department Of Internal Medicine, Seoul-South Korea ⁵

Background / Hypothesis: The association between metabolic dysfunction-associated steatotic liver disease (MASLD) and chronic kidney disease (CKD) is well known, yet data identifying high risk patients remain scarce. We investigated whether the European Association for the Study of the Liver (EASL)/ Korean Association for the Study of the Liver (KASL) and the American Gastroenterological Association (AGA) algorithms can stratify CKD risk in patients with MASLD.

Materials and Methods: This retrospective cohort study included 3,240 MASLD patients without pre-existing CKD who underwent vibration-controlled transient elastography between April 2006 and October 2018. The primary outcome was incident CKD, defined as estimated glomerular filtration rate (eGFR) <60 mL/min/1.73m² or proteinuria (≥1+ on dipstick) on two consecutive measurements. Secondary outcome included a 25% eGFR decline on two consecutive visits and 3- and 5-year CKD risk.

Results: The mean age was 51.7 years and 1,899

(58.6%) patients were male. During a mean follow-up of 3.3 years, 187 (5.8%) patients developed incident CKD. When stratified by EASL/KASL algorithms, multivariable Cox models revealed a 2.40-fold (95% confidence interval [CI], 1.57-3.66) higher risk of incident CKD in the high risk group compared to the low risk group. The high risk group also had a 2.16-fold higher risk (95% CI, 1.63-2.87) of a 25% eGFR decline (mean follow-up 4.3 years) and a 2.24-fold (95% CI, 1.29-3.91) higher 5-year CKD risk. Similar findings were observed for the AGA algorithm.

Conclusions: The two-step algorithms proposed by the EASL/KASL and AGA can effectively stratify CKD risk in patients with MASLD.

Yerevan Scientific Medical Center, Infection Diseases, Yerevan-Armenia ³
Yerevan State Medical University, Radiology, Yerevan-Armenia ⁴
Yerevan State Medical University, Histology, Yerevan-Armenia ⁵

Background / Hypothesis:

Oral cavity examinations in chronic diffuse liver diseases are of great interest to dentistry, since pathological processes developing in the liver usually lead to organic and functional disorders in the oral cavity. Every year, 30,000 healthcare workers worldwide become infected with HBV in their professional activities, one of whom dies. Stomatologists are a high-risk group for hepatitis B virus infection. The aim of this study was to describe the marginal gingiva in patients with HBV.

Materials and Methods:

The study included 95 patients with HBV, 24 (25.3%) women and 71 (74.7%) men. The mean age of patients was 40.17 ± 13.48 (mean±SD). In addition to examining the stomatological status, biopsies were

E-POSTER ABSTRACTS

taken from the marginal gingiva for pathological examination. The tissue samples were fixed in 10% neutral formalin, dehydrated, and embedded in paraffin according to standard histological procedures. A series of 5- μ m-thick sections were made from the blocks and stained with hematoxylin and eosin and picrofuchsin according to Van Gieson for a general assessment of the condition of the tissues being studied. The slides were examined using a Primostar Zeiss trinocular microscope at 100x and 400x, (immersion) magnification.

Results:

In the oral cavity, the primary site of pathological process was the alveolar gingiva—in 100% of patients. Inflammatory infiltration was lymphoplasmacytic in 95% (90) of patients ($p < 0.001$). Neutrophil admixture was observed in 40% (38) of patients ($p < 0.005$). Circulatory disorders were manifested by edema, hemorrhage. Changes in the squamous epithelium were in the form of acanthosis, parakeratosis and thickening (Fig. 1,2). The inflammatory infiltrate was primarily composed of lymphocytes, plasma cells, and segmented leukocytes ($p < 0.001$). This is a manifestation of both severe chronic inflammation and the involvement of immune mechanisms in the development of the pathological process.

Conclusions: Thus, numerous morphological signs in patients with HBV can be conditionally divided into those that are indicators of the severity and activity of inflammation and those associated with a long-term chronic course of inflammation of the alveolar part of the gum.

Keyword(s) : HBV, marginal gingiva, oral cavity, biopsies

2036 - Targeting T Cell Exhaustion in Chronic Hepatitis B Therapeutic Potential and Mechanisms of Traditional Chinese Medicine and natural products

Xinyu Zhao¹

Beijing University Of Chinese Medicine, Dongzhimen Hospital, Beijing-China¹

Background / Hypothesis: Hypothesis Chronic hepatitis B (CHB) remains a global health challenge, with functional cure rarely achieved by nucleos(t)ide analogues (NAs) due to the profound exhaustion of HBV-specific T cells. Unlike in oncology, single-target checkpoint blockade in CHB often fails due to the

compensatory redundancy of inhibitory networks and deep-seated epigenetic and metabolic barriers. We hypothesized that Traditional Chinese Medicine (TCM) and natural products, characterized by their multi-component and holistic regulatory properties, could offer a systems-level therapeutic strategy to synergistically dismantle these multifaceted exhaustion mechanisms and restore durable antiviral immunity.

Materials and Methods: This review systematically synthesizes mechanistic insights, preclinical experimental evidence, and clinical data to evaluate the therapeutic potential of TCM in ameliorating HBV-specific T cell exhaustion. We categorized and analyzed distinct bioactive phytochemicals (flavonoids, terpenoids, alkaloids, and polysaccharides) and compound formulas, focusing on their specific molecular interventions in antigen persistence, inhibitory receptor signaling, metabolic dysfunction (e.g., mitochondrial depolarization), and the immunosuppressive hepatic microenvironment.

Results: Pharmacological evidence demonstrates that active TCM components exert a "dual-action" effect: they directly suppress viral replication to lower the antigen load driving exhaustion and simultaneously remodel the intracellular metabolic and transcriptional landscapes of T cells to reverse functional paralysis. Specifically, agents like Astragalus polysaccharides and various Ginsenosides were found to enhance T-cell bioenergetics and downregulate inhibitory checkpoints (PD-1, TIM-3). Clinically, meta-analyses and randomized controlled trials indicate that integrating TCM with NAs significantly improves HBsAg clearance rates, promotes HBeAg seroconversion, and reduces off-therapy virological relapse compared to NA monotherapy, with a favorable safety profile.

Conclusions: TCM represents a vital mechanistic partner to conventional antivirals, capable of breaching the barriers of T-cell exhaustion that current therapies cannot address alone. To advance this from an alternative therapy to precision immunotherapy, future research must leverage multi-omics and deep phenotyping to rigorously map molecular targets and standardize "minimal effective sets" for global clinical

E-POSTER ABSTRACTS

application.

2037 - Assessment of hemoglobin A1c in hemodialysis patients with diabetes before and after erythropoietin treatment

Mohamed Abdelmegeed Ahmed¹, Amira K. El-alfy¹,
Fawzy Megahed Khalel¹, Mai Alsoudy Ali Baraka¹,
Ahmed Refaat Mohamed¹
Benha University, Internal Medicine Department,
Benha-Egypt¹

Background / Hypothesis:

Hemoglobin A1c (HbA1c) remains the most widely utilized laboratory marker for assessing long-term glycemic control. However, its reliability as a metabolic indicator in diabetic patients (DM) undergoing hemodialysis (HD) and receiving erythropoietin (EPO) therapy continues to be a subject of ongoing debate, primarily due to altered erythrocyte turnover characteristic of this patient population. Objectives were to assess EPO treatment effect on HbA1c levels and its reliability as a glycemic marker in diabetic patients undergoing regular HD.

Materials and Methods:

This prospective cohort study was carried out on 80 patients with renal disease undergoing regular HD, both prior to and following a three-month course of EPO therapy. Participants were stratified into two groups: Group I (n = 40) comprised EPO-naïve diabetic patients on regular HD, while Group II (n = 40) consisted of EPO-naïve nondiabetic patients receiving same treatment. All patients underwent clinical evaluation, comprehensive laboratory testing, and HbA1c assessment at baseline and after three months of EPO administration.

Results:

At baseline, Group I showed significantly higher HbA1c ($7.5 \pm 0.61\%$ vs. $4.4 \pm 0.68\%$, $P < 0.001$), fasting insulin, and HOMA-IR relative to Group II. After EPO therapy, HbA1c significantly declined in Group I (to $5.2 \pm 0.61\%$, $P < 0.001$) without significant changes in FBG. HbA1c demonstrated a significant moderate negative

correlation with Hb levels post-EPO in both groups ($r = -0.585$, $P < 0.001$, Group II).

Conclusions:

HbA1c proved to be an unreliable indicator of glycemic control in this patient population, as EPO therapy in diabetic individuals undergoing regular HD was associated with a notable reduction in HbA1c levels, despite the absence of a corresponding change in FBG and a lack of direct correlation between HbA1c and FBS.

Keyword(s) : HbA1c, EPO, Hemodialysis, Chronic kidney disease

2038 - Normal FIB 4 values do not exclude advanced fibrosis in Egyptian MASLD patients

Mohamed Abd Elmaged Ahmed¹, Abdel Ghani
Atef abdel Ghani Badran²

Benha University, Internal Medicine Department,
Benha-Egypt¹ Specialized Medical Center-damas Liver
Center, Git And Hepatology, Hepatology And
Gastroenterology, Mansoura-²

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is the leading cause of chronic liver disease worldwide. Early identification of individuals at risk of advanced fibrosis is essential to ensure timely referral to specialist care. Current guidelines recommend initial risk stratification using non-invasive fibrosis scores such as FIB-4 and/or the NAFLD Fibrosis Score, followed by transient elastography when indicated. This study aimed to evaluate the performance of low FIB-4 values in patients with MASLD compared with transient elastography and histology at baseline, and to document their long-term clinical outcomes.

Materials and Methods:

Consecutive patients diagnosed with MASLD between 2023 and 2025 were retrospectively reviewed. Clinical, anthropometric, and biochemical data, as well as outcomes at the end of follow-up, were collected. Clinical outcomes included mortality, cardiovascular events, extrahepatic malignancies, and liver-related outcomes (new cirrhosis, hepatocellular carcinoma, or hepatic decompensation defined as encephalopathy, variceal bleeding, or ascites). Baseline FIB-4 values were compared with liver stiffness measurements (LSM)

E-POSTER ABSTRACTS

obtained by FibroScan®, fibrosis stage on liver biopsy, and subsequent clinical events. Statistical analyses were performed using SPSS.

Results:

A total of 263 patients were included; 66% were male, the median age was 51 years, and the median BMI was 29.6 kg/m². One hundred forty-two patients (54%) had both a low FIB-4 score (<1.3) and normal LSM (<8 kPa), representing true negatives. Fifty-two patients (9%) had a low FIB-4 but elevated LSM (>8 kPa), constituting the false-negative group. Thirty patients with FIB-4 <1.3 underwent biopsy; notably, 15% had advanced fibrosis (stage ≥3). Among the false-negative cohort, 4 patients (7.7%) developed cirrhosis (median time 8 years), 4 (7.7%) experienced cardiovascular events (median 6.5 years), and 1 developed extrahepatic cancer. Hypertension was independently associated with false-negative FIB-4 results in multivariate analysis, regardless of whether LSM or biopsy fibrosis stage was used as the reference standard.

Conclusions: A substantial proportion of MASLD patients with low FIB-4 scores had undetected advanced fibrosis or elevated liver stiffness, highlighting a clinically vulnerable group that would be overlooked under current guideline-recommended pathways. These findings underscore the need to refine referral strategies and validate enhanced risk-stratification approaches in prospective studies.

Keyword(s) : MASLD; FIB-4, Fibrosis

2040 - Analysis of Clinical Characteristics in Patients with Early Stage Primary Biliary Cholangitis Complicated by Portal Hypertension

Hongxiao Hao¹, Xin Wei¹, Min Chang¹, Yao Lu¹, Lu Zhang¹, Yao Xie¹, Minghui Li¹

Beijing Ditan Hospital, Capital Medical University, Department Of Hepatology Division 2, Beijing-China¹

Background / Hypothesis:

Analyze the clinical characteristics of patients with primary biliary cholangitis complicated by portal hypertension in the early histological stage, and compare them with those of patients with primary biliary cholangitis complicated by portal hypertension in histological stage IV (cirrhosis stage).

Materials and Methods:

A retrospective study was conducted on patients diagnosed with PBC via liver biopsy at Beijing Ditan

Hospital, Capital Medical University, between April 1, 2020, and December 1, 2023. The study included 21 cases of histologically early-stage (stage I/II) PBC with clinical manifestations of portal hypertension and 14 cases of histologically stage IV PBC with portal hypertension. Clinical characteristics of the early-stage group were analyzed and compared with those of the stage IV group.

Results:

Liver elasticity measurement showed that 81% of patients had an LSM value <20 kPa, mainly concentrated in the range of 10 - 15 kPa (47.6%). In the group of patients with histological stage IV combined with portal hypertension, the disease course was longer (48 (18.5, 120) months vs 24 (10, 60) months), and the proportion of asymptomatic patients was lower (14.3% vs 38.1%), but the differences were not statistically significant. Compared to the early-stage group, stage IV patients had a longer disease duration (48 [18.5, 120] vs. 24 [10, 60] months) and fewer asymptomatic cases (14.3% vs. 38.1%), though these differences were not statistically significant. Stage IV patients were older (59.29 ± 10.33 vs. 49.62 ± 11.19 years, P < 0.05) and had lower white blood cell counts (P < 0.05). ALT, AST, TBIL, GGT, ALP, and TBA were higher in the stage IV group, while ALB, albumin/globulin ratio, and CHE were lower, though only AST and albumin/globulin ratio showed statistically significant differences. Lipid profiles and serum creatinine did not differ significantly between groups. Anti-gp210 antibody positivity was higher in the early-stage group (52.4% vs. 14.3%, P < 0.05). LSM values were significantly higher in the stage IV group (27.65 vs. 12, P < 0.05). Splenomegaly was more pronounced in the early-stage group, while varices and ascites were more common in the stage IV group, though these differences were not statistically significant.

Conclusion:

Diagnosing PBC with portal hypertension at an early histological stage remains challenging, and liver biopsy remains essential. However, age at onset, anti-gp210 positivity, LSM, AST levels, and albumin/globulin ratio may assist in distinguishing early-stage PBC with portal hypertension from cirrhotic PBC.

2042 - Prevalence and Risk Factors of Metabolic Dysfunction Associated Fatty Liver Disease in the Adult Georgian Population A Nationwide Multiregional Clinic Based Study

E-POSTER ABSTRACTS

Tatia Khachidze¹, Gocha Barbakadze²

Grigol Robakidze University, Gastroenterology, Tbilisi-Georgia¹ Tbilisi State Medical University, Gastroenterology, Tbilisi-Georgia²

Background / Hypothesis: In Georgia, the prevalence of MAFLD remains poorly defined, as evidence largely stems from small-scale hospital studies. This research used a nationwide multiregional clinic-based sample to estimate MAFLD prevalence and its associated factors.

Materials and Methods: A cross-sectional, clinic-based study was conducted on 11,269 adults attending check-up clinics across Georgia from 2021 to 2025. A stratified random sampling approach considering age, sex, BMI, comorbidities and region was used to derive a representative analytic sample (n = 5,602). MAFLD was diagnosed using ultrasound and international consensus positive diagnostic criteria.

Results: MAFLD affected 51.6% of Georgian adults, with higher prevalence in older age, men and individuals with obesity or metabolic comorbidities. Prevalence varied significantly across regions, with the highest in Tbilisi.

Conclusions: MAFLD is highly prevalent in Georgia. Due to the clinic-based nature of the sample, results should be interpreted with consideration of potential selection bias.

Keyword(s) : Metabolic dysfunction-associated fatty liver disease, MAFLD, prevalence, Georgia, obesity, diabetes, metabolic syndrome.

2043 - Effects of immunosuppressants on HAV replication in human hepatoma cell lines

Tatsuo Kanda¹, Reina Sasaki-tanaka², Hiroaki Okamoto³, Hiroyuki Abe², Akira Sakamaki², Takeshi Yokoo², Kazunao Hayashi², Hiroteru Kamimura², Kenya Kamimura⁴, Shuji Terai²

Jichi Medical University School Of Medicine, Division Of Virology, Department Of Infection And Immunity, Shimotsuke-shi-Japan³ Niigata University School Of Medicine,, Department Of General Medicine, Niigata-Japan⁴

Background / Hypothesis: Although hepatitis A breakthrough infections after hepatitis A vaccination are rare, breakthrough HAV infections may look more common in immunocompromised people. It is important for patients treated with immunosuppressants to develop anti-HAV. The effects of several immunosuppressants on HAV replication are investigated.

Materials and Methods: We examined the effects of azathioprine, cyclosporin or mycophenolic acid on HAV and HAV replicon replications in human hepatoma cell lines Huh7 and HuhT7, respectively. HAV HA11-1299 genotype IIIA or HAV HM175/18f genotype IB competent replicon and incompetent replicon were used in Huh7 and HuhT7 cells, respectively. HAV RNA levels were measured by real-time RT-PCR. HAV replicon replication was evaluated by reporter assays. HAV internal ribosomal entry site (IRES) activity was measured by reporter assay. Cytotoxicity was evaluated using MTS assay.

Results: (1) In Huh7 cells, 50 ng/mL and 250 ng/mL cyclosporin or 1 µg/mL and 10 µg/mL mycophenolic acid had no inhibitory effects on HAV replication without cytotoxicity. (2) In Huh7 cells, azathioprine had inhibitory effects on HAV replication significantly (0.6-FC (p < 0.05) and 0.4-FC (p < 0.05) at 0.5 µmol/mL and 1.0 µmol/mL, respectively). These concentrations of azathioprine had no cytotoxicity to Huh7 cells for 48 hrs. (3) In HuhT7 cells, 0.5 µmol/mL and 1.0 µmol/mL azathioprine, respectively, also had inhibitory effects on HAV competent replicon (68% (p < 0.01)). However, azathioprine had no effects on incompetent replicon replication. (4) Azathioprine had no inhibitory effects on HAV IRES activity at same concentrations.

Conclusion: Among immunocompromised hosts, severe or prolonged hepatitis A is occasionally observed. Azathioprine could inhibit HAV replication in vitro.

2044 - Spatiotemporal Changes in the Burden of Viral Hepatitis and the Influence of COVID 19 in China A 20 Year Analysis

Yuan-hai Zhou¹, Yu-hong Qin¹, Qiao Tang¹, Yong-lu Su¹, Peng Hu¹

E-POSTER ABSTRACTS

The Second Affiliated Hospital Of Chongqing Medical University, Department Of Infectious Diseases, Chongqing-China ¹

Background / Hypothesis: Viral hepatitis remains a critical public health challenge in China, characterized by complex spatiotemporal heterogeneity. The COVID-19 pandemic and associated non-pharmaceutical interventions (NPIs) significantly disrupted infectious disease transmission and reporting systems. This study aims to characterize the 20-year spatiotemporal trends of viral hepatitis in China and quantify the impact of the COVID-19 pandemic.

Materials and Methods: Data on the incidence and mortality of viral hepatitis (types A, B, C, and E) from 2004 to 2023 were sourced from the China Information System for Disease Control and Prevention. We employed Joinpoint regression to calculate Average Annual Percent Changes (AAPC). To quantify the pandemic's impact, we constructed a counterfactual inference framework. ARIMA and hybrid ARIMA-LSTM models were trained on pre-pandemic data (2004–2017) and validated using 2018–2019 data. The optimal model for each hepatitis subtype was selected based on Root Mean Square Error (RMSE) minimization to generate "expected" incidence rates for 2020–2023, which were then compared with observed surveillance data to assess relative and absolute rate differences.

Results: From 2004 to 2023, 25,527,158 cases and 17,261 deaths of viral hepatitis were reported. Geographically, the disease burden exhibited a persistent "West-to-East" gradient. High-incidence clusters of Hepatitis B and C were predominantly concentrated in the northwestern provinces of Xinjiang and Qinghai, as well as the southern region. Temporally, Hepatitis A declined significantly (AAPC = -10.5%). Conversely, Hepatitis C showed a concerning upward trend (AAPC = 7.5%), while Hepatitis B maintained a high-level stable epidemic (AAPC = -0.1%). The pandemic impact was heterogeneous. Enteric Hepatitis E experienced a sharp but temporary decline in 2020, with an incidence 32.88% lower than expected. Blood-borne Hepatitis C remained consistently suppressed throughout the pandemic (2020 RRD: -16.07%). Uniquely, Hepatitis B displayed a volatile trajectory: following an initial decline, it exhibited a significant post-pandemic rebound in 2023,

where the observed incidence (74.69 per 100,000) substantially exceeded the counterfactual expectation (70.41 per 100,000).

Conclusions: Although the burden of viral hepatitis has decreased, blood-borne hepatitis remains a severe challenge, particularly in western China. The COVID-19 pandemic exerted a complex inhibitory effect; however, the significant rebound of Hepatitis B in 2023 suggests a compensatory rise in case detection and the rapid recovery of healthcare services. Post-pandemic control strategies must prioritize resource allocation to high-risk western regions to mitigate the rising burden.

Keyword(s) : viral hepatitis; COVID-19; Spatiotemporal analysis

2046 - Clinical Characteristics and Outcomes for Hepatocellular Carcinoma with Extrahepatic Metastases

Wei Lun Tsai ¹, We-chih Sun ², Chia-ming Lu ³
Kaohsiung Veterans Hospital, Internal Medicine, Kaohsiung-Taiwan ¹ Kaohsiung Veterans General Hospital, Internal Medicine, Kaohsiung-Taiwan ² Kaohsiung Veterans General Hospital, Internal Medicine, Kaohsiung-Taiwan ³

Background / Hypothesis: Hepatocellular carcinoma (HCC) is a significant health concern in Taiwan, ranking fifth in incidence and second in cancer-related deaths. HCC with extrahepatic metastases (EHM) impacted overall survival and systemic therapies were recommended by several guidelines. The role of aggressive locoregional control for advanced-stage HCC with EHM remains controversial.

Materials and Methods:

An analysis of 4,161 HCC patients admitted to Kaohsiung Veterans General Hospital between 2005 and 2022 were performed and 552 patients with EHM at initial diagnosis were identified. Clinical characteristics and outcomes were analyzed.

Results: EHM was detected in 552 (13.3%) of patients. Metastases to lymph nodes in 266 (48.2%), lungs in 182 (33%), bones in 61 (11%), adrenal glands in 34 (6.2%), and other sites in 8 (1.4%) patients were found.

E-POSTER ABSTRACTS

Various treatments were administered, including locoregional, systemic, and combined locoregional and systemic treatments and palliative treatment. Multivariate analyses revealed alcohol use, tumor numbers more than 2, tumor size greater than 5 cm, and portal vein invasion as significant risk factors for developing EHM. Patients without EHM had a significant longer median survival than those with EHM (24 Vs. 3 months, $p < 0.001$). In HCC patients with EHM, tumor numbers more than 2, tumor size greater than 5 cm, and portal vein invasion were independent risk factors for survival. In patients with EHM who received systemic treatments had longer survival (6 Vs. 2 months, $P = 0.016$). In EHM patients who received systemic therapy, combined locoregional therapy demonstrated a significant survival benefit (8 Vs. 3 months, $p < 0.001$).

Conclusions:

This study disclosed the clinical features and prognostic factors of HCC with EHM. In EHM patients who received systemic therapy, combined locoregional therapy demonstrated a significant survival benefit

Keyword(s) : HEPATOCELLULAR CARCINOMA, METASTASIS, EXTRAHEPATIC

2048 - INVESTIGATION OF THE RELATIONSHIP BETWEEN SUBCUTANEOUS AND VISCERAL FAT TISSUE MEASUREMENTS AND NON INVASIVE FIBROSIS SCORES (FIB 4 APRI AAR) IN THE EVALUATION OF LIVER DAMAGE ASSOCIATED WITH CELIAC DISEASE

Abdullah Emre Ceylan ¹, Sedat Çiçek ², Mehmet Yalınız ², Ibrahim Halil Bahçecioğlu ²

Firat Üniversitesi, İç Hastalıkları, Elazığ-Türkiye ¹ Firat Üniversitesi, Gastroenteroloji, Elazığ-Türkiye ²

Background / Hypothesis: Celiac disease (CD) is a chronic autoimmune enteropathy that occurs in genetically predisposed individuals due to gluten consumption. CD can affect multiple extraintestinal systems, including the liver. Although elevated liver enzymes are common in CD, the diagnostic value of non-invasive fibrosis scores (FIB-4, APRI, AAR) in assessing liver damage in these patients is unclear. In this study, we aimed to more comprehensively evaluate CD-related liver involvement by examining the relationship between adipose tissue distribution (visceral and subcutaneous fat) and non-invasive fibrosis markers.

Materials and Methods: A retrospective analysis was conducted on 103 celiac patients and 51 healthy controls followed at Firat University Hospital. Celiac diagnosis was confirmed by serological testing and duodenal biopsy. Biochemical parameters, the presence of hepatosteatosis using abdominal CT and ultrasonography, and visceral and subcutaneous fat tissue measurements were examined in all subjects. Additionally, FIB-4, APRI, and AAR scores were calculated using standard formulas and their relationship to liver damage was analyzed. ROC analyses were performed to determine the severity of hepatosteatosis.

Results: AST and ALT levels were significantly higher in the CD group compared to the control group ($p < 0.001$). Glucose, triglyceride, LDL, HDL, vitamin D, and HbA1c values were significantly lower in the CD group ($p < 0.001-0.009$). FIB-4, APRI, and AAR showed inadequate diagnostic performance in determining the severity of hepatosteatosis in both groups (AUC not significant; $p > 0.05$). No significant correlation was found between VAD/SAD measurements and non-invasive fibrosis scores.

Conclusions: Our study demonstrates that elevated liver enzymes are frequently observed in celiac patients, independent of hepatosteatosis, and may be associated with immune-mediated celiac hepatitis. Low glucose, lipid, and vitamin D levels, along with decreased subcutaneous fat, were found to be consistent with active malabsorption. However, FIB-4, APRI, and AAR scores were insufficient to predict the severity of hepatosteatosis. These findings emphasize that non-invasive scores alone are not sufficient to assess liver involvement in celiac patients

Keyword(s) : Celiac disease, Hepatosteatosis, Visceral adipose tissue, Non-invasive fibrosis scores

2049 - Zinc acetate enhances glucose regulated protein 78 and anti HAV activity of ribavirin in vitro

Tatsuo Kanda ¹, Reina Sasaki-tanaka ², Hiroaki Okamoto ³, Hiroyuki Abe ², Akira Sakamaki ², Kazunao Hayashi ², Takeshi Yokoo ², Hiroteru Kamimura ², Kenya Kamimura ⁴, Shuji Terai ²

Uonuma Institute Of Community Medicine, Niigata University Medical And Dental Hospital, Division Of Gastroenterology And Hepatology, Minami-uonuma-Japan ¹ Graduate School Of Medical And Dental Sciences, Niigata University, Division Of Gastroenterology And Hepatology, Niigata-Japan ²

E-POSTER ABSTRACTS

Jichi Medical University School Of Medicine, Division Of Virology, Department Of Infection And Immunity, Shimotsuke-shi-Japan ³ Niigata University School Of Medicine,, Department Of General Medicine, Niigata-Japan ⁴

Background / Hypothesis: Hepatitis A virus (HAV) infection occasionally leads to acute liver failure or acute-on-chronic liver failure, which is often fatal, especially in patients with diabetes mellitus or elderly individuals. However, effective drugs for hepatitis A are currently unavailable. Glucose-regulated protein 78 (GRP78/BiP/HSPA5) is an antiviral agent that has been reported to prevent HAV replication. Zinc sulfate inhibits HAV replicon replication in the accompany with the enhancement of GRP78 expression. Although ribavirin has anti-HAV activity, its use is limited due to multiple adverse events. In this study, we investigated the safety and efficacy of zinc acetate for hepatitis A in vitro.

Materials and Methods:

Effects of zinc acetate on HAV HA11–1299 genotype IIIA or HAV HM175/18f genotype IB replication and changes in GRP78 expression levels in human hepatocytes with or without HAV infection were examined by real-time RT-PCR and ELISA, respectively. The cytotoxicity of zinc acetate and ribavirin was evaluated by MTS assay. We also examined the enhancement of zinc acetate on the effects of anti-HAV activity of ribavirin.

Results: Zinc acetate inhibited HAV replication in both Huh7 and GL37 cells. Inhibition of HAV replication by zinc acetate was similar those of zinc sulfate or zinc chloride. Zinc acetate also inhibited HAV replication in both low- and high-glucose media. The IC₅₀ value of zinc acetate was 13.6 μ M for the suppression of HAV RNA. We did not observe any acute hepato-cellular injuries by zinc acetate. Zinc acetate increased the expression of GRP78 in response to HAV infection. The combination of zinc acetate with ribavirin led to the suppression of both HAV HA11-1299 genotype IIIA and HAV HM175/18f genotype IB replication in Huh7 cells than that of ribavirin alone.

Conclusions: Zinc acetate inhibits HAV replication in accompany with the elevation of GRP78 expression without causing cellular toxicity. We also demonstrated that zinc acetate enhances the anti-HAV activities of ribavirin. Thus, combination therapies could help to decrease the ribavirin dose and its adverse events in patients infected with HAV.

2050 - Long term Outcomes of Tenofovir Therapy in Vietnamese Chronic Hepatitis B Patients A 5 Year Retrospective Cohort Study

Hien Chu Thi My¹, Huong Nguyen Thi Cam¹, Thu Le Thai Kim²

School Of Medicine, University Of Medicine And Pharmacy At Ho Chi Minh City (umpsm), Department Of Infectious Diseases, Ho Chi Minh City-Vietnam ¹ School Of Medicine, University Of Medicine And Pharmacy At Ho Chi Minh City (umpsm), Family Medicine Center, Ho Chi Minh City-Vietnam ²

Background / Hypothesis:

Chronic hepatitis B remains a major cause of cirrhosis and hepatocellular carcinoma in Vietnam. Long-term real-world data on Tenofovir disoproxil fumarate (TDF) in Vietnamese patients are still limited. We aimed to evaluate 5-year virological, biochemical, and fibrosis outcomes in chronic HBV patients treated with TDF in routine clinical practice.

Materials and Methods:

We conducted a retrospective cohort study including 145 chronic HBV patients treated with Tenofovir at the Department of Infectious Diseases, UMPSM. Clinical data, HBV DNA, ALT, qHBsAg, APRI, and ARFI measurements were collected at baseline and at multiple time points up to 60 months. Virological response was classified as complete, partial, or non-response based on HBV DNA decline patterns.

Results:

At baseline, 62,8% were male and median age was 46 years. Virological suppression was rapid: at month 12, 92,4% achieved complete response and at month 24, 100% had undetectable HBV DNA. ALT normalization reached 86–90% after 24 months and remained stable thereafter. Fibrosis indices improved significantly: median APRI decreased from 0,58 to 0,30 at month 24, and ARFI from 1,42 m/s to 1,28 m/s, indicating regression from F2 to F1–F0. qHBsAg declined slowly ($\approx 0,40 \log_{10}$ after 60 months). Clinical outcomes were favorable: only 1 case (0,7%) developed HCC and 2 cases (1,4%) had new-onset decompensation during 5-year follow-up.

Conclusions:

Long-term Tenofovir therapy resulted in excellent virological suppression, high ALT normalization rates,

E-POSTER ABSTRACTS

and meaningful improvement in non-invasive fibrosis markers. Real-world outcomes in Vietnamese patients are comparable to international data, supporting early initiation and long-term adherence to TDF therapy.

Keyword(s) : Hepatitis B; Tenofovir; Fibrosis; Virological response; Real-world cohort

2051 - PILOT STUDY ON LONG TERM EFFECTIVENESS OF THE KARLOVY VARY THERMAL SPRING DRINKING CURE FOR MASLD

Ladislav Spisak¹, Alina Huseynli¹, Patrice Marek¹
Institute Of Spa And Balneology\, Clinical, Karlovy Vary-Czechia¹

Objectives

The aim of this pilot study was to provide scientifically substantiated evidence on the long-term effects of the Karlovy Vary mineral spring drinking cure on liver steatosis in individuals with metabolic dysfunction-associated steatotic liver disease (MASLD). The primary outcomes were changes in hepatic steatosis measured by the controlled attenuation parameter (CAP) and steatosis grade after a 6-month period. Liver stiffness measurements (LSM) and selected biochemical markers were also assessed.

Methods

The drinking treatment lasted 21 days, mirroring the duration of the traditional comprehensive spa treatment, and involved thrice-daily intake of prescribed volumes (200–300 ml) of specific mineral springs. The study included 50 patients.

Laboratory parameters were assessed at baseline and post-treatment (3 weeks) in all participants. FibroScan CAP and LSM were performed at baseline, post-treatment, and at 6-month follow-up; complete longitudinal data were available for 37 patients.

Statistical analysis included paired t-tests or Wilcoxon signed-rank tests depending on normality, and the Stuart-Maxwell test for categorical variables. All analyses were performed in R version 4.4.2.

Results

A statistically significant reduction in CAP was observed both immediately after the drinking cure (mean change -25.3 dB/m; $p < 0.001$) and at the 6-month follow-up (-17.2 dB/m; $p = 0.002$). Steatosis grade improved significantly post-treatment ($p = 0.001$) and remained

improved at follow-up ($p = 0.007$). No statistically significant changes were observed in LSM or fibrosis stage. Biochemical parameters showed minimal change; the limited effect on laboratory values was likely due to most parameters being within the normal ranges at baseline.

Conclusion

This study suggests that the Karlovy Vary mineral spring drinking cure has the potential to reduce hepatic steatosis in individuals with MASLD, with effects persisting at 6 months. While fibrosis parameters remained unchanged, the improvement in steatosis grade and CAP supports the potential of mineral water therapy as a non-pharmacological intervention. Further controlled studies are needed to confirm these findings and to better understand the mechanisms underlying the observed effects.

This work was co-developed within the project Spa Research Center – CZ.10.01.01/00/22_001/0000261 supported by the European Just Transition Fund.

Keyword(s) : Balneology, Spa, Mineral Springs, MASLD, FibroScan

2052 - A Young Patient Presenting With Hepatocellular Carcinoma and Portal Vein Thrombosis Developing on A Background of Non Cirrhotic Hepatitis B A Case Report

Ahmet Uyanikoglu¹, Akin Kaya¹
Harran University, Gastroenterology, Sanliurfa-Türkiye¹

Background / Hypothesis: Hepatocellular carcinoma (HCC) is a primary malignant liver tumor that develops in the setting of chronic liver disease, particularly in patients with cirrhosis or chronic hepatitis B virus (HBV) infection. Approximately 75% of primary liver tumors are HCC.

More than 50% of the 770,000 HCC cases seen worldwide are associated with chronic HBV. Patients with chronic HBV infection are at risk of developing HCC even in the absence of cirrhosis.

Here, we present a young patient with HCC that developed on a non-cirrhotic background and presented with portal vein thrombosis.

Case: A 23-year-old male patient presented to the outpatient clinic with complaints of fatigue, tiredness, and epigastric pain. Physical examination revealed a 3 cm hepatomegaly and a 2 cm splenomegaly. Laboratory findings were as follows: platelets $162,000/\text{mm}^3$, AST 160 IU, ALT 35 IU, total bilirubin 0.7

E-POSTER ABSTRACTS

mg/dl, direct bilirubin 0.2 mg/dl, albumin 3.9 g/dl, prothrombin time 14.5 seconds, HBsAg (+), HBeAg (-), Anti-HCV (-), and AFP >1000 ng/ml. Abdominal Doppler ultrasonography (USG) showed a liver of normal size with a heterogeneous parenchymal appearance, and the spleen measured 15 cm. The main portal vein and its branches were observed to be thrombosed, with no detectable flow. Upper abdominal contrast-enhanced magnetic resonance imaging (MRI) revealed a lesion consistent with HCC, measuring 17 × 13 × 15 cm at its widest point, filling the right lobe of the liver, demonstrating arterial phase enhancement, venous phase washout, and diffusion restriction. The portal vein and its branches appeared occluded due to tumor thrombus.

The patient was diagnosed with diffuse HCC and portal vein thrombosis developing on the background of chronic Hepatitis B. As the patient was not considered suitable for liver transplantation, follow-up with medical oncology and outpatient clinic visits was recommended.

Conclusions: Hepatitis B is an important public health issue in our country. Every patient with HBV, even if young, should be screened for HCC.

Keyword(s) : HBV, HCC, portal vein thrombosis

2054 - Association of SGLT2 Inhibitors with Reduced Hepatocellular Carcinoma Risk in Patients with Type 2 Diabetes

Jonggi Choi¹, Vy Nguyen², Eric Przybyszewski³, Jiunn Song³, Allison Carroll⁴, Megan Michta³, Erik Almazan⁵, Tracey Simon³, Raymond Chung³

Asan Medical Center, Department Of Gastroenterology, Seoul-South Korea¹ Harvard Medical School, Harvard Medical School, Boston-United States² Massachusetts General Hospital, Department Of Gastroenterology, Boston-United States³ Massachusetts General Hospital, Department Of Medicine, Boston-United States⁴ Brigham Women's Hospital, Department Of Gastroenterology, Boston-United States⁵

Background / Hypothesis: Sodium-glucose cotransporter-2 inhibitors (SGLT2is) are widely prescribed for type 2 diabetes mellitus (T2DM) and may confer hepatoprotective effects. This study investigated their association with hepatocellular carcinoma (HCC) risk compared with other antidiabetic medications.

Materials and Methods: We conducted a retrospective cohort study using the electronic health records from

Mass General Brigham (Boston, USA) and Asan Medical Center (Seoul, Korea) from 2013 to 2024. Adults with T2DM newly initiating SGLT2i, dipeptidyl peptidase-4 inhibitor (DPP4i), glucagon-like peptide-1 receptor agonist (GLP-1RA), or sulfonylureas were included. A 6-month landmark analysis was employed to minimize early event bias. Inverse probability weighting combined with Fine-Gray competing risk models estimated subdistribution hazard ratios (SHRs) for incident HCC, accounting for transplant and death as competing events.

Results: After weighting, data from 6,733 SGLT2i, 4,495 GLP-1RA, 23,229 DPP4i, and 17,034 sulfonylurea initiators were analyzed. Over a median follow-up of 3.9 years (277,155 person-years), 623 HCC cases occurred. SGLT2i use was associated with significantly lower HCC risk versus sulfonylureas (SHR 0.44, 95% CI: 0.25–0.79) and DPP4i (SHR 0.53, 95% CI: 0.30–0.93). The comparison with GLP-1RA showed comparable risk (SHR 0.87, 95% CI: 0.40–1.91). Subgroup analyses demonstrated consistent protective associations of SGLT2i in patients ≤65 years, males, and those with chronic liver disease. Sensitivity analyses, including 12-month landmark analysis and adjustments for additional confounders, confirmed robustness of findings.

Conclusions: SGLT2 inhibitor therapy was associated with reduced risk of HCC compared with DPP4 inhibitors and sulfonylureas, supporting their potential chemopreventive role in patients with T2DM.

2062 - Clinical Significance of Prognostic Nutritional Index for Prognostication of Decompensated Liver Cirrhosis A Retrospective Cohort Study

Kevin Rae Lumunsad¹, Bacud Louise Nicole¹, Navarro Marc Julius²

St. Luke's Medical Center - Quezon City, Internal Medicine, Quezon City-Philippines¹ St. Luke's Medical Center - Quezon City, Institute Of Digestive And Liver Diseases, Quezon City-Philippines²

Background/Hypothesis Liver cirrhosis represents a significant global health burden, with decompensation markedly increasing mortality risk. While the Model for End-Stage Liver Disease (MELD) variants are the standard for prognostication, their reliance on multiple

laboratory parameters can limit accessibility in resource-constrained settings. The Prognostic Nutritional Index (PNI), derived solely from serum albumin and lymphocyte count, offers a simple marker of immunonutritional status. This study hypothesized that PNI could serve as a viable prognostic tool for decompensated liver cirrhosis (DLC). The objective was to evaluate the predictive accuracy of PNI for short- and long-term mortality in comparison to MELD-Na and MELD 3.0.

Materials and Methods We conducted a single-center, retrospective cohort study utilizing the Liver Banks Data Registry at St. Luke's Medical Center, Quezon City. The study included 260 adult patients diagnosed with DLC excluding patients with non-HCC malignancies, autoimmune diseases, or prior transplants. PNI, MELD-Na, and MELD 3.0 scores were calculated at admission. The primary outcome was all-cause mortality at 3, 6, and 12 months. Diagnostic accuracy was assessed using AUC-ROC curves, and optimal cut-offs were determined using the Youden Index. Survival curves were generated using the Kaplan-Meier method.

Results The cohort had a median age of 66 years and was predominantly male (64.6%), with Hepatitis B (40.8%) and NASH/MAFLD (31.5%) as the leading etiologies. Non-survivors presented with significantly lower serum albumin (2.87 vs 3.38 g/dL, $p < 0.001$) and lymphocyte percentage (13.0% vs 19.2%, $p < 0.001$) compared to survivors. An optimal PNI cut-off of 32.67 was identified. Patients with a High PNI (>32.67) demonstrated significantly better overall survival compared to the Low PNI group ($p < 0.001$). However, PNI displayed limited discriminative ability with an AUC of ~ 0.64 across all time points. In contrast, MELD-Na and MELD 3.0 demonstrated superior accuracy, achieving AUCs ranging from 0.72 — 0.74 and 0.74 0.76, respectively. PNI sensitivity was notably low (~ 55 58%), likely due to its inability to capture renal dysfunction.

Conclusions While the Prognostic Nutritional Index is an independent predictor of mortality in decompensated liver cirrhosis, identifying a high-risk cohort below a cut-off of 32.67, its performance as a standalone prognostic tool is inferior to MELD-Na and MELD 3.0. The exclusion of renal markers in PNI limits its sensitivity in predicting short-term mortality driven by hepatorenal physiology. Nevertheless, PNI remains a valuable, cost-effective adjunctive tool for identifying nutritional frailty, particularly in resource-limited settings where comprehensive scoring is unavailable.

2063 - Research Trends and Hotspots in Autoimmune Hepatitis A Bibliometric Analysis

Jiatu Zhong¹, Fan'e Cheng¹, Xinyu Zhao¹, Chunfeng Mei¹, Yong'an Ye¹, Xiaobin Zao¹
Dongzhimen Hospital, Beijing University Of Chinese Medicine, Gastroenterology, Beijing-China¹

Background / Hypothesis:

Autoimmune hepatitis (AIH) is a chronic, relapsing inflammatory disease of the liver that is characterized by hepatocellular injury, which can progress to cirrhosis and liver failure. The diagnostic and treatment regimen for AIH is based on steroid induction therapy. However, long-term use of corticosteroids can cause significant side effects in patients. Meanwhile, a comprehensive bibliometric analysis of the field of AIH has not been published. The purpose of this paper is to describe the current status and trends of AIH research worldwide using data from the Web of Science (WOS) core database.

Materials and Methods:

The analysis was conducted using data from WOS's core database, to examine articles related to the field of AIH that were published from 2014 to 2024. In addition, the CiteSpace and VOSviewer software were utilized to conduct a comprehensive analysis of publications based on various criteria, including issue, author, journal, country, institution, keyword, co-citation, and reference.

Results:

A total of 2,426 articles were included in this study. The United States has the most publications in this field, followed by China. The University Medical Center Hamburg-Eppendorf (Germany) is the leading institution in AIH, with Lohse from Germany having made significant achievements in this area. We considered the Journal of Hepatology to be a high-impact journal in this field. The keywords were then subjected to a cluster analysis, which resulted in the identification of four primary clusters: (1) primary sclerosing cholangitis, (2) concanavalin A, (3) hepatitis C virus, and (4) drug-induced liver injury.

Conclusions:

This study systematically summarized research findings in the field of AIH from 2014 to 2024. We identified AIH-related research centered on disease diagnosis, treatment, management, efficacy assessment, and the

enterohepatic axis. We also identified four core research directions in the field of AIH and the research trends they reflect (primary sclerosing cholangitis, concanavalin A, multiple sclerosis, and drug-induced liver injury).

2064 - Early Antibiotic Exposure Shortens Progression Free Survival in Unresectable Intermediate Advanced HCC Treated With ICI Plus TKI and TACE A Propensity Score Matched Study

Liyang Ren¹, Chuanzhi Den¹, Shuman Yan¹, Guangde Yang¹, Li Li¹, Xia Wang¹, Xiucheng Pan¹
Affiliated Hospital Of Xuzhou Medical University, Department Of Infectious Diseases, Xuzhou-China¹

Background / Hypothesis:

To evaluate whether early antibiotic (ATB) exposure adversely affects long-term outcomes in patients with unresectable, intermediate-to-advanced hepatocellular carcinoma (HCC) receiving immune-checkpoint inhibitors (ICIs) plus tyrosine-kinase inhibitors (TKIs) and trans-arterial chemo-embolization (TACE).

Materials and Methods:

In this single-centre, retrospective cohort study we consecutively enrolled 224 BCLC stage B/C HCC patients (Child-Pugh A/B) who received at least 3 cycles of ICI+TKI+TACE at the Affiliated Hospital of Xuzhou Medical University between January 2020 and December 2024. (Retrospective analysis approved by the Institutional Review Board of the Affiliated Hospital of Xuzhou Medical University; requirement for informed consent was waived.) Patients who received ATB within 30 days before or after the first ICI dose (n = 25) were compared with ATB-free controls. After 1:1 propensity-score matching (PSM), 20 pairs were analysed. Primary end-points were progression-free survival (PFS) and overall survival (OS); adverse events (AEs) were secondary. Survival distributions were estimated with Kaplan-Meier methods and compared by log-rank test; independent prognostic factors were identified using Cox regression.

Results:

Baseline characteristics were well balanced after PSM. Median OS was 18.2 vs 24.0 months (P = 0.692, not significant). Median PFS was significantly shorter in the ATB group (7.6 vs 12.3 months; HR = 2.76, 95% CI 1.31-5.83, P = 0.006). Multivariate analysis identified ATB exposure, Child-Pugh B status and HBV DNA ≥

E-POSTER ABSTRACTS

2,000 IU/mL as independent predictors of poorer PFS. Subgroup analyses revealed more pronounced PFS loss in patients aged >60 years, Child-Pugh B, BCLC stage C, HBV DNA 20–2,000 IU/mL or AFP $\geq$ 400 ng/mL. Overall and grade 3–4 AE rates did not differ between groups.

Conclusions:

Early ATB exposure did not affect OS but independently shortened PFS in unresectable, intermediate-to-advanced HCC treated with ICI+TKI+TACE. Routine prophylactic antibiotics should be used cautiously, especially in patients with limited hepatic reserve, high tumour burden or intermediate HBV replication, to avoid compromising oncological outcomes.
