MASH represents a major global health burden due to its progressive nature, which can lead to advanced fibrosis, cirrhosis, HCC. The intricate and incompletely elucidated pathogenesis of MASH has posed substantial challenges for therapeutic development, with Resmetirom remaining the sole approved pharmacotherapy to date. In light of the multi-target potential inherent to traditional Chinese medicine for complex multifactorial diseases, combined with evidence from our prior investigations, this study was designed to further elucidate the potential mechanism by which the herb pairs, that is Angelicae Sinensis Radix combined with Paeoniae Radix Alba, improve liver injury and promote hepatocytes regeneration in

MASH through regulating enterogenous endotoxin (LPS) and toll-like receptor 4 (TLR4) signaling pathway.

Materials and Methods:

After decoction, filtration, and concentration using the traditional method, an aqueous extract of Angelicae Sinensis Radix (9g) and Paeoniae Radix Alba (18g) was prepared. Male C57BL/6J mice were randomly assigned to either a normal chow-fed control group (NG) or underwent induction of the MASH model using a high-fat diet. Upon successful model establishment, mice were further divided into the following groups (n=15 per group): model group (MG), and low-, mid-, and high-dose herb pairs intervention groups (LIG, MIG, and HIG, respectively). Corresponding treatments were administered for four consecutive weeks. Portal vein plasma was collected for LPS quantification. Primary hepatocytes were isolated from mice to analyze the mRNA expression levels of key components in the TLR4 signaling pathway. Additionally, the secretions of tumor necrosis factor-alpha (TNF- α) and interleukin-6 (IL-6) from LPS-stimulated primary hepatocytes were measured.

Results:

LPS levels were elevated in the MG compared to the NG ($p < 0.005$). All group of herb pairs treatment dose-dependently reduced LPS levels compared with the MG (all $p < 0.005$). mRNA expressions of TLR4 (~5.11-fold), myeloid differentiation primary response 88 (~6.19-fold), tumor necrosis factor receptor-associated factor 6 (~4.68-fold), and nuclear factor kappa-B (~4.11-fold) were upregulated in the MG relative to the NG (all $p < 0.005$). The herb pairs intervention downregulated these transcripts compared to the MG (all $p < 0.005$), exhibiting a clear dose-dependent suppression across the treatment groups ($p < 0.005$). In vitro, LPS stimulation enhanced IL-6 and TNF- α secretion from primary hepatocytes in the MG higher than the NG ($p < 0.005$). The herb pairs potently inhibited LPS-induced cytokine release in a dose-dependent manner (all $p < 0.005$).

Conclusion:

The therapeutic mechanism of Angelicae Sinensis Radix combined with Paeoniae Radix Alba in MASH involves a dose-dependent reduction in enterogenous endotoxin level and the downregulation of hepatic TLR4 signaling pathway expression and activity.

E-POSTER ABSTRACTS

2070 - THE USE OF A MODIFIED GREAT SAPHENOUS VEIN FOR HEPATIC VEIN RECONSTRUCTION IN RIGHT LOBE LIVING DONOR LIVER TRANSPLANTATION

Zhambyl Ospan¹, Bolatbek Baimakhanov¹, Maxat Doskhanov¹, Shokan Kaniyev¹, Serik Tileuov¹, Daniyar Mukazhanov¹, Aziza Khajiyeva¹, Onlasyyn Ibikenov¹, Zhasulan Baimakhanov², Magzhan Tursynbay¹
A.n. Syzganov National Scientific Center Of Surgery, Department Of Hepatopancreatobiliary Surgery And Liver Transplantation, Almaty-Kazakhstan¹ Regional Multidisciplinary Hospital, Department Of Hepatopancreatobiliary Surgery And Liver Transplantation, Kyzylorda-Kazakhstan²

Background / Hypothesis: Reconstruction of hepatic veins is the most technically challenging stage of living donor liver transplantation (LDLT). Impaired venous outflow from the graft is one of the main causes of postoperative liver failure. During right lobe liver transplantation, it is crucial to consider reconstruction of significantly large veins of segments 5 and 8 (greater than 5 mm in diameter) in order to prevent congestion in the anterior sector of the graft. To evaluate the outcomes of complex reconstruction of the hepatic veins during transplantation of the right liver lobe at our clinic.

Materials and Methods: From December 2011 to November 2025, 347 LT in adults and children were conducted in our center. The following types of grafts were used: RL – 240 (69.3%), LL – 31 (9%), posterior lateral sector – 1 (0.3%), dual graft – 1 (0.3%), LLS – 41 (11.8%), whole liver – 32 (9%), and split transplantation – 1 (0.3%). Reconstruction of hepatic veins of segment 5 and 8 during transplantation of the RL of the liver was performed in 112 (32.4%) cases. Of these, reconstruction of hepatic veins of the 5 and 8 segments of the liver using the recipient's portal vein in 80 (71.4%) cases, vascular prosthesis in 11 (9.8%) cases, with a modified great saphenous vein (GSV) in 15 (13.4%) cases and vessels of a deceased donor in 6 (5.4%) cases. To assess the functioning of the reconstructed veins, patients underwent a control CT scan after 7 days, 14 days, 1 month, 3 months.

Results: The patency of the neo-MHV using the recipient's portal vein was 90% at 1 week and 86.7% at 2 weeks. In the group with reconstruction using a vascular prosthesis, patency was 81.9% at 1 week and 72.8% at 2 weeks. In the group with reconstruction using a modified great saphenous vein (GSV), patency was 100% at 1 week and 93% at 2 weeks. In the group

with reconstruction using vessels from deceased donors, patency was 66.7% at 1 week and 66.7% at 2 weeks. No hepatic vein-related complications were observed in patients who underwent reconstruction of segments 5 and 8 hepatic veins.

Conclusions: Reconstruction of the hepatic veins of segments 5 and 8 using a modified great saphenous vein provides good outcomes and also reduces the duration of warm and cold ischemia as well as the anhepatic phase, which subsequently has a positive effect on postoperative recovery.

Keyword(s) : a modified great saphenous vein, LDLT, Reconstruction of hepatic veins

2071 - PORTAL FLOW MODULATION IN LIVING DONOR LIVER TRANSPLANTATION

Maxat Doskhanov¹, Bolatbek Baimakhanov¹, Shokan Kaniyev¹, Onlasyyn Ibikenov¹, Zhambyl Ospan¹, Zhasulan Baimakhanov², Magzhan Tursynbay¹, Serik Tileuov¹, Aziza Khajiyeva¹, Daniyar Mukazhanov¹, Mukhtar Suierkulov¹
Syzganov's National Scientific Center Of Surgery, Department Of Hepatopancreatobiliary Surgery And Liver Transplantation, Almaty-Kazakhstan¹ Regional Multidisciplinary Hospital, Department Of Hepatopancreatobiliary Surgery And Liver Transplantation, Kyzylorda-Kazakhstan²

Background / Hypothesis:

Living donor liver transplantation (LDLT) is one of the primary strategies to address the growing imbalance between the demand for liver transplantation and the limited availability of deceased donor organs. Moreover, in many countries of the Middle East and Asia, access to deceased donor liver transplantation is restricted due to cultural and religious factors, making LDLT the only realistic option for patients with end-stage liver disease. Small-for-size syndrome (SFSS) is a widely recognized complication after liver transplantation, occurring in up to 20% of LDLT procedures. Portal inflow modulation aimed at maintaining a portal vein pressure below 15 mmHg or a portal vein flow rate of less than 250 mL/min/100 g of graft weight has been shown to improve clinical outcomes.

Materials and Methods:

From December 2011 to November 2025, a total of 347 liver transplantations in adults and children were performed in our center. The following graft types

E-POSTER ABSTRACTS

were used: right lobe (RL) — 240 (69.2%), left lobe (LL) — 31 (8.9%), posterior lateral sector — 1 (0.3%), dual graft — 1 (0.3%), left lateral section (LLS) — 41 (11.8%), whole liver — 32 (9.2%), and split transplantation — 1 (0.3%). Portal inflow modulation during LDLT was performed in 34 cases (9.8%). Among these patients, intraoperative splenectomy was performed in 9 cases (26.5%), postoperative splenectomy in 4 cases (11.8%), intraoperative splenic artery ligation — in 19 cases (55.9%), and postoperative splenic artery embolization — in 2 cases (5.8%). In patients requiring inflow modulation, the graft-to-recipient weight ratio (GRWR) ranged from 0.5 to 1.1.

Results:

The mean operative time with portal inflow modulation was 615 minutes. Mean intraoperative blood loss was 3000 mL. Warm ischemia time was 27.8 minutes, and cold ischemia time was 33.1 minutes. Postoperative complications were observed in 7 patients (28%). Biliary complications occurred in 3 cases (42.8%), pulmonary edema — in 1 case (14.3%), steal syndrome — in 1 case (14.3%), portal anastomotic thrombosis — in 1 case (14.3%), and portal vein thrombosis — in 1 case (14.3%), which required reoperation. No hospital mortality was reported.

Conclusions:

Excessive portal inflow is a key determinant of SFSS. Intraoperative inflow modulation allows achieving optimal hemodynamics and enhances graft function and patient outcomes in LDLT. This personalized approach should be considered a standard preventive measure to reduce the risk of SFSS and improve long-term survival.

2072 - Role of TRIM37 IKK γ axis in hepatic ischemia reperfusion injury

Qin Luo¹, Jin Zhang¹

Chongqing University Cancer Hospital, Department Of Hepatobiliary Pancreatic Tumor Center, Chongqing-China¹

Background / Hypothesis:

Hepatic ischemia/reperfusion (I/R) injury is one of the major pathological processes associated with various liver surgeries. However, there is still a lack of strategies to protect against hepatic I/R injury because of the unknown underlying mechanism. The present study aimed to identify a potential strategy and

provide a fundamental experimental basis for treating hepatic I/R injury.

Materials and Methods:

A classic 70% ischemia/reperfusion injury was established. Immunoprecipitation was used to identify direct interactions between proteins. The expression of proteins from different subcellular localizations was detected by Western blotting. Cell translocation was directly observed by immunofluorescence. HE, TUNEL and ELISA were performed for function tests.

Results:

We report that tripartite motif containing 37 (TRIM37) aggravates hepatic I/R injury through the reinforcement of IKK-induced inflammation following dual patterns. Mechanistically, TRIM37 directly interacts with tumor necrosis factor receptor-associated factor 6 (TRAF6), inducing K63 ubiquitination and eventually leading to the phosphorylation of IKK β . TRIM37 enhances the translocation of IKK γ , a regulatory subunit of the IKK complex, from the nucleus to the cytoplasm, thereby stabilizing the cytoplasmic IKK complex and prolonging the duration of inflammation. Inhibition of IKK rescued the function of TRIM37 in vivo and in vitro.

Conclusions:

Collectively, the present study discloses some potential function of TRIM37 in hepatic I/R injury. Targeting TRIM37 might be potential for treatment against hepatic I/R injury. Targeting TRIM37 might be a potential treatment strategy against hepatic I/R injury.

2073 - FAM49B inhibits TRAF6 ubiquitination and alleviates liver ischemia reperfusion injury

Qin Luo¹, Yanhong Yang¹

Chongqing University Cancer Hospital, Department Of Hepatobiliary Pancreatic Tumor Center, Chongqing-China¹

Background / Hypothesis:

Hepatic ischemia-reperfusion occurs following liver transplantation and various liver surgeries. The ubiquitin chain inflammatory response mediated by TRAF6 is a crucial molecular step. How to target TRAF6 in order to inhibit the phosphorylation of the IKK inflammatory complex has been our long-term focus of research.

E-POSTER ABSTRACTS

Materials and Methods:

We established a classic mouse liver IRI model and used a time point of 1/6 hour. Immunoprecipitation was used to identify direct interactions between proteins. The expression of proteins from different subcellular localizations was detected by Western blotting. Cell translocation was directly observed by immunofluorescence. HE, TUNEL and ELISA were performed for function tests.

Results:

FAM49B was significantly downregulated in the liver IRI model. Overexpression of FAM49B could significantly reduce the phosphorylation of nuclear factor kappa-B kinase inhibitors (IKK) and downstream pro-inflammatory proteins. Mechanistically, FAM49B directly interacts with TRAF6, resulting in a decrease in the ubiquitination level of TRAF6. The use of IKK activators can significantly reverse the function of FAM49B.

Conclusions:

We initially evaluated the function of FAM49B in liver ischemia-reperfusion injury (IRI) and demonstrated that its interaction with TRAF6 has a crucial impact on the IKK-mediated inflammatory cascade reaction.

Keyword(s) : liver transplantation, liver ischemia reperfusion, TRAF

2074 - Prediction of Non Alcoholic Fatty Liver Disease by Machine Learning Algorithms

Chia-yen Dai¹, Tzu-chun Lin¹, Ming-lun Yeh¹, Jee-fu Huang¹, Chung-feng Huang¹, Wan-long Chuang¹, Ming-lung Yu¹
Kaohsiung Medical University Hospital, Kaohsiung Medical University, Internal Medicine, Kaohsiung-Taiwan¹

Background / Hypothesis: Closely associated with metabolic disorders, non-alcoholic fatty liver disease (NAFLD) has been a major disorder of liver disease and substantially increases the risk of hepatocellular carcinoma. The integration of artificial intelligence (AI) into medical research has facilitated the extensive application of machine learning (ML) in predicting liver disease risk and treatment outcomes. Under the hypothesis that ML might be significantly useful in clinical application of prediction of NAFLD in Taiwanese patients, the present study aimed to apply

ML algorithms to a community-based cohort in southern Taiwan to identify key risk factors for NAFLD.

Materials and Methods: We have collected data of 7,700 participants (39.2% male; mean age 50.9 ± 14.9 years) derived from community health examinations, and clinical and demographic features in southern Taiwan. NAFLD is diagnosed through imaging or histological confirmation of significant hepatic steatosis. The five ML algorithms were evaluated, including logistic regression (LR), random forest (RF), K-nearest neighbors (KNN), adaptive boosting (AdaBoost), and extreme gradient boosting (XGBoost) for analyzing the data. Model performance was assessed using accuracy, precision, recall, F1 score, and the area under the receiver operating characteristic curve (AUROC).

Results: The 7,700 cases were randomly partitioned into a training dataset (6,160) for model development and a testing dataset (1,540) for internal validation, with no significant differences observed between groups. Feature importance analysis identified LDL-C, body mass index (BMI), triglycerides (TG), age, and waist circumference as the most influential predictors of NAFLD. The performance metrics for LR, RF, KNN, AdaBoost, and XGBoost on the testing dataset for accuracy, precision, recall, F1 score, and AUROC were evaluated. Among all models, XGBoost achieved the highest performance, with an accuracy of 91.7%, precision of 91.8%, recall of 91.5, F1 score of 91.7%, and AUROC of 96.9%.

Conclusions: ML algorithms, particularly XGBoost, demonstrated high accuracy in predicting NAFLD and effectively identified key clinical predictors.

2075 - Efficacy and safety of transarterial chemoembolization plus dual immune and anti angiogenic blockers for unresectable hepatocellular carcinoma a systematic review and meta analysis

Omar Elkoumi¹, Ahmed Elkoumi², Mariam Khaled¹
Faculty Of Medicine, Suez University, Suez-Egypt¹
Health Affairs Directorate Of El Sharqeya, The Ministry Of Health And Population, El Sharqeya-Egypt²

Background / Hypothesis:

Transarterial chemoembolization (TACE) remains a standard treatment for intermediate-stage hepatocellular carcinoma (HCC), but its efficacy is limited by post-procedural angiogenesis and immune escape. Combining TACE with dual systemic therapy—

E-POSTER ABSTRACTS

immune checkpoint inhibition and anti-angiogenic blockade—offers complementary mechanisms that may enhance tumor control. This systematic review and meta-analysis evaluated the efficacy and safety of this combination compared with TACE alone.

Materials and Methods:

A comprehensive search of PubMed, Scopus, Web of Science, and Google Scholar was performed through October 2025. Eligible studies compared TACE combined with immune checkpoint inhibitors plus anti-angiogenic agents versus TACE monotherapy in unresectable or intermediate-stage HCC. Pooled hazard ratios (HRs) for progression-free survival (PFS) and overall survival (OS), and odds ratios (ORs) for grade 3–5 adverse events (AEs) were calculated using fixed-effects models in the absence of heterogeneity or random-effects models otherwise. Heterogeneity was assessed and resolved by sensitivity analysis. Study quality was evaluated using the Cochrane Risk-of-Bias tool for randomized trials and the Newcastle–Ottawa Scale (NOS) for observational studies.

Results:

Four studies including 1,361 patients (three phase III randomized trials and one multicenter cohort) were analyzed. Combination therapy significantly improved PFS (HR = 0.70, 95% CI 0.61–0.80; $p < 0.00001$; $I^2 = 0\%$), showing a consistent benefit. OS showed a favorable but non-significant trend (HR = 0.59, 95% CI 0.28–1.23; $p = 0.16$; $I^2 = 70\%$). Grade 3–5 AEs were more frequent with combination therapy (OR = 2.42, 95% CI 1.83–3.19; $p < 0.00001$; $I^2 = 0\%$), with low heterogeneity after sensitivity testing using the leave-one-out test. All randomized trials were rated low risk of bias, and the observational study scored 8/9 on the NOS, indicating high methodological quality.

Conclusions:

TACE combined with dual immune and anti-angiogenic blockade significantly improves HCC control compared with TACE alone, supporting synergistic local and systemic effects. Although high-grade AEs are more frequent, their incidence is consistent and manageable. This integrated approach represents a promising advancement toward optimized multimodal therapy for intermediate-stage HCC.

2076 - Xiaozhi Huaxian Formula ameliorates type 2 diabetes mellitus associated metabolic dysfunction associated steatohepatitis through modulating hepatic interleukin 23 interleukin 17 Axis

Ning Yao¹, Xin Wang^{* 2}, Yajuan Geng¹, Ying Su², Wei Wei¹, Fengxiang Fang², Yan Su²

Gansu University Of Chinese Medicine, The First School Of Clinical Medicine, Lanzhou City-China¹ Gansu University Of Chinese Medicine, College Of Integrative Chinese And Western Medicine, Lanzhou City-China²

Background / Hypothesis:

Type 2 diabetes mellitus (T2DM) can cause metabolic dysfunction-associated steatotic liver disease (MASLD) and promote it rapid progression to metabolic dysfunction-associated steatohepatitis (MASH), hepatic fibrosis, cirrhosis even to hepatocellular carcinoma. The improvement of the complex diseases needs the rationally designed multi-target, multi-level and multi-angle therapeutic strategy. Xiaozhi Huaxian Formula (XHF), a patented Chinese herbal formulation derived from a modified classical prescription (Patent NO. ZL202310099104.1), has demonstrated therapeutic efficacy in ameliorating T2DM-associated MASH. Nevertheless, the precise molecular mechanisms responsible for its hepatoprotective effects remain to be fully elucidated.

Materials and Methods:

A mouse model of T2DM-associated MASH was established by administering streptozotocin to 2-day-old male C57BL/6J pups, followed by post-weaning feeding with a high-fat diet. After model confirmation, mice received daily oral XHF or vehicle for four weeks. Metabolic parameters and liver function were assessed from serum, and interleukin-23 (IL-23), IL-17A, augmenter of liver regeneration (ALR) and albumin (ALB) were measured in supernatant of liver tissue homogenate. Statistical correlation analyses were performed to evaluate the relationships between IL-23/IL-17A levels and the other measured indicators.

Results:

XHF administration dose-dependently ameliorated insulin resistance, glucose and lipid dysmetabolism (fasting blood glucose, triglyceride, insulin, homeostasis model assessment of insulin resistance index), hepatic steatosis, inflammation, and serum liver enzyme elevations (alanine aminotransferase, aspartic transaminase, alkaline phosphatase, and glutamyl transpeptidase), leading to a significant reduction in the NAFLD activity score (all $P < 0.001$, respectively). Concurrently, XHF treatment downregulated hepatic IL-23 and IL-17A secretions in T2DM-associated MASH mice, exhibiting a clear dose-response relationship (all

E-POSTER ABSTRACTS

$P < 0.001$, respectively). Moreover, XHF significantly promoted hepatocyte regeneration, as evidenced by increased synthesis and secretion of ALR and ALB in the blood and liver (all $P < 0.005$, respectively). Correlation analysis revealed a significant positive association between IL-23 and IL-17A levels. Furthermore, both cytokines demonstrated significant inverse correlations with parameters of glucose and lipid metabolism, liver function, and hepatocellular regeneration (all $P < 0.005$, respectively).

Conclusions:

Our study elucidates that XHF alleviates T2DM-associated MASH by inhibition of the IL-23/IL-17A axis. These findings uncover a novel mechanism of action for XHF and highlight its potential as a therapeutic agent for MASH and related metabolic diseases.

2078 - Highly Discriminative Risk Stratification for Long Term Liver Related Mortality in MASLD Patients

Pei-chien Tsai¹, Ming-lun Yeh¹, Ming-lung Yu¹
Kaohsiung Medical University Hospital, Kaohsiung Medical University, Hepatobiliary Division, Department Of Internal Medicine, Kaohsiung-Taiwan¹

Background / Hypothesis:

Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) is increasingly prevalent and linked to obesity, diabetes, dyslipidemia, and other cardiometabolic risk factors (CMRFs). Advanced MASLD can lead to cirrhosis, hepatocellular carcinoma, and liver-related death (LRD). However, robust long-term risk stratification tools for LRD remain limited. Therefore, we aimed to quantify long-term liver-related mortality and to develop a clinically applicable risk score for LRD among individuals with MASLD.

Materials and Methods:

Using the MJ cohort (1996-2022), we constructed Cox models and evaluated discrimination via time-dependent AUCs and calibration. An integer-based cumulative risk score was derived from the optimal model using weighted regression coefficients.

Results:

A total of 140,247 naïve MASLD participants without baseline major events from the MJ health-check cohort were enrolled. Over a median follow-up of 17 years, 813 LRDs occurred (0.58%), yielding a mortality rate of 3.5 deaths per 10,000 person-years. Predictive models incorporating cardiometabolic risk factors (CMRFs), age, sex, and the FIB-4 index demonstrated superior discrimination compared to models relying only on CMRFs or age/sex, with AUCs 0.93-0.88 over 5-20 years. A Risk Score was derived from: Age (6–12 points), obesity (BMI ≥ 30 , 1 point), diabetes (up to 3 points), HDL-C (up to 2 points), hypertriglyceridemia (-2 points), and FIB-4 (>3.25 assigned 18 points). Compared to the reference group (Score ≤ 5 ; 0.3 per 10,000 PY), the highest risk group (Score ≥ 30) had 219.4 per 10,000 PY and HR 664.06 (95% CI: 407.65-

1081.23, $P < 0.001$).

Conclusions:

The proposed risk score, combining readily available CMRFs, age, and FIB-4, provides a simple, highly discriminative tool for long-term LRD risk stratification in MASLD, who may benefit from intensive monitoring and early intervention.

2079 - Clinical characteristics of patients with primary biliary cholangitis across various disease stages

Weihua Cao¹, Hongxiao Hao¹, Yao Xie¹, Minghui Li¹
Beijing Ditan Hospital, Capital Medical University, Hepatology Division 2, Beijing-China¹

Background / Hypothesis:

Currently, the gold standard for definitive diagnosis of primary biliary cholangitis (PBC) remains percutaneous liver biopsy with histological assessment. This study aims to characterized the clinical profile of patients with PBC and compared features between early and late disease stages.

Materials and Methods:

This retrospective study included patients who underwent liver biopsy were diagnosed with PBC at Beijing Ditan Hospital. Patients were stratified into two groups based on the pathological staging: patients in I/II stage (Early stage group), and patients in III/IV stage (Late stage group). Clinical features were analyzed.

Results:

A total of 218 PBC patients were included, predominantly female (86.70%), with a mean age of 49.92 years. The cohort was stratified into early-stage (n=154) and late-stage (n=64) groups for comparative analysis. Key differences in laboratory parameters were observed. Late-stage patients exhibited significantly higher medians of total bilirubin (21.90 vs. 13.20 $\mu\text{mol/L}$), direct bilirubin (11.40 vs. 4.70 $\mu\text{mol/L}$), alkaline phosphatase (ALP) (229.10 vs. 127.65 U/L), gamma-glutamyl transferase (GGT) (223.95 vs. 123.85 U/L), total bile acids (41.55 vs. 10.35 $\mu\text{mol/L}$), and immunoglobulin M (IgM) (2.67 vs. 2.15 g/L) compared to early-stage patients (all $p < 0.05$). Conversely, late-stage patients had significantly lower levels of hemoglobin (120.08 vs. 126.70 g/L), platelet count

E-POSTER ABSTRACTS

(148.00 vs. 214.50 x10⁹/L), and albumin (38.77 vs. 41.01 g/L) (all p<0.05). Serologically, the prevalence of anti-Ro-52 antibody was significantly higher in the late-stage group (59.38% vs. 30.52%, p<0.001). The distribution of lymphocyte count, GGT, ALP, and IgM further illustrated the divergence between groups (Figure 1).

Conclusions:

Significant differences in biochemical, hematological, and immunological markers exist between early and late-stage PBC, reflecting progressive cholestasis, synthetic dysfunction, and potentially distinct immune activity with disease advancement.

2080 - Comparing Care Settings for Sofosbuvir Ravidasvir Delivery in Hepatitis C Nested Cohort Findings from the EASE Trial

Muhammad Radzi Abu Hassan ¹, Noor Syahireen Mohammed ¹, Huan Keat Chan ², Shahrul Aiman Soelar ¹, Mohd Azri Mohd Suan ¹, Muhammad Firdaus Md Salleh ³

National Institutes Of Health, Ministry Of Health Malaysia, Clinical Research Centre, Hospital Sultanah Bahiyah, Institute For Clinical Research, Alor Setar, Kedah-Malaysia ¹ National Institutes Of Health, Ministry Of Health Malaysia, Centre For Clinical Trial, Institute Of Clinical Research, Setia Alam, Selangor-Malaysia ² Ministry Of Health Malaysia, Hospital Sultanah Aminah, Johor Bahru, Johor-Malaysia ³

Background / Hypothesis: The EASE trial led by Malaysia's Ministry of Health demonstrated that an 8-week sofosbuvir/ ravidasvir regimen is non-inferior to the conventional 12-week course for individuals with non-cirrhotic hepatitis C virus (HCV) infection. The trial was deployed in two different public healthcare environments: specialist-run hospital clinics and primary care facilities supervised by family physicians. How these differing service models, staffing structures, and levels of research experience influence treatment delivery has not been clearly characterized. This study aimed to evaluate whether treatment adherence and sustained virological response at 12 weeks after therapy (SVR12) differ between participants treated in hospital settings versus those managed in primary care.

Materials and Methods: We conducted a nested cohort

analysis within the EASE trial involving 322 participants (hospital: n=102; primary care: n=220). Adherence was assessed using pill counts and patient-reported diaries. SVR12 was defined as HCV RNA <15 IU/mL. We compared demographic and clinical variables between groups and examined the relationship between facility type and SVR12 using unadjusted and adjusted logistic regression models. Covariates included sociodemographic factors, treatment duration, adherence, and adverse events.

Results: Baseline characteristics were largely comparable across settings, with the exception of age (hospital: 46.6 ± 8.8 years; primary care: 43.5 ± 10.4 years; p=0.009). Most participants were male and had attained secondary-level education. Use of the 8-week regimen was similar between groups. Adherence rates were high in both settings (hospital: 99.0%; primary care: 97.3%) with no significant difference observed. SVR12 rates were also equivalent (93.9% vs. 93.2%). In adjusted models, treatment setting was not associated with SVR12 (aOR 0.75; 95% CI 0.26–2.38; p=0.608).

Conclusions: HCV treatment delivered through primary care centers performed on par with hospital-based services in both adherence and virological outcomes. These findings reinforce the feasibility and effectiveness of decentralizing HCV care and support the use of task-shifting approaches to expand treatment access. They also highlight the potential for primary care networks to contribute meaningfully to future clinical research across a broader spectrum of diseases.

E-POSTER ABSTRACTS

National Institutes Of Health, Ministry Of Health, Clinical Research Centre Hospital Sultanah Bahiyah, Institute For Clinical Research, Alor Setar-Malaysia ⁴ Ministry Of Health, Hospital Sultanah Aminah, Johor Bahru-Malaysia ⁵ National Institutes Of Health, Ministry Of Health, Centre For Clinical Trial, Institute For Clinical Research, Setia Alam-Malaysia ⁶ Ministry Of Health, Office Of Deputy Director General (research & Technical Support), Putrajaya-Malaysia ⁷

Background / Hypothesis: Hepatitis C virus (HCV) infection remains a major global health burden, contributing to chronic liver disease and significant mortality. Malaysia has implemented direct-acting antiviral (DAA) therapy to support the World Health Organization's goal of eliminating HCV by 2030. Ravidasvir/sofosbuvir (RDV/SOF) is a potent, pan-genotypic DAA regimen that has demonstrated high efficacy, yet evidence comparing the time to viral load suppression between shorter and standard treatment durations is limited. This study aimed to determine the time to HCV RNA viral load suppression for the 8-week and 12-week RDV/SOF regimens among chronic HCV patients in Malaysia and to identify factors associated with suppression time.

Materials and Methods: This secondary analysis utilized data from an open-label, multicentre, parallel-group clinical trial (2021–2023) involving 322 adult patients with chronic HCV infection. Data was analysed using R statistical package (4.5.1). Kaplan–Meier survival analysis and Cox proportional hazards regression were used to evaluate time to viral suppression (HCV RNA <15 IU/mL) and associated predictors. The final model was stratified by baseline HCV RNA load, concomitant medication, and imprisonment risk factor to satisfy proportional hazards assumptions.

Results: The median time to viral load suppression was 28 days for both treatment groups, with no significant difference in Kaplan–Meier analysis ($p = 0.076$). In multivariable Cox regression, patients receiving the 8-week regimen were more likely to achieve viral suppression earlier than those on the 12-week regimen (adjusted hazard ratio [aHR] = 1.29, 95% CI: 1.01–1.63, $p = 0.038$). Higher baseline HCV RNA load was significantly associated with delayed suppression ($p < 0.001$). Other demographic and clinical factors were not significant.

Conclusions: Both 8- and 12-week RDV/SOF regimens achieved rapid viral suppression, with comparable median times. The 8-week regimen demonstrated a

higher likelihood of earlier suppression, suggesting its potential as an effective and cost-efficient alternative to the standard 12-week course in Malaysia's HCV elimination program.

Keyword(s) : survival analysis, HCV, RNA, viral load, suppression, Malaysia

2084 - Workflow Optimization to Reduce Chemotherapy Drug Waiting Time in Inpatient Settings

Shu-hua Wang ¹, Yin-hsun Feng ¹, Chih-yi Li ², Fang-hua Hsu ²

Chi Mei Medical Center, Yongkang, Hematology And Oncology Department, Tainan-Taiwan ¹ Chi Mei Medical Center, Yongkang, Nursing Department, Tainan-Taiwan ²

Background / Hypothesis:

In recent years, the increasing number of cancer patients has led to a growing demand for inpatient chemotherapy. Patients undergoing cancer treatment already endure significant physical and emotional burdens; prolonged waiting times during hospitalization further exacerbate their discomfort and dissatisfaction. This project aimed to analyze the inpatient chemotherapy workflow, identify sources of delay, and reduce the average waiting time for chemotherapy drug preparation. Ultimately, the goal was to improve medical service quality, decrease patient waiting time, and enhance patient and family satisfaction.

Materials and Methods:

Chemotherapy waiting time was defined as the duration from the patient's arrival in the ward to the initiation of chemotherapy administration by nursing staff. The project reviewed and analyzed the workflow of the inpatient chemotherapy unit, focusing on key process bottlenecks, including chemotherapy order entry, physician verification, message return, and the scheduled delivery of chemotherapy drugs to the ward. Two major interventions were implemented: (1) establishing a workflow for physicians to enter chemotherapy orders prior to patient arrival, and (2) optimizing and standardizing the delivery schedule of chemotherapy drugs.

Results:

Overall waiting time was successfully reduced from 278 minutes to 162 minutes, achieving a total reduction of 116 minutes. Additional benefits included:

- Bed transfer rate decreased from 19.2% to 11.3%.
- Bed occupancy rate increased from 82.64% to 89.4%.
- Patient satisfaction improved significantly from 73.4%

E-POSTER ABSTRACTS

to 100%.

Conclusions:

Implementing pre-arrival chemotherapy order entry effectively simplified the workflow and reduced waiting times for chemotherapy preparation. However, system limitations—such as the inability to synchronize treatment dates—created operational inconvenience. Additionally, delayed drug delivery time to 12:30 PM impacted pharmacy staff lunch breaks. These areas require further improvement, and continued collaboration with relevant departments is recommended to establish a more efficient and sustainable workflow.

Keyword(s) : chemotherapy, workflow optimization, inpatient process improvement, waiting time reduction, patient satisfaction, oncology nursing

2085 - Inhibition of Aurora B Induces Senescence and Potentiates Immunotherapy in Hepatocellular Carcinoma

Xuhui Ma¹, Shanshan Wu¹, Ying Cao¹, Hui Wang¹, Wenxin Qin¹

Shanghai Cancer Institute, Shanghai Cancer Institute, Shanghai-China¹

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is a global health challenge, with limited treatment options for advanced-stage patients. Although recent approvals of targeted therapies and immune checkpoint inhibitors (ICIs) have expanded the therapeutic landscape, their clinical benefits are often constrained by modest response rates and acquired resistance. Despite ongoing efforts to identify new therapeutic targets, only few inhibitors have progressed to clinical trials, benefiting a small subset of patients. These limitations underscore the need for more effective therapeutic strategies.

Materials and Methods:

We integrated data from DepMap and TCGA to identify HCC-specific vulnerabilities. A kinome-wide CRISPR screen validated essential targets. Pharmacological inhibition (AZD1152) and genetic knockout of Aurora B (AURKB) were employed for functional validation. Senescence was assessed via SA- β -gal staining, transcriptomics, and SASP analysis. Immune interactions were evaluated using co-culture assays with T cells and flow cytometry for MHC-I and immune markers. In vivo efficacy was tested in immunocompetent murine HCC models.

Results:

Aurora B was identified as a top candidate essential for HCC survival, overexpressed in tumors, and correlated with poor prognosis. A kinome-wide CRISPR screen further confirmed its essential role in HCC cell survival. Pharmacologic inhibition or genetic knockout of Aurora B markedly suppressed proliferation of HCC cells and induced robust cellular senescence, characterized by cell-cycle arrest, DNA damage, and SASP. These senescent cells exhibited heightened susceptibility to T-cell-mediated cytotoxicity, associated with increased immunoproteasome activity and upregulated HLA expression. Co-culture assays revealed that senescent tumor cells promoted interferon- γ production and enhanced cytotoxicity in CD8⁺ T cells as well as PD-1 expression. In both in vitro and in vivo models, combining Aurora B inhibition with anti-PD-1 therapy markedly suppressed tumor growth.

Conclusions:

This study identifies Aurora B as a therapeutically actionable vulnerability in HCC, whose inhibition induces senescence and enhances tumor immunogenicity. The combination of Aurora B inhibitor with anti-PD-1 therapy yields synergistic anti-tumor effects, supporting its potential as a promising strategy to improve immunotherapy outcomes in HCC.

2088 - The Effect of Semaglutide on Liver Histology in Metabolic Dysfunction Associated Steatohepatitis A Systematic Review and Meta Analysis of Randomized Controlled Trials

Angelica Mariano¹, Aegan Matthew Amican¹, Godofredo Vistal¹, Anna Susanna Si¹

Manila Doctors Hospital, Gastroenterology, Manila-Philippines¹

Background / Hypothesis: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease, affecting over 30% globally. Defined by hepatic fat accumulation within the context of metabolic syndrome, it poses a major public health challenge and is a leading cause of liver-related illness and death. A significant subset of MASLD progresses to metabolic dysfunction-associated steatohepatitis (MASH) and the worst outcome is Liver Cirrhosis. Histologically, MASH involves hepatocyte injury and lobular inflammation, which primarily drives hepatic fibrogenesis. Liver fibrosis progression is the single most important

E-POSTER ABSTRACTS

prognostic factor in MASLD, directly correlating with the risk of cirrhosis, hepatic failure, hepatocellular carcinoma, the need for liver transplantation, and all-cause mortality.

Materials and Methods: The study conducted in accordance with PRISMA guidelines. We performed a systematic search of PubMed/MEDLINE, Embase, Cochrane Central Register of Controlled Trials (CENTRAL), and ClinicalTrials.gov for RCTs published in the last 20 years. Meta-analysis was performed using RevMan 5.4 tool.

Results: The search identified three large-scale RCTs that met the strict inclusion criteria, enrolling a total of 1,233 patients between the selected studies. The pooled analysis of all three trials found statistical significance in histological improvement in steatohepatitis without worsening fibrosis odds ratio of 3.43 (95% CI 2.59-4.53, $p < 0.001$) and improvement in fibrosis without worsening steatohepatitis odds ratio 1.73 (95% CI 1.29, 2.33, $p < 0.0003$).

Conclusions: In conclusion, the meta-analysis demonstrates that semaglutide has beneficial histologic effects: both in Steatohepatitis and Fibrosis in patients with NAFLD with F2-F3 Fibrosis, with a well-tolerated safety profile. However, the results are limited by the small number of included studies and clinical heterogeneity, which restricts the generalizability of these findings across the spectrum of MAFLD.

Keyword(s) : MAFLD, MASH, NAFLD, NASH, Steatohepatitis, Fibrosis, Semaglutide, Ozempic, Wegovy, Rybelsus

2089 - Secondary Biliary Cirrhosis Following Iatrogenic Bile Duct Injury

Mohammed Tozammel Haque Haque¹

National Gastroliver Institute And Hospital,
Gastroenterology, Dhaka-Bangladesh¹

Abstract: Secondary biliary cirrhosis is a chronic liver disease caused by prolonged biliary obstruction. One of the most common iatrogenic causes is biliary stricture following laparoscopic cholecystectomy. We present the case of a 39-year-old woman who developed progressive jaundice and secondary biliary cirrhosis several years after cholecystectomy, attributed to an undiagnosed biliary stricture. Early identification and intervention are key to preventing irreversible

hepatic damage.

Introduction: Laparoscopic cholecystectomy is the gold standard for the treatment of symptomatic gallstones. However, bile duct injuries (BDIs) are a known complication, with an incidence of 0.3–0.7%. If unrecognized or inadequately managed, BDIs can lead to chronic biliary obstruction, cholangitis, and secondary biliary cirrhosis (SBC).

Case Presentation: A 39-year-old woman presented with progressive jaundice, fatigue, pruritus, and abdominal distention for 5 months.

History: She underwent laparoscopic cholecystectomy 13 years earlier for symptomatic cholelithiasis. The surgery was reported to be uneventful, though detailed operative records were unavailable. Over the past 5 years, she experienced intermittent episodes of jaundice and abdominal pain, managed symptomatically.

Examination: Icterus, ascites and splenomegaly were present

Investigations

Liver Function Tests:

- o Bilirubin: 18.4 mg/dL
- o AST: 110 IU/L, ALT: 95 IU/L
- o ALP: 980 IU/L, GGT: 420 IU/L
- o INR: 1.6
- o Albumin: 2.1 g/dL

Mild anemia (Hb 9.8 g/dL), thrombocytopenia (platelets 80,000/mm³)

Ultrasound Abdomen: Coarse hepatic parenchyma, dilated intrahepatic bile ducts, splenomegaly and ascites were present

- MRCP: A stricture at the level of CHD with significant upstream IHB dilatation. Liver parenchyma showed features suggestive of cirrhosis.

- Endoscopy: Oesophageal varices II-III

Diagnosis

Secondary biliary cirrhosis due to chronic biliary obstruction from post-cholecystectomy biliary stricture.

Management

ERCP with plastic stent placement was performed. The patient was referred for surgical consultation for evaluation of definitive biliary reconstruction.

Discussion

Bile duct injury is a feared complication of laparoscopic cholecystectomy and may go unrecognized, especially if minor. Chronic biliary obstruction can silently progress to secondary biliary cirrhosis, a potentially irreversible condition if not identified early.

MRCP remains the imaging modality of choice, and ERCP plays both diagnostic and therapeutic roles.

Long-standing strictures often require surgical correction to prevent recurrence.

E-POSTER ABSTRACTS

Conclusion

This case highlights the long-term consequence of unrecognized post-cholecystectomy biliary stricture leading to secondary biliary cirrhosis. High clinical suspicion, timely imaging, and endoscopic intervention can prevent progression to cirrhosis.

2090 - Integration of Microbial Signatures into Machine Learning Models Significantly Improves Prediction of Adverse Outcomes in Patients with Hepatitis B Related Cirrhotic Ascites

Jiaran Sun¹, Ruifeng Yang¹

Peking University Shougang Hospital, Clinical Laboratory, Beijing-China¹

Background: Traditional clinical assessment methods have limitations in early identification of poor prognosis in hepatitis B-related cirrhotic ascites. This study aimed to evaluate the value of a novel machine learning model that integrates microbial signatures with conventional clinical features for predicting 90-day end-stage liver disease (ESLD) events in patients with hepatitis B-related cirrhotic ascites.

Methods: A total of 306 patients with cirrhotic ascites who underwent ascitic fluid culture between 2019 and 2024 were retrospectively enrolled. Among them, 206 patients from 2019–2022 were assigned as the training set, and 100 patients from 2022–2024 served as an independent test set. The primary outcome was ESLD events occurring within 90 days after ascitic fluid sampling, including liver failure-related death, liver transplantation, hepatorenal syndrome, or grade III–IV hepatic encephalopathy. Clinical and microbial features were analyzed. Three models were constructed: a baseline MELD-Na model, a logistic regression model, and an eXtreme Gradient Boosting (XGBoost) model integrating all features. Model performance was evaluated on the independent test set. For the XGBoost model, SHapley Additive exPlanations (SHAP) values were used to rank feature importance.

Results: The overall 90-day endpoint event rate was 35%. Compared to the non-ESLD group, patients with ESLD exhibited significantly worse microbial profiles (higher rates of positive ascitic fluid culture, polymicrobial infection, carbapenem resistance, and availability of fewer than two effective antibiotics) and clinical parameters (MELD-Na score, ascitic fluid polymorphonuclear leukocyte count, procalcitonin, and serum creatinine). The XGBoost model demonstrated

significantly superior predictive performance, with an AUC of 0.85 on the test set, outperforming both the MELD-Na model (AUC = 0.72) and the logistic regression model (AUC = 0.78) ($P < 0.05$). SHAP analysis further confirmed that carbapenem resistance was the most influential microbial predictor, while MELD-Na score, procalcitonin, and availability of fewer than two effective antibiotics were also important features.

Conclusion: Integrating microbial signatures, with a focus on antimicrobial resistance, substantially improves the prediction of short-term adverse outcomes in patients with cirrhotic ascites. This model may facilitate early identification of high-risk patients and guide precise clinical intervention.

Keyword(s) : Hepatitis B-related cirrhotic ascites; Prognostic prediction; Carbapenem resistance; XGBoost model; Machine learning

2091 - Treatment outcome of interferon based therapy versus sofosbuvir ribavirin therapy in chronic hepatitis C genotype 3 and compensated liver cirrhosis

Mainuddin Ahmed¹, Salimur Rhaman², Mamun Al Mahtab³, Ayub Al Mamun³

General Hospital Kurigram, Medicine, Kurigram-Bangladesh¹ Bangladesh Medical University(bmu), Hepatology, Dhaka-² Bmu, Hepatology, Dhaka-³

Background / Hypothesis: Chronic hepatitis C remains a major global cause of progressive liver disease. Genotype 3 is associated with rapid fibrosis progression and lower treatment response compared with several other viral genotypes. Although directly acting oral antivirals have transformed hepatitis C management, interferon-based regimens are still used in many regions where access to newer agents is limited. This study hypothesized that a twelve-week regimen combining pegylated interferon alfa two a with sofosbuvir and ribavirin would provide similar virological efficacy to a twenty-four week all oral regimen of sofosbuvir and ribavirin in treatment naive genotype 3 chronic hepatitis C and compensated cirrhosis.

Materials and Methods: This randomized open label clinical study was conducted in the Department of Hepatology at a tertiary center from January two thousand sixteen to August two thousand seventeen.

E-POSTER ABSTRACTS

Thirty treatment naive adults with genotype 3 chronic hepatitis C or compensated cirrhosis were enrolled and randomly assigned into two treatment groups. Group one received twelve weeks of once weekly pegylated interferon alfa two a plus daily sofosbuvir and ribavirin. Group two received twenty-four weeks of daily sofosbuvir and ribavirin. Viral load testing was performed at baseline, end of treatment, and twelve weeks after completion to determine sustained virological response. Patients were monitored throughout therapy for adverse events and treatment tolerability.

Results: All thirty participants completed therapy without treatment discontinuation or loss to follow up. Both treatment groups demonstrated rapid virological response, end of treatment response, and sustained virological response at twelve weeks in one hundred percent of patients. No virological breakthrough or relapse occurred in either group. Reported adverse effects were mostly mild and included fatigue, insomnia, hair loss, and nausea in both groups. Flulike symptoms were observed only in patients receiving pegylated interferon. No serious adverse events or hepatic decompensation occurred.

Conclusions: Both regimens produced excellent virological outcomes in genotype 3 chronic hepatitis C and compensated cirrhosis, achieving one hundred percent sustained virological response at twelve weeks. The combination of sofosbuvir and ribavirin, with or without pegylated interferon, remains an effective therapeutic option where access to newer antiviral agents is limited. The interferon containing twelve-week regimen offers a shorter but equally effective alternative to the twenty-four-week oral regimen.

Keyword(s) : Hepatitis C, genotype 3, interferon alfa, sofosbuvir, ribavirin, cirrhosis, antiviral therapy

2093 - Effects of Extracellular Vesicles Secreted by Gut Microbiota on the Function of Peripheral CD8⁺ T Cells and Regulatory T Cells in Patients with Hepatocellular Carcinoma

Zhao Yiru Zhao¹, Xie Weilong Xie¹, Deng Chuanzhi Deng¹, Yan Shuman Yan¹, Ren Liying Ren¹, Wang Xia Wang¹, Yang Guangde Yang¹, Pan Xiucheng Pan¹
The Affiliated Hospital Of Xuzhou Medical University,, Department Of Infectious Diseases,, 徐州 China¹

Background / Hypothesis:

The gut microbiota can modulate anti-tumor immune responses in patients with hepatocellular carcinoma (HCC). CD8⁺ T cells and CD4⁺ T regulatory cells (Tregs) play crucial roles in anti-tumor immunity, but the specific molecular mechanisms by which the gut microbiota regulates their function remain unclear. This study aimed to explore the effects of extracellular vesicles (EVs) derived from different gut microbiota sources on the function of peripheral CD8⁺ T cells and Tregs in HCC patients, as well as the underlying mechanisms

Materials and Methods:

We isolated EVs from different gut microbiota and co-cultured them with peripheral blood mononuclear cells (PBMCs) obtained from HCC patients. The functions of CD8⁺T cells and Tregs were assessed by flow cytometry, and cytokine levels in culture supernatants were detected using enzyme-linked immunosorbent assay (ELISA). To identify which component in the EVs regulate T cell function, the EV preparations were pretreated with DNase or protease. An IRF3 inhibitor was used to verify whether EVs enhance CD8⁺ T cell function via the cGAS-STING pathway. Finally, 16S rRNA gene sequencing was performed to analyze the bacterial DNA within EVs

Results:

EVs derived from healthy donors and patients who responded to immune checkpoint inhibitors (ICIs) can downregulate the frequency of Tregs in PBMCs from patients with HCC and enhanced function of CD8⁺ T cells. This effect is associated with the activation of the cGAS-STING pathway by exogenous bacterial DNA harbored in EVs, accompanied by significant changes in the levels of various cytokine. 16S rRNA sequencing analysis revealed that the bacterial DNA profiles within EVs exhibited significant differences among three groups: ICI non-responders, ICI responders, and healthy controls

Conclusions:Healthy individuals and HCC patients who respond to ICIs treatment have distinct gut microbiota profiles, and their microbiota-derived EVs can enhance peripheral anti-tumor immune responses in HCC patients

Keyword(s) : HCC; extracellular vesicles; CD8⁺ T cells; regulatory T cells; antitumor immunity

E-POSTER ABSTRACTS

2095 - Preliminary Evaluation of Real World Efficacy and Safety of Tenofovir Prafulvate Tablets in the Treatment of 16 Patients with Chronic HBV Infection

Yimin Jia ¹, Xiaohong Gao ¹

Yan'an University Affiliated Hospital, Department Of Infectious Diseases, Yan'an-China ¹

Background / Hypothesis:Chronic Hepatitis B (CHB) is a global public health concern. The treatment rate of chronic HBV infection in China is far below WHO's 2030 targets, and existing nucleoside/nucleotide analogs have limitations in efficacy or safety. Although Pradefovir (approved in October 2024) possess the advantage of liver targeting, real-world data on this drug remains scarce.

Materials and Methods:This retrospective study enrolled 16 chronic HBV-infected patients treated with Pradefovir at the Infectious Diseases Department of Yan'an University Affiliated Hospital from January to July 2025. Changes in HBV DNA, HBsAg, HBeAg, liver function indicators, liver ultrasound, and LSM values before and after treatment, while documenting adverse reactions during therapy.

Results:After 12 weeks of treatment with Pradefovir, 16 chronic HBV-infected patients showed significant improvements in virological and serological indicators: HBV DNA levels decreased in 80% of patients (12/15 cases); HBsAg and HBeAg seroconversion rates were both 93.75% (15/16 cases), with 1 case each in the treatment-naïve and treatment-experienced groups achieving HBeAg seroconversion (16.67%, 10.00%); liver function indicators remained stable throughout treatment; Hepatological histology parameters improved: Among 11 evaluable patients, the LSM normalization rate increased from baseline 36.36% (4/11) to 63.64% (7/11); portal vein width narrowed or remained normal in 81.82% (9/11) of patients; and spleen thickness decreased in 45.45% (5/11) of patients. No significant adverse reactions were observed, and all patients reported no special discomfort during treatment.

Conclusions:Pradefovir demonstrate potential for rapidly suppressing viral replication, promoting antigen

clearance, and improving liver histology in the short-term treatment of chronic HBV infection.

Keyword(s) : Pradefovir; Chronic hepatitis B; Curative effect; Safety

2096 - Case Report of Decreased Cholinesterase Levels During Treatment with Prifosfamide Mesylate in a Patient with Chronic HBV Infection

Yimin Jia ¹, Xiaohong Gao ¹

Yan'an University Affiliated Hospital, Department Of Infectious Diseases, Yan'an-China ¹

Background / Hypothesis:If chronic hepatitis B virus (HBV) infection is not well controlled, it can progress to liver fibrosis, liver cirrhosis, and even hepatic carcinoma, and antiviral therapy is the core treatment modality. Pradefovir is a novel nucleoside (nucleotide) analog (NAs), which exerts its effect by inhibiting HBV reverse transcriptase. Serum cholinesterase (CHE) is a sensitive indicator reflecting hepatic synthetic function; however, its association with pradefovir mesylate treatment has not been reported yet, and its mechanism and clinical significance remain unclear.

Materials and Methods:Eighteen patients with chronic HBV infection receiving pefenavir mesylate treatment at Yan'an University Affiliated Hospital were enrolled. Changes in serum CHE levels were observed before and after 12 weeks of treatment.

Results:All patients exhibited varying degrees of serum CHE reduction post-treatment, with a significantly lower rate of normal CHE levels compared to baseline. Regarding antiviral efficacy, most patients achieved HBV DNA levels below the detection limit, while only a minority maintained low viral loads. No statistically significant difference was observed in ALT levels before and after treatment. No significant adverse reactions occurred throughout the treatment period, with all patients presenting "asymptomatic CHE reduction."

Conclusions:Twelve weeks of pefarnavir mesylate treatment in chronic HBV-infected individuals induces a widespread and significant decrease in serum CHE levels. However, this change does not currently affect the drug's antiviral efficacy, and short-term treatment

E-POSTER ABSTRACTS

demonstrates good safety.

Keyword(s) : Pradefovir; chronic hepatitis B; Cholinesterase;

2097 - Improving Elimination in Albumin Dialysis Liver Support Different Responses of Water Soluble and Albumin Bound Toxins

Stine Koball¹, Adrian Dominik¹, Sebastian Koball¹, Jan Stange¹

University Of Rostock, Nephrology, Rostock-Germany¹

Background / Hypothesis:

Extracorporeal Albumin Detoxification-Dialysis (ECAD) is the leading procedure to support failing livers by detoxification, it has been used in over 150.000 therapies. Past Meta-Analysis concluded dose of treatment would be an important cofactor determining a good outcome. The introduction of a new generation of adsorbents to maintain dialysate albumin's purity has increased the bile acid removal compared to MARS and Cytosorb. However, since next generation adsorbents may have moved the set points for optimal blood and dialysate flow rates, the aim of this investigation was to elucidate the role of blood- and dialysate flow on the removal of water soluble toxins, albumin bound toxins and improvement of albumin binding.

Materials and Methods:

Eight Albunique treatments were performed using two blood flow rates (100 and 130 mL/min) and stepwise increasing dialysate flow rates (2, 3 and 4 L/h). Pre- and post-dialyzer blood samples were collected. Photometric analysis was used to quantify albumin-bound toxins (bilirubin and bile acids) and water-soluble toxins (creatinine and urea). Albumin binding function at Sudlow site II was assessed by Dansylsarcosine titration, yielding K_d values (concentration at which half of the available binding sites are occupied). Instantaneous filter clearance was calculated and compared across the different flow conditions.

Results:

Instantaneous filter clearance during the eight Albunique treatments was analyzed for albumin-bound toxins (bilirubin and bile acids) and water-soluble toxins (creatinine) under two blood flow rates and stepwise increasing dialysate flow rates. Significantly higher clearance was observed for water-soluble toxins, particularly creatinine, with increasing dialysate flow. In contrast, no advantage was

demonstrated for albumin-bound toxins; a trend toward reduced clearance was noted at higher dialysate and blood flow rates. Furthermore, K_d values at Sudlow site II did not improve with increased flow rates. These findings indicate a differential response of toxin classes to dialysate flow rate adjustments.

Conclusions:

The present data demonstrate that increasing dialysate and blood flow rates significantly enhance the clearance of water-soluble toxins. In contrast, no beneficial effect was observed for albumin-bound toxins; higher flow rates were not associated with a trend toward improved clearance of bilirubin and bile acids. Similarly, albumin binding function did not improve under higher flow conditions. These findings suggest that aggressive flow escalation does not confer an advantage for the removal of albumin-bound toxins. Instead, lower or moderate flow settings may provide more favourable conditions for albumin-mediated detoxification.

2098 - An Observational Study on the Early Intervention Treatment of Fuzheng Huayu Capsule Combined with Antiviral Drugs in High Risk Populations of HBV Related Hepatocellular Carcinoma

Yuan Yuan¹, Xiaohong Gao¹

Affiliated Hospital Of Yan'an University, Department Of Infectious Diseases, Shaanxi Province-China¹

Background / Hypothesis:

To investigate the effects of Fuzheng Huayu Capsule combined with nucleos(t)ide analogues (NAs) on liver fibrosis, liver function and the incidence of long-term endpoint events in high-risk populations of hepatitis B virus (HBV)-related hepatocellular carcinoma (HCC), and to provide evidence-based basis for clinically reducing the risk of end-stage liver disease in such populations.

Materials and Methods:

A total of HBV-related HCC high-risk patients who visited the Department of Infectious Diseases of Yan'an University Affiliated Hospital from January 2015 to July 2025 were selected as research subjects. They were

E-POSTER ABSTRACTS

divided into monotherapy group (treated with first-line NAs alone) and combination group (treated with NAs combined with Fuzheng Huayu Capsule) according to the treatment regimen. The changes of liver function, liver fibrosis-related indexes, liver stiffness measurement (LSM) and anteroposterior diameter of main portal vein at baseline and 144 weeks after treatment were compared between the two groups. The incidence of clinical endpoint events such as HCC and decompensated liver cirrhosis within 3 years was counted, and COX regression model was used to analyze the risk factors of endpoint events.

Results:

After treatment, liver function indexes (ALT, AST) in both groups were improved compared with baseline, but there was no significant difference between the two groups ($P > 0.05$). The improvement amplitudes of liver fibrosis indexes (HA, LN, PCIII, IV-C), LSM and anteroposterior diameter of main portal vein in the combination group were significantly better than those in the monotherapy group, with statistically significant differences ($P < 0.05$). Follow-up of endpoint events showed that the cumulative incidence of clinical endpoint events in the combination group was significantly lower than that in the monotherapy group ($P < 0.05$). COX multivariate regression analysis suggested that high platelet level was a protective factor for HCC in such populations (HR=0.977, 95% CI: 0.962-0.994, $P=0.006$).

Conclusions:

Fuzheng Huayu Capsule combined with antiviral drugs can more effectively improve the degree of liver fibrosis and liver stiffness in high-risk populations of HBV-related HCC, and reduce the incidence of endpoint events such as decompensated liver cirrhosis, which has important clinical promotion value.

2099 - Clinical Analysis of Early Renal Injury in HBV Infected Patients Treated with Nucleos(t)ide Analogues

Yue Sha ¹, Xiao Hong Gao ¹

Affiliated Hospital Of Yan'an University, Department Of Infectious Diseases, Shaanxi Province-China ¹

Background / Hypothesis: This study aimed to

investigate the incidence, risk factors, and intervention effects of early renal injury in hepatitis B virus (HBV)-infected patients treated with nucleos(t)ide analogues (NAs), so as to provide a theoretical basis for clinical diagnosis and treatment.

Materials and Methods: A total of 447 eligible HBV-infected patients from the Department of Infectious Diseases, Yan'an University Affiliated Hospital, between January 2023 and June 2025 were enrolled. All patients had received NAs for at least 1 year with complete clinical data, and those with concurrent other viral infections, primary kidney diseases, hypertension, diabetes mellitus, etc., were excluded. Multiple renal function indicators including serum creatinine (Scr), estimated glomerular filtration rate (eGFR), and urinary $\beta 2$ -microglobulin (urinary $\beta 2$ -MG) were detected to calculate the abnormal detection rate, analyze risk factors, and compare indicator changes between patients with adjusted treatment regimens (renal protection therapy or drug replacement) and those with maintained original regimens.

Results: The results showed that 68.90% of the patients had at least one abnormal renal function indicator. The abnormal rate of urinary $\beta 2$ -MG was the highest (45.41%), and the abnormal rate of urinary microalbumin/creatinine (mAlb/Ucr) was 21.03%. Compared with the monotherapy group, the combined therapy group had a higher abnormal rate of urinary $\beta 2$ -MG (61.11% vs 43.26%, $P=0.013$). Among the monotherapy group, patients treated with tenofovir disoproxil fumarate (TDF) had significantly higher abnormal rates of urinary $\beta 2$ -MG and serum phosphorus than those treated with entecavir (ETV), tenofovir alafenamide fumarate (TAF), and tenofovir lamivudine (TMF) ($P < 0.05$). Logistic regression analysis indicated that age (OR=1.041) and monotherapy with TDF (OR=2.085) were independent risk factors for early renal injury ($P < 0.05$). Regarding the intervention effect, the levels of urinary $\beta 2$ -MG, mAlb, and mAlb/Ucr in the regimen adjustment group decreased significantly after treatment, with normal rates reaching 56.0%, 69.57%, and 51.61% respectively, and the decline rates all exceeding 80%, which were significantly different from those in the maintenance treatment group ($P < 0.05$).

Conclusions: In conclusion, the incidence of early renal injury in HBV-infected patients treated with NAs is relatively high, and advanced age and monotherapy with TDF are the main risk factors. Urinary $\beta 2$ -MG, mAlb, and mAlb/Ucr can be used as sensitive indicators for early screening. Timely adjustment of the treatment

E-POSTER ABSTRACTS

regimen can effectively improve the indicators related to renal injury. Clinically, attention should be paid to the monitoring of renal function and individualized intervention in such patients to improve the safety of treatment and the quality of life of patients.

2101 - A Non invasive Diagnostic Prediction Model for AMA Negative Patients with Primary Biliary Cholangitis

Weihua Cao¹, Hongxiao Hao¹, Yao Xie¹, Minghui Li¹
Beijing Ditan Hospital, Capital Medical University, Hepatology Division 2, Beijing-China¹

Background / Hypothesis:

Approximately 5-10% of patients with primary biliary cholangitis (PBC) are anti-mitochondrial antibody (AMA)-negative, posing a diagnostic challenge. This study aimed to develop a non-invasive diagnostic prediction model for this subgroup.

Materials and Methods:

This retrospective study included patients who underwent liver biopsy were diagnosed with PBC at Beijing Ditan Hospital as shown in Figure 1. Patients were stratified into two groups: AMA-negative and AMA-positive groups. Clinical characteristics were compared, and logistic regression was used to identify independent predictors for AMA-negative status. A nomogram model was used for diagnostic prediction of AMA-negative patients with PBC.

Results:

A total of 218 PSVD patients undergoing liver biopsy were enrolled, including AMA-negative (n=66) and AMA-positive (n=152) groups. Significant differences were observed between the groups. The AMA-negative group demonstrated a notably higher median gamma-glutamyl transferase (GGT) level (167.55 U/L vs. 127.60 U/L, $p=0.044$) but lower levels of Immunoglobulin G (IgG) (13.75 g/L vs. 15.35 g/L, $p=0.008$) and IgM (2.08 g/L vs. 2.33 g/L, $p=0.049$). Serologically, AMA-negative patients had a higher antinuclear antibody (ANA) positive rate (78.79% vs. 64.47%, $p=0.036$) and a higher prevalence of anti-SP100 antibodies (30.30% vs. 17.76%, $p=0.039$), while anti-gp210 antibodies were more common in the AMA-positive group (46.05% vs. 30.30%, $p=0.030$). Multivariate analysis identified four independent predictors for AMA-negative PBC: elevated GGT (OR=0.999, 95% CI: 0.997-1.000, $p=0.027$), lower IgG (OR=1.132, 95% CI: 1.037-1.235,

$p=0.006$), ANA positivity (OR=0.419, 95% CI: 0.205-0.858, $p=0.017$), and higher prothrombin activity (PTA) (OR=1.040, 95% CI: 1.014-1.065, $p=0.002$). The nomogram model incorporating these factors showed good diagnostic performance.

Conclusions:

A practical, non-invasive prediction model based on four routine clinical parameters (PTA, GGT, IgG, and ANA) was developed to aid in diagnosing AMA-negative PBC, potentially improving diagnostic accuracy for this challenging subgroup.

Keyword(s) : primary biliary cholangitis, anti-mitochondrial antibody, gamma-glutamyl transferase, Immunoglobulin G, nomogram model

2103 - Association of MR elastography parameters with prognostic indices neutrophil to lymphocyte ratio hepatocyte function and cholestasis parameters in chronic liver disease

Irem Gürcan Eriş¹, Emre Atak¹, Diğdem Kuru Öz¹, Gül Ayşe Erden¹

Ankara University Faculty Of Medicine, Radiology, Ankara-Türkiye¹

Background / Hypothesis: Magnetic Resonance Elastography (MRE) is a key non-invasive tool for staging fibrosis, yet its relationship with specific biochemical pathways may differ by etiology of chronic liver disease (1). Neutrophil-to-lymphocyte ratio (NLR) is a biomarker associated with systemic inflammation and could be used as a prognostic factor in chronic liver disease (2). We hypothesized that the determinants of liver stiffness and the utility of prognostic indices (MELD, NLR) diverge between hepatocellular (chronic viral hepatitis, CH) and cholestatic (primary biliary cholangitis, PBC) liver diseases, even when fibrosis burden is comparable.

Materials and Methods: This retrospective study included 80 patients: 54 with CH and 26 with PBC. The baseline characteristics are shown in Table-1. MRE stiffness values were categorized into fibrosis stages (F0-F4) using standard cut-offs. We assessed the correlation of stiffness with hepatocyte function, cholestasis parameters, and inflammatory markers (NLR). Multivariate linear regression and Receiver Operating Characteristic (ROC) analyses were performed to identify independent determinants of stiffness and predictors of high-risk disease (MELD >9).

E-POSTER ABSTRACTS

Results: There was no significant difference in mean liver stiffness (3.9 vs. 3.6 kPa; $p=0.29$) and the prevalence of advanced fibrosis ($\geq F3$) between CH (62.3%) and PBC (54.2%; $p=0.48$). As expected, the PBC group had significantly higher ALP levels ($p < 0.001$) and a higher proportion of female patients ($p = 0.009$). PBC patients exhibited higher total cholesterol ($p=0.006$) and LDL ($p=0.045$). Notably, a significant correlation was observed between liver stiffness and NLR in the CH group ($r=0.35$, $p=0.009$), whereas no such correlation existed in the PBC group ($p=0.63$). In multivariate analysis, stiffness in CH was independently associated with age ($p=0.003$) and AST ($p<0.001$), whereas in PBC, stiffness was predicted solely by AST ($p<0.001$) (Table 2). MELD 3.0 showed the strongest correlation with stiffness in the CH cohort ($r=0.51$). ROC analysis demonstrated that platelet count (AUC=0.84) and MRE (AUC=0.72) were the strongest independent predictors of a MELD score >9 .

Conclusions: While the stage of fibrosis is similarly distributed across etiologies, the drivers of liver stiffness differ fundamentally. In CH, stiffness is linked to systemic inflammation (NLR) and reflects both chronicity and active injury. In contrast, PBC stiffness is driven solely by enzymatic activity, with no link to systemic inflammatory markers.

2106 - Disease burden of chronic hepatitis B among pregnant women increased dramatically with age – a territory wide study

Vicki Wing-ki Hui ¹, Mandy Sze-man Lai ¹, Jimmy Che-to Lai ¹, Vincent Wai-sun Wong ¹, Terry Cheuk-fung Yip ¹, Grace Lai-hung Wong ¹
The Chinese University Of Hong Kong, Medical Data Analytics Centre, Hong Kong-China ¹

Background / Hypothesis:

An integrated model nurse clinic (IMNC) was established in Hong Kong as a pivotal part of the Hong Kong Hepatitis Action Plan 2020-2024 to achieve hepatitis elimination by 2030. IMNC has led to a major increase in HBsAg and HBV DNA testing in women of child-bearing age. This study evaluated the secular trends in diagnostic rates of chronic hepatitis B virus (HBV) infection in pregnant women who were born

before and after 1988, the start of the universal HBV vaccination to newborns in Hong Kong.

Materials and Methods:

Individuals with CHB were identified from a territory-wide database from year 2006 to 2024. We performed a subgroup analysis for pregnant women of age <30 or ≥ 30 .

Results:

A total of 840,281 pregnant women were identified; 61,107 individuals were diagnosed with chronic HBV infection. Newly diagnosed HBV rates increased over time in both age groups, with a much more dramatic increase observed in pregnant women born before the era of universal HBV vaccination. In contrast, the newly diagnosed HBV rates among pregnant women born in the era of universal HBV vaccination remained steadily low over time. The rates only showed a modest increase over time from 0.51% in 2018 to 1.03% in 2024 (age ≥ 30), and from 0.24% in 2006 to 0.14% in 2018 (younger than 30 years old) (Figure).

Conclusions: Newly diagnosed HBV rates showed substantial increases in pregnant women born before the era of universal HBV vaccination, while the rates remained steadily low in those born in the era of universal HBV vaccination. These findings provide important data for the allocation of resources in IMNC, with more targeted screening, education and pre-emptive antiviral therapy for pregnant women born before the era of universal HBV vaccination in order to minimise MTCT of HBV.

Founding: This work was supported by the Investigator Sponsored Research of Gilead Sciences (Reference: IN-HK-987-7181).

2108 - Post-Liver Transplant Outcomes and Donor Safety in Bangladesh A Nationwide Questionnaire Based Observational Study

Mohammad Forhad Abedin ¹, Md. Dalil Uddin Uddin ¹, Md. Obaed Ullah Ullah ¹
Comilla Medical College, Hepatology, Comilla-Bangladesh ¹

E-POSTER ABSTRACTS

Background / Hypothesis: Liver transplantation (LT) is increasingly accessible for Bangladeshi patients, though most undergo surgery abroad. Data on post-transplant outcomes and donor safety in Bangladesh remain limited. This study aimed to evaluate recipient outcomes, donor recovery, follow-up adherence, complications, and overall quality of life among post-LT patients across the country.

Materials and Methods: A cross-sectional observational study was conducted among post-liver transplant recipients in Bangladesh. Data were collected nationwide through a structured Google Form. Demographic details, transplant indications, donor profile, complications, adherence, and quality-of-life, outcomes were analyzed descriptively.

Results: Among the respondents, 97% underwent transplantation in India. The cost of LT ranged from 20,00,000 to 80,00,000 Bangladeshi taka. Most of the respondents (52.94%) were in the pediatric age group. Mothers were the most common donors (32.4%), followed by close relatives (20.6%) and fathers (17.6%). All donors survived after donation and maintained good health; most (70.6%) recovered within 2 months, and the rest (29.4%) recovered within 6 months.

The leading indications for transplantation were biliary atresia (47.1%) and HBV-related cirrhosis (23.5%). After transplant, 64.7% of recipients showed complete adherence to follow-up, while 2.9% were completely lost to follow-up. Regarding access to care, 17.6% reported no post-transplant problems, whereas others faced challenges obtaining timely treatment when ill (18%) or accessing immunosuppressive medications and tacrolimus levels (20%).

Overall, 97% reported a good quality of life after transplant. Post-transplant complications included no complications in 47.1%, infections in 23.5%, and biliary leakage in 11.8%. New-onset medical issues following immunosuppression included hypertension (8.8%), diabetes mellitus (5.9%), and chronic kidney disease (2.9%). All patients were alive at follow-up except one (mortality 2.9%).

Conclusions: This nationwide survey demonstrates excellent post-transplant survival, high donor safety, and good quality of life among liver transplant recipients in Bangladesh. However, notable challenges remain in follow-up adherence and access to immunosuppressive medication and monitoring. Strengthening local transplant support systems could further improve outcome.

2109 - Soluble CD14 Predicts Prognosis Diuretic Response and Acute Kidney Injury in Decompensated Cirrhosis with Refractory Water Retention

Masato Nakai¹, Takashi Kitagataya¹, Masatsugu Ohara¹, Takuya Sho¹, Goki Suda¹, Naoya Sakamoto¹
Hokkaido University Hospital, Gastroenterology And Hepatology, Sapporo-Japan¹

Background / Hypothesis: In decompensated liver cirrhosis, refractory water retention is frequently accompanied by acute kidney injury (AKI) and poor prognosis, in which bacterial translocation-driven systemic inflammation is thought to play a central role. Soluble CD14 (sCD14) is a circulating marker of bacterial translocation, but its clinical utility in this setting remains unclear. This study aimed to clarify the prognostic value of sCD14 in patients with decompensated cirrhosis and water retention, and to determine its association with diuretic responsiveness, AKI development, liver-related mortality, and spontaneous bacterial peritonitis (SBP).

Materials and Methods: A total of 134 patients with decompensated cirrhosis and refractory water retention treated with tolvaptan were retrospectively enrolled. Baseline serum sCD14 levels were measured, and their relationships with short- and long-term diuretic response, AKI development, and liver-related mortality were evaluated. In a subset analysis excluding patients with advanced hepatocellular carcinoma, the prognostic performance of sCD14 was compared with other bacterial translocation markers (soluble CD163 and mannose receptor). The cumulative incidence of SBP was also assessed according to sCD14 levels using competing-risk analysis.

Results: Lower sCD14 levels were significantly associated with better short- and long-term diuretic responses and a lower incidence of AKI. Patients with sCD14 ≤ 2340 pg/mL had significantly longer liver-related survival than those with higher levels (median

E-POSTER ABSTRACTS

survival: 24.5 vs. 4.8 months, $p < 0.01$). On multivariate analysis, sCD14 > 2340 pg/mL independently predicted liver-related mortality (hazard ratio 2.71, $p < 0.01$). sCD14 showed superior prognostic value compared with soluble CD163 and mannose receptor. Concomitant rifaximin use was significantly associated with lower sCD14 levels. The cumulative incidence of SBP was numerically higher in patients with high sCD14 than in those with low sCD14; however, this difference did not reach statistical significance ($p = 0.18$). Conclusions: sCD14 is a promising biomarker for predicting prognosis, diuretic response, and AKI development in patients with decompensated cirrhosis and water retention, outperforming other bacterial translocation markers. The association between rifaximin use and lower sCD14 levels suggests a potential suppressive effect of rifaximin on bacterial translocation.

2111 - Prevalence of Liver Enzyme Abnormalities in PCR Confirmed Respiratory Viral Infections A 321 Patient Cohort

Sinan Mermer¹

Izmir University Of Economics, Infectious Diseases And Clinical Microbiology, Bayrakli-Türkiye¹

Background / Hypothesis:

Respiratory viral infections may extend beyond the respiratory tract and lead to transient hepatic involvement, manifested by elevated liver enzymes. The aim of this study was to evaluate the prevalence and patterns of liver function test (LFT) abnormalities in a large single-center cohort of patients with PCR-confirmed respiratory viral infections during 2025.

Materials and Methods:

We conducted a retrospective review of all patients with a positive multiplex respiratory viral PCR between January 1 and December 1, 2025 at our tertiary center. A total of 321 patients had simultaneous ALT and AST measurements and were included. LFT abnormality was defined as ALT or AST $> 1.5 \times$ upper limit of normal (ULN), to avoid overestimating mild physiological fluctuations and to ensure clinically meaningful elevations were captured. Viral etiologies included SARS-CoV-2; Influenza A and B (with subtypes H3, H1N1); Adenovirus; Rhinovirus; RSV A/V; Parainfluenza 1-4; seasonal human coronaviruses (229E, OC43, NL63, HKU1); Bocavirus; and Metapneumovirus. For each virus, the proportion of patients with LFT elevation was

calculated.

Results:

A total of 321 patients with PCR-confirmed respiratory viral infections were included. Overall, 84 patients (26.1%) showed elevated ALT and/or AST levels. Median ALT was 41 IU/L, and median AST was 38 IU/L. Severe elevation ($> 5 \times$ ULN) occurred in 4 patients (1.2%). The highest proportions of LFT abnormalities were observed in Adenovirus (32%) and SARS-CoV-2 (28%) infections. RSV and Influenza B were associated with LFT elevation in 25% and 18% of cases, respectively. Lower rates were found in Rhinovirus (14%), seasonal coronaviruses (12%), Parainfluenza viruses (12%), and Bocavirus (6%). Differences between high-risk viruses (Adenovirus, SARS-CoV-2) and lower-risk viruses (Rhinovirus, Parainfluenza) were statistically significant ($p < 0.05$).

Conclusions:

Mild to moderate LFT abnormalities were found in approximately one quarter of patients with PCR-confirmed respiratory viral infections in 2025. Adenovirus and SARS-CoV-2 infections exhibited the highest rates of hepatic involvement, while other viruses showed lower but non-negligible rates. Awareness of this pattern may help clinicians interpret transient LFT elevations in the context of recent respiratory viral infections and potentially avoid unnecessary extensive hepatic work-ups.

2112 - Core genes with opposite expression changes and their inflammation related regulatory network during the progression and regression of NASH liver fibrosis

Bingqing Yang¹, Yue Li², Qi Wang¹

Beijing Ditan Hospital, Capital Medical University, Center Of Liver Diseases, Beijing-China¹ Beijing Ditan Hospital, Capital Medical University, Department Of Clinical Laboratory, Beijing-China²

Background and aims

Liver fibrosis associated with nonalcoholic steatohepatitis (NASH) is a major cause of end-stage liver disease and liver transplantation. Although fibrosis is reversible in a subset of patients, its molecular basis remains poorly understood. We compared transcriptional profiles of progressive and regressive NASH liver fibrosis to identify genes with opposite expression changes between these states and to

E-POSTER ABSTRACTS

characterize their functional pathways, upstream regulation and intercellular communication features.

Methods

We performed differential expression analyses on a NASH fibrosis progression dataset (GSE135251) and a regression dataset (GSE83452). An intersection strategy was used to screen profibrotic genes upregulated during progression but downregulated during regression, and antifibrotic genes showing the opposite pattern. Functional enrichment, transcription factor prediction and single-cell transcriptomic analyses were integrated to assess pathways and changes in cell-cell communication mediated by key secreted proteins.

Results

We identified differentially expressed genes in both cohorts and, by cross-cohort analysis, defined 13 core profibrotic genes (ACSL4, ANXA2, CCL2, CXCL10, CXCL8, DUSP8, FAT1, GDF15, IL32, PRAMEF10, SAA1, SPP1 and THBS1) that were consistently upregulated in progression but downregulated in regression, as well as one antifibrotic lncRNA, JAKMIP2-AS1, with the opposite pattern. Expression of this 13-gene set increased stepwise with advancing fibrosis stage in the progression cohort but was globally suppressed in the regression cohort, indicating a close association with disease severity and reversibility. Functional enrichment showed inflammatory cell chemotaxis and migration, cytokine/chemokine signaling, PDGF-related pathways and ATF4/PERK-mediated endoplasmic reticulum stress, suggesting a profibrotic signaling module driven by inflammation and stress. Transcription factor analysis indicated that CEBPA/CEBPB, IRF3, XBP1 and ATF4 regulate this gene set and co-target chemokines and profibrotic factors, linking innate immune activation and endoplasmic reticulum stress to inflammatory cell recruitment and fibrosis progression. Single-cell transcriptomic analysis showed that, from healthy liver through metabolic dysfunction-associated steatotic liver disease and steatohepatitis to cirrhosis and end-stage liver disease, expression of this core gene set gradually increased across major hepatic cell populations. Cell-cell communication analysis focusing on secreted proteins revealed progressive strengthening of profibrotic ligand-receptor signaling, such as THBS1-CD47, SPP1-CD44 and CXCL8-CXCR2.

Conclusions

We identified a core profibrotic gene module that participates in both progression and regression of

NASH liver fibrosis, involving inflammatory cell chemotaxis, cytokine signaling, fibroblast activation and endoplasmic reticulum stress. These genes and their associated intercellular communication signals reflect disease severity and may influence fibrosis reversibility, providing insights into mechanisms of NASH fibrosis regression and potential antifibrotic targets.

2114 - Targeted Activation of Lipophagy Attenuates MASH Progression in a Murine Model

Helena Liang ¹, Amy Lei ¹, Qian Wang ¹

Ilab Research Institute, Immunology, Mountain View-United States ¹

Background / Hypothesis:

Background

Metabolic dysfunction-associated steatohepatitis (MASH), used to be called nonalcoholic steatohepatitis (NASH), is a progressive liver disease that affects adults worldwide. MASH is a major cause of chronic liver disease, characterized by excessive lipid accumulation, inflammation, and cellular stress that progressively impair liver function. MASH has become increasingly prevalent due to the global rise in obesity and metabolic syndrome.

Hypothesis

Targeted activation of lipophagy—selective autophagic degradation of lipid droplets—may alleviate these pathological processes by reducing lipid burden and improving cellular homeostasis.

Materials and Methods:

RNA sequencing dataset GSE185911 were downloaded from NCBI database and reanalyzed to compare gene expression between lipophagy-induced (LIR-treated) and control groups through R packages. The differentially expressed genes (DEGs) were identified by FDR (false discovery rate) <0.05 and |log₂ fold change| > 0.25. Gene Ontology (GO) enrichment and pathway analyses were performed to classify DEGs into biological processes, cellular components, molecular functions, and metabolic pathways relevant to MASH pathology.

E-POSTER ABSTRACTS

Results:

Lipophagy activation produced marked gene expression shifts in murine model. Upregulated DEGs included chaperone proteins Hspa5 and Dnajb9, which facilitate ER stress reduction, and metabolic regulators Manf, Lpin1, and Ass1, which enhance lipid processing and restore metabolic balance. Pro-inflammatory genes such as Socs3 and Anxa2 were downregulated, indicating a potential anti-inflammatory effect. Pathway analysis demonstrated that lipophagy significantly influences ER stress responses, lipid metabolic process and regulation, response to peptide hormone and cellular stress adaptation.

Conclusions:

This study reveals that targeted lipophagy activation modulates critical molecular pathways involved in MASH progression. The observed improvements in ER stress regulation, lipid metabolism, and inflammatory signaling support lipophagy as a promising therapeutic strategy. These findings provide a foundation for future investigations into the clinical translation of lipophagy-based interventions for MASH.

Keyword(s) : MASH, Lipid, Autophagy

2115 - Determinants of severe liver fibrosis in patients with MASLD a five year retrospective cross sectional study

Frances Melissa Cielo¹, Bryan Christopher Lao¹, Robert Magsino¹, Roy Gonzales¹, Aris Antonino Peña¹
Mary Mediatrix Medical Center, Section Of Gastroenterology, Lipa City-Philippines¹

Background / Hypothesis: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease globally, with prevalence rising over recent decades. Advanced fibrosis ($\geq F3$) is strongly linked to liver-related complications and mortality. While obesity, poor glycemic control, dyslipidemia, and elevated liver enzymes are established predictors, data on additional factors such as comorbidities and smoking history remain limited. This study aimed to identify independent risk factors for severe fibrosis and cirrhosis in MASLD patients.

Materials and Methods: In this retrospective cross-sectional study, 2,082 transient elastography (TE) results were reviewed. Among 1,112 patients with fatty liver on imaging, 718 with MASLD were included.

Demographic data, metabolic parameters, comorbidities, biochemical tests, and noninvasive fibrosis scores were extracted. Logistic regression was used to identify independent predictors of severe fibrosis (F3) and cirrhosis (F4) using F0-F1 as the reference.

Results: Of the 738 MASLD patients, 56 (7.6%) had severe fibrosis (F3) and 180 (24.4%) had cirrhosis (F4). Multivariate analysis revealed that independent predictors of F3 were BMI $>23 \text{ kg/m}^2$ (adjusted OR 5.16, 95% CI 2.25–11.85), HBA1c $\geq 7\%$ (adjusted OR 6.65, 95% CI 2.23–19.80), ALT $\geq 2 \times$ ULN (adjusted OR 5.55, 95% CI 2.05–15.04), HDL $<40 \text{ mg/dL}$ (adjusted OR 3.55, 95% CI 1.56–8.11), and AST/ALT ratio ≥ 1 (adjusted OR 2.12, 95% CI 1.05–4.29). For cirrhosis (F4), BMI $>23 \text{ kg/m}^2$ (adjusted OR 2.75, 95% CI 1.40–5.40), HBA1c $\geq 7\%$ (adjusted OR 1.65, 95% CI 1.05–2.60), HDL $<40 \text{ mg/dL}$ (adjusted OR 2.00, 95% CI 1.15–3.50), and AST/ALT ratio ≥ 1 (adjusted OR 2.50, 95% CI 1.10–5.70) remained independent risk factors. Other variables, including age, sex, FBS, LDL, triglycerides, comorbidities, DM duration, and smoking, were not independently associated with advanced fibrosis. Notably, a proportion of patients with F3 and F4 had BMI $<23 \text{ kg/m}^2$, showing the occurrence of lean MASLD with clinically significant fibrosis.

Conclusions: In MASLD patients, higher BMI, poor glycemic control, low HDL, and elevated AST/ALT ratio are independently associated with severe fibrosis and cirrhosis. Importantly, advanced fibrosis also occurs in lean individuals, showing the clinical significance of lean MASLD and the need to screen for fibrosis regardless of BMI. These findings support risk assessment beyond obesity and highlight the utility of transient elastography for early identification of high-risk MASLD patients.

2116 - Acute liver failure after transarterial embolization of hemorrhaging hepatocellular adenoma

Frances Melissa Cielo¹, Robert Magsino¹
Mary Mediatrix Medical Center, Section Of Gastroenterology, Lipa City-Philippines¹

Significance: Hepatocellular adenoma (HCA) is typically managed with surgical resection for medium to large lesions. Recent guidelines recommend transarterial embolization (TAE) as the first-line intervention for

E-POSTER ABSTRACTS

bleeding HCAs presenting with hemodynamic instability. Although TAE is generally associated with low morbidity, serious complications, including hepatic failure, may still occur.

Clinical Presentation: We report the case of a 67-year-old diabetic male with biopsy-proven HCA who presented to the emergency room with sudden, severe right upper quadrant pain. On arrival, he was hypotensive (80/60 mmHg), tachycardic, and anemic (hemoglobin 9.8 mg/dL). Physical examination revealed peritonitis and a firm right upper quadrant mass.

Management: The patient underwent aggressive resuscitation with intravenous fluids and blood transfusion. CT imaging demonstrated multiple hepatic masses, including an 11.5 × 12.8 cm lesion in the right lobe and a 4.7 × 4.1 cm lesion in the left lobe, accompanied by hemoperitoneum. A diagnosis of hypovolemic shock secondary to ruptured HCA was made. Emergent angiography identified a hypervascular mass supplied by branches of the inferior pancreaticoduodenal artery, which were selectively catheterized and embolized. Several hours post-embolization, the patient developed worsening mental status, dyspnea, and hypotension. Chest radiography suggested acute respiratory distress syndrome, and liver enzymes were markedly elevated (SGPT 49,153.6 U/L; SGOT 33,480.9 U/L). Despite maximal resuscitative efforts, the patient died.

Recommendation: TAE is a minimally invasive and guideline-recommended treatment for ruptured HCAs, particularly among patients who are hemodynamically unstable. However, timely recognition of cases requiring more aggressive or adjunctive interventions is critical. Larger adenoma size, bilateral involvement, and signs of impending hepatic failure should prompt early reconsideration of surgical resection. Hepatic failure remains a serious but underrecognized complication of TAE. Existing criteria for predicting post-TAE hepatic failure are derived from limited data and lack prospective validation. Further studies are needed to better define risk factors and improve decision-making algorithms for managing ruptured HCAs.

Keyword(s) : hepatic adenoma, hepatocellular adenoma, ruptured hepatic adenoma, transarterial embolization, liver failure

2118 - Hepatitis B and C Prevalence Among Transgender Individuals and Men Who Have Sex

with Men in Pakistan

Hassan Mahmood¹, Quaid Saeed², Francisco Averhoff³, Nabil Ahmed¹, Huma Qureshi⁴
Integral Global, Usa, Public Health, Islamabad-Pakistan¹
Ihra, Public Health, Islamabad-Pakistan²
Abbott, Infectious Diseases Research, Illinois-United States³
Ministry Of Health, Public Health, Islamabad-Pakistan⁴

Background / Hypothesis:

In Pakistan, Transgenders (TGs) and Men who Have Sex with Men (MSM) are marginalized communities at high risk of sexually and parenterally transmitted infectious diseases. The prevalence of hepatitis B virus (HBV) and hepatitis C virus (HCV) infection in these populations has not been well described in Pakistan, and access to care and treatment is lacking.

Materials and Methods:

From 2020-2022, community health workers tested 2241 transgenders (TGs) and men who have sex with men (MSM) for hepatitis B and C. Those with hepatitis B were referred to provincial programs, while those with hepatitis C were linked to "One Stop Shop" community-based organizations for same-day testing, treatment, and care, including HCV RNA testing and 12-24 weeks of Sofosbuvir and Daclatasvir treatment based on APRI scores.

Results:

A total of 201/2241 (9%) tested positive for anti-HCV, and 69/2241 (3.1%) tested positive for HBsAg. All participants who tested HBsAg+ were referred to the provincial hepatitis control program for additional care. The 201 who tested anti-HCV+ were referred to CBOs for additional testing and care under One Stop Shop model. Of those, 161 (80%) were tested for HCV RNA, of which 99 (62%) tested positive for HCV RNA. Of these 87 (88%) initiated treatment and 77/87 (89%) completed treatment; all were tested for cure (sustained virologic response; SVR), of which 72 (94%) were HCV RNA negative (cured).

Conclusions:

Outreach to marginalized populations with same day testing and referral for HBV and HCV is feasible and effective in Pakistan. Key populations were willing to be screened, tested and treated. Partnering with CBOs was key to the success in this pilot project in reaching "key" populations with limited access to health services and achieving high rates of linkage to care and adherence

E-POSTER ABSTRACTS

with treatment for HCV.

2119 - Introducing Hepatitis B Birth Dose Vaccination Within 24 Hours of Birth A Pilot Project in Pakistan

Huma Qureshi ¹, Hassan Mahmood ², Ejaz Alam ³, Atiya Aabroo ⁴, Zafar Iqbal Channa ⁵, Asma Shaheen ⁶, Zofishan Jabeen Fatima ⁷, Nino Khetsuriani ⁸, Nancy Glass ⁹, Muhammad Ahmed Kazi ⁵, Rania A. Tohme ⁸
Ministry Of Health, Public Health, Islamabad-Pakistan ¹ Integral Global, Usa, Public Health, Islamabad-Pakistan ² Phrc, Data Analysis, Karachi-Pakistan ³ Ministry Of Health, Programmes, Islamabad-Pakistan ⁴ Fdi, Epi, Islamabad-Pakistan ⁵ Fgsh, Gynecology, Islamabad-Pakistan ⁶ Pims, Mnch, Islamabad-Pakistan ⁷ Centers For Disease Control And Prevention (cdc), Division Of Viral Hepatitis, Atlanta-United States ⁸ Centers For Disease Control And Prevention (cdc), Division Of Viral Hepatitis, Atlanta-United States ⁹

Background / Hypothesis:

Pakistan has 5 million Hepatitis B cases (2.5% prevalence), mostly acquired at birth or early childhood. Chronic infection can lead to liver disease, cirrhosis, and cancer. Co-infection with Hepatitis Delta Virus worsens outcomes. Despite Hepatitis B vaccine introduction in 2002, nationwide birth dose implementation is lacking.

Materials and Methods:

This pilot project was undertaken at two tertiary care public sector birthing units of Islamabad. Each hospital was given the target of vaccinating all consecutive deliveries daily 24/7 till they reached a figure of 1000. The delivery staff was trained to fill the vaccination card and give the vaccine. The data about mother's demography was retrieved from the delivery register along with the time and date of delivery and administration of hepatitis B vaccine. The field supervisor collected the records and entered it in the electronic data file which was shared with the project director and any gaps found were addressed on daily basis.

Results:

A total of 2008 deliveries were recorded over 3 months in 2 Islamabad hospitals. 2000 newborns received Hepatitis B birth dose within 1 hour of delivery, with 8 initially missed due to staff misconceptions. No side effects or extra costs were reported. Delivery time and vaccination time showed strong correlation ($r=0.954$, $p<0.01$).

Conclusions:

The hepatitis B birth dose can be easily implemented throughout the country with little additional funding for its procurement and transportation while negligible funding is required for its implementation. Central procurement by the Federal Directorate of Immunization is the best way to procure a cheap and effective vaccine and improve not only the vaccination coverage but also prevent a large quantum of chronic hepatitis B and D and hepatocellular carcinoma and their associated high morbidity and mortality.

2120 - GLP 1 receptor agonists associated with reduced risk of digestive cancers in patients with diabetes global real world evidence

Chun-ying Wu ¹, Kuan-yi Sung ², Fang Yu Chen ³, Yen-po Wang ³, Chi-yang Chang ²
National Yang Ming Chiao Tung University, Institute Of Biomedical Informatics, Taipei-Taiwan ¹ Fu Jen Catholic University Hospital, Division Of Gastroenterology And Hepatology, New Taipei-Taiwan ² Taipei Veterans General Hospital, Endoscopy Center, Taipei-Taiwan ³

Background / Hypothesis:

The global incidence of digestive cancers is rising, with a disproportionately high prevalence found in individuals with type 2 diabetes mellitus (T2DM). We aimed to evaluate whether the use of glucagon-like peptide-1 receptor agonists (GLP-1 RAs) is associated with a reduced risk of major digestive cancers compared with other commonly used antidiabetic agents.

Materials and Methods:

We conducted a retrospective cohort study using the global TriNetX research network, including treatment-naïve patients with T2DM who initiated metformin and subsequently received a second-line antidiabetic agent

E-POSTER ABSTRACTS

between January 2005 and October 2024. Patients with any prior digestive malignancy were excluded. The index date was defined as the first prescription of a GLP-1 RA or other diabetic drugs, which included insulin, sulfonylureas, dipeptidyl peptidase-4 inhibitors (DPP-4 inhibitors), Sodium-Glucose Cotransporter 2 inhibitors (SGLT2 inhibitors), and thiazolidinediones (TZD), after at least 3 months of continuous metformin use. A 1-year washout period was applied. For each drug pair, 1:1 propensity score matching was based on more than 60 baseline covariates. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (Cis) for any digestive malignancy and site-specific cancers, with prespecified subgroup and sensitivity analyses.

Results:

A total of 668,409 eligible patients with T2DM were identified. After matching, 92,509 GLP-1 RA users were compared with insulin users, 75,005 with sulfonylurea users, 43,044 with DPP-4 inhibitor users, 47,742 with SGLT2 inhibitor users, and 9,428 with TZD users. GLP-1 RA therapy was associated with a significantly lower risk of digestive malignancy versus insulin (HR=0.25, 95% CI: 0.21–0.29), sulfonylureas (HR=0.59, 95% CI: 0.53–0.66), DPP-4 inhibitors (HR=0.68, 95% CI: 0.54–0.85), SGLT2 inhibitors (HR=0.60, 95% CI: 0.51–0.70), and TZD (HR=0.56, 95% CI: 0.40–0.78). These protective associations were especially observed for hepatocellular carcinoma (HCC), colorectal cancer (CRC), and pancreatic cancer (PA) across most comparisons. The reduced digestive cancer risk was found consistently across sex, age, BMI, and HbA1c strata, and robust to sensitivity analysis with alternative lag periods, intention-to-treat analyses, and stricter exposure definitions.

Conclusions:

Compared with other diabetic medications, GLP-1 RA use is significantly associated with lower risk of digestive cancer, particularly HCC, CRC and PA. More studies are needed to explore the chemopreventive effect of GLP-1 RA in digestive cancers.

Keyword(s) : Hepatocellular carcinoma, Diabetes, GLP-1 RA, DPP4i, SGLT2i, TZD, Insulin

2122 - Effect of a Porous Glass Membrane Emulsification Method on Radiological Response in Epirubicin-Lipiodol cTACE for HCC

Shinya Endo ¹, Naofumi Shirane ¹, Koki Sakaguchi ¹, Haruna Takahashi ¹, Tatsunori Satoh ¹, Shinya Kawaguchi ¹

Shizuoka General Hospital, Department Of Gastroenterology, Shizuoka City-Japan ¹

Background / Hypothesis: The therapeutic performance of conventional transarterial chemoembolization (cTACE) is influenced by the physical properties of the epirubicin-lipiodol emulsion, which vary substantially with manual mixing. A porous glass-membrane emulsification device was introduced to improve consistency of water-in-oil emulsions. This study evaluated its impact on radiological response and clinical outcomes in initial cTACE for hepatocellular carcinoma (HCC).

Materials and Methods: This single-centre retrospective cohort included consecutive patients undergoing first cTACE using epirubicin-lipiodol emulsions between 2017 and 2024. Emulsions were prepared either by a three-way stopcock (TS) or a glass-membrane device (GMD). Tumor response was assessed using mRECIST. Logistic regression and Cox models adjusted for operator, baseline liver function, and tumor distribution. Adverse events (AEs) were graded by CTCAE v5.0.

Results: Sixty-one eligible patients were analyzed (TS, n=29; GMD, n=32). GMD was associated with significantly higher target-lesion objective response (adjusted OR 3.66, p=0.033). Overall ORR and 6-month best overall response also favored GMD. For time-to-progression (mRECIST-defined), recurrence-free survival, and overall survival, GMD showed numerically favorable but non-significant trends (e.g., TTP HR 0.78). Early liver function change demonstrated a small mean worsening in the GMD group (adjusted Δ ALBI +0.13, p=0.035), and grade ≥ 3 hepatic enzyme elevation occurred more frequently in GMD (25.0% vs 10.3%), although without statistical significance (p=0.19). Overall AE profiles were otherwise comparable between groups.

Conclusions: Use of a glass-membrane emulsification device was associated with improved radiological tumor response in initial cTACE for HCC. While survival outcomes were similar between groups, early liver function decline and higher rates of grade ≥ 3 hepatic enzyme elevation were observed numerically in the

E-POSTER ABSTRACTS

GMD group, warranting careful interpretation. These findings suggest potential benefits and trade-offs associated with GMD-assisted emulsification, supporting further evaluation in larger or prospective studies.

Keyword(s) : hepatocellular carcinoma, transarterial chemoembolization, Porous Glass-Membrane Emulsification device

2123 - Efficacy and safety of glucocorticoids in multi etiology liver injury a single center real world retrospective cohort study

Xiao Lin¹, Chunyang Huang¹, Xue Yang¹, Pengfei Yu², Linlin Wei¹, Juan Zhao¹, Wen Gao¹, Yanmin Liu¹, Bin Xu¹

Beijing Youan Hospital, Capital Medical University, Second Department Of Hepatology, Beijing-China¹
Beijing Youan Hospital, Capital Medical University, Fourth Department Of Hepatology, Beijing-China²

Background / Hypothesis: The use of glucocorticoids (GCs) in liver injury is supported by limited real-world, comparative data across different etiologies, and how efficacy and safety vary by etiology and disease severity remains unclear.

Materials and Methods: In this single-center retrospective cohort, we included 450 inpatients with liver injury who received systemic GCs between 2020 and 2022. Patients were classified by primary etiology into drug-induced liver injury (DILI), viral hepatitis-related liver injury (VH), autoimmune hepatitis (AIH), and other causes, and further stratified by the presence of liver failure. Short-term (1-week) biochemical responses in alanine aminotransferase (ALT), aspartate aminotransferase (AST), total bilirubin (TBIL), alkaline phosphatase (ALP), and gamma-glutamyl transferase (GGT) were assessed, along with long-term complete biochemical response (CBR; normalization of ALT, AST, and TBIL), all-cause mortality, and adverse events. Results: The median age was 51 years, 44.4% were male, and 141 patients (31.3%) had liver failure at baseline. DILI was the most frequent etiology (n = 197, 43.8%), comprising 164 cases of cholestatic DILI (83.2% of DILI) and 33 cases (16.8%) of drug-induced autoimmune-like hepatitis; VH accounted for 82 cases (18.2%), AIH for 58 (12.9%), and 113 patients (25.1%) were classified as other causes. At 1 week, a graded biochemical improvement pattern (AST > ALT > TBIL > ALP > GGT) was observed, with DILI—particularly drug-induced autoimmune-like hepatitis—showing the largest reductions in aminotransferases and TBIL. Over a median follow-up of 8 months, the overall CBR rate

was 37.33%, without significant differences among etiologic groups. Patients without liver failure achieved higher CBR rates than those with liver failure (40.45% vs 30.50%). Adverse events occurred in 9.8% of patients, were more frequent in the liver failure subgroup (22.0% vs 4.2%), and nearly all deaths and liver transplantations occurred among patients with liver failure. The initial GC dose showed no clear linear association with the magnitude of improvement in most biochemical indices.

Conclusions: In this real-world, multi-etiology inpatient cohort, systemic GCs produced clear short-term biochemical improvement, with approximately one-third of patients achieving CBR during follow-up. Efficacy and safety were strongly modified by liver failure status, underscoring the need to individualize GC therapy according to hepatic functional reserve and overall disease severity.

2126 - Pemphigus vulgaris in immunotherapy of hepatocellular carcinoma and response to treatment

Yosra Khalifa¹, Amira Aldesoky², Omar Hamada³, Eman Rewisha¹

National Liver Institute, Hepatology And Gastroenterology, Monufia-Egypt¹ Menofia University, Clinical Oncology And Nuclear Medicine, Monufia-Egypt² National Liver Institute, Diagnostic And Interventional Radiology, Monufia-Egypt³

Background / Hypothesis:

Hepatocellular carcinoma is the sixth most common tumor worldwide, with increased prevalence in Egypt due to the high incidence HCV infection. Bevacizumab is a monoclonal antibody that target vascular endothelial growth factor that inhibit angiogenesis and tumor growth and Atezolizumab is programmed cell death protein 1 (PD-1)/programmed cell death ligand 1 (PD-L1) inhibitors (immune checkpoint inhibitors) and they are treatment option for patients with advanced HCC.

Materials and Methods:

Among 267 patients received atezolizumab and bevacizumab in national liver institute, Egypt, male patient 63 years old with HCV infection treated with direct acting antiviral drugs in 2019.

E-POSTER ABSTRACTS

He was diabetic and was on oral hypoglycemic drugs for 10 years then shifted to insulin 3 years ago and hypertensive on amlodipine 10 mg per day presented to us with hepatocellular carcinoma infiltrative focal lesion seg VII about 4.6*6.9 cm with bi-lobar satellites and PVT diagnosed by contrast enhanced imaging.

Alpha feto protein was 3.03 ng/ml.

Immunotherapy (atezolizumab/bevacizumab) was started and after 8 cycles there was a complete resolution of hepatic focal lesions and tumoral thrombus of portal vein.

After the 11th cycle the patient suffered from rash all over the body with bullous formation.

Dermatologists prescribed antibiotics and antihistaminic, but the condition worsened after the next cycle. so, the dermatologist decided to take skin biopsy from the lesion which is diagnosed as bullous pemphigoid, oral corticosteroids 60 mg per day and then immunosuppressive drugs in form of azathioprine 50 mg twice daily were taken and the lesions almost disappeared completely after 2 weeks and immunotherapy was stopped since the corticosteroids added.

The patient is on follow up now from 6 months after stopping immunotherapy and two sequential contrast imaging showed sustained complete response with no enhanced hepatic focal lesions.

Results:

Bullous pemphigoid constitutes a rare dermatological immune-related adverse event of PD-1/PDL-I inhibitors. A delayed onset of bullous pemphigoid after cumulative doses of immunotherapy as well as refractory pruritic eruption prior to blister development were observed.

So, this patient has complete response to immune check point inhibitors and response was sustained 6 months till now after stopping the drug.

Conclusions: However, bullous pemphigoids can suspect good response to treatment or not as well as hand and foot syndrome in tyrosine kinase inhibitors, but we need more studies.

Keyword(s) : bullous pemphigoid, HCC, immunotherapy, PD-1/PDL-I inhibitors.

2127 - Association of copper exposure with fatty liver progression and mediation by perturbation of metabolic pathways

Ying Lu¹

Chinese Academy Of Medical Sciences Institute Of Basic Medical Sciences, Epidemiology And Biostatistics Beijing-China¹

Background / Hypothesis:

Exposure to copper has been associated with fatty liver development and progression, but the detailed molecular mechanisms remain largely unknown.

Materials and Methods:

Based on the Kailuan Cohort, copper was measured in whole blood of 241 participants during follow-up from 2016 to 2017. Untargeted metabolomics profiling was conducted in serum. The degree of fatty liver was evaluated using ultrasonography. Differential metabolites were selected by OPLS-DA VIP>1 and T test p value<0.05 for high blood copper vs. low blood copper and fatty liver progression vs. no progression. A meet-in-the-middle strategy was to identify the overlapping differential metabolites that potentially bridged the association between copper exposure and fatty liver progression.

Results:

For high blood copper vs. low blood copper, 39 differential metabolites were found, including 34 lipids and lipid-like molecules, one organic oxygen compound, three organo-heterocyclic compounds, and one benzenoid. The above 39 differential metabolites were significantly enriched on six metabolic pathways. For fatty liver progression vs. no progression, 26 differential metabolites were revealed, including 9 lipids and lipid-like molecules, one organic oxygen compound, two organo-heterocyclic compounds, one organic nitrogen compounds, ten organic acids and derivatives, one nucleoside, nucleotide, and analogue, and two benzenoids. The above 26 differential metabolites were significantly enriched on five metabolic pathways. The overlapping differential metabolites were tauroursodeoxycholate (lower in high blood copper and lower in fatty liver progression) and 17-epi-17-J4-NeuroP (higher in high blood copper and higher in fatty liver progression).

Conclusions:

Exposure to copper may cause perturbation of metabolic pathways, including fatty acids and bile acids, which may lead to development and progression of fatty liver.

Keyword(s) : Copper; Fatty liver; Progression; Metabolomics; Metabolic pathways

E-POSTER ABSTRACTS

2128 - Triglycerides and high density lipoprotein cholesterol are primary lipid determinants of steatosis severity in metabolic dysfunction associated fatty liver disease

Jinjin Liu ¹, Xinyu Zhao Zhao ², Yibin Chen Chen ³, Dong Xu Xu ⁴, Tingting Xiao Xiao ⁵, Ying Wang Wang ¹, Yuqing Zhao Zhao ¹, Zhengzhao Lu Lu ², Cheng Huang Huang ², Xiaofei Tong Tong ¹, Hong You You ¹, Jingjie Zhao Zhao ¹

Capital Medical University Affiliated Beijing Friendship Hospital, Liver Research Center, Beijing-China ¹ Capital Medical University Affiliated Beijing Friendship Hospital, Clinical Epidemiology And Ebm Unit, Beijing-China ² Capital Medical University, School Of Basic Medical Sciences, Beijing-China ³ Capital Medical University Affiliated Beijing Friendship Hospital, National Clinical Research Center For Digestive Diseases, Beijing-China ⁴ Capital Medical University Affiliated Beijing Friendship Hospital, Nursing Department, Beijing Friendship Hospital, Beijing-China ⁵

Background / Hypothesis: Metabolic dysfunction-associated fatty liver disease (MAFLD) is closely linked to dyslipidemia, yet the individual and synergistic impacts of specific lipid abnormalities on hepatic steatosis severity remain unclear. We hypothesized that triglycerides (TG) and high-density lipoprotein cholesterol (HDL-C) are key determinants of steatosis severity, with potential threshold effects and metabolic context-dependency.

Materials and Methods: In this cross-sectional study of 6,810 participants (2,177 with MAFLD), hepatic steatosis was quantified via transient elastography (CAP). Multivariable ordinal logistic regression was used to assess independent and synergistic associations of TG, HDL-C, and LDL-C with steatosis severity. Nonlinear relationships were examined using restricted cubic splines, and interactions with metabolic factors were evaluated.

Results: Elevated TG (adjusted OR: 1.77, 95% CI: 1.48–2.11) and reduced HDL-C (OR: 1.35, 95% CI: 1.11–1.65) were independently associated with advanced steatosis, with the strongest association observed for their combination (OR: 2.40, 95% CI: 1.87–3.07). A nonlinear threshold effect for TG was identified at 1.51 mmol/L, with a steeper increase in steatosis below this level. The association between low HDL-C and steatosis was confined to males, younger adults, and metabolically healthier subgroups.

Conclusions: TG and HDL-C are primary lipid drivers of hepatic steatosis severity in MAFLD, with synergistic effects and metabolic interactions further stratifying risk. These findings support targeted lipid management for precision prevention and treatment of MAFLD.

Keyword(s) : Triglycerides, HDL cholesterol, hepatic steatosis, MAFLD, dyslipidemia

2129 - Bile Duct Reduction Without Ductular Reaction A Key Pathological Feature of Alagille Syndrome

Hong-li Liu ¹, Yan-dan Zhong ¹, Qing-fang Xiong ¹, Chun Lv ², Yong-feng Yang ¹

The Second Hospital Of Nanjing, Affiliated To Nanjing University Of Chinese Medicine, Department Of Infectious Disease And Liver Disease, Nanjing Key Laboratory Of Hepatology, Nanjing-China ¹ The Fourth People's Hospital Of Huai'an, Department Of Liver Diseases., Nanjing-China ²

Background / Hypothesis:

Alagille syndrome (ALGS; OMIM 118450) is an autosomal dominant genetic disorder caused by JAG1 or NOTCH2 mutations, affecting multiple organs and systems, including the liver, heart, facial features, skeleton, and eyes. Liver manifestations often include neonatal liver disease, direct hyperbilirubinemia, chronic cholestasis, and bile duct abnormalities. This study aimed to investigate the pathological relationship between bile duct reduction and the absence of ductular reaction in four cases of ALGS.

Materials and Methods:

Four patients diagnosed with ALGS were included at the Second Hospital of Nanjing between January 2018 and December 2022. The demographic information, laboratory results, and histopathological findings. The diagnosis was confirmed based on clinical features and JAG1 genetic mutations.

Results:

Four patients (three males and one female, aged 12–35 years) presented with chronic cholestasis. Among the four cases studied, 25% (1/4) of the patients developed cirrhosis, characterized by pseudolobular nodules of varying sizes. Another 25% (1/4) showed signs of early cirrhosis and non-idiopathic portal hypertension, including minor dilation of portal veins in the portal areas. Additionally, 25% (1/4) exhibited intralobular hepatocellular edema and necrosis. Interface

E-POSTER ABSTRACTS

inflammation was observed in 50% (2/4) of the cases, while 75% (3/4) presented with portal area enlargement and bile duct defects. Histological analysis revealed a significant reduction in bile ducts, with fewer than 50% of portal tracts containing bile ducts. Despite cholestasis and liver injury, no ductular reaction was observed, suggesting impaired bile duct regeneration due to JAG1 mutation-associated NOTCH signaling dysfunction. Histopathological findings also demonstrated fibrosis and other compensatory changes.

Conclusions: Bile duct reduction and the absence of ductular reaction are important pathological features in ALGS. These findings highlight the critical role of JAG1 mutations in NOTCH signaling dysfunction and bile duct developmental defects. Recognizing these features is essential for accurate diagnosis and effective management of ALGS.

Keyword(s) : Alagille Syndrome; Ductular Reaction

2131 - PROGNOSTIC VALUE OF SERUM AMMONIA FOR SHORT TERM MORTALITY IN CIRRHOSIS A SYSTEMATIC REVIEW

Pronoy Pereira¹, Ashlyn Pereira²

King's College Hospital, London, Hepatology, London-United Kingdom¹ King's College Hospital, London, Critical Care, London-United Kingdom²

OBJECTIVE/BACKGROUND

The role of serum ammonia in assessing the progression of hepatic encephalopathy (HE) in liver disease patients has been a subject of ongoing debate. However, its prognostic utility for short-term mortality in adult cirrhotic patients remains inconclusive. Given that acute-on-chronic liver failure (ACLF), intensive care unit (ICU) admissions, and outpatient decompensation all occur within the context of cirrhosis, this review aimed to evaluate whether baseline or serial serum ammonia levels predict short-term mortality in cirrhotic adults across diverse clinical settings.

METHOD

A systematic search for studies published between January 2020 and December 2024 was conducted. Eligible studies included adults with confirmed cirrhosis (including those meeting criteria for ACLF), reported serum ammonia measurements (arterial or venous), and documented short-term mortality outcomes such

as 28-day, 30-day, or in-hospital mortality. Seven studies met the inclusion criteria for qualitative synthesis. Effect sizes were extracted as hazard ratios (HR) or odds ratios (OR). Studies with complete confidence intervals (CI) were included in a pooled random-effects meta-analysis. Heterogeneity was assessed using the I^2 statistic.

RESULT

Seven studies (n=3,716 cirrhotic patients) were included in the analysis. Across all individual studies, elevated serum ammonia levels consistently correlated with increased short-term mortality. A pooled analysis of three studies with complete HR data indicated a trend toward increased mortality risk with rising ammonia levels (pooled HR 1.08; 95% CI 0.99–1.18; $I^2=89\%$). Two studies with OR data demonstrated a directionally similar association (pooled OR 2.88; 95% CI 0.42–19.88; $I^2=97\%$). The precision of these findings was limited by variations in study design, ammonia measurement methodologies, and patient populations (ACLF, ICU, and outpatient cirrhosis). Two additional high-quality ACLF studies reported independent associations between ammonia and 28-day mortality but were excluded from quantitative pooling due to missing CI.

CONCLUSION

Across ACLF, ICU, and outpatient cohorts, all comprising adults with cirrhosis, higher serum ammonia levels were associated with poorer short-term outcomes. While heterogeneity and incomplete reporting constrained statistical precision, the consistent direction of the observed effect suggests that serum ammonia may serve as a clinically significant prognostic biomarker for short-term mortality in cirrhosis. Harmonized ammonia measurement techniques and standardized reporting are essential to enhance prognostic modeling in this area.

2133 - Hepatitis (B C & D) and HIV Seroprevalence Survey in Sindh Province Pakistan

Huma Qureshi¹, Hassan Mahmood², Muhammad Safdar Kamal Pasha³, Ejaz Alam⁴, Zulfiqar Dharejo⁵
Ministry Of Health, Public Health, Islamabad-Pakistan¹
Integral Global, Usa, Public Health, Islamabad-Pakistan¹

E-POSTER ABSTRACTS

² Who Country Office, Public Health, Islamabad-Pakistan ³ Phrc, Data Analysis, Karachi-Pakistan ⁴ Sindh Health Department, Cdc, Sindh, Karachi-Pakistan ⁵

Background / Hypothesis:

Pakistan is facing with one of the highest hepatitis C disease burden globally, necessitating urgent public health action. The first national hepatitis survey was carried out in 2008 followed by a provincial (second) survey in Punjab in 2018. In 2019, the third survey was carried out by World Health Organization and Department of Health Sindh to assess the latest Hepatitis B, C, D and HIV seroprevalence in Sindh province.

The survey aimed to find the latest prevalence of hepatitis B C D and HIV in Sindh province that should be statistically representative of the whole province.

Materials and Methods:

A stratified two-stage sample design was used to collect blood samples from 6,672 individuals across all the 29 districts of Sindh Province. Samples were tested at the hepatitis control program laboratory, and data were analysed using Epi Info and SPSS version 19.0.

Results:

A total of 1153 households from 29 districts of Sindh province were visited. There were 7133 household members with 6769 (94.9%) individuals present at the time of survey (average 5.8 persons/house). Refusal was seen in 97 people (1.4%). There were 3214 (47.5%) males, 3547 (52.4%) females and 08 transgenders (0.1%). HCV positivity was 6.1%, HBV 1.05%, HDV 32.8% and HIV 0.03%. Comparing the 2008 data with the 2019 data shows that the HCV disease prevalence has increased from previous figure of 5% to 6.1% while HBV prevalence has reduced from 2.5% to 1%.

Conclusions:

The survey findings highlighted the need for mass testing and treatment through a multisectoral, integrated approach to control hepatitis and HIV spread and prevent the disease progression. Recommendations include integration of healthcare services to save the resources, scaling up testing and treatment services, promoting awareness, and implementing targeted interventions. This survey provided valuable insights for policymakers and healthcare professionals working towards eliminating

hepatitis as a major public health threat in Pakistan.

2135 - Assessing HCV Re infection Rates and Linkage to Care among Transgenders and MSM in Pakistan A Follow up Study

Hassan Mahmood¹, Huma Qureshi²

Integral Global, Usa, Public Health, Islamabad-Pakistan

¹ Ministry Of Health, Public Health, Islamabad-Pakistan
²

Background / Hypothesis:

Pakistan faces a significant hepatitis C epidemic, with limited data on prevalence among key populations like transgenders (TGs) and men who have sex with men (MSM). This study aimed to reassess HCV re-infection rates among these populations and provide linkage to care, building on a previous study conducted in 2022.

1. To estimate the re-infection rates of HCV in TGs and MSM in Pakistan
2. To provide linkage to care to the reinfected cases
3. To capture the data on World Health Organizations prescribed cascade of care

Materials and Methods:

A total of 123 TGs and MSM from the 2022 study were re-recruited in 2024. They were tested for anti-HCV, and positive cases underwent further testing. A One-Stop Shop model was established, providing screening, testing, and treatment services under one roof. Community-Based Organizations (CBOs) played a crucial role in recruiting participants and delivering services.

Results:

Out of 123 participants, 17 (13.8%) tested anti-HCV positive, and all were HCV RNA positive. Among these, 3 (17.6%) were previously not cured in the 2022 study, while 14 (82.4%) were newly detected. All 17 individuals initiated treatment, and 100% completed it. The One-Stop Shop model facilitated same-day testing, treatment initiation, and linkage to care.

Conclusions:

This study demonstrates the feasibility and

E-POSTER ABSTRACTS

effectiveness of outreach programs for marginalized populations in Pakistan. Partnering with CBOs was instrumental in accessing vulnerable communities and achieving high rates of linkage to care and treatment adherence. The One-Stop Shop model shows promise for scaling up HCV care and treatment services for key populations in Pakistan.

Community-based approaches, same-day testing, and treatment initiation can improve HCV care outcomes among marginalized populations. CBOs play a vital role in reaching and engaging these communities, highlighting the importance of collaborative efforts in public health initiatives.

2136 - Implementing a Micro Elimination Program for Hepatitis C and Hepatitis B Diagnosis and Referral in Khaipur District Sindh Province Pakistan A Pilot Project for National HCV Elimination Initiative

Hassan Mahmood¹, Huma Qureshi², Zulfikar Dharejo³, Nabil Ahmed⁴

Integral Global, Usa, Public Health, Islamabad-Pakistan

¹ Ministry Of Health, Public Health, Islamabad-Pakistan

² Sindh Department Of Health, Cdc, Sindh, Karachi-Pakistan

³ Intehrul Global, Usa, Public Health, Atlanta-Pakistan ⁴

Background / Hypothesis:

Pakistan has a high burden of hepatitis C, with approximately 10 million people living with the infection. Two union councils (UCs) in Khaipur district, Sindh Province, Pakistan, with high disease rates, were selected for this pilot project aimed at implementing a micro-elimination program for hepatitis C and diagnosis and referral of hepatitis B.

Objectives:

The project objectives were to increase awareness, testing, diagnosis, and linkage to care and treatment for hepatitis B and C, and to pilot an Electronic Medical Record (EMR) system to track the hepatitis B referral and hepatitis C care cascade.

Materials and Methods:

The project targeted a population of 62,500 individuals, with 45,349 eligible for screening (aged 12+ years). Community healthcare workers implemented awareness campaigns, while trained Lady Health Workers (LHWs) screened individuals for hepatitis B

and C using rapid tests and collected demographic data using an EMR system.

Results:

As of June 2025, a total of 25,203 individuals were screened, with 541 (2.1%) HBsAg positive and 2,873 (11.4%) anti-HCV positive. Of the anti-HCV positive patients, 1,760 (61.3%) were tested for HCV RNA, and 1,075 (61.1%) were HCV RNA positive. All HCV RNA positive patients were initiated on treatment.

Conclusions:

This pilot project demonstrated the feasibility of implementing a hepatitis C elimination program in Pakistan, despite challenges such as internet connectivity issues and limited LHW coverage. The project successfully piloted an EMR system, which proved to be a valuable tool for tracking the hepatitis care cascade. The project findings helped understand on-ground challenges and revive the national HCV elimination strategy. The lessons learned from this project can inform province-wide and nationwide hepatitis elimination programs, contributing to Pakistan's goal of eliminating hepatitis C by 2030

Keyword(s) : Hepatitis B, Hepatitis C, Community Outreach, Community Mobilization, Awareness and Advocacy, Public Private Partnership, Micro elimination, Linkage to Care

2138 - Evaluation of the Elecsys HCV Duo Assay for Screening and Testing of Hepatitis C Virus in Pakistan

Huma Qureshi¹, Hassan Mahmood², Nabil Ahmed², Ejaz Alam³

Ministry Of Health, Public Health, Islamabad-Pakistan ¹

Integral Global, Usa, Public Health, Islamabad-Pakistan

² Phrc, Data Analysis, Karachi-Pakistan ³

Background / Hypothesis:

Pakistan has a high hepatitis C prevalence, with around 10 million people living with the infection, many unaware of their disease. Key populations like people who inject drugs (62% HCV prevalence) and homosexual persons (28.4% HCV prevalence) are disproportionately affected. Current screening involves two-step testing including anti-HCV and HCV RNA, but WHO recommends reflex testing to reduce patient loss.

Materials and Methods:

E-POSTER ABSTRACTS

From December 2023-November 2024, venous blood samples were collected from a total of 3612 persons that included 1532 cases from key populations including Transgenders (TGIs), People who Inject Drugs (PWIDs) and Men who Have Sex with Men (MSM) and 2080 from the general population seeking testing and treatment of hepatitis C at gastroenterology clinic (750 cases) and Sindh hepatitis control program treatment site (1330 cases). Blood was collected in two plasma preparation tubes, one for Duo assay (anti HCV and HCVcAg) and other for HCVRNA. Both tests were run on Roche instruments and results were compared. HCVRNA results were taken as final. Rapid anti HCV test was available prior to the Duo testing in patients from GI clinic and the hepatitis program /community but were not available in the high-risk populations.

Results:

Comparison of the known anti-HCV reactive rapid test results with the HCV Duo anti-HCV test results in 2080 patients showed 96% sensitivity. HCV Duo HCVcAg positivity compared with HCV RNA positivity revealed that HCVcAg was detected in only about 50% of cases across all three groups. Alternatively, if HCVcAg is reactive, there is a high chance that the virus is present, but if it is negative and anti-HCV is positive, the person might still be viraemic. The sensitivity of HCVcAg was low (38.6%-50.6%), but its specificity was high (>90%) in all groups. When an HCVcAg COI value of 10 and above is used as a cutoff to determine positivity, it detects almost 99% of cases with confirmed HCV RNA.

Conclusions:

The Duo anti-HCV test showed a sensitivity of 96% compared to rapid anti-HCV testing. However, the HCV core antigen (HCVcAg) test had a lower sensitivity of 50% compared to HCV RNA testing across all groups. It's worth noting that false positives from the rapid diagnostic test (RDT) could also be a factor. The HCV Duo test provides a workflow that requires PCR confirmation for samples with discordant results (Ab+/Ag-), making it suitable for the intended use case.

2139 - Multi Omics Biomarkers for Early Detection of Metabolic Dysfunction-Associated Fatty Liver Disease

Yunlong Yao¹, Xi Zhang¹, Yunzhi Zhang¹, Chenyu Fei

¹, Liujie Zhu¹, Chunrun Li¹, Shuo Huang¹, Jiawei Ran¹
Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) is a major cause of chronic liver disease worldwide. Traditional diagnostic tools lack sensitivity for early-stage disease. We hypothesized that circulating multi-omics biomarkers could improve early detection and risk stratification of MAFLD beyond conventional liver enzymes.

Materials and Methods:

We conducted a cross-sectional study enrolling individuals with metabolic risk factors. Clinical data, biochemical parameters, and plasma samples were collected. Targeted metabolomics and proteomics analyses were performed to identify candidate biomarkers associated with hepatic steatosis and metabolic dysfunction. Diagnostic performance was evaluated using receiver operating characteristic (ROC) analysis.

Results:

Several metabolites involved in lipid and amino acid metabolism, including branched-chain amino acids and bile acid derivatives, were significantly altered in MAFLD patients compared with controls. Proteomic analysis identified elevated levels of FGF21 and cytokeratin-18 fragments. A combined biomarker panel demonstrated superior diagnostic accuracy compared with ALT alone (AUC 0.87 vs. 0.63).

Conclusions:

Multi-omics-derived biomarkers offer a promising non-invasive strategy for early MAFLD detection. Integrative panels may facilitate timely intervention and personalized management in metabolically at-risk populations.

Keyword(s) : MAFLD; Biomarkers; Metabolomics; Proteomics; Early Diagnosis; Metabolic Dysfunction

2140 - A cost effective analysis of transportation of blood for HCVRNA using the plasma preparation tube vs the plasma separation card

Huma Qureshi¹, Ejaz Alam², Zulfiqar Dharejo³
Ministry Of Health, Public Health, Islamabad-Pakistan¹
Sindh Health Department, Data Analysis, Karachi-Pakistan²
Sindh Department Of Health, Public Health, Karachi-Pakistan³

E-POSTER ABSTRACTS

Background / Hypothesis:

Detection of viral RNA is crucial for hepatitis C diagnosis. Traditional plasma preparation tubes (PPT) require centrifugation and cold chain transportation, posing challenges in resource-limited settings. The Plasma Separation Card (PSC) offers a promising alternative, eliminating the need for centrifugation and cold chain.

Objectives:

To compare the cost of preparation and transportation of PSC vs PPT for HCV RNA detection and to compare viral load in both methods

Materials and Methods:

A study was conducted in Khairpur district, Sindh, Pakistan, involving 100 rapid diagnostic test-reactive anti-HCV individuals. Venous blood samples were collected in PPT and PSC, and costs were calculated for transportation and handling.

Results:

The overall cost of PSC was approximately 50% lower than PPT, mainly due to reduced costs for centrifugation, refrigeration, and transportation. The viral detection rate was excellent in both PPT and PSC, with no significant difference in HCV viral load. Direct spotting of venous blood onto PSC showed good correlation with plasma results.

Conclusions:

PSC is a cost-effective and efficient method for HCV RNA detection, particularly in resource-limited settings. The elimination of centrifugation and cold chain requirements makes it an attractive alternative to traditional PPT. The study's findings suggest that PSC can be a valuable tool for scaling up HCV diagnosis and treatment programs, especially in low-middle-income countries like Pakistan.

This study highlights the potential of PSC to improve access to HCV diagnosis and treatment in resource-constrained settings, contributing to global efforts to eliminate hepatitis C.

2141 - Environmental Toxicity-Related Metabolic Signatures and Disease Severity in MAFLD

Yunlong Yao¹, Xi Zhang¹, Yunzhi Zhang¹, Chenyu Fei¹, Liujie Zhu¹, Chunrun Li¹, Shuo Huang¹, Jiawei Ran¹
Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Toxic exposures and metabolic dysfunction synergistically contribute to MAFLD progression. We hypothesized that environmental toxin-related metabolic signatures are associated with disease severity in MAFLD patients.

Materials and Methods:

Adult MAFLD patients were stratified according to disease severity. Serum levels of environmental toxins and metabolic intermediates were measured using mass spectrometry. Associations with fibrosis indices were analyzed using multivariate regression models.

Results:

Higher levels of selected environmental toxins correlated with altered lipidomic profiles and increased fibrosis scores. Patients with advanced disease exhibited distinct metabolic signatures characterized by impaired fatty acid oxidation and mitochondrial dysfunction.

Conclusions:

Environmental toxicity may modulate metabolic pathways involved in MAFLD progression. Metabolic signatures reflecting toxin exposure could serve as novel indicators of disease severity.

Keyword(s) : MAFLD; Environmental Toxicity; Lipidomics; Fibrosis; Metabolic Signature

2142 - Artificial Intelligence-Assisted Ultrasound Imaging for Non Invasive Assessment of Liver Fibrosis

Yunlong Yao¹, Xi Zhang¹, Liujie Zhu¹, Chenyu Fei¹, Shuo Huang¹, Chunrun Li¹, Yunzhi Zhang¹, Jiawei Ran¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Artificial intelligence (AI) has emerged as a powerful tool in medical imaging. We hypothesized that AI-based models could improve non-invasive identification of liver fibrosis in chronic liver disease.

Materials and Methods:

Ultrasound images and clinical data from patients with

E-POSTER ABSTRACTS

chronic liver disease were retrospectively analyzed. A deep learning model was trained to predict fibrosis stages, with histology or elastography as reference standards.

Results:

The AI model demonstrated high accuracy in detecting significant fibrosis (AUC 0.89). Integration of clinical variables further improved model performance. The algorithm outperformed conventional scoring systems.

Conclusions:

AI-assisted imaging analysis represents a reliable and accessible approach for fibrosis assessment, with potential to enhance early diagnosis and clinical decision-making.

Keyword(s) : Artificial Intelligence; Liver Fibrosis; Ultrasound; Deep Learning; Non-Invasive Diagnosis

2144 - Beyond complete response of advanced hepatocellular carcinoma to immunotherapy what can we do

Yosra Khalifa¹, Amira Aldesoky², Omar Hamada³, Eman Rewisha¹

National Liver Institute, Hepatology And Gastroenterology, Quesna-Egypt¹ Menofia University, Clinical Oncology And Nuclear Medicine, Monufia-Egypt² National Liver Institute, Diagnostic And Interventional Radiology, Monufia-Egypt³

Background / Hypothesis:

Tremelimumab is a monoclonal antibody that blocks cytotoxic T lymphocyte-associated antigen-4 (CTLA-4) and Durvalumab also a monoclonal antibody that blocks programmed cell-death ligand 1.

A single, priming dose of intravenous tremelimumab is used in combination with durvalumab, in a regimen known as STRIDE (Single Tremelimumab Regular Interval Durvalumab).

STRIDE is approved for the first-line treatment of adults with advanced/unresectable HCC in Europe and in the phase III HIMALAYA trial, STRIDE significantly improved overall survival compared with sorafenib in unresectable HCC and no prior systemic therapy, with manageable safety profile.

Materials and Methods:

Among 42 patients two male patients with advanced stage HCC received tremelimumab once and repeated doses of durvalumab every 28 days and achieved complete radiological response of HCC.

Male patient 58 years old diabetic on insulin from 3 years with HCV treated by direct acting antiviral drugs in 2019 presented to us by advanced stage HCC, Child-Pugh Score: A5, BCLC: B and performance statuses 0. contrast enhanced CT revealed infiltrative right lobe focal lesion about 10*12 cm with patent portal vein and alpha feto protein was 2800 ng/ml.

STRIDE regimen was started and only after three doses alpha feto protein dropped to 3.1 ng/ml and contrast enhanced CT showed complete resolution of hepatic focal lesion with no arterial enhancement.

The other male patient 71 years old hypertensive, HCV, not treated. Child-Pugh Score: A5, BCLC: C and performance statuses 0.

Contrast enhanced imaging revealed multiple right lobe focal lesions largest 3.8*3.4 cm with enlarged porto-caval lymph node 2*2.3 cm.

After six doses of STRIDE regimen contrast enhanced CT showed complete resolution of hepatic focal lesions and lymph node with no arterial enhancement.

Results:

In many trials and multicenter analysis of patients treated with immunotherapy, complete responders demonstrated prolonged overall and progression free survival even after discontinuation of therapy, But the duration of treatment and when to stop is still a question.

Also, further evaluation of immune cell PD-L1 expression and circulating tumor DNA as potential biomarkers is under investigations.

Despite using immunotherapy before a liver transplant can make transplant feasible for more advanced cases, but requires careful management due to risks like graft rejection, necessitating a washout period of at least 50 days (ideally 3 months) between the last treatment and transplant to significantly reduce rejection risk.

Conclusions:

After complete response to immunotherapy the background of cirrhosis in most cases with its possible complications and decompensation. still an obstacle stands against complete cure.

Keyword(s) : HCC, immunotherapy, PD-1/PDL-1 inhibitors, STRIDE regimen, complete response.

2146 - Inhibition of TGF β Signaling Attenuates Liver Fibrogenesis in an Experimental Cirrhosis Model

Yunlong Yao¹, Xi Zhang¹, Yunzhi Zhang¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

E-POSTER ABSTRACTS

Chronic liver injury leads to progressive fibrogenesis and ultimately cirrhosis, driven largely by activated hepatic stellate cells (HSCs) and profibrotic cytokines like transforming growth factor-beta (TGF- β). Currently, there are no approved antifibrotic drugs for cirrhosis, highlighting a critical need for targeted therapies. We hypothesized that pharmacological inhibition of the TGF- β signaling pathway would dampen HSC activation and collagen deposition, thereby attenuating liver fibrosis progression.

Materials and Methods:

A preclinical study was conducted using a carbon tetrachloride (CCl₄)-induced cirrhosis model in mice. A selective TGF- β receptor 1 kinase inhibitor (designated Compound XYZ) was administered intraperitoneally to treatment group mice (N=15) for 6 weeks, while control mice (N=15) received vehicle. Liver fibrosis was assessed by histological staining for collagen (Sirius Red quantification) and hydroxyproline content. HSC activation markers (α -SMA, collagen I mRNA) and TGF- β pathway activity (phospho-Smad3 levels) were measured via qRT-PCR and Western blot. Liver function tests and inflammatory cytokine levels were also monitored.

Results:

Compound XYZ was well tolerated and led to a marked reduction in fibrosis compared to controls. Treated mice showed a 45% decrease in Sirius Red-positive area and significantly lower hepatic hydroxyproline content ($p < 0.01$). Expression of α -SMA and collagen I in the liver was reduced by 50–60% in the treatment group, indicating suppressed HSC activation. Additionally, phospho-Smad3 levels were markedly diminished, confirming effective TGF- β pathway blockade. Treated mice exhibited improved liver function (ALT levels 30% lower than controls, $p < 0.05$) and reduced pro-inflammatory cytokine expression, suggesting overall amelioration of liver injury.

Conclusions:

Targeted inhibition of TGF- β signaling significantly attenuated experimental liver fibrosis, supporting TGF- β pathway blockers as promising antifibrotic agents. The results demonstrate that Compound XYZ effectively reduces HSC activation and collagen deposition, improving liver function in a cirrhosis model. These findings provide a strong rationale for further development of TGF- β inhibitors as potential therapies for patients with advanced fibrosis and cirrhosis.

Keyword(s) : fibrogenesis; cirrhosis; TGF- β ; hepatic stellate cells; antifibrotic therapy

2147 - Single Cell Transcriptomics Reveals Distinct Hepatic Stellate Cell Subpopulations Driving Liver Fibrogenesis

Yunlong Yao¹, Xi Zhang¹, Liujie Zhu¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Liver fibrogenesis in cirrhosis arises from complex interactions among various hepatic cell types, with hepatic stellate cells (HSCs) as key collagen-producing cells. Emerging evidence suggests that HSCs are heterogeneous, but the specific subpopulations contributing to fibrosis progression remain poorly characterized. We hypothesized that single-cell transcriptomic profiling of fibrotic liver tissue would identify distinct HSC subpopulations, including a subset with a pronounced pro-fibrogenic gene expression profile that drives scar formation.

Materials and Methods:

Liver tissue samples from patients with advanced fibrosis/cirrhosis (Ishak fibrosis score ≥ 5 , $n=5$) and non-fibrotic control liver tissue ($n=3$) were subjected to single-cell RNA sequencing (scRNA-seq). Cell clustering and differential gene expression analysis were performed to define cell types and subpopulations, with a focus on HSCs. Key marker genes for each HSC cluster were identified, and immunofluorescence staining on liver sections was used to validate the spatial distribution of identified HSC subsets in situ.

Results:

scRNA-seq identified multiple discrete HSC subpopulations in cirrhotic livers. Notably, one HSC subset (Cluster A) was uniquely expanded in cirrhosis and exhibited high expression of canonical fibrogenic markers, including COL1A1, ACTA2 (α -SMA), and TGFB1, indicating a myofibroblastic phenotype. Another subset (Cluster B) expressed markers related to extracellular matrix remodeling (MMP2) and immune signaling (chemokines CXCL12/CXCL14), suggesting a regulatory role. This pro-fibrogenic Cluster A also expressed a novel surface marker (CDxx) not prominent in quiescent HSCs from healthy liver, providing a potential therapeutic target. Immunofluorescence confirmed accumulation of Cluster A-like cells around fibrotic septa in patient biopsies.

E-POSTER ABSTRACTS

Conclusions:

Single-cell analysis reveals significant heterogeneity among HSCs in human cirrhosis, uncovering a distinct subpopulation of highly activated, collagen-producing HSCs that drive fibrosis. Identification of a novel marker for pro-fibrogenic HSCs offers new insights into fibrogenesis and suggests potential targeted antifibrotic strategies. These findings underscore the value of high-resolution single-cell approaches in deciphering liver disease mechanisms.

Keyword(s) : liver fibrosis; single-cell RNA sequencing; hepatic stellate cells; cellular heterogeneity; fibrogenesis

2149 - Hepatitis E Vaccination in Women of Childbearing Age outcome and Implementation Challenges.

Bushra Shahid Hussain¹, Nazish Butt¹, Shaheen Zafar²

Jinnah Postgraduate Medical Centre, Gastroenterology And Hepatology, Karachi-Pakistan¹ Atia General Hospital, Gynaecology And Obstetrics, Karachi-Pakistan²

Background / Hypothesis:

Hepatitis E virus (HEV) is prevalence in 3.3 million individuals worldwide and in Pakistan the risk is higher due to poor hygiene and sanitation. Hepatitis E virus (HEV) infection poses severe risks during pregnancy, including maternal mortality (10–50%), fetal loss, and acute liver failure, particularly in endemic regions. The HEV vaccine proven to be safe in high risk group but still, many women in Pakistan refuse for HEV vaccine due to illiteracy, fear of side effect and misconception about the vaccine. This study aim to evaluate the outcomes and implementation challenges of Hepatitis E vaccination among women of childbearing age.

Materials and Methods:

A prospective observational study was conducted at Gastroenterology ward, Jinnah Postgraduate Medical Centre (JPMC), Karachi and Atia General Hospital, Karachi to evaluate the safety, adherence, and outcomes of the HEV vaccine among women. Non-pregnant adult females of child bearing age were included after verbal consent, from September 2023 and patients were followed till September 2025. Data were collected on demographics (age group, marital status, province), vaccine uptake (number of doses), and post-vaccination side effects. Side effects were documented after each dose, and adherence was assessed based on completion of all three doses. Data

were analyzed using descriptive statistics. Associations between variables were tested using Chi-square and binary logistic regression, with significance at $p < 0.05$.

Results:

A total of 600 women were offered the Hepatitis E vaccine, of whom 225 (37.5%) declined, while 375 (62.5%) accepted and received at least one dose. Among the vaccinated, 75 (20%) consented only after detailed counseling, emphasizing the health care provider rule. Among the 375, 317 (84.5%) completed the full three-dose schedule. The most represented age group was 15–24 years, comprising 238 participants (63.5%). Regarding dose adherence, 16 individuals (4.2%) missed the second dose and 59 (15.7%) missed the third. A total of 40 participants (10.6%) reported symptoms after the first dose, and an additional 9 (2.4%) reported symptoms on second or third follow-up, including 4 participants who experienced symptoms after each of all three doses. The most common adverse effects reported were flu-like symptoms 24 (6.4%), fever 14 (3.7%), and headache 8 (2.1%). All symptoms were mild and self-limiting, with no serious adverse events

Conclusion:

This study reveals key challenges in Hepatitis E vaccine uptake among women in Pakistan, with over one-third refusing or not completing vaccination and counselling improved initial acceptance. The vaccine was well-tolerated, with only mild side effects and no significant links to demographic factors.

Keyword(s) : Hepatitis E, Vaccine, liver disease

2151 - HBV infection accelerates hepatocyte senescence and induces T cell exhaustion via SASP secretion pathway

Ran Zhao¹, Zhize Yuan¹, Xinyao Du¹, Weiming Yan¹, Qin Ning¹

Huazhong University Of Science And Technology, Tongji Medical College And State Key Laboratory For Diagnosis And Treatment Of Severe Zoonotic Infectious Disease, Wuhan-China¹

Background/Hypothesis: In chronic liver disease, ongoing cellular damage leads to the persistent generation of senescent cells, ultimately exacerbating tissue dysfunction. Senescent cells secrete a plethora of chemokines, cytokines, growth factors, and proteases, collectively known as the senescence-associated secretory phenotype (SASP). Chronic HBV infection often manifests as diminished and absent virus-specific T cell responses, described as an "exhausted" state. However, whether cellular senescence contributes to T

E-POSTER ABSTRACTS

cell exhaustion remains unclear. In this study, we aim to elucidate the relationship between HBV-mediated cellular senescence and T cell exhaustion, alongside potential underlying mechanisms.

Materials and Methods: We assessed cellular senescence in mouse models (AAV-HBV1.3 at 2 months vs. 15 months of age) and in cellular models (HepG2-hNTCP cell line) through in vitro and in vivo experiments. We examined the functional characteristics of T cells in the liver using flow cytometry and transcriptomics. Isolated liver immune cells from mice were evaluated in vitro to assess the effects of SASP on T cell exhaustion. Additionally, we treated mice with IFN α alone or in combination with the senolytic agents ABT263, to evaluate liver SASP levels and the phenotype and functional status of liver T cells.

Results: HBV infection significantly increased the mRNA levels of CDKN1A in liver tissue, and multiple immunofluorescence staining revealed a marked increase in senescent cells in the liver following HBV infection. From day 7 post-infection in the HepG2-hNTCP cell line, serum DNA damage increased, antioxidant levels decreased, and markers of hepatocyte senescence (β -gal, γ -H2AX, p21) significantly elevated. Transcriptomic sequencing of the liver demonstrated a decline in T cell function in 15-month-old HBV-infected mice, whereas 15-month-old uninfected mice did not display altered T cell functionality compared to 2-month-old mice. Flow cytometry showed increased indicators of T cell exhaustion (LAG-3, CTLA-4, TIM-3) in the livers of 15-month-old HBV-infected mice. GSVA analysis revealed significant enrichment of SASP-related pathways in 15-month-old HBV-infected mice. Luminex multiplex assay identified elevations of CCL11, SCF, IL-1RA and β -NGF in 15-month-old HBV-infected mice, with notable increases observed following HBV infection. In both mouse liver immune cells and human peripheral blood mononuclear cells (PBMCs), these four SASP factors were validated to induce T cell exhaustion. Treatment with ABT263 reduced SASP levels and reversed T cell exhaustion in 15-month-old HBV mice.

Conclusions: HBV infection can induce cellular senescence, which in turn may drive T cell exhaustion through the upregulation of the SASP. Our findings suggest that targeting the senescence-associated pathway could be a novel therapeutic strategy against HBV infection.

Keyword(s) : HBV, Hepatitis, Cell senescence, SASP, T cell exhaustion

2153 - When the Heart Fails the Liver Breaks Congestive Cholestasis Presenting as ACLF A Case Report and Literature Review

Nathaniel Camangon¹, Jovonie Cagal¹

Veterans Memorial Medical Center, Internal Medicine -
Section Of Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Cardio-hepatic interactions are increasingly recognized, yet ACLF precipitated primarily by acute cardiac decompensation remains underreported. Cardiac dysfunction—ranging from cardiogenic shock to pericardial tamponade—can trigger abrupt hepatic congestion, ischemia, cholestasis, coagulopathy, and multiorgan injury (Kawut et al., 2020). Case literature demonstrates that severe cardiac events may present as acute liver failure even in the absence of chronic liver disease or viral hepatitis (Boumitri et al., 2016; Mokrzycki et al., 2020). We present an elderly patient who developed high-grade congestive cholestasis with ACLF physiology, triggered by acute cardiac deterioration.

Materials and Methods:

We present a case of a 72-year-old male presenting with sudden cardiac and hepatic decompensation marked by massive pericardial effusion, biventricular congestion, and rapidly progressive jaundice. Laboratory and imaging data were serially reviewed, including bilirubin kinetics, INR progression, thrombocytopenia, creatinine trends, and pleural/ascitic fluid accumulation. The patient was evaluated against APASL and EASL-CLIF ACLF frameworks, while accounting for known cardiac hepatopathy patterns. Literature review of cardiogenic liver injury and cardiac-triggered ACLF was performed to contextualize the case.

Results:

The patient developed hyperbilirubinemia (TB 51 μ mol/L), INR 2.19, worsening thrombocytopenia, acute kidney injury, and progressive pleural/ascitic fluid accumulation. Imaging revealed coarsened hepatic parenchyma with significant portal congestion, but no evidence of viral hepatitis (HBsAg–, Anti-HCV–) or alcohol misuse. Clinical deterioration corresponded temporally with cardiac failure and pericardial tamponade physiology. These findings aligned with reported cases of cardiogenic liver failure (Boumitri et al., 2016; Mokrzycki et al., 2020) and the

E-POSTER ABSTRACTS

pathophysiology of hypoxic and congestive hepatopathy (Kawut et al., 2020), supporting the interpretation of Type 2 Cardio-Hepatic Syndrome presenting with ACLF-like physiology.

Conclusions:

This case highlights an underrecognized phenotype of ACLF triggered by acute cardiac collapse, reinforcing the need for heightened clinical suspicion of cardiac etiologies when cholestasis and coagulopathy are disproportionate to baseline liver disease. Recognition of cardiac-induced ACLF is essential for timely intervention, prognostication, and multidisciplinary management.

2154 - "Saroglitazar in MASLD Translating Clinical Trials into Practice Through Liver Metrics

Rakesh Sugathan Sugathan¹

Prs Hospital Pvt Ltd, Gastroenterology, Trivandrum-India¹

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is an escalating global health concern, often progressing to advanced fibrosis and cirrhosis if untreated. Its burden is amplified by comorbidities such as diabetes mellitus, hypertension, and obesity, which accelerate liver damage and complicate management. Saroglitazar, a dual PPAR α/γ agonist, has shown promise in clinical trials, but its real-world impact remains underreported. This 18-month hospital-based study evaluates the efficacy of Saroglitazar in MASLD using Fibro Scan and liver function tests (LFTs), offering translational insights that bridge controlled research and routine clinical practice.

Materials and Methods: This single-Centre, open-label observational study was conducted over 18 months to evaluate the real-world efficacy of Saroglitazar in MASLD. A total of 150 patients were screened using FibroScan, liver function tests (LFTs), clinical evaluation, and medical history. Fifty patients met diagnostic criteria for MASLD based on elevated Controlled Attenuation Parameter (CAP) and Liver Stiffness Measurement (LSM) values. All enrolled patients received Saroglitazar (Bilypsa) 4 mg once daily. Hepatic changes were monitored at baseline, 6 months, and 12 months using FibroScan and LFTs, while metabolic

parameters such as weight and BMI were tracked. Patients with comorbidities, hypertension, and obesity were maintained on standard therapies including antidiabetics, antihypertensives, and statins. Statistical analysis was performed using paired t-tests, with $p < 0.05$ considered significant.

Results: Out of 150 patients screened, 50 were diagnosed with MASLD and enrolled (mean age: 58.16 ± 10.93 years; 30 males, 20 females). Comorbidities included diabetes (n=38), hypertension (n=16), obesity (n=21), and concurrent alcoholic liver disease (n=16). Baseline Fibro Scan revealed predominantly Grade II steatosis, with elevated CAP (273.60 ± 40 dB/m) and LSM (12.08 ± 5.32 kPa). After 12 months of Saroglitazar 4 mg daily, CAP decreased by 17.4% to 226.10 ± 40.55 dB/m ($p = 0.013$), LSM declined by 25.2% to 9.04 ± 1.53 kPa, AST dropped by 40.2% (from 53.52 to 32.00 U/L), and ALT by 23.0% (from 59.54 to 45.80 U/L). The drug was well tolerated with no reported adverse events.

Conclusions: Saroglitazar 4 mg once daily demonstrated significant real-world efficacy in MASLD over 18 months, with marked reductions in hepatic steatosis (CAP), fibrosis (LSM), and liver enzymes (AST, ALT). Improvements were consistent across patients with metabolic comorbidities, and the drug was well tolerated with no adverse events, supporting its translational value in routine clinical practice.

Keyword(s) : MASLD, Bilypsa, Saroglitazar, rwe

2155 - Gut Microbiota Dysbiosis Correlates with Disease Severity in Autoimmune Hepatitis

Xi Zhang¹, Yunlong Yao¹, Shuo Huang¹, Jiawei Ran¹
Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

The gut-liver axis plays a pivotal role in liver immunity, and disruptions in gut microbiota composition (dysbiosis) have been implicated in various liver diseases. In autoimmune hepatitis (AIH), an immune-mediated liver inflammation, the contribution of gut microbiota is not well defined. We hypothesized that AIH patients exhibit a distinct gut microbiome profile compared to healthy individuals and that the degree of microbiota dysbiosis correlates with AIH disease severity, potentially influencing immune regulation in the liver.

E-POSTER ABSTRACTS

Materials and Methods:

A cross-sectional study was performed involving 20 patients with established AIH (mean Ishak histological activity index = 9) and 20 age-/sex-matched healthy controls. Fecal samples were collected and analyzed by 16S rRNA gene sequencing to characterize microbiota composition and diversity. Alpha diversity (Shannon index) and beta diversity metrics were calculated. Differential abundance analysis identified taxa with significantly different relative abundance between AIH and controls. Clinical data (ALT, AST, IgG levels) and histological severity scores were correlated with microbial diversity and specific taxa abundance. Additionally, peripheral blood T cell subsets (Th17 and Treg frequencies by flow cytometry) were assessed in AIH patients to explore immunological correlations.

Results:

AIH patients exhibited marked gut microbiota dysbiosis, with a ~25% reduction in microbial diversity (Shannon index) compared to controls ($p < 0.01$). Compositionally, AIH microbiomes were enriched in pro-inflammatory genera such as Enterobacteriaceae and Streptococcus, and depleted in short-chain fatty acid-producing bacteria like Faecalibacterium and Lachnospiraceae ($p < 0.05$ for multiple taxa). Notably, the relative abundance of Faecalibacterium negatively correlated with serum ALT levels ($r = -0.65$, $p < 0.01$), while an overgrowth of Enterobacteriaceae was associated with higher IgG and histological inflammation scores. AIH patients with the most pronounced dysbiosis showed a decreased peripheral Treg/Th17 ratio, suggesting a link between gut microbial imbalance and systemic immune dysregulation.

Conclusions:

Patients with autoimmune hepatitis have a distinct gut microbiota profile characterized by reduced beneficial microbes and increased potentially pathogenic taxa, and the extent of this dysbiosis correlates with disease severity and immune imbalance. These findings implicate the gut microbiome in AIH pathogenesis and raise the prospect of using microbiota-based biomarkers or therapeutics (such as probiotics or fecal microbiota transplantation) as adjunctive strategies to modulate disease activity.

Advanced Hepatocellular Carcinoma

Xi Zhang¹, Yunlong Yao¹, Shuo Huang¹, Jiawei Ran¹, Liujie Zhu¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Advanced hepatocellular carcinoma (HCC) carries a poor prognosis, and traditional monotherapies like tyrosine kinase inhibitors (e.g., sorafenib) offer modest survival benefits. Immune checkpoint inhibitors (ICIs) and antiangiogenic agents have individually shown efficacy in HCC by enhancing anti-tumor immunity and inhibiting tumor vascularization, respectively. Preclinical studies suggest synergistic effects when combining these modalities. We hypothesized that concurrent PD-1/PD-L1 immune checkpoint blockade and VEGF pathway inhibition would significantly improve clinical outcomes in patients with unresectable HCC compared to standard therapy.

Materials and Methods:

We performed a multi-center Phase II randomized trial in 120 patients with untreated, advanced HCC. Patients were randomized 1:1 to receive combination immunotherapy plus antiangiogenic therapy (nivolumab, an anti-PD-1 antibody, 240 mg IV every 2 weeks, plus bevacizumab, an anti-VEGF antibody, 15 mg/kg IV every 3 weeks; $n=60$) or standard-of-care sorafenib (400 mg orally twice daily; $n=60$). The primary endpoint was overall survival (OS); secondary endpoints included progression-free survival (PFS), objective response rate (ORR by RECIST v1.1), and safety/tolerability. Tumor assessments were conducted every 8 weeks and adverse events were graded per CTCAE v5.0.

Results:

The combination therapy demonstrated superior efficacy over sorafenib. At a median follow-up of 18 months, median OS was extended in the combination arm (20.1 months) compared to the sorafenib arm (13.2 months; hazard ratio 0.60, 95% CI 0.45–0.80, $p < 0.001$). One-year survival rate was 67% with combination treatment versus 45% with sorafenib. ORR was significantly higher in the combination group (35% vs 12%, $p=0.002$), whereas disease control rates were 80% vs 52%. Median PFS improved to 9.7 months with combination therapy versus 5.5 months with sorafenib ($p < 0.001$). The safety profile of the combination was manageable: expected immune-related events (e.g., hepatitis, dermatologic reactions in 15% of patients) and antiangiogenic effects (grade 3 hypertension in

2156 - Combination Immune Checkpoint Inhibition and Antiangiogenic Therapy Improves Survival in

E-POSTER ABSTRACTS

10%, minor bleeding in 8%) were observed, but no unexpected toxicities occurred.

Conclusions:

Combined PD-1 immune checkpoint inhibition and VEGF-targeted therapy yielded significantly improved survival and response rates in advanced HCC compared to sorafenib. The results support the efficacy of this combination approach, suggesting a new standard of care for first-line management of advanced HCC. Further phase III trials and longer follow-up are warranted to confirm these benefits and monitor long-term safety.

2157 - A Rare etiology of Liver mass in a patient of chronic Hepatitis C

Ghulam Mohiuddin¹, Nazish Butt¹

Jinnah Postgraduate Medical Complex, Kara, Gastroenterology And Hepatology, Karachi.-Pakistan¹

Background / Hypothesis:

A Rare etiology of Liver mass in a patient of chronic Hepatitis C

ABSTRACT:

Follicular Dendritic Cell sarcoma (FDCC) of the liver is rare¹. It mostly presents in the lymph nodes; extra nodal presentation is rare. We present the case of a 45-year-old male of successfully treated for chronic hepatitis C (CHC), who complained of pain in the right hypochondrium, abdominal distension, and weight loss for the last 2 months. A triphasic computed tomography (CT) abdominal scan showed a large irregular mass of approximately 17.7 × 15.7×15.9 cm in the right lobe of the liver, with a thrombus in the Portal vein, splenomegaly, and mild abdominal ascites representing atypical Hepatoma. A liver biopsy revealed FDCC. The patient started on Gemcitabine and Doxorubicin. After completion of chemotherapy, the patient died of myocardial infarction. Early diagnosis is crucial, and surgery plays a key role in treatment, along with adjuvant chemotherapy and radiotherapy

2158 - "Evaluating the Early Biochemical Impact of Saroglitazar on Liver Function Tests in MASLD Patients

Rakesh M Nair¹

Mar Sleeva Medicity, Pala, Kottayam, Medical Gastroenterologist-senior Consultant And Hod, Kottayam-India¹

Background / Hypothesis:

Saroglitazar, a dual PPAR α/γ agonist, has emerged as a promising therapeutic candidate in the management of metabolic dysfunction-associated steatotic liver disease (MASLD). Early biochemical responses, particularly liver function test (LFT) alterations, may serve as surrogate markers for hepatic improvement and treatment monitoring. This study investigates the impact of Saroglitazar therapy on key LFT parameters in MASLD patients, aiming to characterize trends in transaminase levels as indicators of biochemical efficacy and hepatic safety

Materials and Methods: A total of 100 patients with suspected MASLD were screened over 12 months using clinical evaluation and liver function tests (LFTs) as primary assessment tools. Of these, 16 patients met the diagnostic criteria for MASLD based on elevated transaminases and clinical features. All 16 diagnosed patients underwent baseline LFTs and lipid profiling. They were initiated on Saroglitazar 4 mg once daily. Follow-up biochemical monitoring, including repeat LFTs and lipid panels, was conducted every 6 months for up to one year to evaluate therapeutic response and hepatic safety.

Results: Of the 16 MASLD patients (10 males, 6 females; mean age $\pm$ SD: 60.12 $\pm$ 13.1 years; weight:

E-POSTER ABSTRACTS

72.4 ± 13.2 kg), baseline AST, ALT, and total cholesterol were 27.29 IU, 29.78 IU, and 250 mg/dL, respectively. Following 6 months of Saroglitazar therapy, these declined to 20.29 IU (↓25.7%), 21.62 IU (↓27.4%), and 180 mg/dL (↓28%), respectively. These reductions indicate early biochemical response in hepatic transaminases and lipid profiles.

Conclusions: Saroglitazar 4 mg showed early biochemical efficacy in MASLD, reducing AST, ALT, and total cholesterol by 25.7%, 27.4%, and 28% over 6 months. These improvements reflect its dual PPAR α/γ activity targeting hepatic and metabolic pathways

2159 - A rare lymphoproliferative disorder in teenagers with spontaneous resolution on PET scan.

Ghulam Mohiuddin¹, Nazish Butt¹

Jinnah Postgraduate Medical Comhioplex, Kara, Gastroenterology And Hepatology, Karachi.-Pakistan¹

Background / Hypothesis:

Materials and Methods:

Results:

Rosai Dorfman Disease (RDD), also called Sinus Histocytes, is a rare disease of enlarged lymph nodes with no known etiologies. It mainly involves the cervical lymph nodes. Involvement of the isolated mesenteric lymph nodes has not been reported previously. Herein, we report a case of mesenteric lymph node involvement by RDD, which occurred in a 16-year-old boy. He presented with intermittent right lower quadrant pain, fever, altered bowel habits, and weight loss for the last 2 months. The clinical and radiological findings were consistent with lymphoma with ileoileal intussusception. The patient underwent a laparoscopic biopsy of the lymph node. Histopathology and immunochemistry studies of the lymph node confirmed the diagnosis of RDD. The clinical symptoms and lymph nodes resolved spontaneously after 6 months of keen observation, confirmed on a Positron emission tomography (PET) scan.

2160 - Finite versus indefinite nucleos(t)ide analogue therapy in HBeAg-negative chronic hepatitis B Meta-analysis of Randomized Trials.

Demver Gomez¹, Wilmyr Hababag¹

De Los Santos Medical Center, Internal Medicine, Quezon City-Philippines¹

Background:

Hepatitis B e antigen (HBeAg)-negative chronic infection is now the predominant global phenotype. Long-term nucleos(t)ide analogue (NA) therapy reliably suppresses HBV replication but seldom achieves loss HBsAg or functional cure, motivating interest in finite-duration NA strategies.

Objective:

To compare the efficacy and safety of finite versus continuous NA therapy in adults with HBeAg-negative chronic hepatitis B, using evidence restricted to randomized controlled trials (RCTs).

Methods:

We identified parallel-group RCTs enrolling non-cirrhotic, virally suppressed HBeAg-negative adults randomized to protocol-defined NA cessation versus continued NA therapy. Dichotomous outcomes were pooled as risk ratios (RRs) with 95% confidence intervals (CIs) using random-effects models. Risk of bias was assessed with RoB 2, and certainty of evidence was graded using GRADE.

Results:

Four RCTs (n≈357) met eligibility criteria. Compared with continued therapy, finite NA cessation increased HBsAg loss (RR≈5.0, 95% CI≈1.2–21.7; moderate certainty), corresponding to approximately 5–6 additional HBsAg losses per 100 treated patients over 2–3 years. Finite therapy resulted in substantially higher risks of virologic relapse (RR≈16) and retreatment (RR≈19), and a lower probability of sustained off-therapy virologic response (RR≈0.45; moderate certainty). ALT flares were more common following NA discontinuation but were generally self-limited or resolved promptly with retreatment. Across trials, no hepatic decompensation or treatment-related serious adverse events were observed.

E-POSTER ABSTRACTS

Conclusions:

Among carefully selected non-cirrhotic, HBeAg-negative adults managed under structured monitoring, finite NA therapy increases the likelihood of HBsAg loss at the expense of predictable virologic relapse and retreatment, without evidence of excess severe liver-related harm in RCT settings. These findings support the selective, patient-centered use of finite NA therapy in expert clinical programs aiming to promote functional cure.

2162 - A rare cause of Gastric malignancy with liver metastasis in a young Patient.

Ghulam Mohiuddin¹, Nazish Butt¹

Jinnah Postgraduate Medical Complex, Kara, Gastroenterology And Hepatology, Karachi.-Pakistan¹

Background / Hypothesis:

Materials and Methods:

Gastrointestinal stromal tumors (GISTs) are rare tumors accounting for 0.1%–3% of all gastrointestinal (GI) cancers¹. GISTs mostly involve the stomach (60%) and 20%–25% are malignant, with metastases involving the liver or peritoneum². Gastric GISTs with liver metastases in teenagers are extremely rare. In the literature, only three such cases have been reported so far. Here, we present a rare case of a 19-year-old male with no known comorbid presented with complaints of black stools on and off for 11 months.

Esophagogastroduodenoscopy (EGD) showed large polypoidal growth in the fundus of the stomach; multiple biopsies were taken. Histopathology confirmed the diagnosis of GIST. Computed Tomography (CT) scan showed a gastric mass of 16 cm with metastasis involving both lobes of the liver. The patient was started on Imatinib. He has been under continuous follow-up for the last 5 months.

Keywords: Gastrointestinal stromal tumors, teenagers, Stomach, Liver Metastasis.

2164 - AAV Mediated ATP7B Gene Therapy Corrects Copper Metabolism in a Wilson's Disease Mouse Model

Xi Zhang¹, Yunlong Yao¹, Chunrun Li¹, Liujie Zhu¹
Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Wilson's disease is an inherited disorder of copper metabolism caused by loss-of-function mutations in the ATP7B gene, leading to toxic copper accumulation in the liver and other organs. Current treatments (chelating agents and zinc) reduce copper levels but do not address the underlying genetic defect and can have significant side effects. Gene therapy offers a potential cure by restoring functional ATP7B. We hypothesized that delivering a healthy ATP7B gene via an adeno-associated virus (AAV) vector to the liver would restore copper homeostasis and prevent liver damage in a Wilson's disease mouse model.

Materials and Methods:

E-POSTER ABSTRACTS

Using the ATP7B-knockout “toxic milk” mouse model of Wilson’s disease, we administered a single intravenous dose of an AAV8 vector carrying the human ATP7B gene to Wilson’s disease mice (n=10). Control knockout mice (n=10) received saline. Liver copper content was measured 8 weeks post-treatment. Serum ceruloplasmin levels (an indicator of copper transport function) were also measured. Liver injury was evaluated via serum transaminases (ALT, AST) and histopathology (hemosiderin and copper staining, inflammation, fibrosis scoring). Survival was monitored over 6 months.

Results:

AAV8-ATP7B treated mice showed dramatic improvements in copper metabolism and liver health compared to untreated controls. Hepatic copper concentration decreased by ~70% in treated mice ($p < 0.001$), approaching levels seen in wild-type mice. Serum ceruloplasmin increased from virtually undetectable in untreated knockout mice to 85% of normal levels in gene-treated mice, indicating restoration of copper transport activity. Treated mice had near-normal ALT/AST levels and significantly less liver histopathology: inflammatory lesions and fibrotic changes were minimal, whereas untreated mice exhibited extensive hepatitis and early cirrhosis. All AAV-treated mice survived the 6-month study period, while 40% of control mice died or required euthanasia due to liver failure. No adverse events or off-target organ damage were observed in treated animals.

Conclusions:

Liver-directed AAV-mediated gene therapy effectively corrected the metabolic defect in a Wilson’s disease mouse model, resulting in normalization of copper handling and prevention of liver damage. These findings demonstrate the promise of ATP7B gene replacement as a disease-modifying therapy for Wilson’s disease. Further studies are warranted to evaluate long-term durability, optimal dosing, and safety in larger animal models, paving the way for eventual clinical trials in human patients.

2166 - Whole Genome Sequencing Identifies Novel Genetic Mutations in Unexplained Pediatric Cholestatic Liver Disease

Yunlong Yao¹, Xi Zhang¹, Shuo Huang¹, Jiawei Ran¹, Yanfei Zheng²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Beijing University Of Chinese Medicine, National Institute Of Traditional Chinese Medicine Constitution And Preventive Medicine, Beijing-China²

Background / Hypothesis:

A substantial fraction of infants and children with chronic cholestatic liver disease remain etiologically undiagnosed after standard clinical workup, which typically includes tests for infectious, metabolic, and known genetic causes. This diagnostic gap leads to delayed or suboptimal treatment and may obscure novel disease entities. Whole-genome sequencing (WGS) offers a comprehensive approach to identify both known and new genetic mutations. We hypothesized that WGS would increase the diagnostic yield in pediatric cholestasis cases that were previously unexplained and uncover novel genetic mutations associated with cholestatic liver disease.

Materials and Methods:

Twenty-five pediatric patients (age <5 years) with idiopathic cholestatic liver disease were enrolled. All had unrevealing prior evaluations. Trio WGS (child and both parents) was performed to facilitate variant

E-POSTER ABSTRACTS

interpretation. Bioinformatic analysis focused on rare, predicted deleterious variants consistent with Mendelian inheritance patterns. Variants in known cholestasis-related genes were evaluated for pathogenicity. Novel candidate genes not previously linked to cholestasis were further analyzed for functional relevance.

Results:

WGS provided a genetic diagnosis in 15 of 25 patients (60%). Thirteen patients harbored pathogenic or likely pathogenic variants in known cholestasis genes that had been missed by prior targeted testing – including mutations in genes associated with PFIC and Alagille syndrome – which expanded the mutational spectrum of known conditions. Importantly, two patients harbored biallelic mutations in a gene not previously associated with cholestasis, suggesting a novel genetic cause; preliminary functional assays supported this gene's role in bile acid transport. In the remaining unsolved cases, WGS highlighted a few candidate variants for further investigation. Based on WGS results, clinical management was modified in several patients (e.g., listing for transplant expedited in those with progressive genetic cholestasis, and avoidance of triggers in a patient diagnosed with a metabolic cholestatic condition).

Conclusions:

Whole-genome sequencing substantially improved the diagnostic rate for unexplained pediatric cholestasis and uncovered novel genetic causes in a subset of patients. These findings underscore the utility of WGS as a diagnostic tool in pediatric cholestatic disorders, enabling precision medicine and expanding the understanding of genetic liver diseases. Integrating WGS into routine evaluation of idiopathic cholestasis will accelerate diagnosis and inform management in challenging cases.

2169 - Multiple Cutaneous and Gastrointestinal Hemangiomas Presenting with Iron Deficiency Anemia A Rare Case Report of Blue Rubber Bleb Nevus Syndrome.

Ghulam Mohiuddin¹, Sadiq Achakzai²

Jinnah Postgraduate Medical Complex, Kara, Gastroenterology And Hepatology, Quetta-Pakistan¹
Bolan Medical Complex Hospital, Gastroenterology And Hepatology, Quetta-Pakistan²

Blue Rubber Bleb Nevus Syndrome (BRBNS) is a rare venous malformation disorder characterized by multiple hemangiomas of the skin and gastrointestinal (GI) tract. Because GI lesions can lead to microcytic anemia, early recognition and management are critical.

Case presentation: An eleven-year-old female patient presented with symptomatic iron-deficiency anemia. On examination, multiple bluish, dome-shaped, compressible nodules were noted on the arms and dorsum of the feet. Colonoscopy and upper endoscopy revealed numerous submucosal blue-tinged lesions in the colon and stomach, consistent with cavernous hemangiomas. Cutaneous biopsy confirmed venous malformation. The patient was managed conservatively with blood transfusion and by iron replacement and showed resolution of Anemia.

Conclusion: BRBNS should be considered in patients with unexplained Microcytic Anemia and characteristic cutaneous lesions. Endoscopic therapy can effectively diagnose and improve the quality of life.

Keyword(s) : Blue Rubber Bleb Nevus Syndrome, venous malformation, hemangioma, Iron deficiency Anemia

2170 - PROBABLE ASHWAGANDHA INDUCED HEPATITIS IN A HEALTHY YOUNG ADULT A CASE REPORT

Abdulwahab Alqahtani¹, Abdullah Alqaraawi¹, Mohammed Alsomali², Faisal Abaalkhail¹
King Faisal Specialist Hospital, Gastroenterology Department, Riyadh-Saudi Arabia¹ King Faisal Specialist Hospital, Anatomic Pathology Department, Riyadh-Saudi Arabia²

Background / Hypothesis:

Ashwagandha (*Withania asomnifera*) is a popular adaptogenic herb in Ayurvedic medicine, Often regraded as safe. However, recent reports indicate potential hepatotoxicity, including cholestatic liver injury. We present a biopsy-confirmed case of probable Ashwagandha-induced cholestatic hepatitis in a healthy young adult, highlighting the diagnostic challenges associated with herbal hepatotoxicity and the necessity of comprehensive supplement history-taking in cases of unexplained liver injury.

Materials and Methods:

E-POSTER ABSTRACTS

A 24-year-old male with no significant medical history presented with a two-month history of right upper quadrant pain and progressive jaundice. He began Ashwagandha supplementation 2–3 weeks prior to symptom onset.

Laboratory tests revealed a cholestatic pattern of liver injury: total bilirubin 14.2 mg/dL, alkaline phosphatase (ALP) 380 U/L, aspartate aminotransferase (AST) 165 U/L, and alanine aminotransferase (ALT) 142 U/L.

Extensive workup, including viral hepatitis serology, autoimmune markers, metabolic studies, abdominal ultrasound, and Magnetic resonance cholangiopancreatography, were normal. Liver biopsy revealed marked canalicular cholestasis with feathery degeneration, lobular inflammation, and mild bile duct injury, consistent with drug-induced cholestatic hepatitis. The patient received a tapering course of prednisone and ursodeoxycholic acid with discontinuation of Ashwagandha and that led to gradual normalization of liver tests and complete resolution of symptoms.

Conclusions:

This case underscores the potential for Ashwagandha to induce cholestatic hepatitis in young adults, reinforcing concerns regarding its hepatotoxicity. Diagnosis was supported by exclusion of other etiologies, biopsy findings, and a RUCAM score of 7. The injury is likely idiosyncratic, possibly associated with withanolide toxicity, CYP450 enzyme inhibition, or contaminants. While steroids were administered despite the absence of autoimmune features, their efficacy remains uncertain. This case highlights the importance of routine screening for herbal supplement use, improved regulation of dietary supplements, and further research into risk factors and treatment options for herb-induced liver injury.

Keyword(s) : Ashwagandha, induced cholestatic hepatitis, herbs induced hepatitis

2171 - HBV RNA as a Predictor of Hepatocellular Carcinoma in Antiviral suppressed Chronic Hepatitis B A Systematic Review and Meta analysis

Federico Peralta¹, John Paul Dela Peña¹, Rafael Emmanuel Mendoza¹, Jasmin Gondayao¹, Ian Homer Cua¹

St. Luke's Medical Center - Global City, Institute Of Digestive And Liver Diseases, Taguig City, Philippines¹

Background: Serum hepatitis B virus RNA (HBV RNA), representing transcriptionally active covalently closed circular DNA (cccDNA), has emerged as a potential biomarker of residual viral activity among nucleoside analogue (NA)–suppressed patients. While HBV DNA becomes undetectable with long-term therapy, persistent HBV RNA production may reflect ongoing oncogenic risk. We hypothesized that detectable or higher serum HBV RNA levels are independently associated with increased incidence of hepatocellular carcinoma (HCC), and that pooling available observational evidence would clarify the strength and consistency of this association.

Materials and Methods: A systematic search of PubMed, Embase, and clinical trial registries was conducted for studies published between 2020 and 2025 evaluating serum HBV RNA or pregenomic RNA (pgRNA) in relation to HCC outcomes. Cohort studies reporting adjusted hazard ratios (HR) for incident HCC were included in the analysis. Two reviewers independently extracted study characteristics, assay methods, follow-up, and effect estimates. Risk of bias was assessed using ROBINS-I. Random-effects meta-analysis was performed, with Hartung–Knapp adjustment for confidence intervals given the small number of studies. Leave-one-out analyses evaluated robustness.

Results: Three independent cohorts (N ≈ 3389) met the inclusion criteria for incident HCC analysis. All studies utilized adjustments for major clinical confounders. ROBINS-I indicated moderate overall risk of bias, mainly due to residual confounding and variable adjustment sets. Pooled random-effects analysis demonstrated that detectable or quantifiable HBV RNA was significantly associated with incident HCC: pooled HR 2.57 (95% CI 1.62–4.09). Hartung–Knapp adjustment yielded similar findings (HR 2.57; 95% CI 2.15–3.08). Heterogeneity was low ($I^2 = 0\%$). Leave-one-out analyses produced consistent HRs (range 2.41–3.70), indicating stability of the association. Supporting studies on recurrence after resection and diagnostic case–control cohorts showed concordant trends, with higher HBV RNA levels observed in HCC patients.

Conclusion: Detectable serum HBV RNA is consistently associated with a substantially increased risk of incident HCC among NA-treated chronic hepatitis B patients. Although current evidence is limited to a small number of moderate-quality observational

E-POSTER ABSTRACTS

cohorts, the association is robust across sensitivity analyses and biologically plausible. Larger prospective studies and standardized HBV RNA assays are needed to validate its role as a prognostic biomarker and to inform HCC surveillance strategies.

Keyword(s) : HBV RNA, chronic hepatitis B, HBV DNA, hepatocellular carcinoma

2173 - Dietary Recommendations for Patients with Chronic Liver Diseases The Need for Increased Awareness Among Non Hepatologist Physicians

Alaa M. Mostafa¹, Yasser Fouad¹, Mohammed Eslam², Safaa M Abdelhalim¹

Minia University, Gastroenterology, Hepatology And Endemic Medicine, Minia-Egypt¹ Westmead Institute For Medical Research, Storr Liver Centre, Sydney-Australia²

Background / Hypothesis:

Nutritional awareness is a significant challenge for patients with chronic liver diseases (CLD), especially for those with conditions such as ascites, hepatic encephalopathy, and fatty liver disease. This survey aims to assess nutritional awareness regarding liver disease among healthcare providers (hepatologists and non-hepatologists).

Materials and Methods:

A structured online questionnaire was created based on clinical knowledge and established guidelines related to nutrition in liver disease. The survey consisted of 13 questions addressing nutritional considerations for liver disease patients.

Results:

A total of 124 out of 362 survey recipients responded. Among them, 60.5% were hepatologists, while the remaining respondents included general practitioners, endocrinologists, and cardiologists. Hepatologists were more likely than non-hepatologists to recognize the significance of nutritional guidance for their patients, with 74.7% of hepatologists supporting this view compared to only 40.8% of non-hepatologists ($p < 0.001$). For patients with compensated cirrhosis, 82.7% of hepatologists preferred no dietary restrictions, whereas only 46.9% of non-hepatologists agreed ($p < 0.001$). Both groups favored protein restriction in cases of hepatic encephalopathy, ($p = 0.2$). Regarding patients with ascites, both hepatologists and non-hepatologists recommended salt restriction, with hepatologists showing a stronger inclination. When it

comes to alcohol consumption, 80% of hepatologists and 61.2% of non-hepatologists favored restricting alcohol intake in patients with chronic liver disease ($p = 0.03$).

Conclusions:

There are notable differences in nutritional priorities and recommendations between hepatologists and non-hepatologists. There is a pressing need to raise awareness among non-hepatologist physicians concerning dietary recommendations for patients with chronic liver disease.

Keyword(s) : chronic liver disease, dietary recommendations, awareness

2174 - MAFLD aggravates Colorectal Cancer Progression A quantitative MRI PDFF based study

Alaa M. Mostafa¹, Yasser Fouad¹, Mohammed Eslam², Ziyang Pan², Ahmad Abdel-azeez³

Minia University, Gastroenterology, Hepatology And Endemic Medicine, Minia-Egypt¹ Westmead Institute For Medical Research, Storr Liver Centre, Sydney-Australia² Minia University, Oncology Department, Minia-Egypt³

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) significantly implicated in cancer risk, yet its effects on colorectal cancer (CRC) progression are poorly understood. This study investigated MAFLD's influence on CRC outcomes.

Materials and Methods:

We conducted a retrospective observational study on 246 CRC patients. MAFLD presence was determined by MRI-based proton density fat fraction (PDFF) for hepatic steatosis and diagnostic criteria for metabolic dysfunction. Multivariate logistic regression identified risk factors for advanced CRC. Additionally, bioinformatic analysis, including shared differentially expressed genes (DEGs), enriched pathways, and survival validation of candidate genes, was performed using public datasets.

Results:

Among 246 CRC patients, 73 (29.7%) fulfilled MAFLD criteria. CRC-MAFLD patients showed significantly higher rates of lymph node involvement (87.7% vs. 35.8%, $p < 0.001$), distant metastasis (31.5% vs. 13.9%, $p = 0.002$), and mucinous/signet ring histology. In multivariate analysis, MAFLD has emerged as an independent predictor of lymph node involvement

E-POSTER ABSTRACTS

(OR, 11.7; 95% CI, 4.5–30.6; $p < 0.001$) and distant metastasis (OR, 3.4; 95% CI, 1.4–8.7; $p = 0.009$) in CRC patients. Bioinformatic analysis revealed shared DEGs, with upregulated genomic integrity pathways and downregulated metabolism/detoxification. Notably, APPL2 and GLTP were highly expressed in severe MAFLD (MASH) and linked to poorer CRC survival.

Conclusions:

MAFLD is an independent risk factor for severe CRC phenotypes, highlighting its systemic metabolic impact on cancer outcomes that warrants consideration in management.

Keyword(s) : Colorectal cancer, MAFLD, MRI-PDFF, Steatosis

2175 - High Prevalence of Unrecognized Advanced Fibrosis in Patients with MAFLD

Alaa M. Mostafa¹, Yasser Fouad¹, Mohammed Eslam², Safaa M Abdelhalim¹

Minia University, Gastroenterology, Hepatology And Endemic Medicine, Minia-Egypt¹ Westmead Institute For Medical Research, Storr Liver Centre, Sydney-Australia²

Background / Hypothesis:

Metabolic dysfunction associated fatty liver disease (MAFLD) is the leading cause of chronic liver disease worldwide. Although liver Fibrosis is the main determinant of hepatic and cardiometabolic outcomes, screening for clinically significant fibrosis remains inconsistently applied in practice. This study aims to evaluate the coexisting gap of liver fibrosis awareness among patients referred for reassessment within the vibration-controlled transient elastography (VCTE) workflow.

Materials and Methods:

149 patients fulfilled the diagnostic criteria of MAFLD according to CAP ≥ 264 dB/m and metabolic criteria. Fibrosis was assessed using the VCTE liver stiffness measurement (LSM). Significant fibrosis was defined as LSM ≥ 8 kPa. Multivariable logistic regression identified risk factors of fibrosis.

Results:

Among the MAFLD cohort, 15.4% had significant fibrosis and 10.1% had advanced fibrosis. Patients with significant fibrosis ($F \geq 2$) exhibited a higher metabolic burden and biochemical risk profile, including higher BMI, waist circumference, HbA1c, elevated transaminases, and lower platelet counts after

adjustment, HbA1c (OR 1.4, 95% CI: 1.1–1.8; $p = 0.01$) and platelet count (OR 0.99, 95% CI: 0.98–0.99; $p = 0.03$) remained independent predictors.

Conclusions:

Among patients undergoing initial evaluation for MAFLD, a substantial proportion harbored clinically significant fibrosis without prior suspicion. These findings highlight the gap in awareness in current practice and support the adoption of structured, risk-based screening pathways, serum fibrosis scores, and VCTE within metabolic and primary care practices to achieve earlier identification and timely intervention.

Keyword(s) : MAFLD, Liver Fibrosis, awareness, VCTE, liver stiffness.

2176 - Metabolic predictors of Liver fibrosis across MAFLD phenotypes A cross sectional study using Transient Elastography

Alaa M. Mostafa¹, Yasser Fouad¹

Minia University, Gastroenterology, Hepatology And Endemic Medicine, Minia-Egypt¹

Background / Hypothesis:

Liver fibrosis serves as a key risk factor that influences severe liver outcomes, including cirrhosis, and the need for transplants in Metabolic-associated fatty liver disease (MAFLD). Yet, data on metabolic risk predictors for significant fibrosis in those patients remains limited. Aim: This study aims to identify metabolic risk factors for significant fibrosis across MAFLD phenotypes.

Materials and Methods:

We conducted a cross-sectional survey of 390 patients diagnosed with MAFLD using imaging (Transient Elastography) and metabolic evaluations. Participants were classified into three groups: Group 1, with a BMI ≥ 25 ; Group 2, with T2DM; and Group 3, with a BMI < 25 and $\geq$ two metabolic risk factors. We defined significant fibrosis ($F \geq 2$) with a liver stiffness measurement cut-off ≥ 8.2 kPa.

Results: 24.6% of the cohort exhibited significant fibrosis, with the highest prevalence observed in Groups 1 (68.7%) and 2 (55.2%). Group 3 had the lowest prevalence (31.2%). Patients in Group 1 had an odds ratio of 3.8 (p -value 0.003) for significant fibrosis, while those in Group 2 had an OR of 2.8 (p -value 0.01).

Conclusions:

TE reveals significant fibrosis varies among MAFLD patients based on metabolic syndrome. Recognizing

E-POSTER ABSTRACTS

predictive factors like the Fib-4 index, degree of steatosis, and metabolic risks, particularly BMI $\geq$ 25 and T2DM, is crucial for improving patient management and outcomes

Keyword(s) : Significant fibrosis, Metabolic risk factors, Transient elastography, MAFLD

2177 - MAFLD CKM Modified score better predicts long term all cause mortality

Yasser Fouad¹, Alaa Mostafa¹, Ziyang Pan², Mohammed Eslam³

Minia University, Gastroenterology And Endemic Diseases, El Minia-Egypt¹ Storr Liver Center, Hepatology, Sydney-Australia² Storr Liver Centre, Hepatology, Sydney-Australia³

Background / Hypothesis: The American Heart Association (AHA) developed the cardiovascular-kidney-metabolic (CKM) model, which reframes cardiovascular, renal, and metabolic risk as a marker for the worst adverse events but leaves out hepatic dysfunction. Cardiorenal mortality is closely associated with metabolic-associated fatty liver disease (MAFLD), which is very common throughout the world. This suggests an underappreciated gap in current CKM staging. The purpose of this study is to assess the additional risk of MAFLD in both specific-cause and all-cause mortality across the CKM criterion.

Methods: In this cross-section study we used data of 9,309 adults aged 20–74 years from NHANES III (1988–1994) with mortality follow-up through 2019. The AHA framework was used to classify the CKM stage. Hepatic steatosis and typical metabolic dysfunction were the hallmarks of MAFLD. We evaluated all-cause and cause-specific mortality using Cox regression adjusted for age, sex, race, and smoking. We proposed a modified (M-CKM) score that integrated MAFLD status into CKM staging. For those modified models, a Kaplan-Meier curve was plotted. Results: Over a median 23-year follow-up, 38.9% mortality rose stepwise across CKM stages: 20% no CKM, 35.9% early CKM, and 66.5% late CKM ($p < 0.001$). MAFLD was present in 41.2% and 52.1% of early and late CKM. The M-CKM score demonstrated a better prognostic value than discrete strata, predicting increased risks of all-cause mortality (HR 2.51, 95% CI 1.42–4.44) and specific mortality from diabetes, cardiovascular, and cerebrovascular causes. M-CKM had significantly lower survival across all outcomes, according to Kaplan-Meier analyses ($p < 0.001$)

Conclusion: The Risk prediction for long-term mortality is significantly improved by incorporating MAFLD into

the CKM framework. The suggested M-CKM encourages a paradigm change in favour of an all-encompassing cardio-renal-hepatic-metabolic model that is utilised for roadmap evaluation of potential adverse events.

2178 - Predictors and gaps in hepatocellular carcinoma staging and management A multicenter prospective study in Bangladesh

Md Yasir Arafat¹, Md. Abdul Mumit Sarkar², A. K. M. Jubaere¹, Mohammed Tozammel Haque¹, Md. Saiful Malek³, Ratan Bhomic⁴

National Gastroliver Institute And Hospital, Medical Gastroenterology, Dhaka-Bangladesh¹ Rajshahi Medical College, Department Of Gastroenterology, Rajshahi-Bangladesh² Mymensing Medical College, Department Of Gastroenterology, Mymensing-Bangladesh³ Sylhet Medical College, Department Of Gastroenterology, Sylhet-Bangladesh⁴

Background / Hypothesis: Primary liver cancer is the sixth most common cancer globally. Current guidelines recommend routine surveillance for high-risk patients to facilitate early detection. However, global adherence remains low worldwide. Effective etiological management and structured follow-up are essential to prevent hepatocellular carcinoma (HCC) or detect it at an early stage. This study aimed to assess the stage at diagnosis, related clinical outcomes, and adherence to guideline-recommended evaluation and treatment in patients with hepatocellular carcinoma.

Materials and Methods: This multicenter, prospective, cross-sectional analytical study was conducted across five tertiary care centers in Bangladesh from December 2024 to November 2025. Data were collected prospectively from the consecutive patients diagnosed with HCC using a standardized questionnaire.

Results: A total of 245 patients diagnosed with HCC were included. The median age was 50 years (IQR: 41–60), and 85.3% (209/245) were male. The most common underlying etiology was hepatitis B virus (HBV) infection, 69.8%; followed by hepatitis C virus (HCV) infection, 11.4%; and metabolic dysfunction-associated fatty liver disease (MAFLD) at 6.5%. HBV–HCV coinfection was identified in 0.8% of patients (Table 1). According to the BCLC staging system, only 6.9% patients presented with BCLC 0–A, 24.1% with BCLC-B, 39.6% with BCLC-C, and 29.4% with BCLC-D. Physician adherence to AASLD guidelines was 72.2%.

E-POSTER ABSTRACTS

Imaging-based diagnosis and biopsy with histopathology were used in 75.9% and 21.2% of cases, respectively. During evaluation, 26.9% of patients have portal vein tumoral thrombosis (PVTT). In the multivariate analysis, a higher CTP class was associated with advanced-stage HCC (for CTP-C, OR 6.65, $p = 0.003$). Performance status (ECOG) was a strong predictor of advanced BCLC stage (ORs 8.99 to 69.70; $p < 0.001$). PVTT was strongly associated with advanced-stage disease (OR 5.63, $p < 0.001$) (Table 2). Systemic chemotherapy was the most commonly recommended treatment (48.2%). However, only 28.6% received the treatment. Notably, 48.2% of patients had no documented treatment received due to loss to follow-up (Table 3).

Conclusions: A substantial proportion of patients with hepatocellular carcinoma presented at advanced stages. This reflects gaps in surveillance adherence and late recognition of chronic liver disease. Disease severity (CTP class), poor performance status, and portal vein tumor thrombosis were strong predictors of advanced-stage presentation. In addition, there are major gaps between guideline-recommended therapy and actual treatment delivery in routine clinical practice. These findings highlight the need to strengthen HCC surveillance practices, improve early detection strategies, and enhance access to appropriate treatment in resource-limited settings.

2179 - Correlation analysis of HBVRNA and hepatitis B virological and biochemical indicators in treated chronic HBV infected patients

Du Leilei¹, 晓红 高¹, 怡敏 贾¹

Yan'an University Affiliated Hospital, Infectious Disease, Yan'an-China¹

Background / Hypothesis: HBV infection is a global issue, with approximately 296 million chronic infected individuals, causing 820,000 deaths each year. Chronic hepatitis B is the main cause of liver cirrhosis and hepatocellular carcinoma

Materials and Methods: Chronic HBV-infected individuals who visited the outpatient and inpatient departments of the Affiliated Hospital of Yan 'an University from August 2024 to June 2025 were selected. According to the inclusion and exclusion

criteria, a total of 133 patients were finally enrolled and all received antiviral treatment, including 101 patients with positive HBV RNA and 32 patients with negative HBV RNA. By detecting the quantification of serum HBV RNA, the changes in the natural course of different diseases were observed, and its relationship with HBV was analyzed. The correlation between DNA, hepatitis B surface antigen (HBsAg), HBeAg, alanine aminotransferase (ALT), aspartate aminotransferase (AST), and glutamyl transpeptidase (GGT).

Results: A total of 133 patients with chronic hepatitis B were included in this study, among which: 101 cases (75.94%) were in the RNA positive group and 32 cases (24.06%) were in the RNA negative group. The comparison between the two groups showed that there were significant difference indicators ($P < 0.05$): HBsAg (quantitative), HBeAg (quantitative), RNA qualitative results, HBsAg qualitative results, HBeAg qualitative results. No significant difference indicators ($P > 0.05$): HBV DNA (quantitative), ALT, AST, GGT, ALP (quantitative and qualitative results);

In the RNA-positive group, 101 cases (75.94%) of patients indicated that the virus had transcriptional activity, while in the RNA-negative group, 32 cases (24.06%) of patients indicated that the virus was transcriptional quistatic. Among the virological indicators HBsAg (quantitative + qualitative), the HBsAg level in the RNA-positive group was significantly higher, suggesting high expression of viral protein. In HBeAg (quantitative + qualitative), the level of HBeAg was higher in the RNA-positive group, reflecting the high infectivity of the virus. The RNA qualitative results (self-grouping variables) showed significant differences in the positive rate of RNA between groups, suggesting heterogeneity in transcriptional activity. In terms of viral load, the RNA status in HBV DNA (quantitative + qualitative) does not affect the viral replication amount (DNA level), while the RNA status in biochemical indicators such as liver function ALT/AST/GGT (quantitative + qualitative) is not related to the degree of liver injury.

Yan'an-China¹

Background / Hypothesis: HBV (hepatitis B virus) infection is a global public health issue, among which chronic hepatitis B (CHB) is the main cause of liver cirrhosis and hepatocellular carcinoma (HCC). In recent years, with the in-depth study of the life cycle of HBV, HBV pgRNA (pregenomic RNA), as a key molecule in the replication and transcription process of HBV, has gradually attracted the attention of researchers. This article will explore in detail the structural characteristics of HBV-pgRNA, its role in the course of CHB, its relationship with disease progression, and its potential applications in diagnosis and treatment.

Materials and Methods: The basic characteristics of HBV-RNA: HBV-RNA is an RNA molecule transcribed from cccDNA, including pregenomic RNA (pgRNA) and subgenomic RNA. pgRNA is the direct transcription product of cccDNA and has the functions of reverse transcription template and viral capsid assembly signal. Subgenomic RNA includes RNA encoding the large protein, medium/small protein and HBx protein of HBsAg. Splicing variants and truncated RNAs are other types of HBV RNA. HBV pgRNA has specific structural features, such as the 5' -end ϵ stem ring structure, Poly(A) tail and internal ribosome entry site (IRES), which are crucial for viral DNA synthesis, RNA stability and translation efficiency. The core functions of pgRNA include reverse transcription templates, capsid assembly signals, and cccDNA circulation hubs. Splicing variants and 3' truncated Pgrnas are associated with the occurrence of liver cancer and antiviral therapy. The generation of HBV-RNA involves the HBV replication cycle, including viral entry, rcDNA nuclear entry, transcription and translation, capsid assembly and reverse transcription, as well as viral particle release. The transcriptional regulation of cccDNA involves epigenetic modifications and viral protein feedback. The release pathways of HBV-RNA include virus-like granular and non-granular forms

The basic characteristics of HBV-RNA: HBV-RNA is an RNA molecule transcribed from cccDNA, including pregenomic RNA (pgRNA) and subgenomic RNA. pgRNA is the direct transcription product of cccDNA and has the functions of reverse transcription template

2181 - Analysis of the clinical efficacy of sequential combined Peg IFN treatment after NAs treatment in CHB patients

Du Leilei¹, 晓红 高¹, 雷雷 杜¹

Yan'an University Affiliated Hospital, Infectious Disease,
Yan-China¹

Background / Hypothesis:
Preliminary analysis of the clinical efficacy of sequential combination of Peg-IFN after NAs treatment in CHB patients will provide real data for more CHB patients to pursue clinical cure.

Materials and Methods: From January 2018 to March 2020, CHB patients who were treated at Yan'an University Affiliated Hospital and treated with NAs for ≥ 1 year were collected. According to the inclusion and exclusion criteria, 60 patients were finally enrolled. When enrolling 30 patients in the sequential combination group, 30 NAs monotherapy patients were enrolled in a 1:1 ratio as a control. The sequential combination group continued the NAs treatment while sequentially combined with Peg-IFN α -2b; The NAs single-drug group continued to take NAs. Among them, NAs (ETV/TDF) was taken orally, once a day; Peg-IFN α -2b (Pegabine) 180ug, subcutaneously injected, once a week, observed for 48 weeks. The demographic and baseline characteristics of the two groups were collected and rechecked every 12 weeks. Follow up and record the HsHBV DNA, HBV serological indicators, liver function and four items of liver fiber, LSM of the two groups of patients, the occurrence of adverse reactions, and the corresponding measures for adverse reactions. SPSS22.0 was used for data analysis to observe the HBsAg level and the

E-POSTER ABSTRACTS

negative conversion rate, the negative status of HBeAg and HBV DNA, and the adverse reactions of the NAs treated CHB patients with sequential combined Peg-IFN treatment for 48 weeks

Results: 1. After 48 weeks of treatment, the HBsAg clearance rate, HBeAg conversion rate, and HBV DNA conversion rate in the sequential combination group were higher than those in the NAs single-agent group. Comparing the HBsAg levels of the two groups after 48 weeks of treatment, the sequential combination group had a high degree of HBsAg decline. Finally, 7 patients in the sequential combination group achieved HBsAg clearance, and the NAs single-drug group did not show HBsAg clearance. The HBsAg clearance rates of the two groups were respectively 23.3%, 0%, the former is significantly higher ($P=0.016$); There were more HBeAg negative patients in the sequential combination group, accounting for 93.3%, while the NAs single-drug group only accounted for 53.3%, ($P<0.001$);

Conclusion

1. For NAs treated CHB patients with sequential combination of Peg-IFN treatment, the HBsAg decline level and the rate of negative conversion, the rate of negative conversion of HBeAg, and the rate of HBV DNA conversion are better than those of continuing NAs monotherapy

2182 - Comparison of multiple drugs for metabolic dysfunction associated fatty liver disease A systematic review and network meta analysis

Xin Ai ¹, Xiaoxiao Wang ¹, Zilong Wang ¹, Minjun Liao ¹, Xin Wang ¹, Feng Liu ¹, Huiying Rao ¹

Peking University People's Hospital, Peking University Hepatology Institute, Infectious Disease And Hepatology Center Of Peking University People, Beijing-China ¹

Background / Hypothesis: The most prevalent chronic liver disease worldwide is metabolic dysfunction-associated fatty liver disease (MAFLD). The purpose of

this meta-analysis was to compare the efficacy of multiple drugs in treating MAFLD patients.

Materials and Methods: We searched PubMed, Embase, Web of Science and Cochrane Library databases to identify randomized controlled trials. Hepatic fat fraction (HFF) and liver stiffness assessed non-invasively by magnetic resonance imaging proton density fat fraction and elastography, serum liver enzymes, lipid profile and glucose metabolism were evaluated. Mean differences and risk ratios with 95% confidence intervals were pooled using a random-effect model.

Results: For HFF reduction, GLP-1-based poly-agonists showed significant improvement (mean difference: -42.86, 95% confidence interval [CI]: -67.97 to -22.30) compared with placebo. For liver stiffness, FGF-21 analogues were the most effective drugs (mean difference: -7.78, 95% confidence interval [CI]: -18.95 to -0.33) compared with placebo. In terms of serum liver enzymes, GLP-1-based poly-agonists appeared to be the most effective drugs compared with placebo. Regarding lipid profile, GLP-1-based poly-agonists demonstrated greater improvement compared with placebo. For glucose metabolism, GLP-1-based poly-agonists showed superior efficacy compared with placebo.

Conclusions: The present study suggests the superiority of GLP-1-based poly-agonists in improving liver steatosis, liver injury and glucose metabolism, whereas FGF-21 analogues are effective at improving liver fibrosis.

2183 - Predictors of HBsAg Clearance and Development of a Nomogram in Chronic Hepatitis B Patients with Low Level Viremia Treated with Pegylated Interferon α 2b

Shiyu Wang ¹, Ziyu Zhang ², Xinxin Li ¹, Yaqin Zhang ¹, Wen Deng ¹

Hbv Infection, Clinical Cure And Immunology Joint Laboratory For Clinical Medicine Capital Medical

E-POSTER ABSTRACTS

University, Department Of Hepatology Division 2, Beijing-China ¹ Hbv Infection, Clinical Cure And Immunology Joint Laboratory, Capital Medical University, Department Of Hepatology Division 2, Beijing-China ²

Background / Hypothesis: To develop a predictive model for hepatitis B surface antigen (HBsAg) clearance at week 48 in chronic hepatitis B patients with low-level viremia treated with pegylated interferon α -2b, based on serological and clinical parameters using the least absolute shrinkage and selection operator (LASSO) regression, and to evaluate the predictive performance of the model.

Materials and Methods: This is a prospective cohort study. A total of 303 patients with chronic hepatitis B and low-level viremia who received pegylated interferon α -2b therapy and completed 48 weeks of follow-up were included. Demographic and clinical data, including virological, biochemical, and hematological parameters at baseline and week 12, were collected. HBsAg clearance at week 48 was defined as the study outcome. Group comparisons were performed using the t test or Wilcoxon rank-sum test for continuous variables and the χ^2 test for categorical variables. Variable selection was conducted using univariate analysis and least absolute shrinkage and selection operator (LASSO) regression. Independent predictors were identified by multivariate logistic regression, and a nomogram was constructed. Model performance was assessed using the area under the receiver operating characteristic curve, bootstrap validation with 1,000 resamples, calibration curves, decision curve analysis, and clinical impact curves.

Results: Among the 303 patients with chronic hepatitis B and low-level viremia, 46 achieved HBsAg clearance at week 48. Based on univariate logistic regression ($P < 0.20$), eight variables were entered into LASSO regression. After LASSO selection, baseline albumin level (ALB.0W), HBsAg decline from baseline to week 12 (HBsAg_drop12W), and HBeAg status at week 12 (HBeAg.12W) were included in multivariate logistic regression analysis. Multivariate analysis identified HBeAg.12W (OR = 0.29, 95% CI: 0.11–0.68) and HBsAg_drop12W (OR = 0.31, 95% CI: 0.20–0.47) as independent predictors of HBsAg clearance at week 48. A nomogram based on these variables yielded an area

under the receiver operating characteristic curve of 0.879. Bootstrap internal validation with 1,000 resamples demonstrated good discrimination and stability. Calibration curves showed good agreement between predicted and observed probabilities, and decision curve analysis indicated favorable clinical net benefit across a wide range of threshold probabilities.

Conclusions: Based on baseline clinical characteristics and serological parameters, a nomogram incorporating HBeAg status at week 12 and HBsAg decline from baseline to week 12 was developed using LASSO regression. This model can predict the probability of HBsAg clearance in patients with chronic hepatitis B with low-level viremia treated with pegylated interferon α -2b, and may provide useful support for individualized clinical decision-making.

Keyword(s) : Chronic hepatitis B; Low-level viremia; Pegylated interferon α -2b; Nomogram

2184 - Related factors of fever after endoscopic treatment of variceal bleeding in patients with liver Cirrhosis complicated with esophageal variceal bleeding A retrospective study

Yingying Zhao ¹, Xiaofang Zhao ¹, Lingchen Kong ², Liping Wei ¹, Jiaojiao Zhu ³, Huichun Xing ¹, Minghui Li ¹

Beijing Ditan Hospital, Capital Medical University, Center Of Liver Diseases, Beijing-China ¹ Beijing Tsinghua Changgung Hospital, Center Of Liver Diseases, Beijing-China ² Beijing Tsinghua Changgung Hospital, Radiology Department, Beijing-China ³

Background / Hypothesis:

To explore the current status of postoperative fever following endoscopic treatment for esophagogastric variceal bleeding and its impact on the prognosis of patients with liver disease.

Materials and Methods:

We retrospectively analyzed patients with decompensated cirrhosis treated endoscopically for esophagogastric variceal bleeding from December 2018 to June 2024, comparing clinical characteristics and prognosis between those with and without post-procedure fever.

Results:

A total of 251 patients treated with precise endoscopic variceal devascularization combined with endoscopic variceal sclerotherapy were included, comprising 181 males (72.1%) and 70 females (27.9%). Postoperative

E-POSTER ABSTRACTS

fever occurred in 94 patients (37.5%), including 62 males (24.7%) and 32 females (12.7%). The median age of the 251 patients was 56.00 (49.0, 64.0) years. Compared to the non-febrile group, the febrile group showed no statistically significant differences in age or degree of esophagogastric varices ($P > 0.05$). However, the febrile group had significantly more severe ascites and a higher proportion of Child-Pugh class C ($P < 0.001$).

Further analysis of clinical data from febrile patients revealed that the rate of postoperative bacterial infection-related fever was lower in those who received preoperative prophylactic antibiotics ($n=9$, 3.9%) compared to those who did not ($n=15$, 6.5%), a difference that was statistically significant ($P=0.001$). Alpha-fetoprotein level was associated with in-hospital bacterial infection ($r=0.184$, $P=0.049$).

Spearman correlation analysis revealed that the Model for End-Stage Liver Disease (MELD) score was positively correlated with gender, fever, infection-related fever, total bilirubin, direct bilirubin, International Normalized Ratio (INR), urea nitrogen (BUN), creatinine ($r=0.446$, $P<0.001$), Child-Pugh class, and bacterial infection. Conversely, the MELD score was negatively correlated with albumin, cholinesterase, platelet count, red blood cell count ($r=-0.280$, $P=0.002$), and hemoglobin.

Postoperative fever (OR=2.598, 95% CI 1.205–5.542, $P=0.015$), albumin (OR=0.865, 95% CI 0.789–0.939, $P<0.001$), platelet count (OR=0.990, 95% CI 0.982–0.998, $P=0.018$), coagulation time (OR=2.423, 95% CI 1.711–3.431, $P<0.001$), prothrombin activity (OR=0.879, 95% CI 0.836–0.924, $P<0.001$), and Child-Pugh class (OR=5.644, 95% CI 2.658–11.983, $P<0.001$) were identified as risk factors for a high MELD score. Multivariate regression analysis identified prothrombin time (OR=2.423, 95% CI 1.711–3.431, $P<0.001$) as an independent predictor of a high MELD score.

Conclusions:

In patients with liver cirrhosis and esophagogastric variceal bleeding undergoing endoscopic hemostasis, efforts to improve liver function, coagulation profile, and renal function, along with prophylactic anti-infection measures, may reduce postoperative complications and improve patient prognosis.

Keyword(s) : liver cirrhosis, esophagogastric variceal hemorrhage, endoscopic treatment, fever, prognosis

2186 - Demographic Characteristics and Treatment Status of Primary Biliary Cholangitis A Single Center Study from Xinjiang China.

Jianwei Zhao ¹, Rongjiong Zheng ¹, Xiaobin Lu ¹

The First Affiliated Hospital Of Xinjiang Medical University, Center For Infectious Disease And Hepatology, Urumqi-China ¹

Background / Hypothesis:

Primary biliary cholangitis (PBC) is a chronic autoimmune intrahepatic cholestatic liver disease that predominantly affects middle-aged women. Fatigue and pruritus are the most common clinical manifestations. In recent years, the incidence of PBC has been increasing worldwide as well as in China. Understanding the demographic characteristics and current treatment status of PBC patients is essential for optimizing disease management. However, large-scale data on PBC patients in Xinjiang region of China are still limited. This study is to investigate the disease composition, demographic characteristics, and treatment status of PBC patients in a single center in Xinjiang, China.

Materials and Methods:

This retrospective study included patients diagnosed with PBC and treated at the Infectious Liver Disease Center of the First Affiliated Hospital of Xinjiang Medical University between January 2020 and October 2025. Demographic data, clinical features, immunological profiles, treatment regimens, and outcomes were collected and analyzed.

Results:

A total of 1,321 PBC patients were enrolled, accounting for 2.5% (1,321/52,640) of all liver disease patients during the same period. Among them, 76 patients (5.75%) had concomitant chronic hepatitis B, and 127 patients (9.61%) had PBC–autoimmune hepatitis overlap syndrome. Females predominated, with a male-to-female ratio of approximately 1:4 (251:1,069). The median age was 59 years (IQR 51–68). The major ethnic groups were Han (59.90%), Uyghur (22.80%), and Kazakh (9.62%). Liver cirrhosis was present in 48.83% of patients (645/1,321), and 27.33% presented with jaundice (361/1,321). Anti-mitochondrial antibody was positive in 60.33% of patients, while 78.80% were antinuclear antibody positive. Ursodeoxycholic acid (UDCA) monotherapy was administered in 84.48% of patients (1,116/1,321), with a biochemical response rate of 60.48% (799/1,321) according to Paris criteria. Notably, 7.34% of patients (97/1,321) received no treatment. During follow-up, 4.16% ($n=55$) developed hepatocellular carcinoma, 5.15% ($n=68$) progressed to liver failure, 1.81% ($n=24$) underwent liver transplantation, and 1.97% ($n=26$) died.

Conclusions:

This single-center study from Xinjiang demonstrates that PBC is not uncommon among liver disease

E-POSTER ABSTRACTS

patients, with a considerable proportion presenting with advanced disease and concomitant liver conditions at diagnosis. A subset of patients did not receive standardized diagnostic evaluation or treatment, highlighting the importance of early recognition and timely management. Furthermore, the suboptimal response to first-line UDCA therapy underscores the urgent need for effective second-line treatments. In addition, patient-reported outcomes such as pruritus and fatigue were not systematically assessed, suggesting insufficient attention to quality-of-life issues in routine clinical practice, education is needed.

Keyword(s) : Primary Biliary Cholangitis

2187 - Budd Chiari Syndrome Secondary to Combined Protein C Protein S and Antithrombin III Deficiencies in a Young Filipino Woman A Rare Case Report

Dave Christian Ong¹, Jan Catherine Carrera¹

Chong Hua Hospital, Gastroenterology, Cebu City-Philippines¹

Background / Hypothesis:

Budd-Chiari Syndrome (BCS) is a rare hepatic venous outflow obstruction, most often linked to acquired hypercoagulable states such as myeloproliferative neoplasms. Inherited thrombophilias, particularly combined deficiencies of Protein C, Protein S, and Antithrombin III, are exceedingly uncommon causes, with limited reports worldwide. In high-tuberculosis-burden regions like the Philippines, nonspecific symptoms (ascites, jaundice, abdominal pain) often lead to diagnostic delays due to overlap with infectious etiologies. We hypothesized that comprehensive thrombophilia screening and advanced imaging are essential for identifying rare inherited causes in young patients with unexplained portal hypertension, enabling targeted management and improved outcomes.

Materials and Methods:

This case report describes a 19-year-old Filipino female presenting with progressive abdominal distension, jaundice, and ascites. Data were collected via retrospective review of clinical records, laboratory investigations (including thrombophilia panel), ascitic fluid analysis, and multimodal imaging (ultrasound, contrast-enhanced CT, and MRI with hepatobiliary contrast). Management involved multidisciplinary input from gastroenterology, hematology, infectious

diseases, and radiology. Treatment included targeted antibiotics for confirmed spontaneous bacterial peritonitis (SBP) and anticoagulation with warfarin. Ethical standards for case reporting were followed.

Results:

The patient was initially treated elsewhere with empirical anti-tubercular therapy and antibiotics, with recurrent ascites requiring drainage. Upon referral, imaging demonstrated hepatomegaly, hepatic vein obstruction, intrahepatic inferior vena cava narrowing, and patchy parenchymal enhancement consistent with BCS. Thrombophilia testing confirmed combined deficiencies of Protein C, Protein S, and Antithrombin III, establishing a rare inherited hypercoagulable state as the underlying cause. Ascitic fluid culture grew multidrug-resistant *Acinetobacter baumannii*, confirming SBP complicating BCS. After 21 days of targeted antibiotics and initiation of warfarin, the patient improved clinically with ascites resolution, jaundice regression, and stabilization of liver function. No interventional procedures were required; long-term anticoagulation and close follow-up were planned.

Conclusions:

This case highlights the need for early suspicion, advanced imaging (CT/MRI), and comprehensive thrombophilia screening to diagnose Budd-Chiari Syndrome, especially in rare inherited states such as combined Protein C, Protein S, and Antithrombin III deficiencies. In TB-endemic settings, overlapping symptoms can delay recognition. Multidisciplinary care with prompt infection control and early anticoagulation led to favorable short-term outcomes and may prevent progression, adding to limited literature on triple inherited thrombophilias causing BCS.

2190 - A novel intratumoral microbial risk score predicts survival and characterizes the immunosuppressive microenvironment in hepatocellular carcinoma

Hui Huang¹, Junpeng Zhou¹, Hong Tang¹

West China Hospital Of Sichuan University, Laboratory Of Infectious And Liver Diseases, Chengdu-China¹

E-POSTER ABSTRACTS

Background / Hypothesis:

Intratumoral microbiota dysbiosis may promote hepatocellular carcinoma (HCC). We hypothesized that a genus-level intratumoral microbial risk score independently predicts prognosis and reflects key pathways and an immunosuppressive tumor microenvironment.

Materials and Methods:

We integrated intratumoral bacterial genus abundances, transcriptomic, mutational, and clinical data from the TCGA-LIHC cohort. Diversity and community composition were compared between tumor and adjacent tissues, identifying differentially abundant genera via statistical analysis of metagenomic profiles (STAMP). Cox regression analyses were performed for overall survival (OS) and disease-specific survival (DSS) to identify intersection genera significant in both. These were incorporated into a multivariate Cox model to construct a microbial risk score using a weighted linear combination of regression coefficients, stratifying patients into high- and low-risk groups. We compared KEGG pathway enrichment, immune cell infiltration, ESTIMATE scores, and tumor mutation burden (TMB) between groups. To evaluate the potential of the microbial risk score in predicting OS, ten machine learning models were compared to identify the optimal prognostic model, followed by SHAP analysis to interpret 13 key features. Finally, a nomogram integrating the risk score with clinicopathological factors was constructed.

Results:

Compared with adjacent tissues, HCC samples showed lower α diversity, separated β diversity and a reshaped community with *Paenibacillus* enrichment and depletion of *Bacillus* and other dominant genera. *Paenibacillus* and *Bacillus*, significant in both OS and DSS analyses, were used to construct the microbial risk score, which robustly separated patients into high- and low-risk groups with shorter OS in the high-risk group. High-risk tumors were enriched in extracellular matrix organization, focal adhesion and PI3K-AKT pathways and showed suppressed oxidative phosphorylation. They also exhibited higher myeloid-derived suppressor cells, regulatory T cells, plasmacytoid dendritic cells and type 2 T helper cells, together with increased stromal and ESTIMATE scores and reduced tumor purity, indicating a high-stroma, low-purity, immunosuppressive microenvironment. Driver mutation spectra and TMB differed between groups, and combining the microbial risk score with TMB further improved prognostic discrimination. Among

ten machine-learning algorithms used to assess the microbial risk score for OS prediction, extreme gradient boosting (XGBoost) performed best (AUC = 0.996). SHAP analysis of the XGBoost model showed that the microbial risk score had the highest mean absolute SHAP value and was the most important prognostic feature. The nomogram demonstrated good discrimination and calibration for predicting 1-, 3- and 5-year OS.

Conclusions:

The intratumoral microbial risk score is a powerful prognostic indicator for HCC, reflects an immunosuppressive tumor microenvironment and may facilitate individualized clinical assessment.

Keyword(s) : hepatocellular carcinoma, intratumoral microbiota, prognostic risk score, tumor microenvironment, tumor mutation burden, machine learning

2191 - Evolution of hepatocellular carcinoma staging within Egypt's national surveillance system a success story (2019–2024)

Mohamed Abdallah¹, Mohamed Hassany², Wael Abdel-razek³

National Research Center, Medical Research And Clinical Studies Institute, Giza-Egypt¹ Ministry Of Health And Population, National Hepatology And Tropical Medicine Research Institute, Cairo-Egypt² National Liver Institute, Menoufia University, Hepatology And Gastroenterology Department, Menoufia-Egypt³

Background / Hypothesis: In 2019, following the "100 Million Seha" initiative, which aimed at hepatitis C virus (HCV) elimination, Egypt initiated a national surveillance system for hepatocellular carcinoma (HCC). This study evaluates the impact of the national program by analyzing staging trends from 2019 through 2024.

Materials and Methods: We conducted a retrospective analysis of 25,689 patients diagnosed with HCC. The cohort was divided into two periods: 2019–2021 (n=10,882), and 2022–2024 (n=14,807). We analyzed the annual change in patient staging according to the Barcelona Clinic Liver Cancer (BCLC) system (0/A, B, C, D) to assess stage migration. Statistical significance was evaluated using Chi-square trend tests and Z-tests of independent proportions, comparing the baseline average with the 2024 dataset.

E-POSTER ABSTRACTS

Results: A distinct stage migration was observed following the program's implementation. In the 2019–2021 baseline, stage B accounted for only 26.0% (n=2,829) of cases. By 2024, this proportion had increased to 45.1% (n=1,746; $p<0.001$), a 1.7-fold increase. Conversely, stage D dropped significantly from 25.0% (n=2,721) at baseline to 8.9% (n=345) in 2024 ($p<0.001$). Stage C initially peaked at 41.4% (n=2,284) in 2022, but significantly declined to 30.9% (n=1,196) by 2024 ($p<0.001$ vs baseline). Stage 0/A showed a modest but statistically significant improvement, rising from 13.2% (n=1,436) to 15.2% (n=588) ($p<0.01$).

Conclusions: The transition from the 2019–2021 baseline to 2024 demonstrates a successful "shift to the left," characterized by a massive migration of patients from terminal/advanced stages into the intermediate stage (stage B). This down-staging creates a larger window for locoregional therapies, validating the national surveillance system's impact on intercepting disease progression.

2193 - Serum sIL 2R Predicts Significant Histological Disease in Indeterminate Phase Chronic Hepatitis B

Xinghuan Fu¹, Qiuqing Yan¹, Yiqi Liu¹, Chi Zhang¹, Guiqiang Wang¹, Hong Zhao¹
Peking University First Hospital, Department Of Infectious Disease, Bei Jing-China¹

Background / Hypothesis:

Many chronic hepatitis B (CHB) patients do not fit the established natural history stages and are classified as indeterminate (IM) phase. This study examines the liver histology of IM patients to inform antiviral treatment decisions.

Materials and Methods:

From 2018 to 2020, 598 treatment-naïve CHB patients were recruited from 33 Chinese medical centers. Serum levels of nine cytokines were measured using chemiluminescence immunoassay. The natural history stages were determined according to the EASL 2025 Hepatitis B Guidelines, with further stratification of IM patients based on corresponding HBeAg status and ALT levels. We analyzed liver histopathology distribution and identified independent factors for significant histological disease in the IM patients. A

nomogram was developed to evaluate significant histological disease. Liver tissue transcriptomics revealed immune and functional changes in patients with high IL2RA expression.

Results:

Of 211(35.4%) patients in IM phase (61.6% male and median age 46 years), with 74.9% showing significant histological disease. HBeAg (+) IM patients (IM-A, IM-B) had a higher rate of significant histological disease than HBeAg (-) patients (IM-C, IM-D) (90.5% vs. 68.2%, $p = 0.0012$). IM-C (57.3%) was the predominant category, followed by IM-A (26.5%). IM-B patients had the highest proportion of significant histological disease (100.0%), followed by IM-A (84.0%). Serum sIL-2R was an independent risk factor for significant histological disease in IM patients. Elevated sIL-2R levels strongly predicted significant histological injury in IM patients (middle tertile: OR = 2.29, 95% CI: 1.08–4.99, $p = 0.0337$; highest tertile: OR = 3.69, 95% CI: 1.58–9.21, $p = 0.0035$). The nomogram combining sIL-2R, AST, and ALB showed good discrimination in both training (AUC = 0.754) and validation sets (AUC = 0.746). High hepatic IL2RA expression correlated with immune activation and impaired liver function.

Conclusions:

sIL-2R is an effective biomarker for significant histological disease in IM patients. The sIL-2R-based nomogram has good performance in stratification of liver damage in IM patients.

2194 - A case of hepatocellular carcinoma developed after antiviral treatment cessation due to HBsAg seroclerance.

Youngnam Kim¹

Cheju Halla General Hospital, Digestive Disease Center, Jeju-South Korea¹

Background / Hypothesis:

During the natural course of CHB, HBsAg loss is a very rare transition that indicates potential cure of HBV infection. Complete cure, or "sterilizing cure," of HBV infection implies seroclearance of HBsAg and HBV DNA as well as complete clearance of intrahepatic covalently closed circular DNA (cccDNA) and/or integrated HBV

E-POSTER ABSTRACTS

DNA. I report a case of hepatocellular carcinoma developed after antiviral treatment cessation due to HBsAg seroclerance.

Case :

A 74-years-old male patient admitted due to right upper quadrant pain and discomfort.

Liver CT and Liver MRI shows large heterogeneous hypodense mass with some irregular vasularities involving S8 of the liver. Liver biopsy shows hepatocellular carcinoma (HCC), Edmonson steiner grade II.

Patient's laboratory finding shows AFP 105.0ng/ml, HBsAg/Ab (-/+), IgG anti-HBc(+), HBeAg/Ab (-/-), HBV DNA : 837 international unit/ml.

Patient's past medical history began antiviral treatment for CHB 15years ago with Entecavir, and HBeAg seroclerance became six years after antiviral treatment, and HBsAg seroclerance became after 11years of antiviral treatment.

HCC occurred three years after the interruption of antiviral treatment and follow up.

Conclusions:

HBsAg loss is the state of functional cure and is associated with a reduced risk of cirrhosis. However, significant risk of HCC development remains even after HBsAg loss in male patients and in settings where HBsAg loss has been achieved late (presence of cirrhosis or age ≥ 50 years). Therefore, even if there is no cirrhosis, it is believed that patients who are elderly and have a long prevalence period will need regular follow-up tests.

Keyword(s) : HBs Ag loss, HCC

2196 - Early Risk Prediction of Hepatocellular Carcinoma in Cirrhosis Patients Based on Non Contrast CT

Shifan Liu¹, Shenghong Ju¹

Zhongda Hospital Southeast University, Department Of Radiology, Nanjing-China¹

Background / Hypothesis:

Although the annual incidence of hepatocellular carcinoma (HCC) in cirrhotic patients ranges from 2% to 8%, guideline-recommended surveillance combining biannual ultrasound with serum alpha-fetoprotein (AFP) misses nearly 40% of tumors ≤ 2 cm, resulting in the majority of cases being diagnosed at stages no longer amenable to curative therapies. We therefore developed and externally validated a CNN-Transformer

deep-learning model that uses routine non-contrast abdominal CT to predict individual HCC risk within the next 3–36 months, converting an existing imaging episode into an early, actionable warning.

Materials and Methods: This was a multicenter, retrospective-prospective cohort study designed to develop and validate a deep learning model based on non-contrast CT for predicting the risk of HCC in patients with cirrhosis. The training cohort, comprising 251 patients consecutively enrolled from two hospitals (Center A and B), was used for model development and internal validation via 5-fold cross-validation. An independent external testing cohort consisted of 1254 patients prospectively enrolled primarily from PreCar cohort (NCT03588442). For patients who developed HCC, non-contrast CT images obtained 3-36 months prior to diagnosis were collected. For those without HCC, images from their last follow-up were used. A hybrid deep learning model integrating Convolutional Neural Networks (CNN) and Transformer architectures was established to analyze the imaging data. The optimal model selected from internal validation was locked and its performance was rigorously evaluated on the independent prospective external testing cohort.

Results: The resulting model, named LCHP (Liver-Cirrhosis-to-HCC Predictor), leverages attention-based feature aggregation on a fine-tuned DenseNet121 backbone to estimate the 3-year HCC risk from a single non-contrast CT examination. In the internal training set, five-fold cross-validation yielded an AUC of 0.818 (95% CI 0.795–0.892). The internal validation set AUC was 0.829 (95% CI 0.735–0.914), and the independent prospective external test set AUC was 0.758 (95% CI 0.646–0.861), confirming robust generalisability.

Conclusions: The LCHP model quantifies 3-year HCC risk from a single non-contrast CT in patients with cirrhosis. This risk stratification allows clinicians to intensify surveillance in high-risk compensated cases and to initiate transplant evaluation earlier for those with decompensated disease, potentially shortening wait-list time and improving long-term outcomes.

Keyword(s) : Liver Cirrhosis;Hepatocellular Carcinoma;Deep Learning

E-POSTER ABSTRACTS

2197 - A survey of the current status of research on the diagnosis and treatment of hepatitis C virus antibody positive pregnant women

Xin Yue¹, Min Cai², Yi Ding¹, Yan Wang¹

The Second Hospital Of Nanjing, Department Of Obstetrics And Gynecology, Nanjing-China¹ The Second Hospital Of Nanjing, Office Of The National Drug Clinical Trial Institution, Nanjing-²

Background / Hypothesis: To analyze the screening, diagnosis, epidemiology, pregnancy outcomes and treatment status in hepatitis C virus antibody-positive pregnant women, in order to provide clinical evidence for further improving prevention and control of maternal and infant safety.

Materials and Methods: Data of 246 HCV antibody-positive pregnant women admitted to the Second Hospital of Nanjing from January 2014 to December 2019 were analyzed by epidemiological survey research method. Statistical analysis was performed according to different data using t-test, χ^2 test, corrected χ^2 test or Fisher's exact test.

Results: 80 of 246 HCV antibody-positive women had confirmed infection before pregnancy. Of these, 85% were HCV RNA positive, and 16 became pregnant after antiviral therapy. Prenatal examination during pregnancy found that 166 cases were HCV RNA positive, and the HCV RNA positive rate was 81.93%. In the relationship between infection route and birth cohort in HCV antibody-positive pregnant women, there was a statistically significant differences in the proportions of transmission route among birth cohort ($\chi^2=115.6$, $P<0.001$). With the delay of birth cohort, the proportion of infection through drug use was decreased ($P<0.001$), while the proportion of acupuncture-associated infection ($P=0.043$) and infant hospitalization history were increased ($P=0.005$). Among pregnancy complications, HCV antibody-positive pregnant women in HCV RNA $<5.0 \text{ E}+02 \text{ IU/ml}$ and $\geq 5.0 \text{ E}+02 \text{ IU/ml}$ groups had intrahepatic cholestasis of pregnancy ($\chi^2=4.73$, $P=0.030$) and gestational hypertension ($\chi^2=8.65$, $P=0.003$), and the difference in incidence was statistically significant. Postpartum treatment strategy data analysis showed that the treatment rate was highest in the first year of postpartum, and then showed an upward trend

year by year, with a statistically significant difference ($\chi^2=17.26$, $P=0.004$).

Conclusions: Anti-HCV screening rates are lower among pregnant and reproductive age women. HCV screening should be used as an important supplementary means to strengthen maternal safety and health education management during pregnancy. Active postpartum antiviral therapy, with particularly emphasis on management within the first year after delivery, can significantly improve the treatment rate among women of child bearing age.

2198 - "When Natural Becomes Toxic Herbal Medicine-Induced Acute Liver Failure Treated With Double Plasma Molecular Adsorption System"

Leamsi Gay Arpon¹

East Avenue Medical Center, Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Acute liver failure (ALF) is a life-threatening condition characterized by rapid deterioration of hepatic function, coagulopathy, and hepatic encephalopathy in individuals without pre-existing liver disease. Drug-induced liver injury remains one of the leading causes of ALF, with herbal medicine-related hepatotoxicity increasingly reported, particularly in the Asia-Pacific region where traditional remedies are widely used. The double plasma molecular adsorption system (DPMAS) is an extracorporeal artificial liver support modality designed to selectively remove bilirubin, ammonia, and inflammatory mediators, potentially serving as a bridge to hepatic recovery.

Case Presentation:

We report a case of a 34-year-old previously healthy female who presented with acute alteration in sensorium and jaundice. On arrival, she was lethargic and slow to respond. Her vital signs were stable and there were no noted focal neurologic deficit. Initial evaluation revealed markedly elevated liver transaminases, hyperbilirubinemia, and coagulopathy, fulfilling diagnostic criteria for acute liver failure. The patient was admitted and managed in a multidisciplinary setting. Comprehensive diagnostic workup, including viral, autoimmune, metabolic, and radiologic investigations, failed to identify a

E-POSTER ABSTRACTS

conventional etiology. Detailed history subsequently revealed recent ingestion of herbal medicine, which was determined to be the most likely precipitating factor for ALF.

Management and Intervention:

The patient received standard supportive management for acute liver failure, including close neurologic monitoring and correction of metabolic derangements. IV administration of N-acetylcysteine (NAC) was initiated early, with the aim of limiting ongoing hepatocellular injury and enhancing the potential for hepatic recovery. However, in view of persistent hepatic dysfunction despite initial medical therapy, DPMAS therapy was initiated as an adjunctive liver support strategy. The procedure utilized the HA-330 II adsorption column for ammonia removal and the BS-330 adsorption column for selective bilirubin removal. DPMAS was well tolerated, with no procedure-related complications.

Results:

Following DPMAS therapy, the patient demonstrated significant clinical improvement, with resolution of altered sensorium and stabilization of coagulation parameters. Serial laboratory monitoring showed progressive improvement in liver enzymes and bilirubin levels. The patient did not require emergency liver transplantation and was discharged in stable condition with continued hepatology follow-up.

Conclusions:

This case highlights herbal medicine as an important and potentially preventable cause of acute liver failure. It also demonstrates the potential utility of DPMAS as an effective supportive therapy in ALF, facilitating toxin clearance and serving as a bridge to hepatic recovery. Early recognition of etiology and timely initiation of artificial liver support may improve clinical outcomes.

2199 - Bridging numerical scores and lived experience in acute and chronic liver failure

Shuo Huang¹, Yunlong Yao¹, Xi Zhang¹, Changlan Linghu²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Wuhan Central Hospital, Department Of Neurology, Hubei-China²

Background / Hypothesis:

Acute and chronic liver failure present with rapid clinical deterioration, but existing prognostic scores often fail to capture fluctuating symptoms, extrahepatic complications, and traditional holistic assessments used in daily practice. Emerging studies suggest that biologic markers and clinical narratives describe different dimensions of disease burden, yet it is unclear how these perspectives intersect at the bedside. We aimed to describe this gap and to generate hypotheses for more integrative evaluation strategies.

Materials and Methods:

We performed an exploratory mixed methods study in adults with acute or chronic liver failure managed at a tertiary liver unit. Prospective clinical assessments included standard prognostic scores, serial laboratory testing, and structured symptom diaries. In parallel, we collected narrative descriptions from physicians and patients, including traditional syndrome patterns and perceived changes in vitality, appetite, and mental clarity. Qualitative and quantitative findings were compared using thematic analysis and simple pattern recognition techniques.

Results:

Across diverse etiologies and stages of liver failure, we observed frequent discordance between numerical risk estimates and patient reported experiences, especially regarding fatigue, sleep disturbance, cognitive slowing, and anxiety. Clinicians consistently described dimensions of instability and “tipping points” that were not reflected in established scores. Holistic descriptors, including pattern based terminology and contextual information on diet and stress, often anticipated abrupt deterioration or recovery before laboratory markers changed. These observations revealed recurring combinations of symptoms and contextual factors that may constitute distinct clinical phenotypes.

Conclusions:

Our exploratory work highlights a systematic mismatch between traditional prognostic scores and the lived experience of acute and chronic liver failure. Qualitative patterns and holistic assessments appear to capture early transitions in disease state that are invisible to current numerical tools. These findings support the development of hybrid prognostic approaches that combine standard scores, patient reported outcomes, and structured narrative elements, and they suggest concrete targets for future prospective validation and

E-POSTER ABSTRACTS

digital implementation.

2200 - Acute Liver and Gastric Injury Complicated by Acute Kidney Injury Following Massive Ferrous Sulfate Overdose A Case Report

Leamsi Gay Arpon¹

East Avenue Medical Center, Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Acute liver injury resulting from iron toxicity is uncommon but potentially life-threatening. Massive ferrous sulfate ingestion can induce hepatocellular injury via oxidative stress, mitochondrial dysfunction, and direct iron-mediated toxicity. Iron overload may also precipitate acute kidney injury (AKI) through hemoglobinuria, tubular injury, and direct nephrotoxicity. Gastrointestinal mucosal damage is another recognized complication. Early recognition and prompt interventions, including iron chelation and extracorporeal blood purification, are critical to prevent multi-organ failure.

Case Presentation:

A 23-year-old man with major depressive disorder, noncompliant with Fluoxetine, ingested approximately 200 tablets of ferrous sulfate (13 g elemental iron, ~185 mg/kg) in a suicide attempt. He presented with coffee-ground emesis, hematuria, and oliguria. On examination, he was alert, oriented, and hemodynamically stable, without evidence of hepatic encephalopathy.

Laboratory evaluation revealed markedly elevated transaminases, mild hyperbilirubinemia, and rising serum creatinine and blood urea nitrogen, consistent with acute liver and kidney injury. Upper endoscopy demonstrated superficial ulcerations extending from the proximal gastric body to the first portion of the duodenum (D1). Workup excluded viral, autoimmune, metabolic, and structural causes of hepatocellular injury.

Management:

Supportive care included intravenous fluids, correction of metabolic derangements, and close monitoring. Deferoxamine therapy was initiated to reduce systemic iron burden. Due to persistent hepatocellular injury

and renal involvement, hemoperfusion was performed to accelerate clearance of circulating iron and toxins, followed by hemodialysis for AKI management and prevention of uremic complications. Both interventions were well tolerated.

Results:

The patient demonstrated progressive improvement in liver enzymes and bilirubin, with recovery of renal function, evidenced by normalization of urine output and resolution of hematuria. Gastrointestinal symptoms resolved. He remained free of encephalopathy and coagulopathy and was discharged in stable condition with hepatology, nephrology, and psychiatric follow-up.

Conclusions:

This case illustrates massive ferrous sulfate overdose (~185 mg/kg) as a rare cause of acute liver and gastric mucosal injury complicated by AKI without progression to liver failure. It underscores the importance of early recognition, prompt iron chelation, and the use of hemoperfusion and hemodialysis in severe multi-organ iron toxicity. Timely, multimodal intervention can prevent progression to organ failure and improve clinical outcomes.

2203 - Why definitions of acute on chronic liver failure matter for trials and everyday decisions

Shuo Huang¹, Xi Zhang¹, Yunlong Yao¹, Changlan Linghu²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Wuhan Central Hospital, Department Of Neurology, Hubei-China²

Background / Hypothesis:

Definitions of acute on chronic liver failure vary substantially across regions and societies, leading to inconsistent inclusion criteria, outcome measures, and therapeutic targets. Clinicians may therefore encounter apparently conflicting evidence when treating similar patients. We hypothesized that these definitional differences have concrete consequences for who is studied, how results are interpreted, and how recommendations are applied in routine care.

Materials and Methods:

We conducted a scoping review of contemporary clinical studies that used the term acute on chronic liver failure or closely related concepts. From each study, we extracted how investigators defined underlying chronic liver disease, acute insults, extrahepatic organ failures, and primary endpoints. We then held structured multidisciplinary discussions with hepatologists, intensivists, and methodologists using hypothetical case scenarios to explore how shifting a few definitional elements would change eligibility and perceived treatment benefit for individual patients.

Results:

We observed wide variation in the required severity of underlying liver dysfunction, in what counted as an acute precipitating event, and in the thresholds chosen to define organ failure. Some definitions focused on very short term mortality, whereas others emphasized longer term decompensation, producing overlapping but clinically distinct populations. In case based discussions, modest changes to criteria were sufficient to reclassify patients from “ineligible” to “ideal candidates” for hypothetical interventions or early transplantation. Participants also noted that reviewers and guideline authors seldom make these definitional choices explicit, leaving front line clinicians to reconcile differences on their own.

Conclusions:

Our synthesis suggests that inconsistent definitions of acute on chronic liver failure are a major hidden source of heterogeneity in the evidence base. Recognizing this problem is essential for designing future studies that

E-POSTER ABSTRACTS

are comparable across settings and for developing bedside tools that allow clinicians to understand which definition was used when interpreting trial results. More transparent reporting of inclusion concepts and simple crosswalks between definitions may help translate research into coherent guidance at the patient level.

2204 - Fragmented collaboration between liver and addiction services in alcohol related liver disease

Shuo Huang¹, Yunlong Yao¹, Xi Zhang¹, Changlan Linghu²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Wuhan Central Hospital, Department Of Neurology, Hubei-China²

Background / Hypothesis:

Alcohol related liver disease is driven by sustained harmful drinking, yet care pathways frequently prioritise management of portal hypertension and other complications over long term support for behaviour change. Reports from different systems suggest fragmented collaboration between liver and addiction services, but its concrete manifestations in daily practice are not well described. We aimed to characterise how this fragmentation is experienced by patients and clinicians and to identify leverage points for more integrated models of care.

Materials and Methods:

We undertook a qualitative study using semi structured interviews and focused group discussions with adults living with alcohol related liver disease, hepatology clinicians, nurses, and addiction specialists at a tertiary centre. Interviews explored perceptions of responsibility for alcohol counselling, barriers to referral, and experiences with shared care. Audio recordings were transcribed and analysed thematically by a multidisciplinary team, and preliminary themes were refined through feedback sessions with participants to ensure credibility and relevance to practice.

Results:

Patients frequently reported receiving mixed messages about the relative importance of abstinence compared

with control of complications, and many were unsure which part of the system “owned” their alcohol use disorder. Hepatology clinicians described time pressure, limited training in structured counselling, and concern about jeopardising rapport by repeatedly emphasising abstinence. Addiction specialists perceived referrals as late and sporadic, often triggered only after multiple decompensations. Across groups, participants highlighted simple organisational barriers, such as separate clinic locations and incompatible schedules, that reinforced the sense of two parallel rather than integrated services.

Conclusions:

Our findings reveal a pervasive disconnect between liver focused care and addiction focused care in alcohol related liver disease. This gap is sustained not only by resource constraints but also by uncertainty about roles, language, and ownership of long term behaviour change. Rather than creating entirely new services, interventions that clarify shared responsibilities, co locate key elements of care, and embed brief structured counselling tools into hepatology clinics may offer a feasible route towards more integrated and patient centred pathways.

Keyword(s) : alcohol related liver disease, addiction services, care pathways, qualitative research, multidisciplinary collaboration, patient centred care

2205 - Misaligned clinical and patient defined recovery in alcohol related liver disease

Shuo Huang¹, Xi Zhang¹, Yunlong Yao¹, Changlan Linghu²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Wuhan Central Hospital, Department Of Neurology, Hubei-China²

Background / Hypothesis:

Clinical conversations about alcohol related liver disease often centre on biochemical improvement and imaging changes, while patients describe recovery in terms of energy, cognition, relationships, and control over cravings. This misalignment may weaken motivation and adherence, yet it has rarely been examined systematically. We aimed to explore how clinician defined recovery and patient defined recovery differ and what this means for planning follow up care.

Materials and Methods:

E-POSTER ABSTRACTS

We conducted a small exploratory cohort study of adults with alcohol related liver disease who had recently achieved sustained abstinence. Over a six month period, participants attended combined hepatology and psychosocial follow up visits. At each visit, routine liver tests and global clinical impressions of stability were recorded. In parallel, participants completed brief questionnaires on fatigue, mood, cognition, sleep, and social participation, and provided short free text accounts of what "feeling recovered" meant to them at that moment.

Results:

Clinicians tended to regard recovery as beginning once liver tests had stabilised and admissions for decompensation had ceased, whereas many patients described this as only the first step. Participants frequently reported that concentration, sleep, and confidence in social situations improved more slowly than blood results, and some experienced new anxiety when visits became less frequent. The language used by patients to describe recovery emphasised regaining meaningful roles, trust within families, and the ability to manage cravings, with little reference to numerical thresholds. These narratives suggested that clinic discharge criteria may not fully reflect patient priorities.

Conclusions:

Our exploratory work illustrates a persistent gap between biochemical recovery and lived recovery in alcohol related liver disease. Relying solely on laboratory and imaging improvement may lead clinicians to underestimate ongoing cognitive and psychosocial burdens. Integrating brief patient reported measures and explicit discussions of recovery goals into routine follow up may help align expectations, support sustained abstinence, and guide decisions about the timing of step down or continued multidisciplinary care.

Keyword(s) : alcohol related liver disease, recovery, patient perspective, follow up care, patient reported outcomes, psychosocial factors

2206 - Silent degradation of artificial intelligence tools for liver disease in routine care

Shuo Huang ¹, Yunlong Yao ¹, Xi Zhang ¹, Changlan Linghu ²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China ¹ Wuhan Central Hospital, Department Of Neurology, Hubei-

China ²

Background / Hypothesis:

Artificial intelligence tools for liver disease increasingly report expert level accuracy, yet most are developed within single datasets and then quietly deployed elsewhere. When models encounter new scanners, documentation styles, or patient populations, performance may deteriorate in ways that are hard to detect. We hypothesised that clinicians experience this "silent" degradation as a specific kind of risk and that describing their experiences could guide more realistic monitoring strategies.

Materials and Methods:

We carried out a qualitative multi stakeholder study at centres that had piloted artificial intelligence assisted imaging tools for liver disease. Semi structured interviews and workshops were conducted with hepatologists, radiologists, sonographers, and information technology staff. Participants were invited to recount examples of unexpected model behaviour, local responses to perceived errors, and informal practices for monitoring performance over time. Transcripts were analysed using inductive thematic analysis, with specific attention to perceptions of risk, trust, and acceptable thresholds for intervention.

Results:

Participants described an early phase of enthusiasm followed by growing uncertainty as they encountered cases in which artificial intelligence suggestions conflicted with clinical judgement or later outcomes. Most centres lacked formal dashboards or predefined rules for recalibration, relying instead on informal feedback from a few "super users." Clinicians worried that gradually worsening performance might remain unnoticed until a serious error occurred, particularly in busy services where manual audits were unrealistic. At the same time, they expressed reluctance to rely on opaque aggregate metrics that did not clearly translate into risk for individual patients.

Conclusions:

Our study highlights performance drift and silent degradation as under recognised challenges when artificial intelligence tools are moved from development environments into routine liver care. Clinicians articulated a need for simple and interpretable safeguards, such as periodic review of

E-POSTER ABSTRACTS

discordant cases, real time discrepancy flags, and clear procedures for temporarily suspending or retraining models. These user driven insights can inform monitoring frameworks that respect clinical workflows while providing a pragmatic layer of protection for patient safety.

Keyword(s) : artificial intelligence, liver disease, model drift, patient safety, implementation, qualitative study

2207 - Making artificial intelligence in hepatology more holistic and aligned with clinical reasoning

Shuo Huang¹, Xi Zhang¹, Yunlong Yao¹, Changlan Linghu²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Wuhan Central Hospital, Department Of Neurology, Hubei-China²

Background / Hypothesis:

Most artificial intelligence research in hepatology focuses on imaging data and routine laboratory values, while patient reported outcomes and holistic descriptors used in integrative medicine are rarely captured. This narrow view of the patient may limit the relevance and acceptability of artificial intelligence tools. We hypothesised that an audit of current documentation practices could reveal simple opportunities to make future models more reflective of real world clinical reasoning.

Materials and Methods:

We performed an observational documentation audit in hepatology clinics at an academic centre where both conventional and traditional medical frameworks are applied. For consecutive patients with chronic liver disease, we recorded which elements of the consultation were stored in structured fields, which were present only in free text, and which were routinely discussed but not documented at all. We then convened workshops with clinicians, data scientists, and record specialists to prototype alternative templates that could capture additional holistic information in a concise, machine readable format.

Results:

Laboratory values and imaging summaries were consistently structured, whereas symptom patterns, lifestyle context, and traditional syndrome labels were scattered across narrative notes or left undocumented.

Clinicians reported that these under recorded elements played a major role in decisions about follow up timing, suitability for lifestyle or herbal interventions, and perceptions of resilience, yet they were effectively invisible to current artificial intelligence approaches. Workshop participants identified a small set of brief check boxes and scales that could capture much of this information without lengthening visits, while still preserving space for nuanced narrative descriptions.

Conclusions:

Our exploratory work reveals a striking mismatch between the information that shapes everyday hepatology decisions and the data typically available to artificial intelligence models. By modestly redesigning documentation to include concise structured fields for patient experience and holistic assessments, it may be possible to build artificial intelligence systems that are better aligned with clinician reasoning and with integrative models of care, thereby improving both usefulness and trust at the point of care.

Keyword(s) : hepatology, artificial intelligence, documentation, holistic assessment, integrative medicine, clinical reasoning

2208 - How endocrine information is missing from contemporary chronic liver disease research

Shuo Huang¹, Yunlong Yao¹, Xi Zhang¹, Changlan Linghu²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Wuhan Central Hospital, Department Of Neurology, Hubei-China²

Background / Hypothesis:

Endocrine pathways involving thyroid hormones, sex steroids, and adrenal function are increasingly recognised as modulators of liver injury and repair. Nevertheless, major studies in chronic liver disease rarely include detailed endocrine profiling, making it difficult to translate mechanistic insights into clinical tools. We hypothesised that mapping how endocrine variables are currently represented in hepatology research would reveal specific gaps and opportunities for a more integrated endocrine hepatology agenda.

Materials and Methods:

We performed a methodological review of recent clinical studies in chronic liver disease that reported on natural history, prognostic scores, or treatment

E-POSTER ABSTRACTS

outcomes. For each study, we recorded whether thyroid, gonadal, or adrenal measurements were obtained, how these measurements were categorised or analysed, and whether they were discussed as potential modifiers of liver related outcomes. Informal interviews with selected investigators were used to explore practical reasons for including or excluding endocrine variables during protocol development.

Results:

Across a broad range of study designs and disease etiologies, endocrine measurements were rarely treated as core data elements. When hormonal values were collected, they were often reduced to simple binary categories or used as exclusion criteria, rather than explored as mechanistic contributors to variation in liver outcomes. Investigators cited limited funding, competing priorities for laboratory testing, and uncertainty about which assays would be most informative as reasons for omission. Several also noted that dialogue between liver specialists and endocrinologists during protocol design was either brief or absent, leading to missed opportunities for targeted substudies.

Conclusions:

Our review underscores a systematic under representation of endocrine information in contemporary chronic liver disease research. This imbalance limits the ability to test endocrine based hypotheses and may slow the translation of endocrine hepatology concepts into practice. Prioritising a small set of hormonal markers, embedding them into standard data dictionaries, and fostering closer collaboration between hepatology and endocrinology teams may help bridge the current divide and support more mechanistically informed clinical studies.

2209 - Overlapping metabolic reproductive and hepatic disturbance in women with fatty liver disease

Shuo Huang¹, Xi Zhang¹, Yunlong Yao¹, Changlan Linghu²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Wuhan Central Hospital, Department Of Neurology, Hubei-China²

Background / Hypothesis:

Women with fatty liver disease frequently report irregular menses, features of androgen excess, and central adiposity, yet these disturbances are seldom viewed through an integrated endocrine hepatology lens. Clinical experience suggests that such constellations may mark a subgroup with distinct risks and concerns, especially regarding fertility and long term metabolic health. We aimed to describe how this overlapping pattern presents in routine practice and how hepatologists currently respond to it.

Materials and Methods:

We undertook a descriptive case series of women attending a fatty liver clinic who reported menstrual irregularity or clinical signs of androgen excess during routine assessment. For each case, we summarised liver disease severity, metabolic risk profile, reproductive history, and any available endocrine investigations. Brief interviews with treating hepatologists were used to explore referral patterns to gynecology or endocrinology, perceived links between hormonal disturbance and liver outcomes, and practical challenges in coordinating cross specialty care.

Results:

Across cases, we observed recurring clusters of central adiposity, insulin resistance, menstrual disturbance, and clinical hyperandrogenism. However, documentation of formal endocrine diagnoses and targeted hormone testing was inconsistent, and many patients had never been offered a structured discussion of reproductive planning or endocrine risks. Hepatologists often suspected underlying syndromes such as polycystic ovary syndrome but expressed uncertainty about when to initiate referral and which aspects of management should take precedence. Several described liver focused visits as poorly suited to address questions about fertility, contraception, or long term endocrine follow up despite obvious patient interest.

Conclusions:

Our descriptive work points to a recognisable but under addressed pattern of overlapping metabolic, reproductive, and hepatic disturbance in women with fatty liver disease. The current separation between liver and endocrine services leaves many patients navigating fragmented advice and uncoordinated follow up.

E-POSTER ABSTRACTS

Developing shared assessment pathways and joint clinics that explicitly integrate endocrine and hepatology perspectives may better meet patient needs and create a practical platform for future mechanistic and interventional studies in endocrine hepatology.

2210 - "Demographic Characteristics of MAFLD with Emphasis on Young Onset Disease in Pakistan

Anam Shakeel¹

Rawalpindi Medical University, Gastroenterology, Islamabad-Pakistan¹

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) is increasingly being diagnosed at a younger age worldwide. In Pakistan, data regarding the burden of MAFLD among young individuals is limited. We hypothesized that a major proportion of MAFLD patients in Pakistan present at a young age, indicating an emerging public health concern.

Materials and Methods:

This observational study included 211 patients diagnosed with MAFLD. Demographic data including age, sex, and area of residence were recorded. Patients were categorized into two age groups: ≤ 45 years and > 45 years. Descriptive statistical analysis was performed to evaluate the proportion of MAFLD in the younger population and to describe demographic characteristics.

Results:

The mean age of the study population was 44 years, with the youngest patient aged 16 years. Ninety-five patients (45.0%) were aged 45 years or younger, indicating a high proportion of young individuals affected by MAFLD. The cohort consisted predominantly of females ($n=158$), followed by males ($n=52$) and one transgender individual. A majority of patients belonged to urban areas ($n=173$), while 38 patients were from rural regions.

Conclusions: Almost half of the MAFLD patients in this cohort were aged 45 years or younger, exhibiting an early age of presentation in the Pakistani population.

The findings suggest a rising burden of MAFLD in younger individuals, particularly in urban settings. Early identification, lifestyle interventions, and targeted screening strategies are warranted to alleviate long-term liver-related and cardiometabolic complications.

Keyword(s) :

2211 - Frequency of metabolic dysfunction associated steatotic liver disease (MASLD) amongst patients with inflammatory bowel disease (IBD)

Md.musab Khalil¹

National Gastroenterology Institute And Hospital,¹

Background / Hypothesis:

There is paucity of data regarding the frequency of metabolic dysfunction associated steatotic liver disease (MAFLD) amongst patients with inflammatory bowel disease (IBD) in south Asia. This cross-sectional comparative study was conducted to find the frequency of metabolic dysfunction associated steatotic liver disease (MASLD) amongst patients with inflammatory bowel disease (IBD).

Materials and Methods:

This cross-sectional comparative study was conducted at the IBD department of the Asian Institute of Gastroenterology Hospitals, Hyderabad, India from June to December in 2022.

Results:

IBD was 199 patients while Non IBD was 119 patients. One third of the IBD patients had MAFLD. BMI was significantly less among the IBD patients compared to the controls ($p < 0.002$). Significant differences existed regarding smoking habits among the cases and controls where IBD patients had more non smokers and ex smokers whereas as control groups had more current smokers ($p < 0.002$). Liver enzymes namely SGOT and SGPT were significantly higher amongst the control groups ($p < 0.001$). IBD patients had significantly lower FBS compared to the controls ($p = 0.44$). IBD patients had significantly higher Triglycerides level in contrast to the controls ($p < 0.020$). MASLD occurred in comparatively older age in contrast to the controls ($p < 0.001$). Patients having both IBD and MASLD had higher BMI ($p < 0.001$), greater waist circumference ($p < 0.001$), and a higher incidence of Diabetes Mellitus ($p < 0.039$), suggesting that this cohort could be at elevated risk for metabolic complications.

E-POSTER ABSTRACTS

Conclusions:

Metabolic dysfunction associated fatty liver disease (MASLD) needs to be addressed while treating inflammatory bowel disease patients.

Keyword(s) :

2212 - Regorafenib as a second line therapy for Egyptian patients with an advanced stage HCC real life data from a single center

Eman Rewisha¹, Hossam El Din Taha¹, Mohamed Kohla¹, Mohamed Houseni², Eman Ekkhateeb¹, Mostafa Elhelbawy¹

National Liver Institute, Hepatology And Gastroenterology, Monufia-Egypt¹ National Liver Institute, Diagnostic And Interventional Radiology, Monufia-Egypt²

Background / Hypothesis:

Regorafenib has been approved as one of the treatment options for patients with advanced stage colorectal cancer (CRC), hepatocellular carcinoma (HCC), and gastrointestinal stromal tumors (GIST). Aim: To assess the efficacy and safety of regorafenib in Egyptian patients with HCC who progressed on sorafenib treatment, Assessment of drug adverse effects and Assessment of tumor response according to modified Response evaluation criteria in solid tumors (mRECIST).

Materials and Methods:

We conducted a prospective study on 248 patients with advanced HCC who were given sorafenib as first line therapy, 55 patients shifted directly to regorafenib after failure to respond to sorafenib therapy according to (mRECIST) criteria, at National Liver Institute (NLI), Menofia, Egypt from January 2022 to June 2024. Data collected include aetiology, patient demographics, performance status, duration of previous line of treatment, number of treatment cycles, side effects, best-tolerated dose, laboratory, and radiological results and treatment discontinuation due to intolerance. The outcomes included overall survival (OS) and progression-free survival (PFS).

Results:

A total of 55 from 248 patients received regorafenib as a 2nd-line treatment after sorafenib progression. Regarding the BCLC staging system, (61.7%) were in BCLC stage B and (38.3%) were in BCLC stage C. 24 of patients (43.6%) had progressive course of the disease with mean disease free progression period 14.44 [95% confidence interval (CI): 11.29-17.59] months, 36 of

patients (65.45%) died. The mean survival time was 16.78 (95% CI, 13.832 -19.742) months. The most common toxicities were liver decompensation (32.6%), hand-foot skin reaction (13.5%), diarrhea (9.8%). Regarding sorafenib, the mean disease free progression period 18.24 [95% confidence interval (CI): 15.29-21.19] months, 93 of patients (48.18%) died. The mean survival time was 22.253 (95% CI, 19.734 -24.266) months.

Conclusions:

Regorafenib appears to be safe and clinically effective in patients with advanced HCC who progressed on first-line sorafenib. Regorafenib could effectively improve the prognosis of patients after first-line treatment failure.

Keyword(s) : HCC, Regorafenib

2213 - Pain Management Gaps in Hepatocellular Carcinoma A Cross Sectional Survey Study of Patient Perceptions Misconceptions and Unmet Needs

Jina Park¹, Jonggi Choi¹, Jiwon Yang¹, Sung Won Chung¹, Won-mook Choi¹, Danbi Lee¹, Ju Hyun Shim¹, Kang Mo Kim¹, Young-suk Lim¹, Han Chu Lee¹
Asan Medical Center, Department Of Gastroenterology, Seoul-South Korea¹

Background / Hypothesis: Adequate cancer pain control is crucial for quality of life and anti-cancer treatment compliance. However, patients with hepatocellular carcinoma (HCC) with underlying liver cirrhosis often experience inadequate pain management due to misconceptions about analgesics and liver toxicity concerns. This study investigated pain perception and management practices among patients with HCC.

Materials and Methods: A structured 30-item questionnaire was administered to 200 patients with HCC (aged 19-79 years) at Asan Medical Center, Seoul, from January to November 2025. The survey assessed pain presence and intensity (12 items), perceptions of cancer pain (5 items), attitudes toward analgesics including opioids (8 items), and needs for improved pain management (5 items). Statistical analyses included Mann-Whitney U test and Spearman correlation.

Results: Among 200 respondents (mean age 63.3±8.7 years; 87% male), 55 (27.5%) reported current pain with mean intensity of 3.7/10 (maximum pain 5.1/10, minimum pain 1.7/10). Of 55 patients with pain, only 31 (56.4%) were taking analgesics while 24 (43.6%)

E-POSTER ABSTRACTS

remained untreated despite significant pain. Patients on analgesics experienced higher pain intensity (mean 4.0 vs 3.1, maximum pain 6.2 vs 3.8, $p=0.0007$), suggesting both inadequate pain control in treated patients and undertreatment in non-users. Paradoxically, while 54% acknowledged pain should not be inevitable, 69.9% worried about liver damage from analgesics. Opioid-related misconceptions were significantly higher among older patients ($r=0.189$, $p=0.009$) and married/divorced individuals (53.8-56.3%) compared to unmarried patients (15.0%, $p=0.004$). Over 80% requested dedicated pain management nurses and comprehensive analgesic education.

Conclusions: Patients with HCC demonstrate critical gaps in pain management with substantial undertreatment and misconceptions about analgesic safety, particularly regarding liver toxicity and opioid use. Age- and marital status-targeted educational interventions with dedicated pain counseling services are urgently needed to improve pain control in this vulnerable population.

2216 - Gut derived microbial nucleic acids modulate hepatic innate immune responses in steatotic liver disease

Akira Uchiyama¹, Kazuyoshi Kon¹, Shunhei Ymashina¹, Kenichi Ikejima¹

Juntendo University School Of Medicine,
Gastroenterology, Tokyo-Japan¹

Background: Steatotic liver disease (SLD), including metabolic dysfunction-associated steatotic liver disease (MASLD) and alcohol-related liver disease (ALD), is increasingly recognized as a condition driven by dysregulation of the gut-liver axis. Disruption of the intestinal barrier allows translocation of gut-derived microbial components, including nucleic acid-derived pathogen-associated molecular patterns (PAMPs), into the portal circulation. These microbial molecules can activate hepatic innate immune responses through pattern recognition receptors (PRRs), such as Toll-like receptors (TLRs), RIG-I-like receptors (RLRs), and NOD-like receptors (NLRs). However, direct human evidence linking portal microbial translocation with intrahepatic PRR expression remains limited. This study aimed to clarify the association between portal microbial nucleic acids and hepatic PRR expression in patients with SLD with particular focus on sex- and etiology-related differences. **Methods:** Liver biopsy specimens from 62

patients with SLD (MASLD, $n = 44$; ALD, $n = 18$) were analyzed to assess intrahepatic expression of PRRs, including TLR2, TLR3, TLR4, TLR5, TLR9, RIG-I, MDA5, NOD1, and NOD2. Portal venous blood samples were additionally obtained from eight patients undergoing endoscopic variceal treatment (MASLD, $n = 3$; ALD, $n = 3$; other etiologies, $n = 2$). Stool, portal blood, and peripheral blood samples were analyzed using 16S rRNA gene sequencing to characterize microbial nucleic acid profiles and to evaluate microbial translocation into the portal and systemic circulation. **Results:** Female patients exhibited significantly higher hepatic expression of RIG-I and TLR3 than male patients, with a trend toward increased MDA5 expression. In contrast, no significant sex differences were observed for TLR2, TLR4, TLR5, TLR9, NOD1, or NOD2. Disease-based analyses demonstrated significantly higher hepatic expression of RIG-I and TLR4 in patients with ALD compared with those with MASLD. Microbial taxa shared between stool and portal blood were detected in seven of eight patients, including Enterobacteriaceae, Clostridia, Bacteroidia, and Veillonella, indicating frequent portal microbial nucleic acid translocation. Translocation of microbial signatures into peripheral blood was observed more frequently in ALD than in MASLD, suggesting enhanced systemic exposure in ALD. **Conclusion:** Gut-derived microbial components enter the portal circulation and may modulate hepatic innate immune responses in SLD. Variations in PRR expression according to sex and disease etiology likely reflect differences in the amount and characteristics of microbial molecules translocating from the gut to the liver.

2217 - The Impact of Prophylactic Antibiotics on the Prognosis of Patients with Cirrhosis and Upper Gastrointestinal Bleeding

Lisha Shi¹

The Affiliated Hospital Of Xuzhou Medical University,
Department Of Infectious Diseases, Xuzhou-China¹

Background / Hypothesis:

The optimal duration of prophylactic antibiotic therapy and the most suitable patient population for its use in patients with cirrhosis and upper gastrointestinal bleeding remain unclear. This study aimed to investigate the effects of different durations of

E-POSTER ABSTRACTS

prophylactic antibiotics on clinical outcomes in patients with varying risk levels.

Materials and Methods:

A retrospective analysis was conducted on the medical records of 199 patients with cirrhosis and upper gastrointestinal bleeding admitted to the Affiliated Hospital of Xuzhou Medical University from January to December 2023. Based on the use of prophylactic antibiotics, patients were divided into an antibiotic group (89 cases) and a non-antibiotic group (110 cases). Clinical outcomes including rebleeding, readmission, mortality, and infection rates were compared between the two groups. The impact of different Child-Pugh classifications and antibiotic treatment durations on prognosis was also analyzed.

Results:

Within 60 days after discharge, the incidence of rebleeding in the antibiotic group (29.2%) was significantly lower than that in the non-antibiotic group (50.0%), and the difference was statistically significant ($P=0.04$). There were no statistically significant differences between the two groups in readmission rates (33.7% vs. 36.4%), infection rates (25.8% vs. 16.4%), or mortality rates (19.1% vs. 30.0%) (all $P>0.05$). Among patients with Child-Pugh class C cirrhosis, the survival prognosis in the antibiotic group was significantly better than that in the non-antibiotic group (Log Rank $P=0.018$). However, among patients with Child-Pugh class A/B cirrhosis, there was no statistically significant difference in 60-day post-discharge survival prognosis between the two groups (Log Rank $P=0.188$). The mortality rate in the group with an antibiotic course > 6 days (28.2%) was higher than that in the group with a 1~3 day course (8.0%), and the difference was statistically significant ($P=0.049$).

Conclusions: Prophylactic antibiotics can reduce the risk of rebleeding in patients with cirrhosis and upper gastrointestinal bleeding and improve the survival prognosis of patients with Child-Pugh class C cirrhosis. A short-course prophylactic regimen (1~3 days) may be more advantageous, and caution is advised when considering its use in low-risk patients.

2219 - Higher matrix stiffness accelerates liver fibrosis by modulating fatty acid oxidation via PPAR α CPT1A signaling axis in hepatic stellate cells

Guanyue Su¹, Wenlong Miao¹, Xuemei Wang¹, Hongxia Liang¹, Zhigang Ren¹

The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases, Zhengzhou-China¹

Background / Hypothesis:

Matrix stiffness is a key mechanical feature during hepatic fibrosis progression. Fatty acid oxidation (FAO) is a crucial biological process regulating hepatic stellate cell (HSC) activation, which drives fibrosis. This study aimed to investigate the effect of matrix stiffness on FAO in HSCs and its underlying regulatory mechanism during hepatic fibrogenesis.

Materials and Methods:

An in vitro cell culture platform was established to mimic liver tissue stiffness at different pathological stages (1, 8, 16, 32 kPa). The human HSC line LX2 was cultured on these substrates. Activation markers (α -SMA, Collagen I, TIMP1) and key FAO enzymes (CPT1, ACOX1) were detected by Western blot and qRT-PCR. Transcriptome sequencing was used to identify mechanosensitive targets. PPAR α function was validated using agonist treatment and overexpression experiments. A CCl₄-induced mouse model of hepatic fibrosis was established. Histopathological staining assessed fibrosis, and immunohistochemistry verified key molecule expression.

Results:

Increased matrix stiffness significantly upregulated the expression of α -SMA, Col1a1, and TIMP1 in LX2 cells, accompanied by decreased expression of FAO-related genes such as CPT1 and ACOX1. Transcriptome analysis and validation showed that high matrix stiffness markedly downregulated PPAR α expression and inhibited its nuclear translocation. Treatment with the PPAR α agonist WY14643 significantly increased CPT1 expression and FAO levels, thereby inhibiting HSC activation induced by high stiffness. In vivo, the PPAR α agonist significantly attenuated the degree of liver fibrosis in model mice.

Conclusions:

High matrix stiffness promotes HSC activation and drives hepatic fibrosis progression by suppressing the PPAR α -CPT1 signaling axis and subsequently inhibiting fatty acid oxidation in HSCs.

E-POSTER ABSTRACTS

Keyword(s) : matrix stiffness, liver fibrosis, fatty acid oxidation, LX2

2220 - Prospective Study on Prognostic Improvement and Suppression of Hepatocellular Carcinoma Development after Zinc Supplementation in Patients with Liver Cirrhosis

Background and Aim

Atsushi Hosui¹, Tomohide Kurahashi¹, Naoki Hiramatsu¹

Osaka Rosai Hospital, Department Of Gastroenterology And Hepatology, Sakai-Japan¹

Background / Hypothesis:

Serum zinc levels decrease with the progression of hepatic fibrosis in patients with chronic liver disease, and zinc deficiency is a known risk factor for the development of hepatocellular carcinoma (HCC). In our previous retrospective study, zinc supplementation was associated with reduced mortality, and decreased HCC development. This prospective study aimed to evaluate whether long-term zinc supplementation improves prognosis, suppresses HCC development, and prevents deterioration of liver function in patients with cirrhosis treated with zinc acetate (Novelzin) in routine clinical practice.

Materials and Methods:

Among 1,067 consecutive patients diagnosed with liver cirrhosis between May 2018 and October 2023, 563 patients were enrolled after excluding those with a history of HCC, an observation period of less than three months, or lack of informed consent. Patients were classified into a zinc-taking group (n=130) and a zinc-non-taking group (n=433). Changes in laboratory parameters, overall survival, and incidence of cancer development were compared between the two groups.

Results:

The baseline characteristics of the cohort were as follows: mean age 70.4±12.3 years; male/female ratio 343/220; etiology alcohol/HBV/HCV/NASH 231/53/123/105; total bilirubin 1.8±2.5 mg/dL; albumin 3.23±0.73 g/dL; prothrombin time (PT) 70.9±20.1%; serum zinc 56.3±20.3 µg/dL; and mean observation period 17.7±18.5 months. In the zinc-taking group, serum zinc levels, albumin, and PT significantly improved at six months after treatment compared with baseline (51.8→87.6 µg/dL, 3.03→3.35 g/dL, and 66.3→71.7%, respectively; all p<0.01). The zinc-taking group showed significantly better outcomes than the zinc-non-taking group, with a higher 3-year survival rate (69.0% vs. 56.2%, p=0.035) and a lower 3-year

incidence of cancer development (1.5% vs. 8.1%, p=0.043).

Conclusions:

Consistent with our retrospective findings, prospective zinc supplementation significantly improved liver function, reduced HCC incidence, and enhanced survival in patients with cirrhosis. Zinc supplementation may represent an effective therapeutic strategy for cirrhosis regardless of underlying etiology.

Keyword(s) : zinc, cirrhosis, HCC, prognostic improvement

2221 - FABP4 as a Prognostic Biomarker and Its Clinical Relevance in Drug Induced Cholestasis

Tianhui Zhou¹, Yuelin Xiao¹, Haoshuang Fu¹, Shuying Song¹, Xinya Zang¹, Ruidong Mo¹, Rongtao Lai¹, Huijuan Zhou¹, Gangde Zhao¹, Ziqiang Li¹, Qing Xie¹
Ruijin Hospital, Shanghai Jiao Tong University School Of Medicine, Department Of Infectious Diseases, Shanghai-China¹

Background / Hypothesis:

Drug-induced cholestasis (DIC) is a relatively severe and prognostically challenging subtype of drug-induced liver injury (DILI). It is often characterized by a protracted clinical course, a high risk of chronicity, and prolonged hospitalization, imposing a significant burden on patients and healthcare systems. Currently, there is a notable lack of reliable biomarkers for predicting disease progression and outcomes in DIC. Fatty acid-binding protein 4 (FABP4), a key mediator in metabolic inflammation, has not been well characterized in this clinical context. This study aimed to investigate the association between FABP4 and disease severity/prognosis in patients with DIC.

Materials and Methods:

Eighty DILI patients (subtyped as hepatocellular [H-DILI, n=40] and cholestatic [C-DILI, n=40]) and 35 healthy controls (HC) were enrolled. Hepatic FABP4 expression was assessed using immunohistochemistry (IHC) and Western blot, while plasma FABP4 levels were measured via enzyme-linked immunosorbent assay (ELISA). Correlations between FABP4 levels, clinical indicators (total bilirubin [TBil]), and outcomes were analyzed. Complementary mouse models of ANIT (cholestatic) and acetaminophen (APAP, hepatocellular) liver injury were used to validate FABP4 expression patterns.

E-POSTER ABSTRACTS

Results:

C-DILI patients and H-DILI patients exhibited significantly elevated FABP4 expression in liver tissue and plasma compared to HC (Figure A-D, $P < 0.05$). Serum FABP4 levels showed strong positive correlations with liver injury grade ($r = 0.4299$, $P < 0.0001$) and TBil ($r = 0.4016$, $P = 0.0002$) and disease severity, reaching peak values in patients requiring liver transplantation or nonsurvival (Figure D-E, $P < 0.05$). Conversely, FABP4 exhibited significant negative correlations with serum cholesterol ($r = -0.4352$, $P = 0.0003$), LDL ($r = -0.5249$, $P < 0.0001$), and HDL ($r = -0.4948$, $P < 0.0001$) (Figure F, H). Plasma FABP4 demonstrated significant prognostic value for C-DILI outcomes (Figure G, $P < 0.05$). In murine models, both ANIT and APAP-induced liver injury triggered substantial FABP4 upregulation (Figure I-M, $P < 0.05$), with spatial expression patterns highly colocalized with inflammatory infiltrates (F4/80+ macrophages, MPO+ neutrophils) and necrotic areas.

Conclusions:

FABP4 serves as a novel biomarker for disease severity and prognosis in DIC patients. Its expression levels enable clinical stratification and outcome prediction, providing a new tool for precise diagnosis and management of DIC.

Keyword(s) : Drug-induced Cholestasis, FABP4, Prognosis, Biomarker

2222 - The correlation between autoantibody spectrum and clinical pathological phenotype of Primary Biliary Cholangitis Patients

Weihua Cao¹, Hongxiao Hao¹, Yao Xie¹, Minghui Li¹
Beijing Ditan Hospital, Capital Medical University, Hepatology Division 2, Beijing-China¹

Background / Hypothesis:

Primary biliary cholangitis (PBC) is characterized by a broad spectrum of autoantibodies, but their correlations with clinical phenotypes remain to be fully elucidated.

Materials and Methods:

This retrospective study included patients who underwent liver biopsy were diagnosed with PBC at Beijing Ditan Hospital. The prevalence of various autoantibodies—including anti-mitochondrial antibody

(AMA), antinuclear antibody (ANA), anti-centromere antibody (ACA), anti-Ro-52, anti-SP100, and anti-gp210—was analyzed. Patients were stratified based on autoantibody status (e.g., anti-SP100 positive/negative, anti-gp210 positive/negative), and their demographic, biochemical, immunological, and histopathological features were compared using appropriate statistical tests. Correlation analysis was performed between AMA titer and key liver biochemical indicators.

Results:

In the cohort, A total of 218 PSVD patients undergoing liver biopsy were enrolled, and 69.72% were AMA-positive and 68.81% were ANA-positive. The positive rates for anti-gp210, anti-Ro-52, anti-SP100, and ACA were 39.91%, 37.16%, 20.64%, and 17.43%, respectively. Comparative analysis revealed that anti-SP100-positive patients had a significantly higher ANA-positive rate (93.33% vs. 62.43%, $p = 0.007$). Anti-gp210-positive patients exhibited higher levels of total bile acid (TBA) (median 19.90 vs. 11.70 $\mu\text{mol/L}$, $p = 0.038$), total cholesterol (TC) (5.21 vs. 4.75 mmol/L , $p = 0.044$), and IgM (2.84 vs. 2.20 g/L , $p = 0.016$), as well as a higher ANA-positive rate (85.06% vs. 58.02%, $p < 0.001$) and AMA-positive rate (74.71% vs. 61.83%, $p = 0.024$). AMA titer showed significant positive correlations with ALT, AST, GGT, ALP, and IgM levels (all $p < 0.05$). No significant differences were found in the prevalence of advanced fibrosis between the different antibody subgroups.

Conclusions:

The autoantibody profile in PBC patients is heterogeneous. Anti-gp210 positivity is associated with distinct biochemical features (elevated TBA, TC, and IgM), while anti-SP100 positivity is strongly linked to ANA seropositivity. AMA titer correlates with disease activity markers. These findings highlight the clinical relevance of the autoantibody spectrum in stratifying PBC phenotypes.

Keyword(s) : primary biliary cholangitis, anti-mitochondrial antibody, anti-SP100 antibody, anti-gp210 antibody, pathological stage

2223 - Hepatic IGFBP3 Attenuates Osteoblastic Differentiation in Cirrhotic Liver-Bone Axis via NF- κ B Signaling

Xiaoli Ma¹, Guanyue Su¹, Huimin Liu², Wenlong Miao¹, Hongxia Liang¹, Zhigang Ren¹

E-POSTER ABSTRACTS

The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases, State Key Laboratory Of Antiviral Drugs, Pingyuan Laboratory, Zhengzhou-China ¹ The First Affiliated Hospital Of Zhengzhou University, Department Of Neurology, Zhengzhou-China ²

Background / Hypothesis: With the rising prevalence of aging and metabolic disorders, secondary osteoporosis is increasingly common, particularly among patients with liver cirrhosis. Cirrhosis contributes to abnormal bone metabolism, representing a significant risk factor for osteoporosis, though the underlying mechanisms remain unclear. Insulin-like growth factor binding protein 3 (IGFBP3), primarily synthesized in the liver, serves as the major binding protein for insulin-like growth factor 1 (IGF-1) and plays a key role in bone development and remodeling by modulating IGF-1 bioavailability. However, the specific function of IGFBP3 in cirrhosis-associated osteoporosis still requires further clarification.

Materials and Methods: We established a mouse model of cirrhosis-osteoporosis comorbidity by combining ovariectomy with carbon tetrachloride (CCl₄) administration and intervened with IGFBP3. Liver pathology was assessed by histology and serum liver function tests. Bone microarchitecture and morphology were evaluated via micro-CT and histochemical staining. Hepatic and bone IGFBP3 levels, along with osteogenic markers, were determined by Western blotting and immunohistochemistry. Weighted gene co-expression network analysis (WGCNA) was applied to a proteomic dataset from cirrhosis and osteoporosis to identify core differentially expressed genes, which were then subjected to KEGG pathway enrichment analysis and validation. For in vitro studies, an AML12 hepatocytes/MC3T3-E1 osteoblasts co-culture system was established. Following LPS induced liver impairment, IGFBP3 was administered, and Western blotting and RT-qPCR were used to examine osteogenic markers (ALP, OCN, and Runx2) and changes in the NF- κ B signaling pathway.

Results: In vivo, mice with cirrhosis alone or cirrhosis combined with osteoporosis demonstrated exacerbated hepatic inflammation, fibrosis progression, and impaired liver function compared with controls and osteoporosis-only mice. The cirrhosis and cirrhosis-osteoporosis group also showed reduced bone mass and fewer trabeculae relative to mice

without cirrhosis. WGCNA of proteomic data from cirrhosis and osteoporosis models identified core common differentially expressed genes, including significantly downregulated IGFBP3. KEGG analysis showed significant enrichment of these genes in the NF- κ B signaling pathway. In cirrhosis mice, IGFBP3 was decreased in both liver and bone. Exogenous IGFBP3 increased bone mass and osteogenic markers in vivo. In vitro, LPS-stimulated co-culture of AML12 hepatocytes and MC3T3-E1 osteogenic cells impaired osteogenic differentiation, which was restored by IGFBP3 addition along with suppression of NF- κ B signaling.

Conclusions: Cirrhosis exacerbates bone loss and osteoporosis progression, primarily mediated by systemic inflammation. Hepatically-produced IGFBP3 promotes osteoblastic differentiation via suppression of NF- κ B signaling pathway, thereby delaying osteoporosis onset. These findings identify IGFBP3 as a key molecular mechanism linking cirrhosis and osteoporosis, highlighting its therapeutic potential.

Keyword(s) : cirrhosis, osteoporosis, IGFBP3, inflammation

2224 - Hepatitis D related liver disease as a major indication for liver transplantation experience from a new liver transplant program in pakistan

Darayus Percy Gazder ¹, Zaigham Abbas ¹, Zeeshan Hyder ², Aasia Sabeen ²

Ziauddin Hospital, Hepatogastroenterology, Karachi-Pakistan ¹ Ziauddin Hospital, Hepatobiliary Surgery, Karachi-Pakistan ²

Background / Hypothesis:

Hepatitis D virus infection is the most severe form of chronic viral hepatitis and can rapidly progress to cirrhosis and liver failure. In endemic regions such as Pakistan, it contributes substantially to advanced liver disease, yet its representation among liver transplant indications is not well described. We assessed the burden and clinical characteristics of hepatitis D-related liver disease as an indication for liver transplantation in the initial experience of our center.

Materials and Methods:

We retrospectively reviewed the first 42 liver transplants performed for chronic liver disease at our program in Pakistan. Patients were categorized into hepatitis D virus-related disease (n=16) and non-hepatitis D virus etiologies (n=26). Demographics,

E-POSTER ABSTRACTS

transplant indication, Child–Pugh score, Model for End-Stage Liver Disease sodium score, and decompensation status (ascites and/or hepatic encephalopathy) were recorded. Group comparisons were performed using t-tests and chi-square analyses.

Results:

Among 42 transplants, 37 (88.1%) recipients were male, with a mean age of 46.2 ± 10.5 years. Hepatitis D virus–related chronic liver disease was the leading transplant indication (38.1%, n=16), followed by hepatitis C (21.4%, n=9), alcoholic liver disease (19.0%, n=8), hepatitis B (11.9%, n=5), metabolic dysfunction–associated fatty liver disease (4.8%, n=2), primary biliary cholangitis (2.4%, n=1), and autoimmune hepatitis (2.4%, n=1). Hepatitis D virus recipients were significantly younger than non–hepatitis D virus recipients (40.5 ± 11.6 vs 48.9 ± 7.2 years; $p=0.05$). Child–Pugh score (9.7 ± 3.0 vs 8.8 ± 2.1 ; $p=0.276$), Model for End-Stage Liver Disease sodium score (17.3 ± 5.1 vs 14.6 ± 5.2 ; $p=0.108$), and decompensation rates (93.8% vs 76.9%; $p=0.320$) were not statistically different. Hepatocellular carcinoma was present in 25% (n=4) of hepatitis D virus cases.

Conclusions:

In our early liver transplant experience, hepatitis D virus–related liver disease emerged as the most common indication for transplantation and affected significantly younger patients, highlighting its aggressive course in endemic settings. Strengthening screening, early diagnosis, and timely transplant referral pathways for hepatitis D virus infection may help reduce the burden of advanced disease.

2227 - Unilateral Sialadenosis as Initial Presentation of Alcoholic Hepatitis A Case Report

[Emerald Gersava](#)¹, Eda Jo D. Amatong¹

Veterans Memorial Medical Center, Internal Medicine - Section Of Gastroenterology, Quezon City-Philippines¹

Background: Sialadenosis is a non-inflammatory, non-neoplastic, bilateral, painless swelling of the parotid glands or less frequently, the submandibular glands. It is often linked to chronic alcoholism and those with diabetes and malnourishment. We present a first-ever reported case of unilateral Sialadenosis of the right submandibular gland in an alcoholic male patient with alcoholic hepatitis.

Case Presentation: A 51-year-old diabetic and hypertensive, Filipino male, heavy alcohol drinker sought consultation due to right submandibular swelling and jaundice. The swelling in the right submandibular area started four weeks before seeking medical consultation which was subsequently followed by jaundice and generalized body weakness. Pertinent physical examination revealed icterisia, pale conjunctivae, nontender, non-mobile right submandibular mass ~6x5 cm, slightly distended abdomen, and jaundice. Laboratory work-up showed macrocytic anemia, hyperbilirubinemia, hypoalbuminemia, an AST:ALT ratio of 1.88, a MELD-Na score of 29 and Maddrey's Discriminant Function (MDF) 33.2 --- findings consistent with severe alcoholic hepatitis. Neck ultrasound revealed enlarged right submandibular gland, with normal left submandibular and parotid glands. Fine needle aspiration (FNA) biopsy of the right submandibular gland was nondiagnostic with note of few lymphocytes and neutrophils with abundant red blood cells. Further examinations revealed previous hepatitis B, fatty liver changes, minimal ascites, and no concomitant infection. Steroid therapy, along with alcohol cessation, was initiated. Significant clinical and biochemical improvement were observed after a week. Treatment was completed for four (4) weeks with resolution of the submandibular enlargement and jaundice.

Conclusion: This case shows that unilateral sialadenosis can be an initial presentation of alcoholic hepatitis and resolves with appropriate management. It stresses the importance of thorough history-taking and physical examination, along with comprehensive diagnostic tests and apt interventions to ensure better outcomes in patients with alcoholic hepatitis.

2228 - HBsAg Levels as Predictors of Fibrosis in Chronic Hepatitis B A Systematic Review and Meta analysis

[Javaria Younas Muhammad Younas](#)¹, Mahnoor Washdil Washdil²

Bmch, Medicine, Quetta-Pakistan¹ Jpmc, Medicine, Karachi-Pakistan²

Background / Hypothesis: Chronic hepatitis B virus (HBV) infection remains a major global cause of liver-

E-POSTER ABSTRACTS

related morbidity and mortality. Accurate assessment of liver fibrosis is essential for prognostication and treatment decisions. Quantitative hepatitis B surface antigen (HBsAg) levels have emerged as a potential non-invasive marker reflecting viral activity and immune control; however, their role in predicting liver fibrosis remains controversial across studies.

Aim:To evaluate the association between serum HBsAg levels and liver fibrosis severity in patients with chronic hepatitis B.

Materials and Methods:

A systematic literature search was performed using PubMed, Scopus, and Web of Science to identify studies assessing the relationship between quantitative HBsAg levels and liver fibrosis in adult patients with chronic hepatitis B. Studies using histology, elastography, or validated non-invasive fibrosis assessments were included. Data were synthesized using meta-analytic methods, and study quality was assessed using standardized tools.

Results:Across included studies, HBsAg levels demonstrated a significant association with fibrosis severity in chronic hepatitis B patients. Lower HBsAg levels were generally associated with more advanced fibrosis, particularly in HBeAg-negative disease. This relationship was observed across different populations and fibrosis assessment methods, suggesting a potential role for HBsAg quantification in fibrosis risk stratification.

Conclusions:HBsAg levels may serve as a useful non-invasive biomarker for predicting liver fibrosis in patients with chronic hepatitis B. Incorporating quantitative HBsAg assessment into routine clinical evaluation may aid in identifying patients at higher risk of advanced fibrosis and guide monitoring and management strategies.

Keyword(s) : Keywords: Chronic hepatitis B, HBsAg, Liver fibrosis, Non-invasive biomarkers, Meta-analysis

2230 - HBsAg Levels as Predictors of Fibrosis in Chronic Hepatitis B A Systematic Review and Meta analysis

2231 - Hepatocellular Carcinoma Surveillance among Chronic Hepatitis C patients after successful SVR Systematic Review and Meta analysis of Economic Evaluation Studies

Soe Thiha Maung¹, Peerada Valyasevi¹, Roongruedee Chaiteerakij²

Faculty Of Medicine, Chulalongkorn University, Division Of Graduate Affairs, Bangkok-Thailand¹ Faculty Of Medicine, Chulalongkorn University, Integrated Innovation And Digital Technologies Affairs, Bangkok-Thailand²

Background / Hypothesis: Although sustained virologic

E-POSTER ABSTRACTS

response (SVR) significantly reduces the risk of hepatocellular carcinoma (HCC) in chronic hepatitis C (CHC) patients, the residual risk, especially among those with advanced fibrosis or cirrhosis, necessitates consideration of ongoing surveillance. Current guidelines offer inconsistent recommendations. This systematic review and meta-analysis evaluates the cost-effectiveness of HCC surveillance strategies post-SVR, to inform evidence-based clinical and policy decisions.

Materials and Methods: A systematic search was performed in PubMed, Embase, Scopus, Google Scholar, and the Cochrane Library to identify economic evaluations of HCC surveillance strategies in CHC patients post-SVR. Studies reporting cost-effectiveness outcomes. Incremental net monetary benefit (INMB) values were calculated for meta-analysis. Study quality was assessed using the ECOBIAS checklist. Subgroup analyses were conducted based on surveillance modality, interval, and willingness-to-pay (WTP) thresholds.

Results: Of 157 identified records, seven studies were included in the meta-analysis. All studies were conducted in American regions. Four focused exclusively on patients with cirrhosis, while three included both advanced fibrosis (F3) and cirrhosis. Most applied Markov models from a healthcare payer perspective. At a WTP threshold of USD 100,000, pooled INMB was significantly positive (USD 1,743; 95%CI: 468–3,019; $p=0.007$), particularly among cirrhosis-only populations. No significant cost-effectiveness was observed at WTP thresholds of USD 50,000 or 150,000. Subgroup analyses at a WTP threshold of USD 50,000 showed no surveillance strategy yielded statistically significant INMB. Six-monthly ultrasound with alpha fetoprotein (AFP) had the highest pooled INMB (USD –265), though not significant. Across modeling domains, results remained non-significant regardless of surveillance interval, HCC incidence, time horizon, SVR population, or model perspective. Studies assuming lower HCC incidence ($<1.5\%$ /year) tended to report lower INMBs. Overall, substantial consistency across subgroups was observed, with negligible heterogeneity ($I^2=0\%$), suggesting limited cost-effectiveness of post-SVR surveillance under lower WTP thresholds.

Conclusions: Current international guidelines show divergence in post-SVR HCC surveillance recommendations for CHC patients with advanced fibrosis. While AASLD and EASL do not recommend

surveillance in this group, APASL advises semiannual ultrasound with or without AFP up to two years post-SVR, and annually thereafter. Japan and Korea further support routine surveillance regardless of fibrosis stage in these patients population. However, existing cost-effectiveness evidence is based solely on Western settings. HCC surveillance post-SVR may be cost-effective at higher WTP thresholds, especially in cirrhotic patients. Given the economic and epidemiological differences in Asia-Pacific countries, region-specific economic evaluations are urgently needed to guide appropriate surveillance policies and resource allocation in post-SVR populations across diverse healthcare systems.

Keyword(s) : HCC surveillance, Chronic Hepatitis C, Post-SVR, Cost-effectiveness

2232 - Diagnostic Accuracy of FIB 4 Score for Detecting Advanced Fibrosis in NAFLD A Systematic Review and Meta analysis

Javaria Younas Muhammad Younas¹, Sumbul Samad Abdul Samad²

Bmch, Medicine, Quetta-Pakistan¹ Jpmc, Medicine, Karachi-Pakistan²

Background / Hypothesis:

Advanced fibrosis is the key determinant of prognosis in non-alcoholic fatty liver disease (NAFLD). Early identification of patients with advanced fibrosis is crucial to prevent liver-related complications. The FIB-4 score, a non-invasive and cost-effective biomarker-based tool, is commonly used to detect significant fibrosis, but its diagnostic accuracy shows variability across different studies and populations. Aim: To systematically evaluate the performance of the FIB-4 score in diagnosing advanced fibrosis among NAFLD patients.

Materials and Methods:

A comprehensive literature search was conducted in PubMed, Scopus, and Web of Science for studies assessing FIB-4 against liver biopsy or validated non-invasive fibrosis reference standards. Adult NAFLD populations were included. Data on sensitivity, specificity, positive and negative predictive values, and area under the curve (AUC) were extracted. Meta-analytic techniques were applied to pool diagnostic accuracy estimates.

Results:

Analysis of the available studies indicates that FIB-4 demonstrates good discriminative ability for advanced

E-POSTER ABSTRACTS

fibrosis in NAFLD. The score shows reliable sensitivity and specificity across multiple cohorts and remains consistent regardless of study design or geographical region. FIB-4 effectively identifies patients at high risk for advanced fibrosis, allowing clinicians to prioritize further assessment and management.

Conclusions: The FIB-4 score is a practical, non-invasive tool for detecting advanced fibrosis in NAFLD. Its implementation in routine clinical practice can reduce unnecessary liver biopsies and facilitate timely intervention for high-risk patients. These findings underscore the value of FIB-4 as part of risk-stratification strategies in NAFLD management.

Keyword(s) : Keywords: NAFLD, FIB-4, Advanced fibrosis, Diagnostic performance, Non-invasive assessment

2233 - Real World Two Year Outcomes of Atezolizumab and Bevacizumab in Unresectable Hepatocellular Carcinoma Single Center Experience

Shahira El-etreby¹, Omar Abdallah¹, Omar Elmetwally¹, Reham A. Zayed¹, Fady Sabry¹, Mennatallah E Saad¹, Ahmed Nagy¹, Monir Baghat¹, Alyaa R. Elsergany², Usama Shiha³, Mohammed A.elhawary³, Wagdi Elkashef⁴, Amany Eissa⁵, Gehad Hisham¹, Heba Mohab¹, Khaled M. Abouelkhair⁶
Mansoura Faculty Of Medicine, Internal Medicine, Mansoura-Egypt¹ Mansoura Faculty Of Medicine, Medical Oncology, Mansoura-Egypt² Mansoura Faculty Of Medicine, Radiology, Mansoura-Egypt³ Mansoura Faculty Of Medicine, Pathology, Mansoura-Egypt⁴ Kafr Shukr Specialized Hospital Of Medicine, Hepatogly And Gastroenterology, Kafr Shukr-Egypt⁵ Mansoura Faculty Of Medicine, Clinical Oncology, Mansoura-Egypt⁶

Background / Hypothesis

Hepatocellular carcinoma (HCC) ranks as the sixth most prevalent cancer globally and the fourth in Egypt. The combination of atezolizumab (an anti-PD-L1 agent) and bevacizumab (an anti-VEGF therapy) is established as the standard first-line treatment for unresectable HCC, leading to notable improvements in patient survival rates. This study aims to evaluate tumor response, overall survival, progression-free survival, and any potential adverse effects associated with the treatment.

Materials and Methods

Between November 2023 and December 2025, a group

of 169 patients diagnosed with unresectable hepatocellular carcinoma (HCC) who had not undergone systemic therapy prior to this study received a combination of atezolizumab and bevacizumab. Treatment continued until either intolerable adverse effects emerged or there was a decline in clinical efficacy. The main primary outcomes were overall survival and progression-free survival within the intention-to-treat cohort, evaluated using the Response Evaluation Criteria in Solid Tumors, specifically the modified RECIST (mRECIST) guidelines and assessment of AFP level.

Results

The overall survival for patients was 14.32 months (95% CI, 11.364 to 17.285), while the median progression-free survival was reported at 15.21 months (95% CI, 13.05 to 17.36). A complete response was observed in 2 patients (1.2%), while 51 patients (30.2%) demonstrated a partial response. Stable disease was noted in 33 patients (19.5%), and progressive disease was identified in 56 patients (33.1%). Treatment discontinuation occurred for 27 patients (16%), with 6 individuals ceasing treatment due to adverse drug effects and the remaining 21 due to either drug-related issues or high tumor burden.

Adverse effects reported included infusion-related reactions at a rate of 14.8%, hypertension also at 14.8%, and pneumonia affecting 17.1%. Additional side effects encompassed elevated ALT and AST levels in 11.8% of cases, increased bilirubin levels in 13%, bleeding occurring in 8.9%, thyroid disorders impacting 2.9% of patients, and colitis seen in 5.9%. Furthermore, embolization—either arterial or venous—was documented in 4 cases (2.4%). Grade 4 adverse events were reported in 5.3% of our patients, whereas Grade 5 events occurred in 2.9%. Dose adjustments or treatment delays were implemented for 60% of the study cohort.

Conclusions

In patients with unresectable hepatocellular carcinoma, atezolizumab combined with bevacizumab resulted in better overall and progression-free survival outcomes with tolerable adverse effects.

Keyword(s) : Immunotherapy, atezolizumab combined bevacizumab, hepatocellular carcinoma

E-POSTER ABSTRACTS

2234 - Preliminary results of STRIDE regimen in Egyptian HCC patients A Single Center Real World Experience

Shahira El-etreby¹, Omar Abdallah¹, Omar Elmetwally¹, Reham A. Zayed¹, Fady Sabry¹, Mennatallah E Saad¹, Ahmed Nagy¹, Monir Baghat¹, Alyaa R. Elsergany², Usama Shiha³, Mohammed A.elhawary³, Wagdi Elkashef⁴, Amany Eissa⁵, Gehad Hisham¹, Heba Mohab¹, Khaled M. Abouelkhair⁶

Background / Hypothesis

On October 21, 2022, the FDA approved tremelimumab (Imjudo) in combination with durvalumab for adult patients with unresectable hepatocellular carcinoma (HCC). This study aimed to assess the response of tumors and identify any possible side effects related to the treatment.

Materials and Methods

Between January 2025 and November 2025, a group of 52 patients diagnosed with unresectable HCC who had not undergone systemic therapy prior to this study received a combination of durvalumab and tremelimumab. Treatment continued until either intolerable adverse effects emerged or there was a decline in clinical efficacy. All patients evaluated using the Response Evaluation Criteria in Solid Tumors, specifically the modified RECIST (mRECIST) guidelines and assessment of AFP level.

Results

As for the tumor response, one patient (1.9%) experienced a complete response, while 18 patients (26.4%) were classified as partial responders. Additionally, stable disease was observed in 14 patients (26.4%), and 10 patients (18.9%) exhibited progressive disease. Treatment was discontinued for 9 patients (17.3%), with 3 of these cases attributed to adverse effects such as immune-mediated thrombocytopenia, immune-mediated pancreatitis, and severe renal impairment; the remaining 6 discontinued treatment

due to decompensated liver disease. The overall response rate was 36.53%, whereas the disease control rate was 63.46%. Dose modifications or delays in treatment occurred in 30% of the participants in the study cohort. The most frequently reported adverse effects included pruritus at 23%, rash at 11.5%, elevated liver enzymes (ALT, AST) at 23%, increased bilirubin level at 17.3%, and both colitis and thyroid disorders affecting 7.7% of participants each. G3/4 toxicity was noted with a 19% occurrence of rash and a 17% incidence of pruritus. Additionally, G5 toxicity was associated with liver injury, reported at a rate of 2.1%.

Conclusions

Utilizing a combination of tremelimumab and durvalumab in Egyptian patients with unresectable hepatocellular carcinoma led to tumor responses similar to those observed in real-world studies, accompanied by tolerable side effects.

Keyword(s) : Immunotherapy, tremelimumab and durvalumab, hepatocellular carcinoma

2235 - Association Between HbA1c Levels and Risk of Liver Related Events in NAFLD Patients A Systematic Review and Meta analysis

Israr Ullah Abdul Qadeem¹, Ashraf Mehmood Mehmood Khan²

Dhq, Medicine, Ziarat-Pakistan¹ Bmch, Medicine, Quetta-Pakistan²

Background / Hypothesis:

Non-alcoholic fatty liver disease (NAFLD) is closely linked with metabolic disorders, particularly diabetes. Glycated hemoglobin (HbA1c) reflects long-term glycemic control and may influence the risk of liver-related complications. However, the relationship between HbA1c levels and liver-related events in NAFLD patients remains unclear.

Aim :To evaluate the association between HbA1c levels and the risk of liver-related events in patients with NAFLD.

Materials and Methods: A systematic literature search was performed in PubMed, Scopus, and Web of Science for studies reporting HbA1c and liver-related outcomes, including cirrhosis, liver decompensation, hepatocellular carcinoma, or liver-related mortality in NAFLD patients. Data on study design, sample size, HbA1c categories, and liver-related event rates were extracted and synthesized qualitatively and quantitatively.

E-POSTER ABSTRACTS

Results: Evidence across multiple studies suggests that higher HbA1c levels are associated with an increased risk of liver-related events in NAFLD patients. This association was observed in both cohort and cross-sectional studies, independent of age, sex, and other metabolic risk factors. Findings indicate that poor glycemic control significantly elevates the risk of progressive liver disease in this population.

Conclusion: Elevated HbA1c is a significant predictor of liver-related events in NAFLD patients. Monitoring and optimizing glycemic control may help reduce the risk of adverse liver outcomes. These findings support integrating HbA1c assessment into risk stratification and management strategies for NAFLD patients.

Keyword(s) : Keywords: NAFLD, HbA1c, Liver-related events, Glycemic control, Meta-analysis

2236 - Cimicifugae Rhizoma Suppresses Hepatoblastoma Proliferation by Downregulating G6PD Expression

Jiajia Zhou¹, Xilong Tang¹, Jianjin Xue¹, Xiao Li¹, Jie Zhang¹

Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou-China¹

Background / Hypothesis: Hepatoblastoma (HB) is the most common malignant pediatric liver tumor, and treatment options remain limited. Glucose-6-phosphate dehydrogenase (G6PD), a key rate-limiting enzyme in the pentose phosphate pathway, has been shown to promote HB progression. Cimicifugae Rhizoma (CR), a traditional Chinese medicinal herb, possesses antitumor properties, but its effect on HB development and prognosis remains unclear.

Materials and Methods: We first evaluated G6PD expression across cancers using the TIMER database and specifically in HB using three GEO datasets. The diagnostic value of G6PD for HB was assessed via ROC curve analysis. Due to the lack of HB patient prognosis data, its prognostic significance was explored in hepatocellular carcinoma (HCC) using GEPIA 2. Molecular docking analysis using CB-Dock2 were performed to analyze interactions between CR and G6PD. Finally, the effects of three principal active components of CR on HepG2 cells were investigated. Cell proliferation was measured via CCK-8 assay, and G6PD mRNA expression was detected by qRT-PCR.

Results: G6PD was highly expressed in most

malignancies, including HB, and demonstrated strong diagnostic value for HB. Survival analysis linked high G6PD expression with poor prognosis in HCC patients. Molecular docking indicated that the CR components Asiaticoside B, cimifugin, and Prim-O-glucosylcimifugin (POG) exhibited favorable binding affinity for G6PD. Experimental validation confirmed that CR inhibits HepG2 cell proliferation and downregulates G6PD mRNA expression.

Conclusions: This study is the first to demonstrate that Cimicifugae Rhizoma inhibits hepatoblastoma proliferation by modulating G6PD, a key gene in the pentose phosphate pathway, thereby providing novel insights and a potential therapeutic strategy for HB treatment.

Keyword(s) : Cimicifugae Rhizoma, Hepatoblastoma, G6PD, Proliferation

2237 - RSRC1 Promotes Hepatocellular Carcinoma Progression by Mediating Homologous Recombination Repair and Regulates Sensitivity to PARP Inhibitors

Chunyan Ruan¹, Ping Tuo¹, Yuanye Ji¹, Jingjue Pan¹, Hongshan Li²

Ningbo No.2 Hospital, Centre For Medical Research, Ningbo-China¹ Ningbo No.2 Hospital, Liver Disease Department Of Integrative Medicine, Ningbo-China²

Background / Hypothesis:

The dysregulation of DNA damage repair is a critical factor in the development and progression of hepatocellular carcinoma (HCC), yet its core regulatory mechanisms remain unclear. Despite the significant success of PARP inhibitors (PARPi) in cancer therapy, their limited response rate, particularly in HCC, remains a bottleneck for clinical application. Herein, we investigated the molecular basis of the RNA-binding protein RSRC1 in regulating PARPi sensitivity and explored a potential therapeutic strategy for enhancing PARPi efficacy.

Materials and Methods:

The expression level of RSRC1 and its correlation with prognosis were evaluated by analyzing clinical HCC sample databases. In vitro cell proliferation and invasion assays, along with in vivo mouse xenograft tumor models, were employed to validate the biological functions of RSRC1. The interaction between RSRC1 and DNA repair proteins, as well as its recruitment to DNA damage sites, was investigated using techniques such as co-immunoprecipitation and laser microirradiation-induced DNA damage. The

E-POSTER ABSTRACTS

impact of RSRC1 on PARP inhibitor sensitivity was explored using gene knockdown and pharmacological inhibition methods.

Results:

Multi-omics analysis revealed that RSRC1 was significantly overexpressed in HCC tissues, and this high expression was closely associated with poor patient prognosis. Functional experiments confirmed that RSRC1 promoted hepatocellular carcinoma cell proliferation, invasion, and tumor growth. Mechanistic studies demonstrated that under DNA damage stress, RSRC1 was specifically recruited to DNA double-strand break sites, where it directly interacted with RPA2, a key homologous recombination repair protein. This interaction regulated the phosphorylation of RPA2, thereby promoting homologous recombination repair. Importantly, inhibition of RSRC1 expression significantly enhanced the sensitivity of HCC cells to PARP inhibitors. Combined intervention exhibited notable synergistic anti-tumor effects both in vitro and in vivo.

Conclusions:

RSRC1 played a crucial role in promoting HCC progression by activating the DNA repair response. Our findings reveal a novel therapeutic strategy of co-targeting RSRC1 and PARP Inhibitor as a potential treatment for HCC.

Keyword(s) : RSRC1; Hepatocellular Carcinoma; Combination Therapy; DNA Damage; Homologous Recombination

2238 - UNCOVERING THE ONCOGENIC ROLE OF PKMYT1 IN HEPATOCELLULAR CARCINOMA THROUGH INTEGRATED BIOINFORMATICS

Wei Hou¹

Qilu Medical University, Translational Medicine Research Center, School Of Clinical Medicine, Zibo-China¹

Background / Hypothesis:

PKMYT1 (Protein Kinase, Membrane Associated Tyrosine/Threonine 1), a member of the WEE family, plays a crucial role in regulating cell cycle transitions and has recently emerged as a promising therapeutic target in various cancers, including hepatocellular carcinoma (HCC). However, the precise mechanisms governing PKMYT1 expression in HCC remain largely unexplored. This study aims to elucidate the mechanisms of PKMYT1 expression in HCC through comprehensive bioinformatic analyses.

Materials and Methods:

PKMYT1 expression and its prognostic significance across various cancers were assessed using SangerBox. In HCC, we analyzed associations with prognosis, immune infiltration, and mutations utilizing UALCAN, BoxKaplan-Meier Plotter, GEPIA, Human Protein Atlas, TIMER 2.0, and SangerBox. Co-expressed genes were identified using STRING, and miRNA-gene interactions were explored through the DIANA-MicroT Webserver.

Results:

PKMYT1 expression was significantly elevated in a range of cancers, including GBM, LGG, UCEC, BRCA, LUAD, ESCA, STES, KIRP, KIPAN, COAD, PRAD, STAD, HNSC, KIRC, LUSC, LIHC, SKCM, BLCA, THCA, READ, OV, PAAD, UCS, LAML, PCPG, ACC, KICH, and CHOL. In HCC, high levels of PKMYT1 were correlated with poorer survival outcomes and associated with increased immune cell infiltration, particularly CD4 T cells, neutrophils, macrophages, and dendritic cells. Mechanistic analysis identified co-expressed genes, including CCNB1, CCNA2, CCNB2, CKS2, CDK1, PLK1, CDC25A, RPS6KA1, and STEAP3. Correlation analysis indicated that most of these genes exhibited positive correlations with PKMYT1, with the exception of STEAP3, which showed a negative correlation. Additionally, hsa-miR-608 was identified as a potential regulator of PKMYT1 expression.

Conclusions:

Our findings underscore the oncogenic role of PKMYT1 and its prognostic significance across various cancers. In HCC, elevated PKMYT1 expression influences progression, prognosis, and immune regulation, suggesting its potential as a diagnostic biomarker and therapeutic target.

Keyword(s) : PKMYT1; HCC

2239 - The ratio of GGT to PLT indices is a predictive factor for the progression of liver fibrosis in NA treated chronic hepatitis B patients with advanced fibrosis plus PEG IFN α 2a therapy

Xiucheng Pan¹, Guojun Li², Ling Li³, Huili Li³, Yiru Zhao³, Lisha Shi³, Mireyi Suwanbai³, Liying Ren³
The Affiliated Hospital Of Xuzhou Medical University, Infectious Disease, Xuzhou-China¹ The Third People's Hospital Of Shenzhen, Liver Disease, Shenzhen-China² Xuzhou Medical University, Infectious Disease, Xuzhou-China³

Background / Hypothesis:

E-POSTER ABSTRACTS

Combination therapy with pegylated interferon α -2a (PEG-IFN α -2a) and nucleoside analogue (NA) has been shown to improve liver histology in patients with chronic hepatitis B (CHB) and hepatic fibrosis. PEG-IFN α -2a effectiveness was assessed in NA-treated CHB patients with advanced fibrosis/compensated cirrhosis.

Materials and Methods:

This retrospective multicenter study included NA-treated CHB patients with advanced fibrosis/compensated cirrhosis. Patients received 48-week PEG-IFN α -2a plus 24-week follow-up. The primary endpoint was liver fibrosis status 24 weeks post-treatment.

Results:

A total of 102 patients were enrolled in the study, including 35 and 67 baseline HBeAg-positive and HBeAg-negative CHB patients, respectively. At the end of PEG-IFN α -2a treatment, a total of 18 (17.6%) patients achieved HBsAg loss, and 23 (65.7%) achieved HBeAg loss. Sixty-nine patients completed the comparison of liver fibrosis and cirrhosis before and after treatment, of whom 16 (23.2%) experienced progression of liver fibrosis or cirrhosis, 32 (46.4%) experienced liver fibrosis reversal, and 21 (30.4%) remained stable. Penalized logistic regression analysis demonstrated that GPR (Intercept = -1.200; Coefficients = 0.102) and GGT levels (Intercept = -1.198; Coefficients = 0.048) at 24 weeks of PEG-IFN α -2a treatment were independent predictors of fibrosis progression. Among these, GPR at 24 weeks exhibited the highest predictive value (Corrected AUC = 0.805).

Conclusions:

Approximately one-fifth of the NA-treated CHB patients with advanced liver fibrosis and compensated cirrhosis experienced progression of liver fibrosis after PEG-IFN α -2a treatment. The GPR at 24 weeks of treatment was an independent predictive factor for the progression of liver fibrosis in this population.

Keyword(s) : Chronic hepatitis B, advanced liver fibrosis, compensated cirrhosis, pegylated interferon α -2a.

2242 - Dynamic Survival Prediction and Treatment Adjustment System for Advanced Biliary Tract Cancer

Jie Liu¹, Jinhe Guo¹

Zhongda Hospital, Southeast University, Interventional

Radiology, Nanjing-China¹

Background / Hypothesis: First-line treatment for advanced biliary tract cancer (BTC) involves immunotherapy plus chemotherapy (immuno-chemotherapy). However, treatment response varies considerably among patients, requiring ongoing monitoring and treatment adaptations. We aimed to develop an AI system that would dynamically update survival predictions for patients with advanced BTC using evolving clinical data, enabling real-time prognostic stratification and treatment adjustment.

Materials and Methods: This study included patients with advanced BTC who were receiving immuno-chemotherapy across eight centres. Patients were divided into development, internal validation, and external validation cohorts (two retrospective, one prospective). We developed a Bayesian joint model, the Individualized Dynamic Risk Estimation Model for BTC (iDREM-BTC), that integrated baseline clinical and imaging data with serial measurements of C-reactive protein (CRP), carbohydrate antigen 19-9 (CA19-9), and total bilirubin (TBil). An enhanced model (iDREM(Pro)-BTC) also incorporated baseline immunohistochemistry and genetic data. Performance was evaluated via dynamic area under the curve (AUC) and calibration analyses versus baseline Cox models. The models' interpretability was evaluated through ablation study (ClinicalTrials.gov: NCT06849193).

Results: Data from 2314 patients were analysed (development cohort, n=841; internal validation cohort, n=360; external validation cohorts, n=1113). Machine learning methods identified age, ECOG performance status, tumour burden, tumour stage, CRP level, CA19-9 level, and TBil level as predictors of mortality. iDREM-BTC demonstrated robust performance in the development cohort (overall dynamic AUC 0.730 [95% CI 0.689–0.794]), with AUCs progressively improving from 0.688 to 0.798; internal validation cohort (0.718 [95% CI 0.670–0.778], AUCs improving from 0.668 to 0.778), external validation cohort 1 (0.755 [0.707–0.808], AUCs improving from 0.705 to 0.810), external validation cohort 2 (0.705 [0.639–0.773], AUCs improving from 0.633 to 0.779), and prospective external validation cohort (0.745 [0.691–0.802], AUCs improving from 0.690 to 0.804). iDREM(Pro)-BTC achieved better discrimination in the development

E-POSTER ABSTRACTS

cohort (AUC 0.807 [95% CI 0.781–0.839], AUCs improving from 0.780 to 0.839), and external validation confirmed these findings (0.718 [0.669–0.787], AUCs improving from 0.666 to 0.791). The model enables dynamic risk stratification, showing that high-risk patients receive little benefit from later-line immuno-chemotherapy. This suggests early discontinuation or a shift to palliative care.

Conclusions: iDREM-BTC and iDREM(Pro)-BTC offer dynamic, real-time prognostic prediction for patients with advanced BTC undergoing immuno-chemotherapy. The two models suit different clinical scenarios, providing individualized prognostic stratification and treatment adjustment.

Keyword(s) : biliary tract cancer, immuno-chemotherapy, dynamic prediction.

2243 - Qutan huoxue decoction alleviates MASH induced fibrosis by regulating LC3 mediated macrophage mitophagy

Hongliang Liu¹, Sihan Chen², Hongshan Li¹
Ningbo No.2 Hospital, Liver Disease Department Of Integrative Medicine, Ningbo-China¹ Ningbo No.2 Hospital, Department Of Hepatic Oncology, Ningbo-China²

Background / Hypothesis:

MASH has become a prevalent chronic liver disease that progresses to fibrosis in nearly 40% of patients, and considering the current lack of effective therapies, understanding disease mechanisms is crucial. Macrophage mitophagy plays a central role in the progression of MASH-induced liver fibrosis. Based on evidence that Qutan huoxue decoction (QTHX) alleviates MASH, this study investigates its underlying antifibrotic mechanisms.

Materials and Methods:

In this study, we investigated the therapeutic effects of QTHX using liver fibrosis induced by both HFD and CDAHFD diets, and BMDM mitophagy defect model in vitro. Network pharmacology, 4D-DIA proteomic, Single-cell transcriptomics were used to explore the mechanism underlying the effects of QTHX against MAS-induced liver fibrosis.

Results:

QTHX significantly ameliorated MASH-induced liver fibrosis in both HFD and CDAHFD models, as evidenced by improved serum biomarkers, attenuated histopathological injury, and reduced hepatic levels of

Hyp and α -SMA. Single-cell transcriptomics revealed that an association between QTHX and the modulation of the Subsequent in vivo and in vitro experiments confirmed that QTHX enhanced macrophage mitophagy, as evidenced by increased LC3B protein levels. This led to a reduction in cytosolic mtDNA, which in turn suppressed the cGAS–STING pathway and subsequently decreased the production of proinflammatory cytokines, including TNF- α and IL-1 β .
Conclusions:

This study demonstrated that QTHX alleviates MASH-induced fibrosis by promoting LC3-mediated mitophagy in macrophages, thereby inhibiting the cGAS–STING pathway.

Keyword(s) : MASH; Liver fibrosis; Qutan huoxue; Macrophage mitophagy; cGAS–STING.

2246 - Sulforaphane Inhibits N Nitrosodimethylamine induced Hepatocellular Carcinoma Stem Cell Properties via ZNF652 Sonic Hedgehog axis

Jinyi Wu¹, Dongxue Ren², Yejing Rong¹, Hongshan Li¹, Caiyun Zhong², Xiaoting Li²
Ningbo No.2 Hospital, Liver Disease Department Of Integrative Medicine, Ningbo-China¹ Nanjing Medical University, Department Of Nutrition And Food Safety, School Of Public Health, Nanjing-China²

Background / Hypothesis: N-Nitrosodimethylamine (NDMA) is a potent carcinogen implicated in hepatocellular carcinoma (HCC) pathogenesis and cancer stem cell (CSC) emergence. Zinc finger protein ZNF652 exhibits tumor-suppressive properties, while Sonic Hedgehog signaling promotes CSC characteristics. Sulforaphane (SFN), a natural compound, shows anticancer potential, but its regulatory role in NDMA-induced liver CSCs remains unclear.

Materials and Methods: Bioinformatics analyses evaluated ZNF652's prognostic significance and Sonic Hedgehog pathway correlation. In vitro experiments induced LO2 cell malignant transformation via chronic NDMA exposure, performed sphere formation assays, and validated ZNF652/GLI1 interactions through overexpression, downregulation, and dual-luciferase assays. In vivo subcutaneous xenograft models treated with SFN (12.5/25 mg/kg) demonstrated dose-dependent tumor suppression, reduced CD133/GLI1 expression, and restored ZNF652 levels.

E-POSTER ABSTRACTS

Results:Chronic NDMA exposure (1 µg/mL) transformed LO2 hepatocytes into malignant TLO2 cells with CSC traits, including elevated HCC, CSC and EMT markers. ZNF652 expression decreased in metastatic HCC tissues and NDMA-induced CSCs. Overexpressing ZNF652 reduced sphere formation, suppressed CSC markers (CD133, SOX2, OCT4, EPCAM), and inhibited Sonic Hedgehog pathway activity by directly targeting GLI1 via promoter binding. SFN treatment diminished CSC self-renewal, downregulated GLI1 expression, and reversed ZNF652 knockdown-induced CSC properties in vitro. In nude mouse xenografts, SFN dose-dependently reduced tumor volume/weight, lowered CD133/GLI1 levels, and restored ZNF652 expression compared to NDMA-exposed group.

Conclusions:SFN inhibits NDMA-induced liver cancer stemness via the ZNF652/Sonic Hedgehog axis, offering a novel therapeutic strategy for hepatocellular carcinoma.

Keyword(s) : N-nitrosodimethylamine, hepatocellular carcinoma, ZNF652, Sonic hedgehog pathway, sulforaphane, cancer stem cell

2247 - ASSESSMENT OF HEPATOCELLULAR CARCINOMA RISK USING COMBINED SERUM FERRITIN AFP AND PIVKA II BIOMARKERS

Delgermurun Batkhurel ¹, Tserendulam Dorjsuren ¹, Oyunselenge Baatarmunkh ¹, Erkhimtugs Zagdaa ¹, Batzaya Sodnomjamts. ¹, Erdenebayar Gonchig ², Enkhtuya Damba ², Amarsanaa Jazag ²
Happy Veritas Hospital, Mongolian National University Of Medical Science, Ulaanbaatar-Mongolia ¹ Happy Veritas Hospital, Happy Veritas Hospital, Ulaanbaatar-Mongolia ²

Background / Hypothesis:

Hepatocellular carcinoma (HCC) remains a leading cause of cancer-related mortality worldwide, largely due to late-stage diagnosis. Alpha-fetoprotein (AFP) is widely used for surveillance but lacks sufficient sensitivity when used alone. Protein induced by vitamin K absence or antagonist-II (PIVKA-II) provides improved diagnostic performance, particularly in AFP-negative cases. Serum ferritin, a marker of hepatic inflammation and iron overload, has been suggested

to be associated with increased HCC risk. We hypothesized that elevated ferritin levels are associated with concomitant increases in AFP and PIVKA-II, and that a combined biomarker approach may improve HCC risk stratification.

Materials and Methods:

A cross-sectional study was conducted including male and female participants. Subjects were stratified into normal and elevated ferritin groups. Serum ferritin, AFP, and PIVKA-II levels, along with age, were analyzed and expressed as mean ± standard deviation. HCC risk categories were defined using internationally accepted cutoff values: AFP >10 and >400 ng/mL; PIVKA-II 50–149 and ≥150 mAU/mL; ferritin >400 and >1000 ng/mL. Sex- and age-related differences in biomarker profiles were evaluated. A p-value <0.05 was considered statistically significant.

Results:

Elevated ferritin levels were associated with increased AFP and PIVKA-II levels, particularly among male participants. In males, ferritin increased 2.45-fold, accompanied by a 2.14-fold increase in AFP and a 3-fold increase in PIVKA-II. High HCC risk categories were observed in 72.8% of individuals with ferritin levels of 400–1000 ng/mL and in 22.8% with levels >1000 ng/mL. In female participants, ferritin elevation was more strongly associated with advancing age, while PIVKA-II levels largely remained within normal ranges. Combined elevation of biomarkers consistently corresponded to higher HCC risk categories.

Conclusions:

Ferritin is not a tumor-specific marker; however, when combined with AFP and PIVKA-II, it enhances hepatocellular carcinoma risk stratification. A multi-biomarker approach may improve early identification of high-risk individuals and strengthen surveillance strategies.

Keyword(s) : hepatocellular carcinoma, ferritin, alpha-fetoprotein, PIVKA-II, risk stratification, biomarkers

2248 - ERα FGF13 PROX1 cascade regulates fatty acid β oxidation to mediate sexual dimorphism in MAFLD

Xiang Huang ¹

Medical Experimental Department Of Ningbo No.2 Hospital, Ningbo No.2 Hospital, Ningbo City-China ¹

E-POSTER ABSTRACTS

Background / Hypothesis:

MAFLD exhibits marked sexual dimorphism in both prevalence and progression, with males generally experiencing more severe outcomes, including faster progression to metabolic dysfunction-associated steatohepatitis (MASH), liver fibrosis, and hepatocellular carcinoma (HCC). The protective role of estrogen in premenopausal females and the increased risk after menopause highlight the influence of sex hormones in MAFLD pathophysiology. Fibroblast growth factor 13 (FGF13), an X-linked non-secretory FGF homologous factor, has recently been implicated in energy metabolism and obesity, but its role in MAFLD and its underlying mechanisms remain unexplored.

Materials and Methods:

MAFLD was induced in wild-type and liver-specific Fgf13 knockout (cKO) mice by high-fat diet (HFD) feeding for 16 weeks. Liver tissues were collected for histological, biochemical, and molecular analyses. Human MAFLD gene expression datasets (GEO) were analyzed to identify sexually dimorphic genes. Co-immunoprecipitation coupled with mass spectrometry (Co-IP/MS) was used to identify FGF13-interacting proteins. Chromatin immunoprecipitation sequencing (ChIP-seq) data were analyzed to identify PROX1 target genes. Luciferase reporter assays and ER α agonist treatments were performed to validate transcriptional regulation.

Results:

1. MAFLD male mice exhibited more severe hepatic steatosis than females. Bioinformatic analysis of human MAFLD datasets identified FGF13 as a key sexually dimorphic gene.

2. Hepatic FGF13 expression was higher in females than in males under HFD conditions, and liver-specific deletion of Fgf13 exacerbated steatosis, injury, inflammation, and fibrosis in both sexes, abolishing the sex-based differences.

3. Co-IP/MS revealed PROX1 as a major FGF13-interacting protein. FGF13 stabilized PROX1 by inhibiting its ubiquitin-mediated degradation.

4. PROX1 ChIP-seq analysis identified binding to promoters of fatty acid β -oxidation genes (CPT-1A, ACSL3, PGC-1 α). HFD reduced PROX1 binding in both sexes, with greater retention in females; Fgf13 cKO eliminated this sexual difference and downregulated

β -oxidation gene expression.

5. ER α was predicted and validated as a transcriptional regulator of FGF13. Estrogen and ER α agonist treatments upregulated FGF13 expression in vitro and in vivo.

Conclusions:

Our findings demonstrate that ER α -driven FGF13 expression stabilizes PROX1, enhances fatty acid β -oxidation, and protects against hepatic lipid accumulation, thereby contributing to the sexual dimorphism in MAFLD. This newly identified ER α -FGF13-PROX1 regulatory axis provides a mechanistic basis for sex-specific differences in MAFLD progression and highlights potential targets for sex-stratified therapeutic strategies.

Keyword(s) : MAFLD, FGF13, PROX1, fatty acid β -oxidation, sexual dimorphism

2249 - Maternal High Fat Diet Induces Lifelong Epigenetic Priming and Trained Immunity Driving Offspring Susceptibility to MASLD

Hyun Phil Shin¹, Moonhyung Lee¹, Sanghui Park², Yong Joo Ahn³

Kyung Hee University Hospital At Gangdong, Internal Medicine, Seoul-South Korea¹ Ewha Womans University College Of Medicine, Pathology, Seoul-South Korea² Pohang University Of Science And Technology, Convergence It Engineering, Pohang-South Korea³

Background / Hypothesis: Maternal high-fat diet (HFD) is known to increase the risk of metabolic dysfunction in offspring, but the mechanisms driving susceptibility to MASLD remain unclear. Emerging evidence suggests that early-life epigenetic changes and innate immune training may contribute to this vulnerability. We hypothesized that maternal HFD induces epigenetic priming and a trained immunity-like phenotype in offspring Kupffer cells, predisposing them to heightened hepatic inflammation and MASLD progression, especially under secondary dietary challenges.

Materials and Methods: A maternal-offspring mouse model was established by feeding female C57BL/6J mice either an HFD or chow prior to and during pregnancy. Offspring were analyzed at baseline and after postweaning dietary challenges. Liver tissues were evaluated using histology (H&E, Oil Red O, Masson's

E-POSTER ABSTRACTS

trichrome), immunofluorescence (MARCO, IBA1, CD31, H3K14ac), and flow cytometry to assess macrophage phenotypes. Epigenetic profiling included ChIP assays for H3K14ac and H3K27ac and bisulfite sequencing for global DNA methylation. Cytokine levels and inflammatory gene expression were measured via qPCR, Western blotting, and ELISA.

Results: Offspring of HFD-fed dams exhibited markedly increased hepatic steatosis, enhanced M1-polarized macrophage infiltration, and elevated IL-6 and TNF- α levels, despite minimal changes in body weight. Kupffer cells showed strong periportal/pericentral clustering and increased expression of MARCO and IBA1. Epigenetic analyses revealed significant enrichment of H3K14ac and H3K27ac at promoters of inflammatory cytokine genes, along with global DNA hypomethylation in metabolic pathways, suggesting persistent transcriptional activation. Postweaning HFD exposure synergistically exacerbated lipid accumulation and inflammatory activation, consistent with a trained immunity-like phenotype amplifying responses to secondary metabolic stress.

Conclusions: Maternal HFD establishes durable epigenetic priming and trained immunity in offspring hepatic macrophages, increasing susceptibility to MASLD progression. These findings highlight maternal nutrition as a key determinant of intergenerational liver health and suggest that targeting epigenetic regulators or innate immune memory may offer new avenues for MASLD prevention and therapy.

Keyword(s) : maternal high-fat diet, trained immunity, epigenetic programming, Kupffer cells, MASLD, intergenerational metabolic disease

2250 - Piezo1 mediates matrix stiffness induced hepatic stellate cell activation by inhibiting mitophagy in liver fibrosis

Wenlong Miao ¹, Guanyue Su ¹, Xiaoli Ma ¹, Yongjian Zhou ¹, Zhigang Ren ¹

The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases, Zhengzhou-China ¹

Background / Hypothesis:

Liver fibrosis is characterized by excessive extracellular matrix deposition and increased tissue stiffness.

Hepatic stellate cells (HSCs) are the primary effector cells driving fibrosis, and their activation is mechanosensitive. The mechanosensitive ion channel Piezo1 senses matrix stiffness, but its role in HSCs during fibrosis is not fully understood. Mitophagy, the

selective autophagy of damaged mitochondria, is crucial for cellular homeostasis. We hypothesized that increased matrix stiffness promotes HSC activation through Piezo1-mediated impairment of mitophagy.

Materials and Methods:

A carbon tetrachloride (CCl₄)-induced liver fibrosis model was established in mice. Adjustable-stiffness 2D and 3D in vitro platforms (soft: 1 kPa, medium: 8 kPa, hard: 16 kPa) were constructed to mimic the mechanical microenvironment of normal and fibrotic livers. Piezo1 expression was assessed in vivo by Western blot and immunohistochemistry, and in vitro by Western blot, quantitative PCR, and immunofluorescence. By using specific antagonist GsMTx4 or siRNA-mediated knockdown of Piezo1, HSC activation markers (α -SMA and collagen I) were assessed by western blot, quantitative PCR, and immunofluorescence. Mitophagy activity was evaluated by monitoring mitochondrial morphology (MitoTracker), autophagic flux, and the colocalization of mitochondria with lysosomes. The involvement of the PINK1-Parkin pathway.

Results:

Piezo1 expression was significantly upregulated in fibrotic liver tissues and in LX2 cells cultured on stiff substrates. Stiff matrix promoted LX2 activation, concomitant with impaired mitophagy, evidenced by accumulated damaged mitochondria and decreased mitochondrial-lysosome colocalization. Pharmacological inhibition or genetic knockdown of Piezo1 attenuated stiffness-induced HSC activation and restored mitophagic flux in vitro. Furthermore, in vivo inhibition of Piezo1 alleviated CCl₄-induced liver fibrosis. Mechanistically, stiff matrix downregulated the PINK1-Parkin signaling pathway, a key mediator of mitophagy, and this suppression was reversed upon Piezo1 inhibition.

Conclusions:

Our findings demonstrate that increased matrix stiffness upregulates Piezo1 in HSCs, which in turn suppresses the PINK1-Parkin-mediated mitophagy, leading to HSC activation and exacerbation of liver fibrosis. Targeting the Piezo1-mitophagy axis may represent a novel therapeutic strategy for treating liver fibrosis.

Keyword(s) : Piezo1, liver fibrosis, matrix stiffness, mitophagy

2251 - Multisystem Involvement Of Salmonella Infection Liver Abscess With Secondary Pleural Effusion In Diabetes Mellitus

Mery Priyanti Pandiangan ¹, El Varel Baby Berlianza ¹,

E-POSTER ABSTRACTS

Ivan Banjuradja ²

Universitas Indonesia Hospital, Emergency Department, Depok-Indonesia ¹ Universitas Indonesia Hospital, Internal Medicine Department, Depok-Indonesia ²

Background / Hypothesis:

Salmonella liver abscess is an infrequent condition and its occurrence alongside pleural effusion is reported only on rare occasions. Individuals with diabetes mellitus have an elevated susceptibility to severe and unusual infections because of compromised immune defenses.

Materials and Methods:

This case report outlined a 48 years old male patient who developed a hepatic abscess and accompanying pleural effusion as complications of a Salmonella infection in the setting of diabetes mellitus. Clinical information was gathered from the patient's medical history, physical examination, laboratory evaluations, abscess culture, and imaging modalities such as CT scanning and chest X-ray. The therapeutic management and clinical progression were monitored and recorded throughout the hospital stay and follow-up period.

Results:

The patient arrived at the emergency room with complaints of abdominal discomfort and fever a week prior and respiratory manifestations during inpatient care. Laboratory evaluations indicated raised inflammatory markers (CRP: 227.9 mg/L, reference value 0.0-3.0 mg/L) along with elevated blood glucose levels (POCT random blood glucose: 189 mg/dL, reference value <140 mg/dL). Imaging revealed approximately 12.2 × 11 × 15 cm in size of hepatic abscess from MSCT Scan accompanied by a right-sided pleural effusion from chest X-ray. Microbiological analysis of the abscess identified Salmonella species. The patient was treated with targeted intravenous antibiotics and percutaneous drainage of the abscess, leading to progressive clinical improvement. The pleural effusion subsided with continued medical therapy and supportive management. By the time of discharge, the patient had shown marked recovery.

Conclusions:

This report underscores the multisystem manifestations of Salmonella infection in a diabetic patient, evidenced by a hepatic abscess accompanied by secondary pleural effusion. Identifying unusual organ involvement is crucial when managing systemic infections in individuals with diabetes. Prompt imaging,

microbiological confirmation, and timely treatment, including appropriate antibiotics and abscess drainage, are key to avoiding complications and achieving favorable clinical outcomes.

2253 - Discrepancies in Treatment Eligibility Across Different International Guidelines for Chronic Hepatitis B

Jian Wang ¹, Shaoqiu Zhang ¹, Li Zhu ², Tao Fan ³, Ye Xiong ³, Chao Jiang ⁴, Xiaomin Yan ¹, Huali Wang ⁵, Qun Zhang ⁶, Xingxiang Liu ⁷, Chuanwu Zhu ², Chao Wu ¹, Rui Huang ¹

Nanjing Drum Tower Hospital, Affiliated Hospital Of Medical School, Nanjing University, Department Of Infectious Diseases, Nanjing-China ¹ The Affiliated Infectious Diseases Hospital Of Soochow University, Department Of Infectious Diseases, Suzhou-China ² Nanjing Drum Tower Hospital Clinical College Of Nanjing University Of Chinese Medicine, Department Of Infectious Diseases, Nanjing-China ³ Nanjing Drum Tower Hospital Clinical College Of Jiangsu University, Department Of Infectious Diseases, Nanjing-China ⁴ Nanjing Second Hospital, Nanjing University Of Chinese Medicine, Department Of General Practice, Nanjing-China ⁵ Zhongda Hospital, School Of Medicine, Southeast University, Department Of Infectious Diseases, Nanjing-China ⁶ Huai'an No. 4 People's Hospital, Department Of Clinical Laboratory, Huai'an-China ⁷

Background / Hypothesis:

Simplifying treatment and expanding indications are key future directions for chronic hepatitis B (CHB) management. Recently released international guidelines (EASL 2025, AASLD/IDSA 2025, WHO 2024) for the management of CHB have updated treatment recommendations. However, inconsistencies remain, and their impact on real-world treatment eligibility warrants evaluation.

Materials and Methods:

This multicenter, retrospective, cross-sectional study analyzed data from a real-world cohort of 15,763 treatment-naïve CHB patients from five hospitals in China between 2015 and 2025.

Results:

E-POSTER ABSTRACTS

The proportions of patients eligible for antiviral therapy according to the AASLD/IDSA 2025, EASL 2025, and WHO 2024 guidelines were 32.2%, 37.3%, and 70.5%, respectively. The WHO 2024 guidelines identified substantially more patients as eligible for treatment, followed by the EASL 2025 and the AASLD/IDSA 2025 guidelines. Patients with HBeAg-positive had significantly higher treatment eligibility rates compared to HBeAg-negative patients across all guidelines (all $P < 0.001$). Notably, the treatment eligibility rate (92.5%) was substantially higher under the WHO 2024 guidelines than that under the EASL 2025 (74.6%, $P < 0.001$) and AASLD/IDSA 2025 (64.4%, $P < 0.001$) guidelines for HBeAg-positive patients. Similar findings were observed in HBeAg-negative patients. Additionally, treatment eligibility rates gradually increased with age, regardless of the guidelines applied. However, the WHO 2024 guidelines consistently yielded the highest eligibility rates across age categories, compared with the AASLD/IDSA 2025 and EASL 2025 guidelines.

Conclusions:

Substantial differences in CHB treatment eligibility were observed across updated international guidelines, with the highest eligibility proportion (70.5%) observed under the WHO 2024 guideline. Additional studies are warranted to explore optimal treatment criteria for CHB.

Keyword(s) : chronic hepatitis B, treatment eligibility, international guidelines, antiviral therapy

2257 - Construction and Validation of a 90 Day Prognostic Prediction Model for Patients with Acute on Chronic Liver Failure After Artificial Liver Support Therapy

Shuxian Zang¹, Chengjie Cui¹, Yali Zhang¹, Na Fu¹, Yuemin Nan¹

The Third Hospital Of Hebei Medical University, Department Of Traditional And Western Medical Hepatology, Shijiazhuang, Hebei-China¹

Background / Hypothesis:

Acute-on-chronic liver failure (ACLF) progresses rapidly and has a high short-term mortality rate. The artificial liver support system (ALSS) promotes hepatocyte regeneration by removing toxins and inflammatory mediators. This study aims to develop an early prediction model to identify ACLF patients with poor prognosis following ALSS, thereby supporting clinical decision-making.

Materials and Methods:

This study included 182 patients with confirmed ACLF who underwent at least two sessions of artificial liver therapy at the Third Hospital of Hebei Medical University from February 2021 to May 2025. Independent predictors were identified through univariate and forward stepwise multivariate logistic regression analyses, which were subsequently used to construct a prediction model. The area under the curve (AUC) were used to assess the model's accuracy. The calibration curve and decision curve analysis (DCA) were employed to assess the discriminability and clinical effectiveness, respectively. Statistical analyses were performed using Zstats software and R version 4.3.3.

Results:

The baseline characteristics of the included patients and the training cohort are presented in Table 1 and Table 2, respectively. Multivariate analysis identified the MELD score (OR = 1.175, 95% CI: 1.084–1.274) and the number of complications (OR = 1.656, 95% CI: 1.055–2.598) as independent prognostic factors. The model demonstrated good fit (Hosmer-Lemeshow test, $P > 0.05$) and showed no significant multicollinearity, with variance inflation factors (VIF) for all predictors below 5. The prediction model was derived as: $\text{logit (90 day outcome)} = -5.446 + 0.161 \times \text{MELD score} + 0.504 \times \text{Number of complications}$. The AUC were 0.754 for the MELD score, 0.674 for the number of complications, and 0.782 for their combination (Figure 2). The calibration curve confirmed good agreement between prediction and the ideal curve (Figure 3). DCA showed that the model provided a higher net benefit than the treat-all and treat-none strategies across a threshold probability range of 19.35% to 87.70%, supporting its clinical utility (Figure 4). A nomogram was developed to visually present the combined prediction model (Figure 5). In the validation cohort, the combined model demonstrated an AUC of 0.783 (95% CI: 0.658–0.907) (Figure 6). Both the calibration and decision curve analyses indicated good predictive performance and clinical utility (Figures 7, 8).

Conclusions:

This study developed and validated a prediction model for early identification of ACLF patients at risk of poor 90-day prognosis after artificial liver therapy,

E-POSTER ABSTRACTS

demonstrates superior predictive performance compared to MELD score, showing potential to aid clinical decision making.

Keyword(s) : Acute-on-chronic liver failure, Artificial liver therapy, prediction model, MELD score

2258 - DNA Methylation Profiles Predict MASLD Progression

春润 李¹

中医学院, 北京中医药大学, 北京-China¹

Epigenetic modifications represent a critical interface between environmental factors and disease pathogenesis in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD). We hypothesized that specific DNA methylation patterns in liver tissue and peripheral blood are associated with disease severity and can serve as predictive biomarkers for fibrosis progression.

We conducted an integrated translational study combining preclinical and clinical investigations. In a diet-induced murine MASLD model (n=40), we performed genome-wide DNA methylation sequencing (Whole Genome Bisulfite Sequencing) of liver tissues at different disease stages. In a prospective human cohort of 320 biopsy-proven MASLD patients, we validated findings using targeted bisulfite sequencing of candidate loci in both liver biopsies and paired peripheral blood mononuclear cells (PBMCs). Methylation profiles were correlated with histological features and clinical outcomes over 3-year follow-up. In the murine model, we identified 2,147 differentially methylated regions (DMRs) during disease progression, with hypermethylation in fibrosis-related genes showing the strongest association. In human samples, a 5-gene methylation signature (including PPARA, TGFB1, and COL1A1 regulatory regions) demonstrated high concordance between liver tissue and PBMCs. Patients with the "hypermethylated profile" had 3.2-fold increased risk of fibrosis progression (95% CI: 1.8-5.7, p<0.001) and showed more rapid decline in liver function. The methylation score outperformed conventional biomarkers (FIB-4, NFS) in predicting 3-year clinical outcomes (AUC: 0.89 vs 0.71-0.75).

Mechanistically, the identified DMRs were enriched in pathways regulating hepatic stellate cell activation and extracellular matrix organization.

This study establishes disease-specific DNA methylation signatures as novel, accessible biomarkers for MASLD progression. The high concordance between liver and blood methylation patterns enables non-invasive monitoring, addressing a critical need in

public health screening. These findings position epigenetic profiling as a powerful tool for risk stratification and early intervention, potentially transforming MASLD management through precision prevention strategies.

2259 - Managing Portal Hypertension Complications in Hepatic Arterioportal Fistula The Role of Transcatheter Arterial Embolization

Lijuan Chen¹, Hongbin Zhu¹, Chunqing Zhang¹, Guangchuan Wang¹

Shandong Provincial Hospital Affiliated To Shandong First Medical University, Department Of Gastroenterology And Hepatology, Jinan-China¹

Background / Hypothesis:

Hepatic arterioportal fistula (HAPF) is a potential cause of refractory symptomatic portal hypertension, frequently manifesting as variceal hemorrhage and intractable ascites. This article evaluates the short- and long-term clinical outcomes of transcatheter arterial embolization (TAE) for managing symptomatic portal hypertension caused by HAPF.

Materials and Methods:

We conducted a retrospective study of 9 consecutive patients with HAPF-related portal hypertension (manifesting as variceal bleeding/ascites) who underwent TAE at our institution (Jan 2016-Jun 2025). All patients, after the exclusion of hepatocellular carcinoma, were diagnosed by digital subtraction angiography (DSA). The fistulas were embolized using coils and cyanoacrylate glue. Baseline characteristics and follow-up data were analyzed to evaluate procedural efficacy and safety. The primary outcomes were technical success, procedure-related complications, clinical efficacy in controlling variceal bleeding or ascites, long-term rebleeding rate, and survival.

Results:

Technical success was achieved in all patients (9/9, 100%). Intraoperative DSA confirmed complete fistula occlusion in six patients (66.7%) during the initial procedure; the remaining three (33.3%) underwent successful planned repeat embolization. Immediate hemostasis was attained in all five patients (100%) presenting with active variceal bleeding. Refractory ascites significantly resolved or reduced to mild,

E-POSTER ABSTRACTS

controllable levels within four weeks in 83.3% (5/6) of cases. Minor post-embolization syndrome (transient fever or abdominal pain) occurred in four patients (4/9, 44.4%) and resolved with supportive care; no instances of ectopic embolism, hepatic infarction, or other major complications were observed. Liver function and coagulation parameters remained stable throughout follow-up, with significant post-procedural improvements in hemoglobin and albumin levels ($p < 0.05$). Over a median follow-up of 48 months (IQR: 22–50), endoscopic surveillance demonstrated variceal improvement in all five bleeding patients, and complete ascites resolution was radiologically confirmed in all six affected patients. Rebleeding occurred in one patient (20%) at 24 months. The overall survival rate was 100%.

Conclusions:

For portal hypertensive complications arising from HAPF, TAE offers a safe and feasible approach with marked efficacy. Its capability to occlude the fistula and promptly address critical complications like bleeding and ascites translates into meaningful clinical benefits, including improved quality of life and survival.

Keyword(s) : Transcatheter arterial embolization; Hepatic arterioportal fistula (HAPF); Portal hypertension.

2260 - Comparative Analysis of MAFLD in Diabetic vs. Non Diabetic Patients Metabolic and Fibrotic Profiles

Hafsa Abdul Waheed Jadgal¹, Muhammad Siddique Abdul Rehman Chohan²

Suleman Roshan Medical College Tando Adam, Mbbs, Tando Adam-Pakistan¹ Suleman Roshan Medical College, Mbbs, Tando Adam-Pakistan²

Background / Hypothesis:

Type 2 diabetes mellitus (T2DM) is a major metabolic comorbidity frequently associated with metabolic-associated fatty liver disease (MAFLD). The interplay between diabetes and MAFLD progression, particularly fibrosis severity and metabolic dysfunction, requires further investigation

Materials and Methods:

Aim

To compare metabolic parameters and liver fibrosis severity between diabetic and non-diabetic patients

diagnosed with MAFLD.

Method

This study included 150 MAFLD patients, comprising 75 with T2DM and 75 without diabetes, enrolled between January 2024 and March 2025. Diagnosis of MAFLD was based on ultrasound and metabolic criteria. Data collected included BMI, liver enzymes (ALT, AST), lipid profile, fasting glucose, HbA1c, and FibroScan liver stiffness measurements. Statistical analysis compared the two groups with significance set at $p < 0.05$.

Result:

Diabetic patients had higher BMI, ALT, triglycerides, fasting glucose, HbA1c, and liver stiffness than non-diabetic patients.

Non-diabetic patients showed milder metabolic disturbances and lower fibrosis scores.

AST difference was not statistically significant.

Conclusions:

Comparison of Diabetic vs Non-Diabetic MAFLD Patients

MAFLD patients with T2DM exhibit more severe metabolic derangements and greater liver fibrosis compared to non-diabetic counterparts. This underscores the importance of rigorous metabolic control and fibrosis monitoring in diabetic MAFLD patients to prevent progression and complications.

2261 - UNVEILING THE ONCOGENIC AND PROGNOSTIC ROLE OF KRT17 IN HEPATOCELLULAR CARCINOMA

Wei Hou¹

Qilu Medical University, Translational Medicine Research Center, School Of Clinical Medicine, Zibo-China¹

Background / Hypothesis:

KRT17 (Keratin 17) has been implicated in the development of hepatocellular carcinoma (HCC). However, the precise regulatory mechanisms governing HCC progression remain poorly understood. This study aims to conduct a comprehensive analysis of the role of KRT17 in HCC.

Materials and Methods:

Data for this study were sourced from multiple

E-POSTER ABSTRACTS

bioinformatics databases, including GEO (Gene Expression Omnibus), The Cancer Genome Atlas (TCGA), Genotype-Tissue Expression (GTEx), and the Clinical Proteomic Tumor Analysis Consortium (CPTAC). We utilized the R programming language and various online tools to analyze KRT17 expression across different cancer types, particularly in HCC. We also examined its associations with tumor molecular subtypes, immune subtypes, diagnosis, prognosis, clinical characteristics, methylation status, and the immune microenvironment. Mechanistic analyses were performed to identify co-expressed proteins and regulatory microRNAs (miRNAs).

Results:

Compared to normal samples, KRT17 expression was significantly elevated in various cancers, including LIHC. High levels of KRT17 were associated with poorer survival outcomes in HCC and correlated with increased infiltration of immune cells, particularly neutrophils, macrophages, and dendritic cells. Mechanistic analysis revealed co-expressed genes such as KRT5, KRT6A, KRT6B, KRT14, KRT16, KRT18, EGFR, CCHCR1, SFN, and TXNDC9. Similar Genes Detection analysis indicated that TMEM130 exhibited a similar expression pattern and a positive correlation with KRT17. Additionally, hsa-miR-5701 was identified as a potential regulator of KRT17 expression.

Conclusions:

The findings of this study offer important insights into the oncogenic role of KRT17 and its prognostic significance in HCC, highlighting its potential as both a diagnostic biomarker and a therapeutic target. These studies underscore the need for further molecular assays to elucidate the role of KRT17 in tumorigenesis and to establish a foundation for developing novel therapeutic strategies.

Keyword(s) : KRT17; HCC

2262 - Circadian Clock Disruption Drives MAFLD Through Bile Acid Dysregulation

春润 李¹, 云龙 姚¹

中医学院, 北京中医药大学, 北京-China¹

The hepatic circadian clock coordinates metabolic homeostasis, yet its disruption in modern 24/7 lifestyles remains an unquantified public health risk for Metabolic Dysfunction-Associated Fatty Liver Disease

(MAFLD). We hypothesized that genetic or environmental disruption of the core clock gene BMAL1 dysregulates the temporal orchestration of bile acid metabolism, creating a sustained lipotoxic and pro-inflammatory hepatic environment that accelerates MAFLD progression.

We utilized hepatocyte-specific BMAL1 knockout (*LS-Bmal1* KO) mice and wild-type (WT) mice subjected to chronic jet lag (CJL) to model genetic and environmental circadian disruption, respectively. Mice were fed a chow or high-fat diet (HFD) for 16 weeks. Hepatic transcriptomics, serum and hepatic bile acid profiles (by UPLC-MS/MS), and metabolic phenotyping were performed. Human relevance was tested in a cohort of 50 shift workers and 50 day workers matched for age and BMI, who underwent VCTE and serum metabolomic profiling.

Both *LS-Bmal1* KO and CJL-WT mice on HFD developed markedly exacerbated steatohepatitis and fibrosis compared to controls ($p < 0.01$). Transcriptomics revealed a loss of rhythmic expression in key bile acid synthesis (Cyp7a1, Cyp8b1) and transport (Bsep) genes in knockout mice. This led to a pathological accumulation of cytotoxic deoxycholic acid (DCA) and a reduction in protective ursodeoxycholic acid (UDCA) during the rest phase. Restoring bile acid rhythm via timed supplementation of a bile acid sequestrant in CJL mice significantly attenuated liver injury ($p < 0.05$). In humans, shift workers exhibited significantly higher liver stiffness ($p < 0.05$) and a similarly dysregulated, non-rhythmic serum bile acid profile enriched in DCA compared to day workers.

Our findings establish circadian disruption as a direct pathogenic driver of MAFLD, mediated through the loss of temporal control over bile acid metabolism. This links an emerging environmental risk factor (shift work/chronodisruption) to a concrete molecular mechanism. From a public health perspective, this advocates for the integration of circadian health measures into MAFLD prevention guidelines and suggests chrono-nutrition or timed pharmacological interventions as novel, mechanism-based strategies for at-risk populations.

2263 - Social Jetlag Disrupts Pituitary Hormone Rhythm to Drive MASLD

春润 李¹, 云龙 姚¹

中医学院, 北京中医药大学, 北京-China¹

Social jetlag (SJL), the misalignment between social and

E-POSTER ABSTRACTS

biological clocks, affects over 40% of the global population and is a growing public health concern. Beyond the well-known disruption of core clock genes, its impact on endocrine rhythms and subsequent metabolic disease remains unclear. We hypothesized that SJL specifically disrupts the circadian secretion of pituitary prolactin (PRL)—a hormone with emerging metabolic functions—thereby promoting the development of Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD).

We employed a multi-level approach. First, transcriptomic data from a human liver biopsy cohort were analyzed using the Zeitzeiger algorithm to assess SJL's impact on hepatic rhythmic pathways. Second, a PRL global knockout mouse model combined with a simulated SJL protocol (chronic 6-hour light cycle advances) was used to investigate causality. Serum PRL rhythms, liver clock gene expression (ROR α), and key lipogenic enzymes were measured. Finally, a therapeutic proof-of-concept was tested using a novel biomimetic photothermal microneedle system designed for circadian-timed PRL release.

In humans, SJL was associated with significant disruption in the hepatic circadian transcriptome, particularly in PRL receptor signaling and fatty acid metabolism pathways. In mice, SJL attenuated the binding of clock gene ROR α to the PRL promoter, leading to abolished serum PRL rhythm. This resulted in suppressed hepatic MAPK/CCND1 signaling, upregulation of lipogenic enzymes (FAS, ACC), and accelerated liver steatosis. PRL knockout mice confirmed the essential protective role of PRL. Crucially, restoring the PRL rhythm via timed supplementation or the circadian-release microneedle system significantly reduced hepatic lipid deposition, outperforming constant-dose treatment.

Our study identifies the disruption of pituitary-derived PRL rhythm as a novel and critical mechanistic link between the common lifestyle stressor SJL and MASLD pathogenesis. This moves the paradigm beyond hepatocyte-autonomous clock defects to a systemic endocrine axis. The development of a chrono-release therapeutic device underscores the translational potential. From a public health perspective, these findings argue for the assessment of circadian hormonal health in high-risk individuals and pave the way for "chrono-therapeutic" strategies against the escalating MASLD epidemic.

2264 - Impact of Updated International Guidelines on Treatment Eligibility for Chronic Hepatitis B

Jian Wang¹, Li Zhu², Shaoqiu Zhang¹, Tao Fan³, Juan Xia¹, Shengxia Yin¹, Yuxin Chen⁴, Huali Wang⁵, Qun Zhang⁶, Xingxiang Liu⁷, Chuanwu Zhu², Rui Huang¹, Chao Wu¹

Nanjing Drum Tower Hospital, Affiliated Hospital Of Medical School, Nanjing University, Department Of Infectious Diseases, Nanjing-China¹ The Affiliated Infectious Diseases Hospital Of Soochow University, Department Of Infectious Diseases, Nanjing-China² Nanjing Drum Tower Hospital Clinical College Of Nanjing University Of Chinese Medicine, Department Of Infectious Diseases, Nanjing-China³ Nanjing Drum Tower Hospital, Affiliated Hospital Of Medical School, Nanjing University, Department Of Laboratory Medicine, Nanjing-China⁴ Nanjing Second Hospital, Nanjing University Of Chinese Medicine, Department Of General Practice, Nanjing-China⁵ Zhongda Hospital, School Of Medicine, Southeast University, Department Of Infectious Diseases, Nanjing-China⁶ Huai'an No. 4 People's Hospital, Department Of Clinical Laboratory, Huai'an-China⁷

Background / Hypothesis:

Antiviral therapy substantially reduces the complications of chronic hepatitis B (CHB) and improve patient outcomes. The AASLD and EASL updated their guidelines for the management of CHB in 2025, with modified recommendations for antiviral treatment. This study evaluated the impact of updated international guidelines on CHB treatment eligibility by comparing eligibility under the updated guidelines with their respective previous versions.

Materials and Methods:

This study retrospectively included 14,269 treatment-naïve CHB patients from five hospitals in China between 2017 and 2025. The proportion of patients eligible for antiviral therapy was assessed and compared according to the AASLD 2025 and EASL 2025 guidelines, alongside their prior versions (AASLD 2018 and EASL 2017).

Results:

Expanded eligibility for antiviral treatment compared with their respective previous versions (AASLD 2025 vs. AASLD 2018: 31.8% vs. 26.9%, $P < 0.001$; EASL 2025 vs. EASL 2017: 36.7% vs. 31.1%, $P < 0.001$) was observed. The EASL 2025 treatment criteria resulted in a slightly

E-POSTER ABSTRACTS

higher overall treatment eligibility rate compared to AASLD 2025 ($P < 0.001$). This trend was consistent across subgroups stratified by sex and age, as well as among patients with HBeAg negativity. Among HBeAg-positive patients, the treatment eligibility rate based on the updated AASLD 2025 guidelines remained higher than that based on AASLD 2018 (64.7% vs 58.3%; $P < 0.001$), whereas the rates were comparable between the EASL 2025 and EASL 2017 guidelines (74.1% vs 73.4%; $P = 0.529$).

Conclusions:

The updated AASLD and EASL guidelines expanded CHB treatment eligibility, resulting in approximately a 5% increase in the proportion of patients eligible for antiviral therapy under both guidelines. More studies are needed to evaluate real-world treatment uptake despite expanded CHB treatment eligibility under current guidelines.

Keyword(s) : chronic hepatitis B, treatment eligibility, antiviral therapy, clinical practice guidelines

2265 - Construction and Validation of a 90 Day Prognostic Prediction Model for Patients with Acute on Chronic Liver Failure After Artificial Liver Support Therapy

Shuxian Zang ¹, Chengjie Cui ¹, Yali Zhang ¹, Na Fu ¹, Yuemin Nan ¹

The Third Hospital Of Hebei Medical University, Department Of Traditional And Western Medical Hepatology, Shijiazhuang, Hebei-China ¹

Background / Hypothesis:

Acute-on-chronic liver failure (ACLF) progresses rapidly and has a high short-term mortality rate. The artificial liver support system (ALSS) promotes hepatocyte regeneration by removing toxins and inflammatory mediators. This study aims to develop an early prediction model to identify ACLF patients with poor prognosis following ALSS, thereby supporting clinical decision-making.

Materials and Methods:

This study included 182 patients with confirmed ACLF who underwent at least two sessions of artificial liver therapy at the Third Hospital of Hebei Medical University from February 2021 to May 2025. Independent predictors were identified through univariate and forward stepwise multivariate logistic regression analyses, which were subsequently used to

construct a prediction model. The area under the curve (AUC) were used to assess the model's accuracy. The calibration curve and decision curve analysis (DCA) were employed to assess the discriminability and clinical effectiveness, respectively. Statistical analyses were performed using Zstats software and R version 4.3.3.

Results:

The baseline characteristics of the included patients and the training cohort are presented in Table 1 and Table 2, respectively. Multivariate analysis identified the MELD score (OR = 1.175, 95% CI: 1.084–1.274) and the number of complications (OR = 1.656, 95% CI: 1.055–2.598) as independent prognostic factors. The model demonstrated good fit (Hosmer-Lemeshow test, $P > 0.05$) and showed no significant multicollinearity, with variance inflation factors (VIF) for all predictors below 5. The prediction model was derived as: $\text{logit (90 day outcome)} = -5.446 + 0.161 \times \text{MELD score} + 0.504 \times \text{Number of complications}$. The AUC were 0.754 for the MELD score, 0.674 for the number of complications, and 0.782 for their combination (Figure 2). The calibration curve confirmed good agreement between prediction and the ideal curve (Figure 3). DCA showed that the model provided a higher net benefit than the treat-all and treat-none strategies across a threshold probability range of 19.35% to 87.70%, supporting its clinical utility (Figure 4). A nomogram was developed to visually present the combined prediction model (Figure 5). In the validation cohort, the combined model demonstrated an AUC of 0.783 (95% CI: 0.658–0.907) (Figure 6). Both the calibration and decision curve analyses indicated good predictive performance and clinical utility (Figures 7, 8).

Conclusions:

This study developed and validated a prediction model for early identification of ACLF patients at risk of poor 90-day prognosis after artificial liver therapy, demonstrates superior predictive performance compared to MELD score, showing potential to aid clinical decision making.

Keyword(s) : Acute-on-chronic liver failure, Artificial liver therapy, prediction model, MELD score

2266 - Yang Deficiency Constitution and Altered Bile Acid Metabolism in MAFLD

春润李 ¹, 云龙姚 ¹

中医学院, 北京中医药大学, 北京-China ¹

E-POSTER ABSTRACTS

Background / Hypothesis:

While the Phlegm-Dampness constitution is widely recognized as a risk factor for Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD), the metabolic impact of the Yang-Deficiency constitution remains understudied. Individuals with Yang-Deficiency often exhibit cold intolerance and fatigue, traits suggestive of systemic energy metabolism dysregulation. We hypothesized that the Yang-Deficiency constitution is associated with a distinct alteration in host bile acid metabolism, which disrupts hepatic lipid homeostasis and contributes to MAFLD development, offering a novel metabolic explanation for this TCM constitutional type.

Materials and Methods:

We conducted a cross-sectional study involving 180 participants classified into Yang-Deficiency (n=90) and Balanced (Gentle, n=90) constitution groups using the standardized Constitution in Chinese Medicine Questionnaire. All participants underwent abdominal ultrasonography for MAFLD diagnosis and Liver Stiffness Measurement (LSM) via VCTE. Serum levels of primary (cholic acid, CA; chenodeoxycholic acid, CDCA) and secondary bile acids (deoxycholic acid, DCA; lithocholic acid, LCA) were quantified using UPLC-MS/MS. Hepatic gene expression of key bile acid synthesis enzymes (CYP7A1, CYP8B1) and receptors (FXR, TGR5) was analyzed in a subset of 40 patients who underwent liver biopsy for clinical indications.

Results:

The prevalence of moderate-to-severe MAFLD (LSM ≥ 8.0 kPa) was significantly higher in the Yang-Deficiency group (38.9% vs. 16.7%, $p < 0.01$). Serum metabolomic profiling revealed a distinctive signature: Yang-Deficiency individuals exhibited significantly elevated levels of total and secondary bile acids (especially DCA), alongside a reduced CA/CDCA ratio compared to the Balanced group ($p < 0.001$). This profile correlated with increased hepatic steatosis and fibrosis scores ($r = 0.52$ and $r = 0.47$, respectively). Liver tissue analysis confirmed the molecular basis, showing downregulated CYP8B1 expression and a resultant shift in bile acid composition. Furthermore, Yang-Deficiency subjects with this specific bile acid profile had a 3.5-fold increased risk of MAFLD progression over a 2-year follow-up period (OR=3.5, 95% CI: 1.8-6.8).

Conclusions:

This study is the first to link the TCM Yang-Deficiency constitution with a specific, clinically significant dysregulation of bile acid metabolism that drives MAFLD pathogenesis. It moves beyond descriptive association to reveal a tangible metabolic

mechanism—impaired bile acid synthesis and an altered bile acid pool. From a public health and precision medicine perspective, serum bile acid profiling could serve as a novel biomarker for identifying high-risk Yang-Deficiency individuals, enabling early, constitution-targeted dietary or pharmacological interventions (e.g., bile acid sequestrants or FXR agonists) to prevent liver disease progression.

Keyword(s) : Yang-Deficiency Constitution, Bile Acid Metabolism, MAFLD, Precision Medicine, TCM Biomarker, Metabolic Dysregulation

2267 - Qi Stagnation Constitution Predisposes to Hepatic Microcirculatory Dysfunction in MAFLD

春润 李¹, 云龙 姚¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The Qi-Stagnation constitution, characterized by emotional constraint and inhibited Qi dynamics, is traditionally linked to systemic “stagnation” pathologies. We hypothesized that this constitution manifests at the hepatic microvascular level, predisposing individuals to early microcirculatory dysfunction—a critical yet overlooked precursor to inflammation and fibrosis in Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD).

Materials and Methods:

A prospective cohort of 300 treatment-naïve MAFLD patients was rigorously phenotyped using the Constitution in Chinese Medicine Questionnaire (CCMQ). Participants underwent paired assessments: (1) Hepatic Venous Pressure Gradient (HVPG) measurement for indirect portal pressure, and (2) Contrast-Enhanced Ultrasonography (CEUS) with time-intensity curve analysis for direct, real-time quantification of liver perfusion parameters (peak intensity, time-to-peak, mean transit time). Serum metabolomics and autonomic nervous system tone (via heart rate variability) were analyzed. A 12-week mind-body intervention trial (guided music therapy + diaphragmatic breathing) was conducted in a Qi-Stagnation subgroup (n=40) to assess microcirculatory reversibility.

Results:

Patients with Qi-Stagnation constitution (n=102) exhibited a distinct “functional ischemia” profile despite similar steatosis grades. Compared to Balanced-constitution controls, they had significantly prolonged hepatic mean transit time (+38%, $p < 0.001$) and reduced peak intensity (-25%, $p < 0.01$) on CEUS,

E-POSTER ABSTRACTS

indicating impaired microvascular perfusion. Importantly, 85% of Qi-Stagnation patients with abnormal perfusion had normal HVPG (<5 mmHg), confirming isolated microcirculatory impairment preceding macrovascular portal hypertension. Metabolomics revealed elevated kynurenine pathway metabolites, linking emotional stress physiology to local vascular tone dysregulation. The mind-body intervention significantly improved both subjective stress scores and objective CEUS perfusion parameters ($p < 0.05$), demonstrating functional reversibility.

Conclusions:

This study is the first to mechanistically link the TCM Qi-Stagnation constitution to objective, quantifiable hepatic microcirculatory dysfunction in MAFLD. It identifies a novel, "pre-fibrotic" high-risk phenotype where emotional stress and autonomic imbalance may directly compromise liver perfusion. Crucially, we demonstrate this dysfunction is detectable before conventional signs of portal hypertension and is modifiable through non-pharmacological intervention. This bridges TCM theory with vascular pathophysiology, positioning Qi-Stagnation as a key target for early public health strategies focused on stress management and microvascular health to prevent MAFLD progression.

Keyword(s) : Qi-Stagnation Constitution, Hepatic Microcirculation, MAFLD, Contrast-Enhanced Ultrasonography, Mind-Body Intervention, Preventive Medicine

2269 - Hepatoduodenal fistula as a complication of Hepatobiliary tuberculosis A case report

Odessa Pekas¹, Alexander Uy¹

Metropolitan Medical Center, Gastroenterology, Manila-Philippines¹

Background / Hypothesis:

Tuberculosis has a high prevalence in developing countries like the Philippines. Gastrointestinal tuberculosis is the third most common form of extrapulmonary tuberculosis, of which hepatobiliary tuberculosis (HBTB) is the most common, according to a local study. HBTB presents with nonspecific symptoms. A significant minority of cases that affect the bile duct present with jaundice, usually due to hilar obstruction resembling cholangiocarcinoma. Complications such as hepatoduodenal fistula and duodenal mass are very rare occurrences and have very limited data. Our objective for this report is to add this case to the very limited existing literature of hepatobiliary tuberculosis presenting with a hilar mass

extending to duodenum with fistulizing complication (hepatoduodenal fistula), and to describe the successful response to combined treatment that includes establishing good biliary drainage through stent placement on the fistula and compliance with antitubercular therapy.

Materials and Methods:

We present a case of a 46-year-old female who presented with symptoms of cholangitis. CT imaging revealed dilated hepatic ducts with suspicious narrowing of common hepatic duct. Endoscopic retrograde cholangiopancreatography (ERCP) showed a proximal duodenal mass. Cannulation of the native papilla was unsuccessful. Further evaluation of the mass through gastroscopy showed a friable semicircumferential mass in the proximal duodenum along with presumed fistula that intermittently egresses bile. Biopsies were taken for histopathology. Further evaluation through MRCP revealed hilar mass and hepatic nodules, considering central cholangiocarcinoma.

Results:

Biopsy of the duodenal mass revealed chronic granulomatous process; hence, Antikoch's treatment was initiated. After noncompliance with anti-tubercular medications due to adverse effects, the cholangitic symptoms recurred after several months. On ERCP, the native papilla was again identified with no egress of bile. Successful cannulation of the fistulous opening showed its connection to the intrahepatic ducts on cholangiogram. Good biliary drainage was established following successful stent placement through this fistulous opening. A month later, she came again due to jaundice and abdominal pain due to distally migrated stent. A repeat ERCP was done, and ductal clearance yielded stones and sludge. A double pigtail stent was successfully placed. The re-initiation of anti-Koch's led to the resolution of hilar and liver lesions on subsequent follow-up MRCP.

Conclusions:

This case emphasizes the significance of including tuberculosis as differential diagnosis for biliary obstructive diseases and hilar lesions. The development of fistula, though a complication, can help in establishing biliary drainage. However, assessment for adequacy of bile drainage through ductal clearance and stent placement is essential for effective and safer anti-tubercular treatment.

2270 - TweakR promotes hepatic fibrosis via NF- κ B signaling in metabolic dysfunction associated fatty liver disease and intervention by obacunone

Yuanye Ji¹, Sijia Zhang¹, Ping Tuo¹, Yingjun Ning¹, Hongshan Li²

Ningbo No.2 Hospital, Medical Experimental Department, Ningbo-China¹ Ningbo No.2 Hospital, Liver Disease Department Of Integrative Medicine, Ningbo-China²

Background / Hypothesis: Metabolic dysfunction-associated fatty liver disease (MAFLD) is a prevalent chronic liver condition where fibrosis represents a critical pathological stage. Current anti-fibrotic therapies have limited efficacy, highlighting the need for novel drug development. TWEAK signaling is implicated in MAFLD-related fibrosis, yet its precise mechanism is unclear. Based on our preliminary findings, we hypothesized that TweakR promotes MAFLD-associated liver fibrosis by activating hepatocyte NF- κ B, and that obacunone—a key active component of FZHY—binds TweakR with high affinity to block TWEAK pathway, thereby inhibiting NF- κ B signaling and reversing fibrosis.

Materials and Methods: Public database analysis revealed progressive upregulation of hepatic TweakR expression with advancing MAFLD-related fibrosis. Single-cell RNA sequencing of MAFLD patient livers showed TweakR specifically highly expressed in hepatocytes, where NF- κ B signaling pathways were notably activated. Multi-omics data from high-fat diet-induced MAFLD fibrotic mice demonstrated elevated NF- κ B signaling pathway activity at transcriptional, protein, and phosphoprotein levels. TweakR knockout in hepatocyte models significantly reduced expression of the NF- κ B signaling driver p52. Using TweakR-targeted molecular fishing, we identified obacunone from FZHY formula as a high-affinity ligand binding TweakR, confirmed by high-resolution mass spectrometry, molecular docking, and dynamics simulations.

Results: TweakR expression was specifically elevated in hepatocytes and increased with MAFLD fibrosis progression, closely associated with NF- κ B activation. In MAFLD fibrotic mice, NF- κ B pathways were broadly

activated across multi-omics levels, while TweakR knockout downregulated p52. FZHY demonstrated significant anti-fibrotic effects in vivo, reducing TweakR and NF- κ B pathway markers expression. Molecular fishing confirmed obacunone as the primary TweakR-binding ligand in the formula, with docking and dynamics simulations verifying strong binding stability.

Conclusions: TweakR promotes MAFLD-related liver fibrosis by driving NF- κ B signaling pathway. Obacunone, a key constituent of FZHY formula, binds TweakR with high affinity and blocks TWEAK signaling, thereby suppressing NF- κ B and offering a potential therapeutic strategy for MAFLD fibrosis.

Keyword(s) : MAFLD, liver fibrosis, TweakR, obacunone, FZHY

2271 - Machine Learning Predicts MASLD Fibrosis Risk via TCM Constitution Clusters

春润 李¹, 云龙 姚¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The combined predictive value of Traditional Chinese Medicine (TCM) constitutions for Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) progression is unknown. We hypothesized that patients form natural "TCM Constitution Clusters," and that these clusters enhance machine learning models for predicting liver fibrosis risk.

Materials and Methods:

In a multi-center cohort of 1,500 MASLD patients, TCM constitution was assessed using a validated scale. Liver fibrosis was evaluated via VCTE at baseline and 24 months. Unsupervised learning (k-means) identified natural TCM clusters. A Gradient Boosting Machine model predicting 24-month fibrosis progression was trained using these clusters and clinical features (e.g., BMI, ALT), and tested against a clinical-only model.

Results:

Four TCM clusters were identified. The "Complex Dampness-Heat & Blood Stasis" cluster had the highest baseline fibrosis prevalence (32.1%) and progression rate (18.7%). The integrated (TCM + clinical) model significantly outperformed the clinical-only model, with an AUC of 0.89 vs. 0.78 ($P < 0.01$) for predicting progression. It successfully re-stratified 28% of patients deemed "indeterminate risk" by conventional scores.

Conclusions:

E-POSTER ABSTRACTS

TCM constitution clusters provide unique information that significantly improves machine learning-based prediction of MASLD fibrosis progression. This approach enables precise, early identification of high-risk patients for tailored interventions.

Keyword(s) : TCM Constitution, Machine Learning, MASLD, Risk Prediction, Precision Medicine, Fibrosis Progression

2272 - Interventional Embolization of Spontaneous Portosystemic Shunts Improves Survival in Decompensated Cirrhosis A Retrospective Matched Analysis

Hongbin Zhu¹, Lijuan Chen¹, Guangchuan Wang¹, Chunqing Zhang¹

Shandong Provincial Hospital Affiliated To Shandong First Medical University, Department Of Gastroenterology, Jinan-China¹

Background / Hypothesis:

Traditionally viewed as compensatory, spontaneous portosystemic shunts (SPSS) may conversely induce a "portal steal phenomenon," sustaining hepatic hypoperfusion and accelerating liver failure. While embolization (PSSE) is established for refractory hepatic encephalopathy (HE), its potential to restore hepatopetal flow and improve survival in decompensated cirrhosis remains unclear. This propensity score-matched (PSM) study evaluated the impact of PSSE on long-term outcomes.

Materials and Methods:

We retrospectively analyzed patients with decompensated cirrhosis and SPSS (2016–2023). A 1:1 PSM model based on age, sex, and Child-Turcotte-Pugh (CTP) score generated a cohort of 70 patients (35 embolization, 35 standard therapy). Primary endpoints were 24-month overall survival and further decompensation events. Inverse probability of censoring weighting (IPCW) was used to analyze longitudinal trajectories of liver volume, portal vein diameter, and functional reserve.

Results:

Embolization significantly reduced 24-month all-cause mortality compared to controls (11.4% vs. 34.3%, $P=0.023$) and decreased further decompensation events ($P=0.014$). IPCW-adjusted analysis showed the embolization group achieved significant hepatic remodeling, with mean liver volume increasing by 148.67 cm^3 ($P<0.001$) and portal vein diameter widening. Functionally, albumin levels rose and CTP

scores decreased. Conversely, controls exhibited progressive liver volume reduction ($P=0.042$) and INR worsening ($P=0.002$). Subgroup analysis revealed survival benefits were concentrated in patients with CTP <10 ($P=0.004$) and those presenting with HE ($P=0.035$). No survival benefit was observed in patients with CTP ≥ 10 or those presenting with variceal bleeding.

Conclusions:

For decompensated cirrhosis patients with preserved reserve (CTP <10), embolization serves as a disease-modifying strategy rather than merely symptom control. By occluding "portal steal" and restoring hepatopetal flow, it induces hepatic remodeling and functional recovery, translating into long-term survival benefits. Management strategies should balance portal pressure reduction with the maintenance of effective hepatic perfusion.

Keyword(s) : Spontaneous Portosystemic Shunt; Decompensated Cirrhosis; Portosystemic Shunt Embolization

2273 - Yin Deficiency Constitution Predisposes to HCC via Gut Immune Dysregulation

春润 李¹, 云龙 姚¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The Yin-Deficiency (YD) constitution in Traditional Chinese Medicine is characterized by a "hyperactive" metabolic state. We hypothesize that YD creates a permissive gut-liver-immune microenvironment in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD), impairing immunosurveillance and elevating the risk of hepatocellular carcinoma (HCC).

Materials and Methods:

We conducted a nested case-control study within a prospective MASLD cohort ($n=3,200$). YD was determined using the validated CCMQ. A YD-subgroup and matched controls provided stool and blood for metagenomic sequencing and immunophenotyping. Mice with YD traits (induced by chronic heat-stress diet) were used to model HCC susceptibility and investigate gut barrier integrity, bacterial translocation, and hepatic immune landscape via scRNA-seq.

Results:

In the human cohort, YD constitution was an independent risk factor for HCC development over 5 years (HR=2.95, 95% CI: 1.88-4.62). YD individuals

E-POSTER ABSTRACTS

exhibited a distinct gut microbiome with reduced butyrate producers and enriched LPS-bearing pathobionts. This correlated with increased serum intestinal fatty-acid binding protein (I-FABP, gut leakage marker), elevated systemic LPS, and a functionally exhausted peripheral and intrahepatic CD8⁺ T cell profile. In the murine model, YD mice showed accelerated hepatocarcinogenesis. scRNA-seq revealed a depleted resident Kupffer cell population and an expansion of immunosuppressive macrophages in pre-neoplastic livers, a shift traced to increased translocation of gut-derived metabolites.

Conclusions:

This study mechanistically links the TCM YD constitution to HCC risk through a gut-derived "leakage-immunosuppression" axis. It identifies YD as a novel, biologically defined high-risk phenotype for liver cancer. From a public health perspective, screening for YD constitution and its associated gut-immune signature could enable ultra-early, targeted surveillance and preventive interventions (e.g., microbiome modulation) in the MASLD population.

Keyword(s) : Yin-Deficiency Constitution, Hepatocellular Carcinoma, Gut-Liver Axis, Immunosurveillance, MASLD, Precision Prevention

2275 - Dampness Heat Constitution Impairs Adipose Browning in MASLD

春润 李¹, 云龙 姚¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The Dampness-Heat (DH) constitution is prevalent in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) populations. Beyond its metabolic associations, we hypothesize that DH constitution is characterized by intrinsic dysfunction in adipose tissue, specifically an impaired ability of subcutaneous white adipose tissue (scWAT) to undergo "browning" (beiging). This failure in adaptive thermogenesis exacerbates hepatic lipotoxicity and inflammation.

Materials and Methods:

A cohort of 120 patients with biopsy-proven MASLD was assessed for DH constitution using the CCMQ and a quantified tongue coating index. Abdominal subcutaneous adipose tissue biopsies were obtained. Gene and protein expression of browning markers (UCP1, PRDM16, CIDEA) and mitochondrial content in scWAT were analyzed. Systemic inflammatory markers and hepatic transcriptomic profiles were correlated with browning capacity. A diet-induced obese mouse

model receiving a high-fat, high-sugar diet mimicking "DH" etiological factors was used to validate the causal role of impaired browning in liver injury.

Results:

Patients with DH constitution exhibited a significant reduction in scWAT browning capacity, with 60% lower UCP1 protein expression compared to Balanced constitution controls ($p < 0.001$). This "browning deficiency" strongly correlated with increased hepatic saturated diacylglycerol content ($r = -0.68$), higher NAFLD Activity Score ($r = -0.61$), and elevated plasma IL-6 levels ($r = -0.55$). Hepatic transcriptomics revealed upregulation of pathways involved in saturated fatty acid metabolism and chemokine signaling in the DH group. In the mouse model, animals on the DH-mimicking diet developed pronounced impairment in scWAT browning prior to severe steatohepatitis. Pharmacological induction of browning in these mice attenuated liver triglyceride accumulation and lobular inflammation.

Conclusions:

This study identifies impaired adipose tissue browning as a novel, functional metabolic defect underlying the Dampness-Heat constitution in MASLD. It provides a mechanistic link between this TCM phenotype and a worse hepatic phenotype through the lens of inter-organ energy metabolism. Targeting adipose tissue plasticity and browning represents a promising, constitution-specific therapeutic strategy for a significant subset of MASLD patients.

Keyword(s) : Dampness-Heat Constitution, Adipose Tissue Browning, MASLD, Thermogenesis, Inter-organ Crosstalk, Precision Therapy

2277 - Balanced Constitution Maintains HPA Axis and Hepatic Gluconeogenesis

春润 李¹, 云龙 姚¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The Balanced (Gentle) constitution in Traditional Chinese Medicine represents an optimal state of health and resilience. We hypothesize that this constitution is underpinned by a robust and stable Hypothalamic-Pituitary-Adrenal (HPA) axis. This neuroendocrine stability confers metabolic protection in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) by maintaining precise hepatic gluconeogenic flux, preventing both excessive fasting glucose production and lipid overaccumulation.

Materials and Methods:

A multi-center cohort of 400 MASLD patients was

E-POSTER ABSTRACTS

prospectively followed. Participants were classified into Balanced (n=200) or Non-Balanced (n=200, a composite of various unbalanced constitutions) groups using the CCMQ. Diurnal salivary cortisol profiles (4 samples/day) were measured to assess HPA axis rhythm. All participants underwent a 16-hour fasting metabolic assessment with stable isotope tracers ([6,6-²H₂]glucose) to quantify hepatic gluconeogenesis. Liver biopsies were analyzed for expression of gluconeogenic enzymes (PEPCK, G6Pase) and markers of endoplasmic reticulum (ER) stress.

Results:

Individuals with a Balanced constitution exhibited a significantly more robust diurnal cortisol rhythm, characterized by a steeper morning decline and lower evening levels ($p < 0.01$), indicating superior HPA axis regulation. During fasting, the Balanced group demonstrated a 22% more efficient hepatic gluconeogenic rate, meeting systemic glucose demand without overproduction ($p < 0.05$). This "metabolic precision" correlated with lower intrahepatic triglyceride content and reduced expression of ER stress markers (GRP78, CHOP) compared to the Non-Balanced group. In the Non-Balanced group, a blunted cortisol rhythm predicted both excessive gluconeogenesis and more severe hepatic steatosis ($r = 0.58$, $p < 0.001$).

Conclusions:

This study provides the first evidence linking the TCM Balanced constitution to superior neuroendocrine regulation, specifically a resilient HPA axis. This stability translates to precise control of a key hepatic metabolic pathway—gluconeogenesis—offering a novel mechanism for its documented protective role against metabolic disease progression. It shifts the paradigm from studying "risk constitutions" to defining the "protective physiology" of health. This insight paves the way for interventions aimed at restoring HPA axis rhythm and metabolic precision as a therapeutic strategy for MASLD patients with unbalanced constitutions.

2278 - Spatiotemporal Transcriptomics Decodes Constitution Specific Liver Zonation

春润 李¹, 云龙 姚¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

Traditional Chinese Medicine (TCM) constitution theory

posits that individuals have inherent, whole-body physiological predispositions. We hypothesize that these constitutional types are not merely clinical phenotypes but are fundamentally encoded in the spatial architecture and temporal dynamics of the liver itself. Specifically, we propose that different TCM constitutions exhibit unique, spatially resolved transcriptional programs across liver lobules, and that this "constitutional zonation" dictates heterogeneous responses to metabolic stress and progression of Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD).

Materials and Methods:

We performed a high-resolution, multi-modality analysis on ultrasound-guided liver biopsies from a well-phenotyped cohort of 60 individuals, representing Balanced, Qi-Deficiency, and Dampness-Heat constitutions (n=20 each), all with early-stage MASLD. Using spatial transcriptomics (10x Visium) and single-nucleus RNA sequencing (snRNA-seq) on adjacent tissue sections, we mapped the complete transcriptome across the porto-central axis of the liver lobule. A novel computational pipeline was developed to deconvolute spatial data using snRNA-seq references and to quantify zonation gradients. Participants underwent a standardized mixed-meal challenge, with serial blood sampling for metabolomics to assess dynamic metabolic flexibility.

Results:

Spatial transcriptomics revealed constitution-specific distortion of metabolic zonation. The Dampness-Heat constitution exhibited a pronounced expansion of a high-inflammatory, lipogenic transcriptional zone from the periportal region, compressing the normal oxidative metabolic zone. In contrast, the Qi-Deficiency constitution showed a blunted gradient, with loss of zonation sharpness and decreased expression of genes involved in energy metabolism and stress response in the pericentral area. The Balanced constitution maintained the most preserved and harmonious zonation pattern. These spatial maps were corroborated by snRNA-seq, identifying distinct hepatocyte subpopulations enriched in each constitution. Furthermore, the spatial dysregulation score correlated strongly with postprandial metabolic inflexibility ($r = 0.78$, $p < 0.001$) and early fibrosis markers.

Conclusions:

This study pioneers the use of spatiotemporal omics to visualize and quantify the biological basis of TCM constitutions directly within the liver's architectural blueprint. We demonstrate that constitutions correspond to distinct, spatially organized hepatic "ecosystems," providing a novel mechanistic

E-POSTER ABSTRACTS

framework for understanding individualized disease susceptibility and progression. This moves TCM diagnostics from syndromic categorization to a molecularly defined, spatially-aware precision medicine paradigm. Identifying these high-risk spatial architectures early could enable targeted, location-specific interventions (e.g., zonation-aware nutraceuticals or gene therapies) to restore metabolic harmony and prevent MASLD advancement.

Keyword(s) : Spatial Transcriptomics, Liver Zonation, TCM Constitution, Metabolic Heterogeneity, Precision Hepatology, MASLD

2279 - Constitution Specific Gut Flora Directs Liver Epigenome in MAFLD

春润 李¹, 云龙 姚¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

Emerging evidence highlights the gut-liver axis and epigenetic regulation in Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD). We hypothesize that distinct Traditional Chinese Medicine (TCM) constitutions harbor unique gut microbiota profiles, which produce specific metabolite signatures. These microbial metabolites, in turn, function as epigenetic modulators, directly shaping the hepatic DNA methylome and histone landscape, thereby predisposing individuals to divergent MAFLD phenotypes.

Materials and Methods:

In a discovery cohort of 150 biopsy-proven MAFLD patients (balanced, dampness-heat, and qi-deficiency constitutions), we performed multi-omics profiling. Metagenomic sequencing characterized fecal microbiota. Serum and fecal short-chain fatty acids (SCFAs) and bile acids were quantified. Genome-wide DNA methylation (Infinium EPIC array) and H3K27ac histone modification (ChIP-seq) were analyzed in matched liver tissues. Validation was performed in a humanized gnotobiotic mouse model colonized with donor microbiota from different constitutional types.

Results:

We identified constitution-specific microbial consortia and metabolite patterns. The Dampness-Heat constitution was enriched in pro-inflammatory *Escherichia/Shigella* and associated with elevated deoxycholic acid. Its liver tissue displayed significant hypomethylation at promoters of lipogenic (SREBP1) and chemokine (CCL2) genes. Conversely, the Qi-Deficiency constitution showed reduced butyrate-producing flora (*Faecalibacterium*), correlating with

hypermethylation and suppressed expression of mitochondrial β -oxidation genes (PPARA, CPT1A). Mice colonized with Dampness-Heat flora developed more severe steatohepatitis and recapitulated the human epigenetic alterations, which were ameliorated by butyrate supplementation.

Conclusions:

This study establishes a novel "Gut Flora-Metabolite-Epigenome" axis that mechanistically links TCM constitutions to MAFLD pathogenesis. It provides a functional genomic basis for constitutional taxonomy, moving beyond correlation to causality. Our findings position gut microbiota-derived metabolites as both prognostic biomarkers and potential therapeutic targets (e.g., epigenetic diet) for personalized MAFLD management based on TCM constitution.

Keyword(s) : TCM Constitution, Gut Microbiota, DNA Methylation, Epigenetics, MAFLD, Personalized Medicine

2280 - Atopic Constitution Primes Hepatic ILC2 Macrophage Axis in MASLD

春润 李¹, 云龙 姚¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The Atopic (Te Bing) constitution, a subtype in TCM theory, predisposes individuals to allergic and immune-dysregulated states. Its role in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD), a condition of sterile inflammation, is unknown. We hypothesize that the Atopic constitution establishes a liver-resident type 2 immune microenvironment, characterized by expanded group 2 innate lymphoid cells (ILC2s), which drives alternatively activated macrophage polarization, thereby exacerbating hepatic steatosis and fibrosis.

Materials and Methods:

We enrolled 180 biopsy-proven MASLD patients and classified them via the CCMQ, with a focus on identifying Atopic constitution (n=45) versus Balanced controls (n=45). Liver tissues were analyzed by multicolor flow cytometry and spatial transcriptomics (Visium) to map immune landscapes. Serum levels of type 2 cytokines (IL-4, IL-5, IL-13, IL-33) and periostin were measured. A murine model of MASLD was subjected to a protocol inducing allergic airway inflammation to mimic the Atopic state, followed by analysis of liver ILC2 dynamics and intervention with an IL-33 receptor blocker.

Results:

Patients with Atopic constitution exhibited a 3.2-fold increase in hepatic ILC2 frequency compared to

E-POSTER ABSTRACTS

controls ($p < 0.001$). Spatial transcriptomics revealed these ILC2s were clustered in portal areas adjacent to IL-33-expressing stromal cells and CD206⁺ M2 macrophages. This spatial niche correlated with higher histological steatosis and ballooning scores ($p < 0.01$). Serum IL-33 and periostin were elevated and served as predictive biomarkers for faster fibrosis progression ($HR = 2.4$). In the murine model, induction of atopy led to hepatic ILC2 expansion and accelerated steatohepatitis, which was mitigated by IL-33/ST2 pathway blockade.

Conclusions:

This study uncovers a novel immune phenotype linking TCM Atopic constitution to MASLD severity via an ILC2-driven type 2 hepatic axis. It positions allergic predisposition as a previously unrecognized risk modulator for liver disease progression. The identified IL-33-periostin axis offers both a mechanistic target for therapy and a serum biomarker for risk stratification, paving the way for immune-centric precision medicine in MASLD.

Keyword(s) : Atopic Constitution, Group 2 Innate Lymphoid Cells (ILC2s), Type 2 Immunity, MASLD, IL-33, Spatial Immunology

2281 - Reversing Qi Deficiency Slows Hepatocyte Senescence via AI

春润 李¹, 云龙 姚¹, 茜 张¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The Qi-Deficiency constitution in TCM, associated with aging and energy depletion, may accelerate cellular senescence. We hypothesize that this constitution correlates with a specific hepatic senescence-associated secretory phenotype (SASP) and that a machine learning model can predict the efficacy of constitution-targeted herbal therapy in reversing this process in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD).

Materials and Methods:

A 12-month prospective cohort of 300 MASLD patients with Qi-Deficiency was enrolled. Baseline assessments included CCMQ, serum SASP factors (IL-6, PAI-1, MMPs), and liver stiffness measurement (LSM). A 6-month tailored herbal regimen was administered. Single-nucleus RNA sequencing was performed on paired liver biopsies from a subset ($n = 20$) pre- and post-intervention to map senescence signatures. An XGBoost model was trained on multi-omics data to predict LSM response.

Results:

At baseline, Qi-Deficiency strongly correlated with a high hepatic SASP burden. The herbal intervention significantly reduced serum SASP factors and LSM in 68% of patients. snRNA-seq confirmed a marked reduction in senescence programs within hepatocyte subclusters post-treatment. The XGBoost model, incorporating baseline SASP profile and gut microbiota features, predicted treatment responders with 86% accuracy ($AUC = 0.89$). Non-responders were enriched in a distinct, resistant senescent cell population.

Conclusions:

This study mechanistically links Qi-Deficiency to accelerated liver aging via senescence. It pioneers an AI-guided framework to personalize constitution-modifying therapy, demonstrating that reversing a TCM constitution can biologically decelerate a core aging mechanism in MASLD.

Keyword(s) : Qi-Deficiency, Cellular Senescence, SASP, Artificial Intelligence, Herbal Therapy, Precision Medicine

2283 - Phlegm Dampness Constitution Disturbs Hepatic Circadian Rhythms in MASLD

春润 李¹, 云龙 姚¹, 茜 张¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The liver's circadian clock orchestrates daily metabolic cycles. The Phlegm-Dampness (PD) constitution, central to metabolic disorders, may disrupt this temporal order. We hypothesize that PD constitution is associated with dampened circadian oscillations of core clock genes in the liver, leading to a phase shift in lipid metabolism programs that exacerbates Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD).

Materials and Methods:

A cohort of 80 patients with biopsy-proven MASLD (40 PD, 40 Balanced) was recruited. PD diagnosis was based on the CCMQ and a standardized tongue coating score. Liver biopsies were obtained at two circadian times (8:00 AM, 8:00 PM). Rhythmic expression of core clock genes (BMAL1, CLOCK, PER2, CRY1) and key metabolic enzymes (SREBP1, PPAR α) was analyzed using RT-qPCR and RNA-seq. Circadian parameters (amplitude, phase, period) were computed. Plasma melatonin and cortisol rhythms were measured. Circadian locomotor activity was monitored via actigraphy.

Results:

The PD group exhibited significantly dampened amplitude of hepatic BMAL1 (55% reduction, $p < 0.001$)

E-POSTER ABSTRACTS

and PER2 oscillations. Their hepatic transcriptome showed a phase advance of lipogenic genes (SREBP1) and a phase delay of fatty acid oxidation genes (PPAR α), creating a metabolic “mismatch.” This internal desynchrony correlated strongly with higher hepatic triglyceride content ($r = 0.71$) and NAFLD activity score ($r = 0.65$). The PD group also showed blunted plasma melatonin rhythms and disrupted rest-activity cycles. A machine learning classifier using four core clock gene expression levels at a single time point could identify PD constitution with 82% accuracy (AUC=0.86).

Conclusions:

This study establishes for the first time that the TCM Phlegm-Dampness constitution is characterized by a distinct, measurable disruption of the hepatic circadian clock, creating a metabolic state prone to steatosis. It provides a chronobiological mechanism for PD constitution. This insight opens a new avenue for chrono-targeted interventions (e.g., timed diet or light therapy) tailored to reset the circadian phase in PD individuals for MASLD management.

Keyword(s) : Phlegm-Dampness Constitution, Circadian Clock, MASLD, Chronobiology, Phase Shift, Metabolic Rhythm

2284 - Stomach Heat Constitution Impairs Postprandial Hepatic Metabolic Flexibility

春润 李¹, 云龙 姚¹, 茜 张¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The Stomach-Heat (SH) constitution, characterized by excessive “heat” and rapid digestion, is a common but understudied TCM phenotype in metabolic disorders. We hypothesize that this constitution is defined not by static parameters, but by a pathological hyper-response to nutrient influx, leading to impaired hepatic metabolic flexibility. Specifically, we propose that SH individuals exhibit an exaggerated but inefficient switch from fasting to fed state, causing a transient “metabolic traffic jam” that promotes lipogenesis and inflammation in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD).

Materials and Methods:

A dynamic metabolic challenge study was conducted in 100 individuals with early MASLD, stratified into SH and Balanced constitutions using the CCMQ and a quantitative infrared thermography of the epigastrium. Participants underwent a standardized mixed-meal tolerance test. Hepatic metabolic fluxes were quantified in real-time using a combination of [1-¹³C]acetate and [6,²H₂]glucose stable isotope tracers,

coupled with continuous breath ¹³CO₂ analysis. Blood was sampled for metabolomics and inflammatory cytokines at multiple timepoints. A machine learning model integrated baseline multi-omics data (gut metagenomics, serum metabolomics) to predict the dynamic metabolic response.

Results:

Following the meal challenge, the SH group exhibited a 40% greater initial spike in hepatic de novo lipogenesis (DNL) flux compared to the Balanced group ($p < 0.001$). However, this was followed by a significantly delayed and blunted suppression of endogenous glucose production, indicating defective pathway switching. This “metabolic inflexibility” score strongly correlated with postprandial spikes in serum IL-1 β and liver stiffness measurement ($r = 0.69$). The SH gut microbiome was enriched in bacterial genes for rapid carbohydrate fermentation. The machine learning model accurately predicted an individual’s postprandial DNL response from baseline data (AUC=0.84), with the gut microbial signature being the top predictive feature.

Conclusions:

This study redefines the TCM Stomach-Heat constitution through the lens of dynamic systems biology, identifying it as a state of impaired hepatic metabolic flexibility in response to feeding. The trans-omic AI model bridges baseline constitution features with real-time metabolic pathophysiology. This novel framework allows for the early identification of high-risk individuals and suggests personalized, meal-timed interventions (e.g., prebiotics or pharmacological modulators of nutrient sensing) to restore metabolic plasticity and prevent MASLD progression.

Keyword(s) : Stomach-Heat Constitution, Metabolic Flexibility, Stable Isotope Tracers, Postprandial Metabolism, MASLD, Systems Biology

2285 - Blood Stasis EVs Reprogram Hepatic Stellate Cells via YAP

春润 李¹, 云龙 姚¹, 茜 张¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The Blood-Stasis (BS) constitution, a core concept in Traditional Chinese Medicine (TCM), is clinically linked to fibrotic progression in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD). Beyond static circulatory impairment, we hypothesize that BS dynamically communicates pro-fibrotic signals through liver sinusoidal endothelial cell (LSEC)-derived extracellular vesicles (EVs). These “BS-EVs” exhibit a

E-POSTER ABSTRACTS

unique proteomic cargo that aberrantly activates the mechanosensitive YAP/TAZ pathway in hepatic stellate cells (HSCs), driving a persistent fibrogenic phenotype.

Materials and Methods:

A discovery cohort of 80 MASLD patients (40 BS, 40 Balanced) was phenotyped using the CCMQ and nailfold capillaroscopy. LSEC-EVs were isolated from peripheral blood using CD146-immunoaffinity capture and characterized by nanoparticle tracking analysis and proteomics. Functional validation was performed by treating primary human HSCs with purified EVs.

Mechanistic interrogation involved YAP/TAZ inhibition, phosphoproteomics, and a murine model of carbon tetrachloride-induced fibrosis with adoptive transfer of human BS-EVs.

Results:

Patients with BS constitution harbored a significantly higher concentration of circulating LSEC-EVs with a distinct surface phosphatidylserine exposure. Proteomic analysis revealed BS-EVs were enriched in fibronectin and mechanotransduction-related proteins (e.g., ANXA2). Treatment of quiescent HSCs with BS-EVs, but not control EVs, triggered rapid YAP nuclear translocation, actin cytoskeleton remodeling, and a pro-fibrotic gene signature (α -SMA, COL1A1). This effect was abolished by a YAP inhibitor. In vivo, mice receiving BS-EVs developed exacerbated liver fibrosis, characterized by expanded α -SMA+ areas. A diagnostic model combining serum EV concentration and YAP activity signature predicted significant fibrosis ($F \geq 2$) with an AUC of 0.87.

Conclusions:

This study pioneers the concept of "constitution-specific EVs," identifying BS-EVs as novel, circulating mediators that translate a TCM constitutional state into a concrete pro-fibrotic molecular program via YAP/TAZ activation. It redefines blood stasis from a hemodynamic phenomenon to an active, vesicle-based signaling disorder. Targeting the BS-EV-YAP axis offers a promising, constitution-precise therapeutic strategy to halt fibrosis in MASLD.

2286 - Atopic Constitution Primes Liver Metastasis via Gut EV Immunomodulation

春润李¹, 云龙姚¹, 茜张¹

中医学院, 北京中医药大学, 北京-China¹

Background / Hypothesis:

The Atopic constitution, predisposed to allergic and

immune-dysregulated states, may create a permissive microenvironment for hepatic complications beyond simple steatosis. We hypothesize that in Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD), the Atopic phenotype drives increased intestinal permeability, leading to systemic release of gut-derived, immune-modulatory extracellular vesicles (EVs). These EVs preferentially home to the liver, where they reprogram hepatic macrophages toward an immunosuppressive phenotype, thereby priming a fertile soil for hepatocellular carcinoma (HCC) development and metastasis.

Materials and Methods:

A nested case-control study was conducted within a prospective MAFLD cohort (n=2,500). Atopic constitution was identified using a validated TCM questionnaire combined with serum IgE and T-helper 2 (Th2) cytokine profiling. Plasma EVs were isolated from Atopic and non-Atopic subjects, characterized by nanoparticle tracking analysis and proteomics, with gut origin confirmed by intestinal fatty acid-binding protein (I-FABP) and microbial markers. Their effects on primary human monocyte-derived macrophages and hepatic macrophage cell lines were assessed. Liver biopsies were analyzed by multiplex immunofluorescence for macrophage polarization markers (CD206, iNOS) and pre-metastatic niche factors. Findings were validated in a diet-induced MAFLD mouse model with ovalbumin-induced atopy.

Results:

Patients with Atopic constitution had significantly elevated levels of plasma EVs carrying a distinct cargo rich in heat shock proteins (e.g., HSP90) and Th2-skewing cytokines. These EVs were positively correlated with gut permeability markers (serum I-FABP, $r=0.62$) and hepatic steatosis-fibrosis scores. In vitro, Atopic-derived EVs potently induced an M2-like, immunosuppressive phenotype in macrophages, characterized by increased CD206 and IL-10 expression. This was associated with suppressed T cell activation capacity. In liver tissues, Atopic MAFLD patients showed a significant expansion of CD206+ macrophages within steatotic areas compared to controls. The murine model confirmed that atopic sensitization accelerated high-fat diet-induced liver injury and increased the number and immunosuppressive function of hepatic macrophages, which was transferable via adoptive transfer of donor plasma EVs.

Conclusions:

This study reveals a novel "gut-liver-immune" axis where the TCM Atopic constitution exacerbates MAFLD progression towards a protumorigenic state. The

E-POSTER ABSTRACTS

mechanism involves gut barrier dysfunction and the release of specialized EVs that systemically educate hepatic macrophages towards immunosuppression. This positions the Atopic constitution as a novel, biologically defined high-risk phenotype for HCC in MAFLD and identifies gut-derived EVs and their cargo (e.g., HSP90) as potential therapeutic targets and early risk stratification biomarkers.

2287 - Bioactive Folate Supplementation Mitigates Valproic Acid-Induced Liver Injury and Steatosis in a Rat Model

Hajra Ashraf ¹, Tooba Asif ¹, Fatima Baqir ¹, Naila Naz ²
National University Of Sciences And Technology, Biomedicine, Islamabad-Pakistan ¹ Natioanl University Of Sciences And Technology, Biomedicine, Islamabad-Pakistan ²

Background and Aim: Drug-induced liver injury is a major cause of acute and chronic liver disease. Of pharmacotherapies, antiepileptic drugs-notably, valproic acid-are well-documented causes of hepatic steatosis and mitochondrial dysfunction. VPA-induced fatty liver is a unique form of DILI that exacerbates the progression of NAFLD by interfering with folate metabolism, increasing oxidative stress, and activating inflammatory signaling pathways. The present study aimed to evaluate the impact of bioactive folates, folic acid and 5-methyltetrahydrofolate, on sodium valproate-induced nonalcoholic fatty liver disease in rats. Specifically, this study assessed whether folate supplementation would prevent hepatic steatosis and inflammation by mitigating valproic acid induced disruption of folate metabolism and restoring one-carbon cycle functionality.

Methods:Adult female Sprague Dawley rats were divided into three groups: control group, diseased group treated with valproic acid, and diseased + treated group treated with valproic acid and mixture of bioactive folate. Comprehensive analysis including liver function test, histopathological examination, gene expression analysis and molecular docking was carried out.

Results:Liver function tests indicated that the increase in alanine aminotransferase, alkaline phosphatase, and total bilirubin levels was highly significant in the diseased group, indicative of hepatic injury. Histopathological examination demonstrated severe steatosis in VPA-treated animals, which was

significantly improved in the folate-treated group. The NAFLD Activity Score, a mild NAFLD was observed in the diseased group with a total score of 2. Gene expression studies showed high upregulation of HO-1 and pro-inflammatory cytokines TNF- α and IL-6 in the diseased group, whereas downregulation was observed in folate-treated rats. Furthermore, molecular docking studies indicated that folic acid and 5mTHF showed high affinities for binding to KEAP1 protein, suggestive of activation of the Nrf2-KEAP1 antioxidant pathway. Conclusion:Collectively, our data provide significant evidence for the therapeutic approach of bioactive folate supplementation in the amelioration of the VPA-induced liver injury through modulation of oxidative stress, inflammation, and lipid accumulation.

Keyword(s) : DILI, NAFLD, valproic acid, bioactive folates, KEAP1, liver histology, oxidative stress, Nrf2.

2288 - Adverse reaction report of Peg IFN α 2b in 14 cases of compensated hepatitis B liver cirrhosis patients treated with NAs

Yanpeng Fan ¹, Xiaohong Gao ¹
Affiliated Hospital Of Yan'an University, Department Of Infectious Diseases, Yan'an-China ¹

Background / Hypothesis:

Chronic hepatitis B (CHB) is an important cause of liver cirrhosis and hepatocellular carcinoma (HCC). For CHB patients treated with nucleoside analogues (NAs), combining pegylated interferon α -2b (Peg-IFN- α -2b) can increase the possibility of clinical cure. However, the risk of adverse reactions in patients with compensated liver cirrhosis is relatively high, and the safety is still controversial, so close monitoring is required.

Materials and Methods:

A retrospective analysis was conducted on the data of 14 patients with compensated hepatitis B cirrhosis who had been treated with nucleos(t)ide analogs (NAs) and visited the Affiliated Hospital of Yan'an University from January 2019 to June 2025. On the basis of continuing NAs treatment, all patients were combined with Peg - IFN - α - 2b (180 μ g/week, subcutaneous injection). The adverse reactions that occurred during the treatment were recorded, and their composition and outcomes were analyzed.

Results:

E-POSTER ABSTRACTS

During the treatment process, the incidence of adverse reactions was relatively high, mainly manifested as follows:

Influenza-like symptoms (fever, headache, myalgia, etc.): 11 cases (78.57%);

Manifestations of bone marrow suppression: bleeding of the gums or skin and mucous membranes in 5 cases (35.71%), decreased white blood cell count in 4 cases (28.57%);

Endocrine and skin reactions: hyperthyroidism in 3 cases (21.43%), hair loss in 5 cases (35.71%), skin rash in 3 cases (21.43%);

Others: 1 case each of hypertension, anxiety, and erectile dysfunction (7.14% each). All adverse reactions improved after symptomatic treatment or drug withdrawal.

Conclusions:

Combined treatment with Peg - IFN - α - 2b in treatment - experienced compensated hepatitis B liver cirrhosis patients with NAs can achieve partial clinical cure, but adverse reactions are relatively common, especially influenza - like symptoms and manifestations related to bone marrow suppression. In clinical practice, blood routine, thyroid function, liver function and neuropsychiatric status should be closely monitored, and timely intervention should be carried out to ensure the safety of treatment.

Keyword(s) : Compensated hepatitis B cirrhosis; Pegylated interferon; Adverse reactions; Clinical cure

2289 - Tumor burden score combined with alpha fetoprotein stratification Evaluating efficacy of triple conversion therapy in unresectable hepatocellular carcinoma – A multicenter retrospective study

Jian-hong Zhong¹, Zhi-cheng Li², Da-long Yang¹, Lin Ye³, Fan-jian Zeng⁴, Jie Liu⁵

Guangxi Medical University Cancer Hospital, Hepatobiliary Surgery, Nanning-China¹ The First Affiliated Hospital Of Guangxi University Of Chinese Medicine, General Surgery, Nanning-China² Affiliated Hospital Of Guilin Medical University, Hepatobiliary And Pancreatic Surgery, Guilin-China³ Wuzhou Red Cross Hospital, Hepatobiliary Surgery, Wuzhou-China⁴ Guilin People's Hospital, Hepatobiliary Pancreatic

Surgery, Guilin-⁵

Background / Hypothesis:

Hepatocellular carcinoma is a common malignant tumor worldwide. With the development of immunotherapeutic agents, triple conversion therapy (Transarterial Chemoembolization+Tyrosine Kinase Inhibitor+Immune Checkpoint Inhibitors) has emerged as an effective option for patients with unresectable hepatocellular carcinoma. This study aims to combine the tumor burden score and alpha-fetoprotein to stratify patients, identify the population with the optimal benefit, and provide a decision-making basis for clinical diagnosis and treatment.

Materials and Methods:

This multicenter retrospective study included 359 patients with unresectable hepatocellular carcinoma. A novel scoring index was developed by integrating the tumor burden score and alpha-fetoprotein, which was then used to stratify the patients. The Cox proportional hazards model was applied to assess the association of this new index with patient survival and tumor progression. Kaplan-Meier curves were generated, and the log-rank test was conducted to compare differences in overall survival and progression-free survival among different stratified subgroups, with the aim of identifying the population that obtains the optimal benefit from triple therapy.

Results:

In the Cox regression analysis, TBA score value ($p=0.048$; high vs. middle hazard ratio [HR]: 2.775; 95% confidence interval [CI]: 1.231-6.258; middle vs. low HR: 1.943; 95% CI: 0.995-3.794) and undergoing hepatectomy after triple therapy were identified as independent risk factors for patients' overall survival (OS). For progression-free survival (PFS), the independent risk factors included tumor number, TBA score value ($p=0.008$; high vs. middle HR: 2.338; 95% CI: 1.322-4.135; middle vs. low HR: 1.817; 95% CI: 1.189-2.778), and undergoing hepatectomy after triple therapy. In the Kaplan-Meier curve and log-rank test, the low TBA group exhibited the best prognosis: the median progression-free survival (PFS) was 24.3 months, and the median OS was not reached. This outcome was significantly superior to that of the middle TBA group and high TBA group. Notably, the lower the TBA score value, the better the efficacy of conversion therapy in patients.

Conclusions:

The TBA score value, which integrates tumor burden

E-POSTER ABSTRACTS

score and alpha-fetoprotein, can effectively stratify the prognosis of unresectable hepatocellular carcinoma patients receiving triple conversion therapy. Further validation of its broad clinical applicability is required in larger sample sizes and different systemic treatment regimens.

Keyword(s) : TBA score value, unresectable hepatocellular carcinoma, triple conversion therapy, prognosis stratification

2293 - Rhabdomyolysis triggered acute on chronic liver failure in alcohol related cirrhosis a rapidly fatal multiorgan failure case

Ilknur Cakmak¹, Riham Soliman²

North West Anglia Nhs Foundation Trust, Internal Medicine, Peterborough-United Kingdom¹ North West Anglia Nhs Foundation Trust, Hepatology, Peterborough-United Kingdom²

Background / Hypothesis:

Acute-on-chronic liver failure (ACLF) is characterised by acute decompensation of cirrhosis with extrahepatic organ failures and high short-term mortality. While infection is the most common precipitant, non-infectious inflammatory insults such as rhabdomyolysis are increasingly recognised but remain under-reported. Rhabdomyolysis, caused by muscle breakdown with release of myoglobin, creatine kinase (CK) and pro-inflammatory mediators, can exacerbate renal injury, metabolic acidosis and systemic inflammation, thereby accelerating hepatic decompensation. We hypothesised that severe rhabdomyolysis may act as a rare but clinically significant trigger of ACLF in alcohol-related cirrhosis.

Materials and Methods:

We describe a 74-year-old man with recently diagnosed alcohol-related liver disease who presented after a fall and prolonged immobilisation. Clinical data, laboratory results, imaging and CLIF-C ACLF scoring were reviewed to assess disease progression and prognosis. Supportive interventions included intensive care admission, continuous renal replacement therapy (CRRT), rhythm control for atrial fibrillation, and broad monitoring for infection and systemic inflammation

Results:

On admission, the patient had severe rhabdomyolysis (CK 40,721 U/L), acute kidney injury stage 3, metabolic acidosis, coagulopathy (INR 2.31) and hepatic encephalopathy. His CLIF-C ACLF score was 61, predicting high short-term mortality. Despite CRRT,

electrolyte correction and maximal supportive care, multiorgan failure progressed. Inflammatory markers remained persistently elevated (CRP 122–150 mg/L) without a clear infective source. He developed new-onset atrial fibrillation, managed with amiodarone and digoxin. Muscle injury showed biochemical improvement (CK falling to 765 U/L), yet hepatic and renal dysfunction worsened. His CLIF-C ACLF score rose to 75, consistent with extremely poor prognosis (<20% 28-day survival). Following multidisciplinary discussions, treatment was deemed futile and care transitioned to palliation. He died four days after presentation.

Conclusions:

This case highlights rhabdomyolysis as an uncommon but important precipitant of ACLF in alcohol-related cirrhosis. Prolonged immobilisation led to extensive muscle necrosis, with myoglobin-induced renal injury and systemic inflammation driving hyperacute multiorgan failure. Despite aggressive organ support, prognosis remained dismal, as reflected by CLIF-C ACLF scoring. Recognition of rhabdomyolysis as a potential ACLF trigger is essential, and objective scoring systems provide valuable guidance for prognosis and goals-of-care decisions.

Keyword(s) : Acute-on-chronic liver failure (ACLF), Rhabdomyolysis, CLIF-C ACLF score, Alcohol-related cirrhosis

2295 - Acute methyl ethyl ketone peroxide poisoning presenting with polycythemia

Serhat Akpınar¹, Kadir Gisi¹, Ahmet Biçici¹, Mesut Kuş¹, Bülent Kantarçeken¹
Sutcu Imam University, Gastroenterology, Kahramanmaraş-Türkiye¹

Background / Hypothesis: Methyl ethyl ketone peroxide (MEKP) is widely used as a hardener in the production of synthetic rubbers in industrial applications. Ingestion of MEKP causes proximal airway edema and obstruction, corrosive burns leading to stenosis, inhalation pneumonia or acute respiratory distress syndrome, acidosis, liver failure, and kidney failure. MEKP is a colorless liquid indistinguishable from drinking water in appearance and is easily ingested accidentally in daily life. We present this case of someone who accidentally drank about 100 cc from a water bottle filled with MEKP.

Case: A 29-year-old male patient accidentally ingested approximately 100 cc of a 33% methyl ethyl ketone

E-POSTER ABSTRACTS

peroxide (MEKP) solution from a clear plastic bottle while working at his workplace. Upon admission to the emergency department, his blood pressure was normotensive (120/70 mmHg), temperature was normal (36.8 °C), and oxygen saturation was normal (99%), but he had tachycardia (120/min) and tachypnea (25/min). Other physical examination findings were normal. Blood tests performed in the emergency department showed a white blood cell count (WBC): $33730 \times 10^9/L$, HGB: 21.3 gr/dL, and PLT: $351000 \times 10^9/L$. The patient was prescribed intravenous hydration, high-dose pantoprazol, antiemetic therapy, ampicillin-sulbactam, and N-acetylcysteine. Approximately 12 hours after admission, the patient underwent esophagogastroduodenoscopy, which revealed grade 2 corrosive damage in the esophagus. During follow-up, the patient's WBC count rose to $40250 \times 10^9/L$ on day 1 of hospitalization, and the HGB count increased to 22.9 g/dL on day 1. These levels gradually regressed, returning to normal values on day 9. The patient's creatinine level, however, progressed during follow-up, rising to 2.4 mg/dL. The patient, who also had acidosis in blood gas analysis, was referred to nephrology, and hydration and monitoring were recommended, but dialysis was not considered. Creatinine levels began to regress from day 3 of hospitalization and returned to normal values on day 9. Liver enzymes, which were three times higher than normal upon admission, increased up to eight times during follow-up and then progressively regressed.

Conclusion:MEKP is a potentially deadly chemical. Ingestion can cause both corrosive damage and acute organ failure in organs such as the liver and kidneys. However, unlike previous cases, this particular case developed severe polycythemia and recovered without any lasting damage thanks to supportive treatment. Raising public awareness and educating the public is crucial to prevent such toxicities.

2298 - Divergent Oncologic and Survival Implications of Stiffness Regression After SVR A Decade Long Longitudinal FibroScan Study in Advanced Fibrosis

Shuntaro Obi¹, Yoshiki Asahina², Tomoyoshi Murata³, Shoudai Tohyama³, Hiroyuki Amano³, Hiroshi Ashizawa³, Shinya Takaoka³, Yushi Imai³, Yukiko Asakawa³, Hitoshi Mochizuki³, Yuichiro Kojima³, Sumio Hirose³, Masao Omata⁴
Teikyo Univ. Chiba Medical Center, Internal Medicine, Chiba-Japan¹ Yamanashi Central Hospital

Gastroenterology, Yamanashi-Japan² Amanashi Central Hospital, Gastroenterology, Yamanashi-Japan³ The Univ. Of Tokyo, Gastroenterology, Tokyo-Japan⁴

Background

Although liver stiffness regression after sustained virologic response (SVR) is widely interpreted as a marker of fibrosis reversal, its clinical implications across fibrosis stages remain unclear. We aimed to characterize long-term stiffness trajectories and their associations with hepatocellular carcinoma (HCC) incidence and overall survival (OS).

Methods

We analyzed 657 SVR patients with ≥ 2 FibroScan assessments over 10 years. Annual stiffness change (slope, kPa/year) was estimated using mixed-effects models. Stiffness regression was defined according to QIBA criteria. Outcomes included HCC incidence and OS, stratified by fibrosis group (F0–2, F3, F4).

Results

Two distinct post-SVR stiffness trajectories emerged.

Regression patients showed a sustained decline in stiffness (-0.51 kPa/year), whereas non-regression patients remained stable around 9–10 kPa.

Importantly, the clinical implications of regression differed sharply by fibrosis stage.

HCC incidence: In F3 disease, stiffness regression tended to reduce HCC incidence, although not statistically significant.

In contrast, in F4 disease, regression did not suppress HCC risk, and cumulative incidence curves for regression and non-regression groups were nearly identical, indicating that oncogenic risk persists despite stiffness improvement.

Overall survival: In F3, OS was similarly excellent regardless of regression status.

However, in F4, regression was strongly associated with improved OS, whereas non-regression patients had significantly poorer survival. Thus, stiffness regression is oncologically uncoupled from HCC reduction but prognostically coupled with survival benefit in cirrhosis.

Conclusions

Stiffness regression after SVR has fundamentally different implications across fibrosis stages. In cirrhosis, stiffness improvements do not mitigate HCC risk but remain a powerful determinant of survival.

2299 - Shifting hepatitis A virus seroprevalence among healthcare workers and the general population

E-POSTER ABSTRACTS

Irem Aşkin Yilmaz ¹, Selma Tosun ¹, Irem Ciftci ¹
Izmir City Hospital, Infectious Diseases And Clinical
Mikrobiology, Izmir-Türkiye ¹

Background / Hypothesis

Hepatitis A virus (HAV) epidemiology has changed markedly in recent years, both globally and in Türkiye. Improved sanitation and routine childhood vaccination have substantially reduced early-life exposure. Within the national immunization program, children born after March 2011 have been vaccinated against HAV, leading to decreased susceptibility during childhood. In parallel, seronegative healthcare workers are recognized as a risk group and vaccinated when identified. As a result, HAV susceptibility has shifted toward adolescents and young adults. This study aimed to evaluate age-specific HAV seroprevalence patterns among healthcare workers and the general population.

Materials and Methods

This retrospective observational study evaluated anti-hepatitis A virus (HAV) immunoglobulin G (IgG) test results obtained from a tertiary care center. The study was conducted at İzmir City Hospital, a newly established institution with a high number of newly recruited healthcare workers. Anti-HAV IgG results of healthcare workers and individuals from the general population who attended the hospital between October 23, 2023, and September 30, 2025 were retrieved from electronic medical records and the Occupational Health Unit database. Seroprevalence was analyzed according to predefined age groups. Data were summarized as numbers and proportions, and comparisons were performed using the chi-square test, with $p < 0.05$ considered statistically significant.

Results

A total of 3,363 healthcare workers aged 19–68 years and 6,230 individuals from the general population aged 17–98 years were included. Among healthcare workers, HAV seronegativity was highest in the youngest age groups and declined progressively with age. Higher seronegativity was observed up to 35 years, with a marked decrease thereafter, although seronegative individuals remained present in the 40–45-year age group. A similar age-related trend was observed in the general population, characterized by higher seronegativity in younger individuals and increasing seropositivity with advancing age. Overall, seronegativity rates were lower among healthcare

workers, particularly among those born in 2000 or later, likely reflecting vaccination practices.

Conclusions

HAV seronegativity remains significantly higher among young adults under 35 years of age in both healthcare workers and the general population, while seropositivity increases with age, indicating a favorable shift in HAV epidemiology. Despite lower seronegativity among younger healthcare workers due to vaccination, expanding serological screening and vaccination remains essential. In the general population, HAV serology should be assessed regardless of age in the presence of risk factors such as chronic hepatitis (HBV or HCV), immunosuppression, or advanced age, and seronegative individuals should be vaccinated.

Keyword(s) : hepatitis A virus, seroprevalence, young adults, healthcare workers, epidemiologic shift

2301 - Gastric Variceal Rupture due to Sinusoidal Obstruction Syndrome after Oxaliplatin Chemotherapy

Soichiro Hase ¹

Kawasaki Saiwai Hospital, Endovascular Surgery,
Kawasaki-Japan ¹

Background / Hypothesis: While sinusoidal obstruction syndrome (SOS) is a known side effect of oxaliplatin, the presentation of gastric variceal rupture is rare.

Materials and Methods: A male patient in his 50s was transported to our hospital by emergency services complaining of hematemesis, 1 year and 7 months after completing 12 cycles of Modified Fluorouracil + Folinic Acid + Oxaliplatin (mFOLFOX) chemotherapy following surgical resection of a hepatic metastasis and primary sigmoid colon cancer. A CT scan revealed marked hepatosplenomegaly and the development of extrahepatic collateral circulation, which had not been observed before the chemotherapy. Upper gastrointestinal endoscopy confirmed a ruptured gastric varix. The rupture was attributed to gastric varices secondary to oxaliplatin-induced SOS.

Results: Since temporary hemostasis had been achieved, emergency Balloon-Occluded Retrograde Transvenous Obliteration (BRTO) was performed. The patient experienced no further recurrence of symptoms thereafter.

E-POSTER ABSTRACTS

Conclusions: Patients who have undergone oxaliplatin-based chemotherapy require careful long-term follow-up, considering the risk of esophagogastric variceal rupture.

Keyword(s) : oxaliplatin, sinusoidal obstruction syndrome, ruptured gastric varix

2303 - Predictive Value of Peripheral Blood T Cell Counts for HBsAg Clearance in Pediatric Patients with Chronic Hepatitis B Receiving Antiviral Therapy

Ruiyang Yuan ¹, Xiuchang Zhang ¹, Ce Shi ², Jia Liu ², Wenling Wang ², Yuxi Ning ¹, Xueqi Hong ¹, Min Zhang ², Yanwei Zhong ²

Hebei North University, Hebei North University, Zhangjiakou-China ¹ The Fifth Medical Center Of Chinese PLA General Hospital, Department Of Hepatology, Beijing-China ²

Background / Hypothesis:

Response to antiviral therapy varies among pediatric patients with chronic hepatitis B (CHB). This study aims to investigate the predictive value of peripheral blood T cell counts for HBsAg clearance in this population.

Materials and Methods:

A total of 288 HBsAg-positive children with chronic CHB aged 1–18 years old were randomly enrolled. All subjects received 48 weeks of standardized antiviral treatment and subsequent follow-up. The serological indicators were measured through routine laboratory operating procedures. According to the HBsAg clearance status after treatment, the children were divided into the HBsAg clearance group and the non-clearance group. Statistical analysis was used to clarify the correlation between T cell counts and treatment efficacy, and the area under the receiver operating characteristic curve (AUROC) was used to evaluate its predictive value.

Results:

HBsAg clearance was achieved in 26.04% of the enrolled children. The HBsAg clearance group exhibited significantly higher baseline total T cell counts, 12-week CD4+ T cell counts, and 12-week CD8+ T cell counts compared to the non-clearance group; these metrics were negatively correlated with 48-week HBsAg levels ($P < 0.05$). The combined use of these three indicators for predicting HBsAg clearance yielded an AUROC of 0.8078 ($P < 0.0001$), with a sensitivity of 73.3% and specificity of 80.2%.

Conclusions:

The baseline total count of peripheral blood T lymphocytes, the 12-week CD4+ T cell count, and the 12-week CD8+ T cell count are effective predictive indicators for evaluating HBsAg clearance in children with CHB. The combined application of the three indicators can improve the accuracy of prediction and provide valuable references for clinical efficacy evaluation.

Keyword(s) : Chronic hepatitis B; T lymphocyte; Hepatitis B surface antigen clearance; Antiviral therapy

2304 - Hepatocellular carcinoma detection using pre transplant triphasic computed tomography and correlation with explant pathology

Dr Darayus Percy Gazder ¹, Zaigham Abbas ¹, Nahl Nizamani ¹, Zeeshan Haider ², Aasia Sabeen ²

Ziauddin Hospital, Hepatogastroenterology, Karachi-Pakistan ¹ Ziauddin Hospital, Hepatobiliary Surgery, Karachi-Pakistan ²

Background / Hypothesis:

Triphasic CT is widely used to stage hepatocellular carcinoma (HCC) before liver transplantation, yet radiology can underestimate tumor burden relative to explant pathology—especially for multifocal or early lesions. Meta-analyses and guideline frameworks (e.g., Liver Imaging Reporting and Data System) show that CT's sensitivity for HCC is lower than MRI and drops further for early-stage disease, while explant may reveal more tumors than imaging suggests. We aimed to find out the diagnostic yield of triphasic CT scan for HCC in correlation with explant findings.

Materials and Methods:

We retrospectively reviewed 46 consecutive living-donor liver transplants at our new liver transplant program. Pre-transplant triphasic CT scans were compared with explant pathology.

Results:

Of the 46 patients, 41 (89%) were male, with a mean age of 45.2 ± 10.3 years. On computed tomography (CT), 17 patients (36.9%) were diagnosed with hepatocellular carcinoma (HCC). Explant pathology confirmed HCC in 18 patients (39.1%). The additional patient had a dysplastic nodule on CT imaging, accompanied by elevated PIVKA-II levels but normal alpha-fetoprotein (AFP) levels. PIVKA-II was elevated in

E-POSTER ABSTRACTS

all patients with HCC, whereas AFP was elevated in only 8 of 18 patients (44.4%). Multicentric HCC was detected on CT in 12 patients; however, histopathological examination confirmed multicentric disease in 10 of 18 patients (55.5%).

Conclusions:

In this single-center liver transplant cohort, pre-transplant triphasic computed tomography proved to be a reliable modality for the detection of hepatocellular carcinoma, identifying a proportion of cases comparable to final histopathology. Triphasic CT effectively characterized tumor morphology, including multicentric disease, supporting its continued use as a primary imaging tool in the pre-transplant evaluation of HCC. Additionally, elevated tumor markers—particularly PIVKA-II—served as valuable adjuncts in cases with indeterminate or dysplastic lesions on imaging, enhancing diagnostic confidence and aiding clinical decision-making.

Keyword(s) : hepatocellular carcinoma, triphasic computed tomography, liver transplantation, explant pathology, alpha-fetoprotein, PIVKA-II

2305 - Transcriptomic Characteristics of Peripheral Blood T Cells in Pediatric Chronic Hepatitis B with Different Antiviral Therapy Outcomes

Ruiyang Yuan ¹, Min Zhang ², Ce Shi ², Jia Liu ², Wenling Wang ², Yuxi Ning ¹, Xueqi Hong ¹, Xiuchang Zhang ¹, Yanwei Zhong ²

Hebei North University, Hebei North University, Zhangjiakou-China ¹ The Fifth Medical Center Of Chinese PLA General Hospital, Department Of Hepatology, Beijing-China ²

Background / Hypothesis:

Currently, antiviral therapy is the main method for clinical cure in children with chronic hepatitis B (CHB). However, there are significant interindividual differences in treatment efficacy during antiviral therapy in children. The underlying mechanisms of such differences have not been fully elucidated so far. At present, variations in clinical outcomes of children with CHB after antiviral therapy have become a key bottleneck restricting their functional cure. The purpose of this study is to analyze the transcriptomic characteristics of peripheral blood T cells in children with different clinical outcomes, clarify the key immune cell subsets and target genes associated with HBsAg clearance so as to provide experimental evidence for improving the clinical cure rate of antiviral therapy in children.

Materials and Methods:

A total of 8 pediatric patients with CHB receiving antiviral therapy were enrolled. 10× Genomics single-cell RNA sequencing was performed on peripheral blood T lymphocytes from CHB children with different treatment responses. After data quality control, Seurat software was used for cell clustering and subset annotation to screen differential cell subsets by inter-group comparison. Differential gene expression analysis was conducted on these subsets, combined with GO and KEGG enrichment analyses to clarify key genes mechanism in antiviral response.

Results:

Single-cell RNA sequencing identified multiple peripheral blood T cell subsets. Significant proportional differences of cell subsets existed between groups, with specific subsets enriched in the response group. The proportion of CD4-*ISG*-Treg was significantly higher in the functional cure group ($p = 0.036$) and was negatively correlated with HBsAg levels ($r = -0.8$, $p = 0.017$). *ISG15* was the most significantly upregulated gene in CD4-*ISG*-Treg, and the baseline plasma *ISG15* level was significantly higher in the HBsAg clearance group than in the non-clearance group ($p = 0.0002$). The area under the receiver operating characteristic curve (AUROC) of *ISG15* for predicting HBsAg clearance was 0.749 (95% confidence interval [CI] = 0.633 – 0.865, $p < 0.0001$), with an optimal cutoff value of 176.87 pg/mL, a sensitivity of 83.8%, and a specificity of 55.2%. The "*ISG15* antiviral mechanism" pathway was highly enriched in CD4-*ISG*-Treg; *ISG15* promoted the development of this subset.

Conclusions:

The CD4-*ISG*-Treg subset plays a pivotal role in HBsAg clearance. *ISG15* maybe a potential therapeutic target in pediatric patients with CHB, which may help improve the functional cure rate.

Keyword(s) : Chronic hepatitis B; Antiviral therapy; T lymphocytes; Transcriptomic characteristics

2307 - The Thirteen Year Shadow Delayed Biliary Cirrhosis Following Gallbladder Tuberculosis in a Young Filipino Female

Desiree Jane Lacuin ¹, Suzette Kho-herman ², Mabel Angela Sarita ²

Makati Medical Center, Section Of Gastroenterology,

E-POSTER ABSTRACTS

Makati City-Philippines ¹ Akati Medical Center, Section Of Gastroenterology, Makati City- ²

Background

Gallbladder tuberculosis (GBTB) is an extremely rare form of extrapulmonary TB, even in areas where TB is common with a global prevalence of 1% of all abdominal TB cases. Similar to global data, specific large-scale prevalence data for isolated Gallbladder TB in the Philippines is limited and primarily documented through case reports. Its nonspecific clinical presentation frequently leads to misdiagnosis as more common hepatobiliary conditions, with definitive diagnosis often established only through histopathological examination following surgery. Chronic inflammation from hepatobiliary TB may result in biliary obstruction or strictures, leading to prolonged cholestasis, progressive hepatic injury, and eventual secondary biliary cirrhosis.

CASE PRESENTATION:

We report a case of a 32-year old Filipino female who presented with progressive abdominal distention, jaundice and bloatedness. Thirteen years, the patient was diagnosed with gallbladder tuberculosis after presenting with Acute Cholecystitis for which she underwent Laparoscopic Cholecystectomy. Histopathology report revealed GBTB and she completed a full course of anti-tuberculous therapy with apparent clinical resolution. Despite successful treatment, she developed a delayed sequela: an extrahepatic biliary stricture resulting in chronic cholestasis and progressive liver damage.

Her current presentation reflected decompensated liver cirrhosis with evidence of severe portal hypertension, including moderate ascites, hypersplenism, splenomegaly, and the formation of portosystemic collaterals.

Esophagogastroduodenoscopy (EGD) performed revealed one column of small esophageal varices and small gastric varices, without portal hypertensive gastropathy.

Laboratory studies showed markedly elevated bilirubin levels and severe cholestasis. Abdominal MRI confirmed features of advanced cirrhosis, demonstrated pronounced hepatic duct dilatation at the confluence, and characterized the high-grade extrahepatic biliary stricture as the likely driver of her deteriorating hepatic function.

Given her young age and lack of other significant comorbidities, liver transplant was offered as the definitive treatment option; however, the patient refused the procedure. The patient was managed medically for her portal hypertension with the non-selective beta-blocker Carvedilol and IV albumin infusion.

Conclusions:

This case highlights the importance of long-term surveillance following localized hepatobiliary tuberculosis, even after successful primary medical treatment. Fibrotic and structuring process initiated by the initial Mycobacterium tuberculosis infection can progress insidiously over years, culminating in secondary biliary cirrhosis and life-threatening portal hypertension. Managing these complex late complications requires addressing both the ongoing effects of biliary obstruction and the consequences of portal hypertension. Increased awareness of these rare but severe late sequelae is essential, particularly in TB-endemic regions.

Keyword(s) :

2308 - Application of Anti HBc in Clinical diagnosis for Pediatric Hepatitis B

Ce Shi ¹, Min Zhang ¹, Fang Chu ¹, Jia Liu ¹, Wenling Wang ¹, Yuxi Ning ², Xueqi Hong ², Yanwei Zhong ¹
The Fifth Medical Center Of Chinese PLA General Hospital, Department Of Hepatology, Beijing-China ¹
Hebei North University, Hebei North University, Zhangjiakou-China ²

Background / Hypothesis:

Chronic hepatitis B (CHB) is often accompanied by liver inflammation, and invasive liver biopsy remains the gold standard for assessing inflammatory severity. Serum quantitative hepatitis B core antibody (qanti-HBc) has emerged as a potential non-invasive biomarker for liver disease activity in adult CHB patients, but its diagnostic value in pediatric populations remains unclear. This study aimed to investigate the role of qanti-HBc in diagnosing significant liver inflammation in treatment-naïve HBeAg-positive children.

Materials and Methods:

A total of 60 HBeAg-positive children with CHB were enrolled in this study. Baseline serum qanti-HBc levels were quantified using a double-antigen

E-POSTER ABSTRACTS

immunosandwich assay, and liver biopsy specimens were evaluated for histological inflammation (G0–4) and fibrosis (S0–4) stages by experienced pathologists. Patients were divided into non-significant (G0–1) and significant (G2–4) liver inflammation groups. Pearson correlation, multifactorial logistic regression, and receiver operating characteristic (ROC) curve analyses were performed to assess the diagnostic performance of qanti-HBc.

Results:

Baseline qanti-HBc levels showed a significant positive correlation with liver tissue inflammation grade ($r=0.60$, $p<0.001$) and fibrosis stage ($r=0.29$, $p=0.019$). Multifactorial regression analysis identified baseline qanti-HBc (odds ratio [OR]=10.910, $p=0.013$) as the only independent predictor of significant liver inflammation in pediatric CHB. The area under the ROC curve (AUROC) of qanti-HBc for diagnosing significant liver inflammation was 0.815 (95% confidence interval [CI]: 0.708–0.921), which was superior to ALT (AUROC=0.624, 95%CI: 0.484–0.763) and AST (AUROC=0.710, 95%CI: 0.484–0.763). A cutoff value of qanti-HBc $>4 \log_{10}$ IU/mL yielded a sensitivity of 67.0%, specificity of 88.0% for significant liver inflammation.

Conclusions:

Serum qanti-HBc maybe a new non-invasive diagnostic indicator for significant liver inflammation in treatment-naïve HBeAg-positive children.

Keyword(s) : Children; Chronic hepatitis B; Liver inflammation; Quantitative hepatitis B core antibody

2312 - A Rare Case Report of Primary Hepatic Lymphoma Complicated by Hemophagocytic Lymphohistiocytosis

Airu Liu¹, Linting Xun¹, Yu Zhang¹

The First People's Hospital Of Yunnan Province, Gastroenterology, Kunming-China¹

Background / Hypothesis:

Primary hepatic lymphoma (PHL) is a rare disease characterized by non-specific clinical manifestations, laboratory findings, and imaging features, which may lead to misdiagnosis as hepatocellular carcinoma or hepatic infectious lesions. However, whether PHL can secondarily develop hemophagocytic lymphohistiocytosis (HLH) like other hematological lymphomas has not been reported.

Materials and Methods:

We present a diagnostically challenging case initially mimicking a pyogenic liver abscess. A 74-year-old woman with no history of past illness was admitted with persistent high fever accompanied by fatigue and loss of appetite for three weeks. Her vital signs were normal on physical examination. Computed tomography, magnetic resonance imaging, and 18F-FDG PET/CT showed a liver infectious lesion as a hepatic abscess. A subsequent laparoscopic exploration and liver biopsy confirmed the diagnosis of germinal center B-cell-like diffuse large B-cell lymphoma. Concurrently, with the progressive thrombocytopenia and hemoglobin reduction alongside persistent fever, the life-threatening complication of hemophagocytic lymphohistiocytosis (HLH) secondary to PHL was first reported by the further workup per the HLH-2004 criteria.

Results:

The modified R-ECHOP chemotherapy regimen was initiated to address both conditions. While during subsequent follow-up evaluations, significant myelosuppression was identified in the patient. The second-cycle chemotherapy regimen was modified to the R-miniCHOP protocol. After four cycles of chemotherapy, the follow-up PET-CT scan indicated complete response of the liver tumor lesions.

Conclusions:

PHL is rare and frequently clinically mistaken for a liver abscess. Histopathological examination remains the gold standard for definitive diagnosis. Similar to other hematological lymphomas, PHL may also secondarily develop HLH. Early recognition, diagnosis, and intervention are critical to improving prognosis.

2313 - The role of hepatic CD36 in metabolic dysfunction associated steatotic liver disease

Jie Huang¹, Xin Chen¹, Jiayu Deng¹, Danman Guo¹, Weilan Zeng¹, Cuiting Liu¹, Junmin Shi¹, Yisi Chen¹, Jing Li¹, Yan Wang¹

Southern Medical University, Biomedical Research Center, Guangzhou-China¹

Background/Hypothesis: CD36, a type B scavenger receptor, exhibits multifunctionality and conserved primary structure across various mammalian and vertebrate cell types. It facilitates fatty acid binding and

E-POSTER ABSTRACTS

transport, with increased expression observed in hepatocytes and circulating systems of metabolic dysfunction-associated steatotic liver disease (MASLD) patients and animal models, suggesting a potential role in MASLD pathophysiology. However, conflicting evidence exists regarding whether CD36 expression exacerbates hepatic injury. This study aimed to analyze changes in CD36 expression induced by MASLD and examines its impact on hepatocyte injury and lipid profiles.

Materials and Methods: We developed CD36 genetically-engineered zebrafish lines and hepatocyte lines. MASLD mouse model and zebrafish model were constructed by high fat, high cholesterol diet maintenance. Histological and biochemical examinations were conducted to observe liver injury and regeneration. High-resolution fluorescence imaging was used to observe the dynamic subcellular distribution of CD36. Liquid chromatography mass spectrometry (LC-MS) and QToF desorption electrospray ionization mass spectrometry imaging (MSI)-based lipidomics analyses were performed to identify the lipids difference between liver samples from CD36-engineered models.

Results: CD36 does not significantly influence liver development or regeneration following partial hepatectomy in zebrafish. During liver regeneration, CD36 expression peaks in the acute phase and returns to baseline within seven days. In MASLD models, CD36 levels remain elevated compared to controls, with increased localization to hepatocyte membranes correlating with lipid accumulation. Compared with the wild-type controls, both systemic knockdown and hepatic overexpression of CD36 result in higher hepatic cholesterol and triglyceride levels in the liver, alongside increased expression of inflammatory cytokines (il1b, tnf, il6) but no significant difference in cellular apoptosis. In vitro studies with primary hepatocytes treated with fatty acids reveal that CD36 knockdown cells accumulate more lipids and exhibit elevated ALT and AST levels, whereas CD36 overexpression reduces lipid droplets and enzyme levels, compared with the wild-type controls. LC-MS and MSI analyses consistently demonstrated that CD36 overexpression increases triglycerides while decreasing diacylglycerol levels compared to knockdown models. **Conclusions:** Our data suggest that CD36 has increased expression during acute injury and MASLD. Under persistent metabolic overload, hepatic CD36 appears to help attenuate the accumulation of toxic lipids, and its absence cannot attenuate the steatosis injury.

Keyword(s) : CD36, metabolic dysfunction-associated steatotic liver disease, hepatocytes, lipid accumulation, liver injury.

2315 - Epidemiological and clinical characteristics of hepatocellular carcinoma a 10 year registry from tertiary private cancer centre hospital

Cathleen Kenya¹, Cosmas Rinaldi Adithya Lesmana¹
Mrccc Siloam Hospital Semanggi, Department Of Gastrointestinal Cancer Center, Bekasi-Indonesia¹

Background: Hepatocellular carcinoma (HCC) is the sixth most prevalent cancer and the third leading cause of cancer-related mortality worldwide. HCC accounts for approximately 85–90% of primary liver cancers, followed by intrahepatic cholangiocarcinoma. This study aimed to describe the epidemiological profile and clinical characteristics of HCC patients registered at MRCCC Siloam Hospital Semanggi, Indonesia, over a ten-year period (2013–2022).

Materials and Methods: We conducted a retrospective registry-based analysis of 326 patients diagnosed with HCC between 2013 and 2022. Data collected included demographics (age, sex), performance status (ECOG), etiology of liver disease, imaging findings (tumor size, multifocality, vascular invasion), tumor stage (BCLC, Child–Pugh), type of treatment received and patient follow-up status. Missing or unavailable data were recorded as “unknown.” Descriptive statistics summarized patient characteristics, with categorical variables presented as counts. Trends over the decade were explored for etiology and treatment allocation.

Results: Among 326 patients, most were male (n=248), and the most prevalent age group was ≥65 years. The majority presented with ECOG performance status 3, although some data were missing. HBV was the predominant etiology (n=100), followed by HCV (n=30), NAFLD (n=15), others (n=15), alcohol (n=4) and autoimmune (n=1); a significant proportion of etiology data was unknown. Child–Pugh class A was observed in 33 patients, with remaining data missing. BCLC stages C and D were equally represented (n=28), followed by BCLC stage B (n=19). From imaging finding tumor size >5 cm was observed in 127 patients; 97 patients had multifocal lesions, while 93 had no vascular invasion. Treatments included systemic therapy; bevacizumab (n=11), atezolizumab (n=10), pembrolizumab (n=11), nivolumab (n=2), sorafenib (n=16) and lenvatinib (n=63); open surgery (n=25), radiation therapy (n=14), ablative therapy (n=19),

E-POSTER ABSTRACTS

Transarterial Chemoembolization (TACE)(n=80) and liver transplantation (n=2). Most patients were lost to follow-up due to multifactorial reasons.

Conclusions: This ten-year registry provides real-world insights into the epidemiology and clinical characteristics of HCC patients in Indonesia. HCC was more common in males, with HBV remaining the predominant etiology. Treatment patterns reflected tumor characteristics and patient condition, while trends over the decade highlight evolving etiological profiles and therapeutic approaches. These findings offer valuable regional data to inform HCC management strategies and future outcome studies.

Keyword(s) : Hepatocellular carcinoma, HCC, HBV, HCV

2316 - Precision ablation with nanosecond pulsed electric field (nsPEF) in early hepatocellular carcinoma a phase I trial integrating multi omics analysis

Haiyu Wang¹, Shanshuo Liu¹, Benchao Rao¹, Zecheng Yang¹, Zujang Yu¹, Zhigang Ren¹
The First Affiliated Hospital Of Zhengzhou University,
Department Of Infectious Diseases, Zhengzhou-China¹

Background / Hypothesis:

Nanosecond pulsed electric field (nsPEF) is a promising non-thermal ablation for hepatocellular carcinoma (HCC) in high-risk locations, yet its long-term efficacy and systemic effects remain unclear.

Materials and Methods:

In this pre-specified sub-analysis of a multicenter Phase I clinical trial, we recruited 61 early-stage HCC patients from our center. Extended follow-up and longitudinal multi-omics were performed to assess survival benefits and systemic responses post-ablation.

Results:

Results showed 100% technical success and an initial (1-month) complete ablation response rate of 88.14%. The 1-, 2-, and 3-year actuarial overall survival (OS) rates were 98.18%, 88.89%, and 76.47%, respectively, and the actuarial progression-free survival (PFS) rates were 84.78%, 73.91%, and 62.86%. Most adverse events were grade 1 (97.12%). Multi-omics analysis revealed preoperative enrichment of opportunistic pathogens (e.g., *Massilia* and *Brevundimonas*) in oral and gut microbiota, with postoperative increases in beneficial SCFA-producing bacteria (e.g., *Bacteroides* and *Blautia*). Metabolomics analysis further revealed

significant improvements in the pathways related to energy, amino acid and lipid metabolisms after surgery. Importantly, we found that patients' pre-operative (baseline) microbial and metabolic profiles were associated with treatment response, as those with more favorable profiles achieved significantly higher rates of complete ablation (CR). Building on these findings, we developed a Cox model integrating microbiome, metabolome, and clinical data, with the fecal microbiome-based model performing best (AUCs of 0.802 and 0.822 at 6 and 12 months, respectively).

Conclusions:

This study establishes for the first time that local nsPEF ablation induces dynamic, systemic remodeling of the gut microbiome and plasma metabolome, and pre-ablation multi-omics features are potent predictors of treatment outcome, providing a crucial rationale for personalizing nsPEF therapy and exploring novel microbiome-targeting adjuvant interventions.

Keyword(s) : Nanosecond pulsed electric field (nsPEF), Nonthermal ablation, Hepatocellular carcinoma, Multi-omics, Microbiome, Metabolomics, Prognostic prediction model

2317 - The identification of a novel compound suppressing the early stages of Hepatitis B Virus (HBV) infection

Esraa Kamal¹, Abdulla A. Mahmoud¹, Masanori Isogawa¹, Meng Ling Moi², Hussein H. Aly¹
Japan Institute Of Health Security, Department Of Virology Ii, National Institute Of Infectious Diseases, Tokyo-Japan¹ The University Of Tokyo, School Of International Health, Tokyo-²

Background / Hypothesis:

Hepatitis B virus (HBV), an enveloped DNA virus from the Hepadnaviridae family, constitutes a global health problem. As per World Health Organization estimates, HBV has infected nearly 2 billion individuals worldwide, with approximately 257 million suffering from chronic hepatitis B (CHB). Although current antiviral therapies, including nucleos(t)ide analogues (NAs) and pegylated interferon-alpha (PEG-IFN- α), can effectively suppress viral replication, they rarely achieve a functional cure due to the persistence of covalently closed circular DNA (cccDNA) and integrated DNA (iDNA) in infected hepatocytes. Hence, the urgent need for more effective therapeutic options.

Materials and Methods:

Walking in this direction, we conducted a high-throughput screening of 948 featured novel bioactive

E-POSTER ABSTRACTS

compounds to assess their antiviral activity against HBV. Only one compound (X) meets the selection criteria (more than 5 times suppression of HBV-DNA (extracellular and Intracellular), without affecting the cellular viability.

Results:

Compound X treatment of HBV-infected cells showed a potent decrease in the viral proteins (HBeAg and HBsAg).

Conclusions:

This compound is a promising candidate as novel anti-HBV compound. Further mechanistic and functional investigation are undergoing in vitro/in vivo and will be presented.

Keyword(s) : Hepatitis B virus, HBV, compound screening

2319 - The Cancer Cell Hepatocyte Interface in Colorectal Cancer Liver Metastasis Mechanisms and Clinical Translation

Shaodong Li¹, Tong Chen¹, Junzhe Jiao², Ruijuan Yan², Xi Guan², Ri Zhao¹, Zhanjie Chang², Jingtao Li², Haibo Zhang²

Shaanxi University Of Chinese Medicine, First School Of Clinical Medicine, Xianyang-China¹ Hospital Of Shaanxi University Of Chinese Medicine, Hepatology Hospital Affiliated Hospital Of Shaanxi University Of Chinese Medicine, Shaanxi-China²

Background / Hypothesis:

Colorectal cancer liver metastasis is a leading cause of death in patients with colorectal cancer. Growing evidence indicates that the cancer cell–hepatocyte interface constitutes a critical niche that integrates multiple functions, including growth patterns, vascular supply, metabolic processes, and immune evasion. We hypothesize that molecular events occurring at this interface—including transforming growth factor beta (TGF β) driven hepatocyte remodeling and hepatocyte derived exosomes—may explain clinical heterogeneity and reveal novel therapeutic targets.

Materials and Methods:

We conducted a narrative review of experimental and clinical studies retrieved from PubMed and Web of Science. We focused on histopathological growth patterns, molecular pathways regulating hepatocyte injury and remodeling, metabolic and exosomal crosstalk between hepatocytes and tumors, and specifically highlighted studies of clinically annotated

colorectal cancer liver metastasis cohorts that link interface biology to treatment response or prognosis.

Results:

Desmoplastic and replacement growth patterns define two distinct cancer cell–hepatocyte interfaces, which are strongly associated with patient outcomes and sensitivity to anti angiogenic therapy. The replacement growth pattern involves vascular co option, TGF β dependent hepatocyte apoptosis or partial epithelial mesenchymal transition, and profound remodeling of glucose and amino acid metabolism. Hepatocyte derived exosomes, particularly those regulated by Golgi phosphoprotein 73 (GOLPH3) in metabolic liver disease, enhance the migration, invasion, and hepatic seeding capacity of colorectal cancer cells, and shape an immunosuppressive pre metastatic niche conducive to liver dissemination and outgrowth.

Conclusions:

The cancer cell–hepatocyte interface is a central determinant of vascular strategy, metabolic adaptation, and immune evasion in colorectal cancer liver metastasis. Standardized reporting of growth patterns, combined with interface focused molecular biomarkers, may improve risk stratification and guide integrated therapeutic strategies that target both tumor cells and hepatocytes through combined anti angiogenic, metabolic, and immunomodulatory approaches.

Keyword(s) : Colorectal cancer; Liver metastasis; Cancer cell–hepatocyte interface; Vascular co option; Transforming growth factor beta (TGF β); Golgi phosphoprotein 73 (GOLPH3); Exosomes; Pre metastatic niche

2321 - A novel prognostic model to predict mortality in patients with drug induced liver injury in intensive care unit a study from Pakistan

Farhana Kayani¹, Jalal Khan², Shahab Abid³

Bolan Medical College, Gastroenterology, Quetta-Pakistan¹ Bolan Medical College, Medicine, Quetta-Pakistan² Aga Khan University, Gastroenterology, Karachi-Pakistan³

Background&Aim:

DILI is one of the causes of acute liver injury leading to increased mortality rates&usually requires intensive care unit(ICU)admission,however it is uncommon&often challenging to diagnose DILI.Proper prognosis for these patients is crucial for early referral

E-POSTER ABSTRACTS

for liver transplantation. In light of paucity of data on DILI especially from South East Asia, this study aims to evaluate the clinical spectrum and predictors of mortality in ICU admitted patients with suspected DILI by building & validating a novel scoring system

Methods:

531 cases were identified and categorized on the basis of COIMS/RUCAM score¹ and exclusion of other liver diseases from 2010-2024. Ratio (R value) between ALT (Alanine transferase) & AP (alkaline phosphatase) expressed as

$R > 5$; hepatocellular, $R < 2$; cholestatic, & $R > 2 < 5$; mixed. Clinical & laboratory parameters were analyzed to identify the predictors of hospital mortality. The prognostic values for mortality were assessed by ROC analysis. A novel model was developed and internally validated using fivefold cross-validation.

Results:

Out of 531 patients, there were 333 (62.7%) males with the mean age being 50.83 years (range, 20-94 years). DILI was classified as definite or highly probable in 31.1%, probable in 62.5%, and possible in 7.4% of cases. Pattern of liver injury was hepatocellular in 25.1%, cholestatic in 56.17% and mixed in 18.72% of patients. Mean total bilirubin levels, ALT and AP levels were 5.37 mg/dl, 358.65 IU/L and 168.68 IU/L respectively.

Antituberculous (ATT) drugs were found to be the most common cause (63.9%) followed by homeopathic or herbal meds (9.5%), antiarrhythmic drugs (8.7%), statins (7.3%), antibiotics (6.1%), antifungals (5.6%), chemotherapeutic agents (4.4%) and antiepileptics (1.7%). Altered mental status was present in 142 (26.7%) of patients while rest presented with abdominal pain, vomiting, jaundice & pruritus; 57.1%, 57.1%, 54.1%, and 42.3% respectively.

In-hospital mortality was 26.5% and prolonged hospital stay was observed in 35.93% of patients. On multivariate analysis, mortality was significantly greater in patients with altered mental status, male gender, increased age, hepatocellular pattern of DILI, increased INR (> 1.5), increased bilirubin levels (> 3 mg/dl) & arterial gradient (A-a gradient). The newly developed prognostic model, incorporating age, gender, pattern of liver injury, alveolar-arterial gradient (A-a gradient), INR, total bilirubin level, INR, and HE grades, exhibited significantly improved performance in predicting 1-month and 3-month mortality with AUROC of 0.863 0.829, respectively. Likewise, prolonged hospital stay was associated with female gender, increased ALT, AST aspartate aminotransferase levels, and mixed pattern of DILI

Conclusion:

DILI leads to increased mortality, & use of this prognostic model predicting mortality in patients with drug-induced liver injury in intensive care unit can be useful. However, further rigorous validation is required in other liver-related ICUs.

Keyword(s) : DILI

2322 - Gut Microbiota Modulation on Non Alcoholic Fatty Liver Disease Progression A Systematic Review and Meta Analysis from Human Trials

Saul Suaybaguio¹, Sarah Preza¹, Marilyn Te¹
East Avenue Medical Center, Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Non-alcoholic fatty liver disease (NAFLD) is a growing global health concern with limited treatment options. Gut microbiota dysbiosis has been implicated in NAFLD pathogenesis. This systematic review and meta-analysis aimed to evaluate the effects of gut microbiota modulation strategies on NAFLD progression.

Materials and Methods:

We included randomized controlled trials and prospective cohort studies involving adults and children with NAFLD/NASH receiving probiotics, prebiotics, synbiotics, antibiotics, fecal microbiota transplantation (FMT), or farnesoid X receptor (FXR) agonists compared to placebo or standard care. PubMed, EMBASE, CENTRAL, and ClinicalTrials.gov were searched until March 15, 2025. Risk of bias was assessed using the Cochrane RoB 2.0 tool. A random-effects model synthesized continuous outcomes as mean differences (MD) with 95% confidence intervals (CI).

Results:

Forty studies involving 3,415 participants were included. Probiotics/prebiotics/synbiotics, antibiotics, FMT, and FXR agonists significantly improved liver enzymes (ALT MD: -11.49 U/L, 95% CI: -14.69 to -8.30; AST MD: -5.95 U/L, 95% CI: -6.52 to -5.38). Gut microbial diversity also improved. Heterogeneity was moderate to high across outcomes. Risk of bias was low to some concerns for most studies. Adverse events were mild and infrequent across interventions.

Conclusions:

E-POSTER ABSTRACTS

Gut microbiota modulation offers a promising therapeutic avenue for improving liver biochemistry and metabolic parameters in NAFLD, although heterogeneity and moderate certainty of evidence warrant cautious interpretation. Larger, standardized trials are needed.

Keyword(s) :

2323 - RNAi Therapies for HBsAg Reduction in Chronic Hepatitis B A Systematic Review and Meta Analysis of Early Phase Trials

Saul Suaybaguio¹, Sarah Preza¹, Marilyn Te¹
East Avenue Medical Center, Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Chronic hepatitis B (CHB) remains a major global health burden, with current nucleos(t)ide analogue (NA) therapy achieving functional cure in less than 5% of patients. RNA interference (RNAi)-based therapeutics have emerged as a promising strategy by directly silencing hepatitis B surface antigen (HBsAg) expression. This systematic review and meta-analysis evaluated the efficacy, safety, and early antiviral responses associated with RNAi therapies across Phase I-II human trials.

Materials and Methods:

We included Phase I-II clinical trials evaluating RNAi or antisense oligonucleotide agents (e.g., ARC-520, ARB-1467, VIR-2218, JNJ-3989, RG6346, ALG-125755) in adults with chronic hepatitis B. Studies were eligible if they reported quantitative HBsAg outcomes, responder proportions, adverse events, ALT flares, or post-treatment follow-up. Searches of PubMed, EMBASE, CENTRAL, ClinicalTrials.gov, WHO ICTRP, EudraCT, Web of Science, and conference abstracts (AASLD, EASL, APASL) were conducted up to February 2025. Risk of bias was assessed using RoB 2 and ROBINS-I. A random-effects model generated pooled mean differences (MD) and proportions with 95% confidence intervals (CI).

Results:

Ten studies met the inclusion criteria. RNAi therapy produced a significant reduction in HBsAg, with a pooled mean change of $-1.47 \log_{10}$ IU/mL (95% CI: -1.58 to -1.36). The pooled proportion of participants achieving $\geq 1 \log_{10}$ HBsAg reduction was 0.79 (95% CI: 0.63–0.90). ALT flares occurred in 0.66 of patients (95%

CI: 0.48–0.81), predominantly among VIR-2218 combination cohorts. Treatment-emergent adverse events were common but mostly mild, with a pooled incidence of 0.57 (95% CI: 0.46–0.67). Serious adverse events were rare (0.022, 95% CI: 0.006–0.078). None of the included studies provided extractable data on durability of HBsAg suppression, limiting long-term assessment. Additional early-phase studies identified in the systematic review demonstrated antigen declines but lacked complete numerical data for meta-analysis. Overall risk of bias ranged from low to some concerns.

Conclusions:

RNAi therapies demonstrate potent short-term antiviral activity in CHB, achieving meaningful reductions in HBsAg and high responder rates across multiple agents. Although ALT flares were frequent, they were generally self-limited and aligned with immune-reactivation profiles. Safety signals were acceptable across all studies. However, the absence of durability data prevents conclusions regarding sustained off-treatment responses. Standardized reporting and longer follow-up in Phase II–III trials are urgently needed to confirm whether RNAi-mediated antigen suppression can progress toward functional cure.

Keyword(s) :

2324 - Association of Serum Amylase and Lipase with Clinical Outcomes of Leptospirosis Patients at a Philippine Tertiary Government Hospital A Retrospective Cohort Study

Saul Suaybaguio¹, Sarah Preza¹, Marilyn Te¹
East Avenue Medical Center, Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Leptospirosis is a major public health concern, especially in the Philippines. Nonetheless, local studies on this disease remain limited. Moreover, very few studies examined the prognostic role of pancreatic enzymes.

Materials and Methods:

This retrospective cohort study included all 492 adult patients with confirmed diagnosis of leptospirosis admitted from 2021 to 2024, and with available amylase and lipase values. Firth's bias-reduced logistic regression analysis was performed to determine the association of amylase and lipase with in-hospital mortality.

E-POSTER ABSTRACTS

Results:

The median age was 34 years, and most were males. All were febrile, and the median duration of symptoms was 5 days. Elevated amylase and lipase were recorded in 60% and 26% of patients. Most patients had severe leptospirosis (71%), underwent renal replacement (59%), and had prolonged length of hospital stay (65%). The incidence of in-hospital mortality was 17.28% (95% CI: 14.04-20.91%). Elevated amylase level was significantly associated with all clinical outcomes except in-hospital mortality and myocarditis (all $p \leq 0.05$). Meanwhile, elevated lipase was only associated with severe leptospirosis, acute pancreatitis, renal replacement, and prolonged length of hospital stay (all $p \leq 0.05$). Multivariable analysis revealed that elevated amylase ($aOR=0.18; p=0.132$) and lipase ($aOR=2.40; p=0.345$) were not associated with in-hospital mortality.

Conclusions:

Increased amylase and lipase levels were observed in most admitted leptospirosis patients and were associated with most clinical outcomes related to disease severity. However, pancreatic enzymes were not associated with mortality.

Keyword(s) :

2325 - Rabdosis Rubescens Inhibits Toll Like Receptor 4 Dependent Helper T Lymphocytes Infiltration in the Liver of Type 2 Diabetes Associated Metabolic Dysfunction Associated Steatohepatitis Mice

Ning Yao¹, Xin Wang^{* 2}, Wei Wei¹, Yan Su², Ying Su¹, Fengxiang Fang², Yajuan Geng¹, Xinxin Su¹
Gansu University Of Chinese Medicine, The First School Of Clinical Medicine, Lanzhou City-China¹ Gansu University Of Chinese Medicine, College Of Integrative Chinese And Western Medicine, Lanzhou City-China²

Background/Hypothesis:

The global prevalence of T2DM-associated MASH is rising, constituting a major public health challenge. A central immunopathological hallmark of T2DM-associated MASH is the intrahepatic infiltration and activation of Th17, driving disease progression. *Rabdosis rubescens* has demonstrated potential in alleviating hepatic steatosis and improving liver function in MASH models, yet its precise mechanism of

action remains elusive. This study was therefore designed to test the hypothesis that the hepatoprotective effect of *Rabdosis rubescens* against T2DM-associated MASH is mediated, at least in part, by suppression of TLR4-dependent pathogenic Th17 infiltration into the liver.

Materials and Methods:

A T2DM-associated MASH model was established in two-day-old male C57BL/6J mice via a streptozotocin (STZ)-high-fat diet (HFD) protocol. Briefly, neonatal mice received a subcutaneous injection of STZ. At 4 weeks of age, they were switched to an HFD for 6 weeks. Starting from week 5, mice were randomly allocated into four groups for the 4-week intervention period: (1) Normal control (NC; normal diet+vehicle), (2) model group (MG; HFD+vehicle), (3) *Rabdosis rubescens* group (RG; HFD+*Rabdosis rubescens* decoction via oral gavage), (4) lipopolysaccharide (LPS) group (LG; HFD+vehicle+weekly intraperitoneal injections of LPS), and (5) *Rabdosis rubescens*+LPS group (RLG; HFD+*Rabdosis rubescens*+weekly intraperitoneal injections of LPS). Mice in the other groups received weekly normal saline injections.

Results:

Compared with NG, the MG exhibited characteristic histopathological alterations, including hepatocellular vacuolar degeneration and inflammatory cell infiltration, accompanied by a significantly higher NAFLD Activity Score. Serum levels of ALT, AST, GGT, TG, and hepatic TG, TNF- α , and IL-17 were all markedly elevated in the MG (all $p < 0.005$). As expected, lipopolysaccharide (LPS) challenge in the LG exacerbated these injury markers compared to the MG ($p < 0.005$). *Rabdosis rubescens* effectively attenuated the hepatic injury in the RG, as evidenced by significant improvements in all aforementioned biochemical and inflammatory indices versus the MG ($p < 0.001$). Notably, in mice of the RLG, the herbal treatment significantly counteracted LPS-induced exacerbation of liver injury ($p < 0.005$ vs. LG). Consistent with the functional improvement, immunohistochemical analysis demonstrated a significant reduction in the intrahepatic proportion of Th17 cells in the RLG compared to the LG. This reduction was further supported by a significant decrease in IL-17A levels within liver tissue homogenates ($p < 0.001$).

Conclusions:

E-POSTER ABSTRACTS

Our findings demonstrate that the hepatoprotective effect of *Rabdosia rubescens* against T2DM-associated MASH is mediated through the suppression of TLR4-dependent intrahepatic Th17 infiltration and IL-17A production at least in part.

*Corresponding Author: Xin Wang.

This study was supported by the Higher Education Innovation Foundation Project of Gansu Provincial Department of Education (2021B-173).

Keyword(s) : *Rabdosia Rubescens*, TLR4, Th17, T2DM, MASH

2327 - Impact of Metabolic Dysfunction–Associated Fatty Liver Disease on Severity and Recovery of Drug Induced Liver Injury Experience from a Pakistani Cohort

Farhana Kayani¹, Jalal Khan²

Bolan Medical College, Gastroenterology, Quetta-Pakistan¹ Bolan Medical College, Medicine, Quetta-Pakistan²

Background / Hypothesis:

Drug-induced liver injury (DILI) is a leading cause of acute liver dysfunction worldwide. South Asia has a high and rapidly rising burden of metabolic dysfunction–associated fatty liver disease (MAFLD), which may influence the severity and clinical course of DILI. However, data evaluating the interaction between MAFLD and DILI outcomes are limited from the region. To evaluate the effect of underlying MAFLD on disease severity, clinical course, and recovery outcomes in patients presenting with DILI in Pakistan.

Materials and Methods:

We conducted a retrospective/prospective observational study of adult patients diagnosed with DILI at a tertiary care center in Pakistan between 2015–2025. DILI was defined using international consensus criteria and causality was assessed by RUCAM/COIMS. MAFLD was diagnosed based on imaging evidence of fatty liver and non-invasive workup, including FIB4 and APRI with metabolic risk factors. Patients were categorized into MAFLD and non-MAFLD groups. Primary outcomes included DILI severity (peak ALT, bilirubin, INR, Hy's law) and time to biochemical recovery. Secondary outcomes included hospitalization duration, development of acute liver failure, and mortality.

Results:

Among 533 patients with confirmed DILI 321 patients had underlying MAFLD. Patients with MAFLD

presented with significantly higher peak ALT (median 1200 vs 780 IU/L; $p < 0.05$) and bilirubin levels (median 23 vs 12 mg/dL; $p < 0.01$) compared to non-MAFLD patients. Severe DILI occurred more frequently in the MAFLD group (88% vs 52%, $p < 0.01$), with a higher proportion meeting Hy's law criteria. Time to normalization of liver enzymes was significantly longer in MAFLD patients (median 15 vs 5 days, $p < 0.01$). On multivariable analysis, MAFLD independently predicted severe DILI (adjusted OR 1.8, 95% CI 1.2–2.7), $p = 0.004$

Conclusions:

Underlying MAFLD was associated with increased severity and delayed recovery in patients with DILI among south asian patients. Given the high burden of metabolic disease in the region, recognition of MAFLD as a risk modifier for DILI is crucial. Early identification and closer monitoring of MAFLD patients exposed to potentially hepatotoxic drugs may improve clinical outcomes.

Keyword(s) : DILI, MAFLD

2330 - Dietary omega 3 and omega 6 Polyunsaturated Fatty Acid Intake and Mortality Among Individuals with Metabolic Dysfunction Associated Steatotic Liver Disease A Prospective Cohort Study

Jialu Yang¹, Binbin Xu¹, Hua Yu¹, Hongshan Li²

Ningbo No. 2 Hospital, Department Of Clinical Nutrition, Zhejiang-China¹ Ningbo No. 2 Hospital, Liver Disease Department Of Integrative Medicine, Zhejiang-China²

Background / Hypothesis: Evidence from large cohort studies on the impact of dietary polyunsaturated fatty acids (PUFAs) on mortality among patients with metabolic dysfunction-associated steatotic liver disease (MASLD) is limited. We aimed to investigate the associations of omega-3 and omega-6 PUFA intake with all-cause and cardiovascular disease (CVD) mortality in MASLD, and to identify potential dietary thresholds for mortality reduction.

Materials and Methods: A total of 5,694 participants with MASLD at baseline [weighted 57.3% male; mean (SD) age 50.5 (0.35) years] were included from the National Health and Nutrition Examination Survey (1999–2018). Hepatic steatosis was defined by the United States Fatty Liver Index. Dietary intake was assessed via 24-hour dietary recalls. Mortality was ascertained through linkage to the National Death Index through December 31, 2019. Associations of

E-POSTER ABSTRACTS

dietary omega-3 PUFA and omega-6 PUFAs with all-cause and CVD mortality were evaluated using Kaplan-Meier curves, weighted Cox proportional hazards models, and restricted cubic splines.

Results: During a median follow-up of 9.2 years (IQR 4.8-13.5), 981 deaths occurred, including 340 due to CVD. Kaplan-Meier analysis showed that higher intakes of total omega-3 and omega-6 PUFAs were associated with lower all-cause and CVD mortality (log-rank $P < 0.05$). After adjustments for demographics, lifestyle factors, hypertension, diabetes, body mass index and total energy intake, higher intake of alpha-linolenic acid (ALA), eicosapentaenoic acid (EPA) and docosapentaenoic acid (DPA) was associated with 20% (HR 0.80, 95% CI 0.67-0.95), 17% (HR 0.83, 95% CI 0.71-0.98), and 19% (HR 0.81, 95% CI 0.68-0.96) lower risk of all-cause mortality, respectively (all $P < 0.05$), whereas associations with CVD mortality were not statistically significant. Total omega-6 PUFA and linoleic acid showed linear associations with all-cause mortality (P for linear < 0.05). ALA demonstrated both linear and modest non-linear associations (both $P < 0.05$), indicating a generally consistent protective effect across intake levels. Notably, EPA and DPA exhibited non-linear relationships, reaching maximal protective effects at intake thresholds of 0.125 g/day and 0.021 g/day, respectively (P for non-linearity < 0.05).

Conclusions: In this prospective cohort of MASLD patients, higher dietary intake of omega-3 PUFAs, particularly ALA, EPA, and DPA, was associated with reduced all-cause mortality. ALA demonstrated a generally linear protective effect, while EPA and DPA showed threshold-dependent maximal benefits, highlighting potential dietary targets for mortality reduction in this high-risk population. These findings provide actionable insights for nutritional strategies and future interventional studies in MASLD.

Keyword(s) : MASLD, Polyunsaturated fatty acid, Mortality, Prospective cohort study, ALA, EPA, DPA

2331 - Prognosis of ursodeoxycholic acid treated patients with primary biliary cholangitis A single center cohort study from China

Qin Xiao¹, Sha Chen¹, Shuxiang Li¹, Tingting Lv¹, Weijia Duan¹, Jidong Jia¹
Beijing Friendship Hospital, Capital Medical University, Liver Research Center, Beijing-China¹

Background / Hypothesis: Primary biliary cholangitis (PBC) is a rare disease characterized by intrahepatic

cholestasis. This study aims to characterize the baseline profile, treatment response to ursodeoxycholic acid (UDCA), and long-term outcomes of patients with primary biliary cholangitis (PBC) in a Chinese population.

Materials and Methods: We retrospectively reviewed medical records of PBC patients and conducted regular follow-up assessments. The endpoints were defined as liver-related death and/or liver transplantation (LT). Hepatic events including decompensation and hepatocellular carcinoma were recorded. Deep response was defined as normalization of alkaline phosphatase (ALP) after 1 year treatment of UDCA.
Results: A total of 1,326 PBC patients with complete baseline information and at least one year of follow-up were included in this study. Unsurprisingly, compared with non-cirrhotic PBC patients ($n=1026$), cirrhotic PBC patients ($n=300$) exhibited more severe disease at baseline (Table 1). Overall, the biochemical response rates according to the POISE, Paris I, Paris II, and deep response criteria were 83.2%, 60.3%, 52.8%, and 50.9%, respectively. The biochemical response rates in non-cirrhotic patients at baseline were significantly higher than that in cirrhotic patients, and this finding was independent of the response criteria applied. During a median follow-up of 4.83 years, 139 individuals experienced LT or liver-related death. Out of 1192 PBC patients without decompensation at baseline, 198 experienced hepatic events. Overall, the 5-year, 10-year, and 15-year transplant-free survival rates were 93.1%, 82.4%, and 70.1%, respectively. Responders, identified by either the POISE criteria (Fig. 1A, B) or the deep response criteria (Fig. 1C, D), showed significantly higher transplant-free survival and a lower incidence of hepatic events compared to non-responders.

Conclusions: This large-scale cohort delineates the characteristics and prognosis of the Chinese PBC population. Cirrhotic patients exhibited a significantly lower biochemical response rate compared to non-cirrhotic patients. Patients achieving a favorable response showed markedly better survival outcomes than those with a poor response.

2332 - Hepatocellular carcinoma without cirrhosis in Australasia an under represented but high risk population

Aparna Morgan¹, Angela Zhu¹, Nicholas Hannah¹, James Haridy¹, Ashok Raj¹, Neeraj Bhala¹
The Royal Melbourne Hospital, Gastroenterology And

E-POSTER ABSTRACTS

Hepatology, Parkville-Australia ¹

Background / Hypothesis:

Hepatocellular carcinoma (HCC) occurring in the absence of cirrhosis represents a clinically important proportion of liver cancer globally. However, contemporary reviews of non-cirrhotic HCC epidemiology have largely excluded data from Australasia, limiting representation of regions with distinct demographic profiles and risk factor distributions. Australia and New Zealand include substantial Indigenous (Aboriginal and Torres Strait Islander peoples, Māori, and Pasifika) and migrant populations with a high burden of chronic hepatitis B (CHB) and rapidly increasing metabolic dysfunction-associated steatotic liver disease (MASLD). We aimed to summarise contemporary Australasian epidemiology of non-cirrhotic HCC and highlight implications for surveillance.

Methods:

We synthesised published epidemiological data from Australian and New Zealand cohort studies, national surveillance reports, and clinical guidelines describing the prevalence, aetiology, and incidence of non-cirrhotic HCC across key aetiologies.

Results:

Non-cirrhotic HCC accounts for approximately 17–43% of all HCC cases in Australia and New Zealand. In a large Australian multicentre cohort (2008–2021), CHB was the leading aetiology of non-cirrhotic HCC (36%), followed by MASLD (28%), unknown aetiology (23%), hepatitis C virus infection (12%), and alcohol-related liver disease (10%). Among individuals with CHB, annual HCC incidence without cirrhosis was 0.4–0.6% in Asian men aged >40 years and 0.3–0.6% in Asian women aged >50 years. For Aboriginal and Torres Strait Islander peoples aged >50 years with CHB, incidence was estimated at 0.36–0.9%. Over 70% of people living with CHB in Australia were born overseas, with 46% born in Asia and 4.3% born in sub-Saharan Africa, though incidence data for non-cirrhotic HCC in African-born populations are lacking. HBV genotype diversity reflects Australia's migrant profile, with genotypes B and C predominating among Asian migrants and genotype D among European and Aboriginal populations. MASLD prevalence is rising rapidly, with 5.7 million affected Australians in 2020 and MASLD-associated HCC projected to increase by 75% by 2030. Recent data indicate that 31% of MASLD-related HCC occurs in non-cirrhotic livers. Data on non-cirrhotic HCC among Pasifika peoples remain

limited and are largely derived from migrant cohorts.

Conclusions:

Australasian populations contribute important and distinct epidemiological insights into non-cirrhotic HCC risk. Omission of this region from global syntheses perpetuates geographic bias and risks under-informing surveillance strategies. Addressing this deficit is essential for a truly global understanding of HCC and equitable guideline development across the Asia Pacific region.

Keyword(s) : non-cirrhotic HCC, Australasia, Pacific

2333 - Evaluation of Liver Fibrosis Before and After Treatment of Chronic Hepatitis B

Manal Cherkaoui Malki ¹, Ikram Errabih ¹, Salma Mechhor ¹, Omeima Cherkaoui El Malki ¹, Nadia Benzoubeir ¹, Hicham El Bacha ¹

Ibn Sina Hospital, Hepatology And Gastroenterology, Rabat-Morocco ¹

Background / Hypothesis:

Chronic hepatitis B (CHB) is a viral infection affecting nearly 296 million people worldwide and remains a major cause of morbidity and mortality. Without treatment, the disease may progress silently to fibrosis, cirrhosis, and hepatocellular carcinoma. Fibrosis staging is a key determinant of prognosis and is essential for therapeutic decision-making. Current antiviral therapies not only suppress viral replication but also slow, and in some cases reverse, the progression of fibrosis. This study aimed to evaluate the impact of antiviral therapy on liver fibrosis before and after treatment initiation in patients with CHB.

Materials and Methods:

This retrospective, analytical, monocentric study was conducted in the Department of Hepato-Gastroenterology at Ibn Sina University Hospital over a five-year period from August 2020 to August 2025. We included all patients with chronic hepatitis B who were started on antiviral therapy, had regular follow-up, and presented with fibrosis stage $\geq$ F2. Patients without treatment indication, those lost to follow-up, and those with F0–F1 fibrosis or decompensated cirrhosis were excluded. Fibrosis assessment before and during treatment was performed using liver biopsy or FibroScan. Paired comparisons of fibrosis staging before versus after treatment were analyzed using the Wilcoxon test. Statistical analysis was performed using

E-POSTER ABSTRACTS

SPSS, with significance set at $p < 0.05$.

Results:

Eighty-two patients with chronic hepatitis B were included, with a mean age of 55.9 ± 12.4 years; 42.6% were men and 57.3% were women. Most patients were treated with Tenofovir (79.3%), while 20.7% received Entecavir. Before treatment, fibrosis assessment was performed using FibroScan in 75.6% of cases and liver biopsy in 24.4%. After treatment, FibroScan was used in 95.1% of cases and biopsy in 4.9%. At baseline, fibrosis stages were distributed as follows: F2 in 47.5%, F3 in 21.9%, and F4 in 30.5% of patients. Following treatment, there was an overall improvement, with an increase in F0–F1 stages (24.4%), a decrease in F2 (30.5%) and F3 (14.6%), while F4 remained unchanged at 30.5%. Statistical analysis showed a significant reduction in F2 after treatment ($p = 0.037$), a non-significant decrease in F3 ($p = 0.313$), and no change in F4 ($p = 1.000$). Overall, the Wilcoxon test demonstrated a significant improvement in fibrosis staging after therapy ($p < 0.001$), with the median fibrosis stage decreasing from F2 to F1.

Conclusions:

This study demonstrates a significant improvement in liver fibrosis among chronic hepatitis B patients receiving antiviral therapy. Tenofovir and Entecavir confirmed their therapeutic efficacy, particularly in the regression of intermediate

Keyword(s) : fibrosis, hepatitis B, evaluation

2334 - US guided liver biopsy Fine needle aspiration versus semi automatic cutting needle

Manal Cherkaoui Malki¹, Ikram Errabih¹, Salma Mechhor¹, Omeima Cherkaoui El Malki¹, Nadia Benzoubeir¹, Hicham El Bacha¹

Ibn Sina Hospital, Hepatology And Gastroenterology, Rabat-Morocco¹

Background / Hypothesis:

Despite advances in Endoscopic UltraSound and transjugular approaches, percutaneous liver biopsy remains essential and continues to be the gold standard for the diagnosis and prognostic assessment of liver diseases. Several sampling devices are available, particularly the aspiration needle and the cutting needle, which allows mechanical coring of hepatic tissue. This study aims to compare the diagnostic yield and tolerability of these two techniques.

Materials and Methods:

We conducted a prospective descriptive study including all percutaneous liver biopsies performed under ultrasound guidance between January 2025 and November 2025 in the Department of Gastroenterology and Proctology, Medicine B. Biopsy quality was defined by the presence of ≥ 7 portal tracts and a specimen length of ≥ 2 cm. Two groups were compared using independent samples t-test: Group A, using an aspiration needle (Menghini type), and Group B, using a semi-automatic cutting needle, both 18G. A p-value < 0.05 was considered statistically significant.

Results:

A total of 38 patients were included, 23 (71.9%) were women and 9 (28.1%) men, with a mean age of 49.5 ± 14.35 years. The aspiration needle was used in 14 patients (43.8%), and the cutting needle was used in 18 patients (56.8%).

The indications were as follows: unexplained liver test abnormalities in 25%, fibrosis assessment in 8.3%, suspicion of autoimmune hepatitis (AIH) in 8.3%, and assessment of AIH activity in 4.2%.

The mean biopsy length was 2.55 ± 1.62 cm in Group A and 2.37 ± 1.31 cm in Group B.

The mean number of portal tracts was 9 ± 3.95 in Group A and 7.07 ± 5 in Group B.

Comparisons between these means showed no statistically significant difference ($p = 0.7$, $p = 0.3$ respectively).

No difference in complication rates was observed between the two groups.

Conclusions:

In our experience, the aspiration needle tended to yield specimens richer in portal tracts than the cutting needle, although the difference was not statistically significant.

Percutaneous liver biopsy proved to be a generally well-tolerated procedure, with a low and transient rate of complications.

2337 - Diagnostic challenges at the interface of drug induced autoimmune hepatitis and classical autoimmune hepatitis a case report

E-POSTER ABSTRACTS

Ian Yang Liew¹, Khoon Leong Chuah², Alyssa Sim¹
Tan Tock Seng Hospital, Gastroenterology And
Hepatology, Singapore-Singapore¹ Tan Tock Seng
Hospital, Pathology, Singapore-Singapore²

Background:

Distinguishing drug-induced autoimmune hepatitis (DI-AIH) from classical autoimmune hepatitis (AIH) remains challenging, even for experienced clinicians, as no single serological or histological feature reliably differentiates the two at presentation. This distinction is clinically important, as misclassification may result in unnecessary long-term immunosuppression or, conversely, delayed treatment. We report a diagnostically challenging case initially managed as drug-induced liver injury (DILI) and DI-AIH, in which longitudinal follow-up ultimately supported a diagnosis of classical (idiopathic) AIH.

Case:

A 46-year-old woman with no significant past medical history presented with a one-week history of abdominal bloating and jaundice. She had travelled to Vietnam two months earlier but remained afebrile with no gastrointestinal symptoms. Admission laboratory tests revealed bilirubin 21 $\mu\text{mol/L}$, AST 693 U/L, ALT 675 U/L, ALP 164 U/L and GGT 564 U/L. Viral hepatitis serologies and autoimmune markers, including IgG, ANA, anti-smooth muscle antibody (SMA), anti-mitochondrial M2, anti-LKM-1, anti-LC-1, and anti-SLA/LP antibodies, were negative. Magnetic resonance cholangiopancreatography (MRCP) demonstrated gallstones without biliary dilatation and a normal liver parenchyma.

Further history revealed recent use of cosmetic whitening supplements, some containing turmeric, which were discontinued on admission. Given fulfilment of Hy's law and concern for severe DILI, an urgent liver biopsy was performed. Histology showed mild to moderate portal inflammation with lymphocytes and plasma cells, lobular inflammation with hepatocyte ballooning, and absence of interface hepatitis, consistent with acute hepatitis with hepatocellular injury.

Unfortunately, despite withdrawal of the suspected agents, liver biochemistry worsened (bilirubin 83 $\mu\text{mol/L}$, AST 946 U/L, ALT 1322 U/L, ALP 236 U/L, GGT 339 U/L), prompting initiation of corticosteroid therapy (prednisolone 30 mg daily) for presumed DI-AIH. This led to marked biochemical improvement with near normalization of liver enzymes. Steroids were

subsequently tapered due to side effects, in keeping with the working diagnosis of DI-AIH. However, upon reduction to prednisolone 10 mg daily, the patient developed an abrupt biochemical relapse. Re-induction with corticosteroids and the addition of azathioprine 50 mg daily resulted in complete and sustained normalization of liver function tests.

Conclusion:

The steroid-dependent, relapsing course strongly supports a diagnosis of idiopathic AIH rather than DI-AIH, indicating the need for long-term immunosuppression. This case highlights the persistent diagnostic ambiguity at the intersection of DILI, DI-AIH, and AIH, where initial serology and histology may be non-specific. In such cases, relapse following steroid withdrawal is a pragmatic discriminator favouring classical AIH and should prompt reclassification and initiation of maintenance therapy.

Keyword(s) : AIH, DI-AIH

2338 - Association between Glycemic Control (HbA1c) and Liver Transaminase Levels (ALT and AST) in Mongolian patients

Khulan Ariunbaatar¹, Khongorzul Enkhtuvshin¹, Anujin Chinzorig¹, Baatarkhuu Oidov², Erdenebayar Gonchig³, Enkhtuya Damba⁴, Amarsanaa Jazag⁵
Masld, Medicine, Ulaanbaatar-Mongolia¹ Mnums, Infectious Diseases, Ulaanbaatar-Mongolia² Glu, Medicine, Ulaanbaatar-Mongolia³ Happy Veritas Hospital, Medicine, Ulaanbaatar-Mongolia⁴ Otochmanramba University, Medicine, Ulaanbaatar-Mongolia⁵

Background / Hypothesis:

This cross-sectional study aimed to assess the prevalence of impaired glycemic control (measured by HbA1c) and elevated liver transaminases (ALT and AST) in a cohort of N = 71 individuals. Secondary aims included determining the correlation between long-term glycemic control and transaminase elevation and identifying potential gender differences.

Materials and Methods:

Data for 71 individuals (46 males, 25 females; mean age 49.5 years) were collected from January to August 2024 and analyzed using descriptive and correlational statistics. Since this was a single-point-in-time assessment, the analysis relied on Pearson correlation coefficients (r) to assess the strength of associations between metabolic and hepatic markers

Results:

E-POSTER ABSTRACTS

The cohort exhibited evidence of significant metabolic and hepatic impairment, with a high mean HbA1c of 7.22%. Both mean ALT (80.62 U/L) and mean AST (50.54 U/L) were substantially elevated above typical reference ranges. A strong positive correlation was found between ALT and AST ($r = 0.762$). Crucially, the correlation between HbA1c and ALT ($r = 0.026$) or AST ($r = 0.142$) was statistically very weak. Gender analysis revealed that males demonstrated higher mean values across all three markers, including HbA1c (7.38% vs 6.93%) and ALT (87.21 U/L vs 68.50 U/L).

Conclusions:

The findings indicate a high co-prevalence of sub-optimal glycemic control and hepatic enzyme elevation in this study population. The lack of a strong association between HbA1c and transaminases suggests that factors independent of hyperglycemia, such as Non-Alcoholic Fatty Liver Disease (NAFLD), may be the primary driver of liver injury. These gender disparities underscore the need for targeted screening and gender-specific management strategies in clinical practice in Mongolia.

Keyword(s) : DM, ALT, AST

2339 - The metagenomics derived gut mycobiome biomarker for non invasive diagnosis of early hepatocellular carcinoma

Shanshuo Liu¹, Haiyu Wang¹, Benchen Rao¹, Zujang Yu¹, Zhigang Ren¹

The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases, Zhengzhou-China¹

Background / Hypothesis:

The early diagnosis of hepatocellular carcinoma (HCC) remains clinically challenging, and the role of gut fungi in hepatocarcinogenesis is poorly understood.

Materials and Methods:

This prospective multi-center study performed metagenomic sequencing on 514 fecal samples. In the training set (HCC vs. healthy controls [HCs]), 117 classification models were developed based on fungal features using nine machine learning algorithms, subsequently validated in cross-regional and cross-disease cohorts. We further assessed clinical applicability using a large public dataset ($n=3487$) comprising multiple diseases and HCs.

Results:

Early HCC patients exhibited reduced gut fungal diversity and altered mycobiota structure with 46 differentially abundant fungal species identified.

Schizosaccharomyces-dominant enterotype was strongly associated with HCC risk (36-fold increase compared to Aspergillus-dominant enterotype). Functionally, HCC showed enriched KEGG pathways such as lipopolysaccharide biosynthesis and shifted carbohydrate-active enzyme profiles. Clinically, a history of chronic hepatitis B (CHB) was the strongest driver of community variation at both taxonomic and functional levels ($R^2 = 0.093$ and 0.060 , respectively). The optimal model, constructed with glm+Ridge algorithm using 11 fungal species, demonstrated strong discriminatory performance across all test sets (average area under curve [AUC] = 0.87) and maintained low false-positive rates in public cohorts. SHAP analysis identified *Pyricularia_ grisea* and *Schizosaccharomyces_pombe* as the top predictive features.

Conclusions:

This study characterizes gut mycobiota dysbiosis in early HCC and provides novel insights into the fungal gut-liver axis. The developed non-invasive fungal model exhibits robust cross-regional validity and high disease specificity, highlighting its translational potential for early and differential diagnosis of HCC.

Keyword(s) : Hepatocellular carcinoma, Metagenomics, Gut Mycobiome, Biomarkers, Non-invasive Diagnosis, Correlation Analysis

2341 - Correlation Between tumor markers (AFP CA19 9 CEA)

Anujin Chinzorig¹, Khongorzul Enkhtuvshin¹, Khulan Ariunbaatar¹, Baatarkhuu Oidov², Erdenebayar Gonchig³, Enkhtuya Damba⁴, Amarsanaa Jazag⁵
Masld, Medicine, Ulaanbaatar-Mongolia¹ Mnums, Infectious Diseases, Ulaanbaatar-Mongolia² Glu, Medicine, Ulaanbaatar-Mongolia³ Happy Veritas Hospital, Medicine, Ulaanbaatar-Mongolia⁴ Otochmanramba University, Medicine, Ulaanbaatar-Mongolia⁵

Background / Hypothesis:

Serum biomarkers such as AFP (alpha-fetoprotein), CA19-9 (cancer antigen 19-9), and CEA (carcinoembryonic antigen) might serve as non-invasive, objective, and repeatable tools for early detection, diagnosis, and monitoring of HCC.

Materials and Methods:

A retrospective cross-sectional study was conducted including $n=150$ outpatients who visited Happy Veritas Liver Center and underwent laboratory tests between March and August 2025. Participants were selected

E-POSTER ABSTRACTS

using random sampling. Inclusion criteria were age ≥ 18 years, complete values for AFP, CEA, and CA19-9, and a diagnosis of primary hepatocellular carcinoma (PHC) or liver cirrhosis. Exclusion criteria included other serious comorbid diseases, patients receiving chemotherapy/radiation therapy, pregnant or breastfeeding women, and incomplete or inconsistent test data. Clinical data collected included demographic information and patients' laboratory test results. All statistical analyses were performed using SPSS 26 software, with statistical significance set at 95% ($p < .05$). Normality of data distribution was assessed using the Shapiro–Wilk test; since the distribution was non-normal, Spearman's rank correlation was used for correlation analysis. The study was approved by the Ethics Committee of Happy Veritas Clinic (Protocol No. HV-2024-02). Personal information such as names, codes, and registration numbers of participants was fully anonymized and used solely for statistical purposes.

Results:

- The correlation between AFP and CA19-9 was very weak positive ($r = 0.03$), at a level with no statistical or clinical significance.
- Between AFP and CEA, an almost negligible weak negative correlation was observed ($r = -0.02$), indicating no linear relationship between these variables.
- Between CA19-9 and CEA, a weak positive correlation ($r = 0.087$) was observed, but the magnitude was small, with no established clinical significance.

Based on the values of Pearson's coefficients, only nominal, clinically insignificant weak associations were observed between all three markers. Within the scope of the study data, these tumor biochemical markers appear to change independently of one another.

Conclusions: The statistical correlation between tumor markers AFP, CA19-9, and CEA is very low and clinically insignificant.

Keyword(s) : Tumor markers

2342 - Performance of Non invasive Baveno Seven Criteria for Predicting Clinically Significant Portal Hypertension in Burned out Metabolic Dysfunction associated Fatty Liver Disease

Adinda Amalia¹, Anita Illahi¹, C. Rinaldi Lesmana¹

Division Of Hepatobiliary, faculty Of Medicine
Universitas Indonesia/ Dr.cipto Mangunkusumo
General National Hospital, Internal Medicine, Jakarta-
Indonesia¹

Background / Hypothesis:

Burned-out metabolic dysfunction-associated fatty liver disease (absent steatosis despite significant fibrosis) may represent a high-risk phenotype for portal hypertension, yet evidence on non-invasive stratification is limited. We hypothesized that burned-out metabolic dysfunction-associated fatty liver disease has a high prevalence of non-invasive clinically significant portal hypertension and that Baveno Seven would place most patients in rule-in or grey-zone categories.

Materials and Methods:

A retrospective single-center pilot study. Baseline liver stiffness measurement, controlled attenuation parameter, platelet count, and Child–Pugh class were collected. Burned-out metabolic dysfunction-associated fatty liver disease was defined as controlled attenuation parameter < 248 dB/m (S0) with liver stiffness measurement ≥ 8 kPa. Clinically significant portal hypertension was defined by a non-invasive surrogate of liver stiffness measurement ≥ 25 kPa. Baveno Seven categories were rule-out (liver stiffness measurement < 15 kPa and platelets $> 150 \times 10^9/L$), grey zone, and rule-in (liver stiffness measurement ≥ 25 kPa). Discrimination was assessed using area under the receiver operating characteristic curve.

Results:

Among 44 patients (median age 59.5 years; 61% male), 16 (36.4%) met criteria for burned-out metabolic dysfunction-associated fatty liver disease. Non-invasive clinically significant portal hypertension was present in 50% overall and was higher in burned-out vs non-burned-out metabolic dysfunction-associated fatty liver disease (62.5% vs 42.9%). In burned-out metabolic dysfunction-associated fatty liver disease, Baveno Seven categorized 62.5% as rule-in, 31.2% as grey zone, and only 6.2% as rule-out. Clinically significant portal hypertension occurred in 55.6% of Child–Pugh A, 80.0% of Child–Pugh B, and 50.0% of Child–Pugh C burned-out patients. Platelet count and Child–Pugh class showed poor discrimination (area under the curve ≈ 0.50 and 0.59).

Conclusions:

Burned-out metabolic dysfunction-associated fatty liver disease is enriched for non-invasive clinically significant portal hypertension, with most patients classified as Baveno Seven rule-in and very few

E-POSTER ABSTRACTS

meeting rule-out thresholds. This suggests limited endoscopy-sparing capacity of current non-invasive criteria in the burned-out phenotype and supports the need for phenotype-specific risk stratification validated in prospective cohorts.

Keyword(s) : Burned-out metabolic dysfunction-associated fatty liver disease; clinically significant portal hypertension; Baveno Seven; non-invasive assessment; liver stiffness measurement

2343 - Gut Microbiome Dysbiosis in Metabolic Associated Fatty Liver Disease A Systematic Review and Meta Analysis Pakistan

Jalal Khan¹, Farhana Kayani²

Bmch, Medicine, Quetta-Pakistan¹ Bmch, Gastroenterology, Quetta-Pakistan²

Background / Hypothesis:

Metabolic associated fatty liver disease (MAFLD) is a leading cause of chronic liver disease worldwide. Recent studies suggest that gut microbiome dysbiosis contributes to the pathogenesis of MAFLD by modulating hepatic inflammation, lipid metabolism, and insulin resistance. However, the specific microbial signatures associated with MAFLD remain heterogeneous across studies.

Aim:

To systematically review and meta-analyze existing evidence on gut microbiome alterations in patients with MAFLD compared to healthy controls, focusing on microbial diversity, composition, and functional implications.

Materials and Methods:

A comprehensive literature search was conducted in PubMed, Embase, and Cochrane Library up to December 2025. Studies reporting gut microbiome profiles in adult patients with MAFLD were included. Data on microbial diversity (alpha and beta diversity), relative abundance of bacterial taxa, and functional pathways were extracted. Meta-analysis was performed using random-effects models for consistent microbial changes. Risk of bias was assessed using the Newcastle-Ottawa Scale.

Results:

A total of 42 studies including 3,560 MAFLD patients and 2,940 healthy controls were analyzed. Patients with MAFLD consistently exhibited reduced gut microbial diversity (pooled standardized mean difference = -0.42, 95% CI -0.55 to -0.29, $p < 0.001$). At the phylum level, an increased Firmicutes/Bacteroidetes ratio and enrichment of Proteobacteria were observed. Genera such as *Escherichia*, *Lactobacillus*, and *Prevotella* were

significantly elevated, while *Faecalibacterium* and *Roseburia* were depleted. Functional analyses suggested enhanced lipopolysaccharide biosynthesis, bile acid metabolism alterations, and short-chain fatty acid dysregulation in MAFLD. Heterogeneity was moderate, primarily driven by geographic and sequencing methodology differences.

Conclusions:

Gut microbiome dysbiosis is a consistent feature of MAFLD, characterized by reduced microbial diversity, pro-inflammatory microbial enrichment, and altered metabolic pathways. These findings underscore the role of the gut-liver axis in MAFLD pathogenesis and highlight potential microbiota-targeted therapeutic strategies. Future longitudinal and interventional studies are warranted to establish causality and clinical utility.

Keyword(s) :

2344 - Is Pneumococcal Vaccination Safe in Patients with Liver Cirrhosis

Kübra Bağır¹, Arda Kaya¹, İlkçe Kurtulmuş², Barış Emekdaş², Tansu Yamazhan¹, Meltem Işıkgöz Taşbakan¹, Ulus Salih Akarca³

Ege University Hospital, Infections Disease, Izmir-Türkiye¹ Ege University Hospital, Internal Medicine, Izmir-Türkiye² Ege University Hospital, Gastroenterology, Izmir-Türkiye³

Background / Hypothesis:

Patients with liver cirrhosis may become susceptible to infectious diseases due to immune system dysfunction. Therefore, vaccination against vaccine-preventable diseases is essential in this population. Pneumococcal infections can cause significant morbidity and mortality in patients with cirrhosis.

The aim of this study was to retrospectively evaluate the pneumococcal vaccination status of patients with liver cirrhosis followed in the hepatology and adult vaccination clinics of our university.

Materials and Methods:

Patients aged 18 years and older with a diagnosis of liver cirrhosis who were followed at the Adult Vaccination Clinic of the Department of Infectious Diseases, Ege University Faculty of Medicine Hospital, between October 2015 and December 2025 were included in the study. Patient data were obtained from the Hospital Information Management System and the Ministry of Health Vaccination Tracking System.

E-POSTER ABSTRACTS

Collected data were analyzed using the SPSS statistical software.

Results:

A total of 533 patients with liver cirrhosis who were referred to the adult vaccination clinic received pneumococcal vaccination. No serious adverse events were observed during follow-up.

Conclusions:

The risk of invasive pneumococcal disease is 2 to 13 times higher in patients with chronic liver disease compared to the general population. Vaccination is the most effective and reliable strategy to prevent pneumococcal infections. Our findings indicate that pneumococcal vaccination is safe in patients with liver cirrhosis in terms of adverse effects.

Keyword(s) : Adult immunization, Liver cirrhosis, Pneumococcal vaccination

2345 - Gut Microbiota Alterations in Patients with Chronic Hepatitis B and Metabolic Associated Fatty Liver Disease Implications for Fibrosis Progression

Farhana Kayani¹

Bmch, Gastroenterology, Quetta-Pakistan¹

Background / Hypothesis:

Background:

Metabolic associated fatty liver disease (MAFLD) is increasingly recognized in patients with chronic hepatitis B (CHB) and may influence disease progression. Emerging evidence suggests that gut microbiota modulates hepatic inflammation, fibrosis, and antiviral immunity. The interplay between MAFLD, HBV, and gut microbiota remains largely unexplored.

Aim:

To characterize the gut microbiota in patients with CHB and MAFLD and evaluate its association with liver fibrosis and HBV activity.

Methods:

A cross-sectional study was conducted including 120 CHB patients, 60 with MAFLD and 60 without. Stool samples were analyzed using 16S rRNA sequencing to assess microbial diversity and composition. Clinical data including HBV DNA, ALT, HBeAg status, and fibrosis (via transient elastography) were collected. Correlations between microbial taxa, metabolic parameters, fibrosis, and viral activity were evaluated.

Results:

Patients with CHB and MAFLD exhibited reduced gut microbial diversity compared to CHB-only patients (Shannon index: 3.2 ± 0.5 vs. 3.8 ± 0.4 , $p < 0.01$). Specific bacterial genera, including Firmicutes and Bacteroides, were significantly enriched in MAFLD patients. Dysbiosis was associated with higher fibrosis scores independent of HBV viral load (OR 2.5, 95% CI 1.3–4.8, $p = 0.005$). Certain microbial metabolites correlated with ALT elevation and insulin resistance, suggesting a link between gut-liver axis alterations and liver injury.

Conclusion:

CHB patients with MAFLD show distinct gut microbiota alterations that are associated with fibrosis progression and metabolic dysfunction. These findings highlight the potential role of the gut-liver axis in modulating liver injury in HBV-infected individuals and may inform microbiota-targeted interventions.

Keyword(s) :

2346 - Correlation Between Liver Biomarkers and Hemoglobin Levels in Mongolian Patients

Khongorzul Enkhtuvshin¹, Anujin Chinzorig¹, Khulan Ariunbaatar¹, Baatarkhuu Oidov², Erdenebayar Gonchig³, Enkhtuya Damba⁴, Amarsanaa Jazag⁵
Masld, Medicine, Ulaanbaatar-Mongolia¹ Mnums, Infectious Diseases, Ulaanbaatar-Mongolia² Glu, Medicine, Ulaanbaatar-Mongolia³ Happy Veritas Hospital, Medicine, Ulaanbaatar-Mongolia⁴ Otochmanramba University, Medicine, Ulaanbaatar-Mongolia⁵

Background / Hypothesis:

Alanine aminotransferase (ALT) and aspartate aminotransferase (AST) are key biochemical markers widely used to evaluate hepatocellular injury. Elevations of these enzymes reflect hepatocyte membrane damage and intracellular enzyme leakage, often associated with viral hepatitis, alcohol-related liver injury, metabolic syndrome, and non-alcoholic fatty liver disease. Hemoglobin (Hb), the primary determinant of oxygen-carrying capacity, can influence tissue oxygenation, redox balance, and mitochondrial function. Alterations in Hb levels may contribute to hepatocellular injury through impaired oxygen delivery and oxidative stress mechanisms, as reported in several studies. However, no published studies to date have assessed the relationship between hemoglobin levels and liver enzymes among the Mongolian population.

E-POSTER ABSTRACTS

Therefore, investigation using real-world clinical data is warranted.

Materials and Methods:

A retrospective cross-sectional study was conducted among $n = 137$ patients who underwent laboratory testing at the Happy Veritas Liver Center between January and August 2025. Participants were selected using simple random sampling. Inclusion criteria included age ≥ 18 years and availability of complete laboratory results for hemoglobin, ALT, and AST collected from the same blood sample on the same day. Normality of the data was assessed using the Shapiro–Wilk test, and because the variables were non-normally distributed, Spearman's rank correlation was applied. The anticipated effect size was $r = 0.25$. Using 80% statistical power and 5% alpha, the required minimum sample size was 123; thus, the collected sample of 137 participants was adequate. The study protocol was approved by the Institutional Review Board of Happy Veritas Hospital (Protocol No. HV-2024-02). All personal identifiers were removed to ensure confidentiality.

Results:

A total of 137 participants were included. The mean age was 41.6 ± 12.8 years (range: 18–72). Of these, 79.6% were male and 20.4% were female. Mean laboratory values were as follows: ALT 53.5 ± 66.0 U/L, AST 38.0 ± 36.2 U/L, and hemoglobin 14.7 ± 1.5 g/dL. Spearman's correlation analysis demonstrated a strong positive correlation between ALT and AST ($r = 0.933$, $p < 0.001$). Hemoglobin showed a moderate positive correlation with both ALT ($r = 0.418$, $p < 0.001$) and AST ($r = 0.434$, $p < 0.001$). Simple linear regression indicated that ALT ($\beta = 0.004$, $p < 0.001$).

Conclusion: Higher hemoglobin levels were moderately associated with increased liver enzyme activity. These findings suggest that elevated hemoglobin may be linked to hepatocellular stress or injury; however, further prospective and mechanistic studies are needed to clarify the causal pathways.

Keyword(s) : Liver enzymes, hemoglobin, correlation, ALT, AST

2348 - Observational study comparing Hepatocellular carcinoma patients on HCC surveillance with those not on surveillance at diagnosis.

Dr. Shoumeta Damle¹, Dr. B. V. Tantry¹, Dr. Anurag Shetty¹, Dr. Sandeep Gopal¹, Dr. Suresh Shenoy¹
Kmc Hospital, Medical Gastroenterology, Mumbai-India¹

Background / Hypothesis:

Surveillance for Hepatocellular carcinoma (HCC) in chronic liver disease to improve disease outcomes.

Materials and Methods:

This observational study included consecutive patients of Hepatocellular carcinoma and were categorized by surveillance status. Group A included patients not on HCC surveillance ($n=71$) and Group B on regular surveillance ($n=60$). Baseline comorbidities, etiologies (NASH, ethanol, viral hepatitis), liver dysfunction severity (MELD, CTP), tumor characteristics (BCLC stage, lesion size/number, AFP, Portal vein thrombosis), radiological response and outcomes were evaluated.

Results:

Comorbidities, etiologies, gender, MELD/CTP, lesion number, AFP and presence of portal vein thrombosis (PVT) in both groups showed no significant differences (all $p > 0.05$). Patients on surveillance showed shift towards early BCLC stages (0/A/B, $p=0.019$) and smaller tumor size (<3 cm: 28 vs 17, $p=0.032$). Higher proportion of patients on surveillance underwent locoregional therapy (48.3% in group B vs 29.5% in group A.) Radiological complete response was higher in group B (48.2% vs 33.3%). Mean time to death was 9.9 months (group A) vs 12.11 months (group B).

Conclusions:

Surveillance enables earlier HCC detection (lower BCLC stage, smaller tumors), enabling access to curative options, which can reduce future mortality and morbidity. This study underscores need of regular screening for HCC in liver disease.

Keyword(s) : Hepatocellular carcinoma, HCC, cirrhosis, AFP, BCLC, PVT, locoregional therapy

2352 - The Economic Burden of Cirrhosis Financial Classification and Disease Severity as Key Predictors of Direct Hospital Costs in the Philippines a Retrospective Analysis

Ron-daniel Gison¹, Ira Yu²

National Kidney And Transplant Institute, Division Of Internal Medicine, Quezon City-Philippines¹ National Kidney And Transplant Institute, Section Of Gastroenterology, Division Of Internal Medicine, Quezon City-Philippines²

Background: Liver cirrhosis represents end-stage liver

E-POSTER ABSTRACTS

disease and is one of the leading causes of morbidity and mortality globally, with significant associated healthcare costs in the developed world. Despite this, cost-of-illness data remain severely limited in developing nations including the Philippines, hindering efforts to formulate cost-containment and policy strategies. This lack of data is especially crucial in the Philippine context where a regular employee is only expected to earn approximately PHP 30,000.00 per month, where a significant hospitalization cost can represent a devastating financial burden. This study aims to quantify direct hospitalization costs and to identify key predictors of higher expenditure among cirrhotic patients.

Materials and Methods: A retrospective, cross-sectional analytical study was conducted. Demographics, clinical profiles, total hospitalization costs and reimbursement data were collected based on available data from January 2023 to December 2024. Data analysis was performed using Stata 17. Normality of continuous variables was evaluated using the Shapiro–Wilk test. Multivariate analysis via Generalized Linear Model (GLM), Gamma distribution, identity-link were used to identify statistical differences and predictors of increased costs. A p-value <0.05 was considered statistically significant.

Results: 282 patients were included in the analysis. The median age was 62 years and 41.13% (n = 116) were female. The predominant etiology of cirrhosis was Hepatitis B (48.23%) with most patients classified as Child-Pugh Class B (n = 143, 50.71%). The average hospitalization cost was PHP 231,242.30 per admission (median PHP 156,077.77). Majority of costs were driven by diagnostic and laboratory fees (33.20%) and professional fees (23.61%). PhilHealth reimbursements accounted for only a minimal fraction of the total costs (median PHP 12,771.76) covering <0.01% of the average total, with patients shouldering 59.59% of expenses out-of-pocket (median PHP 151,850.30). In multivariate analysis, only Child-Pugh Class of B (P = 0.045) and a service financial classification (P = 0.001) remained significant predictors of increased direct healthcare costs.

Conclusions: Hospitalization for liver cirrhosis imposes a substantial and inequitable financial burden, driven predominantly by diagnostic and laboratory costs, with negligible PhilHealth coverage. Financial classification and moderate disease severity (Child-Pugh Class B) were the only significant predictors of higher costs. These findings urgently highlight the need for

expanded insurance coverage and targeted cost-containment strategies focused on diagnostic services to alleviate patient economic distress.

Keyword(s) : Liver cirrhosis, Child-Pugh score, cost of illness, hospital costs, Generalized Linear Model (GLM)

2354 - COMPARATIVE STUDY OF THE ETIOLOGY OF LIVER CANCER AND THE MANIFESTATION OF HEPATIC ENCEPHALOPATHY

Byambatsetseg Togtuunbayar ¹, Baatarkhuu Oidov ², Enkhbold Chinbold ³, Yumchinsarchin Narangerel ⁴, Erkhembayar Dima ⁵, Erdenebayar Gonchig ⁶, Amarsanaa Jazag ⁷

Happy Veritas Hospital, Medicine, Ulaanbaatar-Mongolia ¹ Mnums, Infectious Diseases, Ulaanbaatar-Mongolia ² Second General Hospital, Surgical Oncology, Ulaanbaatar-Mongolia ³ Ncc, Radiology, Ulaanbaatar-Mongolia ⁴ Mongolia-japan Teaching Hospital, Radiology, Ulaanbaatar-Mongolia ⁵ Glu, Medicine, Ulaanbaatar-Mongolia ⁶ Otoch Manramba University, Medicine, Ulaanbaatar-Mongolia ⁷

Background / Hypothesis:

Primary liver cancer typically develops on the background of chronic liver disease, and hepatic encephalopathy—one of the severe manifestations of liver dysfunction—significantly impacts patients' quality of life and mortality. The objective of this study was to classify liver cancer by etiology, compare the frequency of hepatic encephalopathy manifestation, and determine in which etiological group hepatic encephalopathy is more predominant. The study included 216 cases of liver cancer, divided into HBV-related, HCV-related, and non-viral etiological groups for analysis. Results showed that hepatic encephalopathy occurred most frequently in HCV-related liver cancer and least frequently in non-viral liver cancer. This indicates that the etiological classification of liver cancer is an important factor in determining the risk of hepatic encephalopathy.

Materials and Methods:

The study was conducted in a retrospective, observational manner. Clinical records of a total of 216 patients with primary liver cancer were included. Patients were classified into the following three groups based on the etiology of liver cancer:

- HBV-related liver cancer (n = 79)
- HCV-related liver cancer (n = 106)

E-POSTER ABSTRACTS

· Non-viral liver cancer (n = 31)

The diagnosis of hepatic encephalopathy was confirmed based on clinical signs and symptoms, laboratory findings, imaging diagnostics, and physician notes. Study data were compiled quantitatively, and the frequency of hepatic encephalopathy manifestation was compared and analyzed between groups.

Results:

Among the total 216 liver cancer patients included in the study, the manifestation of hepatic encephalopathy varied depending on etiological classification. The highest number of cases was recorded in the HCV-related liver cancer group, with hepatic encephalopathy observed in 106 patients. This was followed by the HBV-related liver cancer group with 79 cases, while the non-viral liver cancer group had the lowest number of hepatic encephalopathy cases, at 31. These results suggest that the prolonged inflammation, liver fibrosis, and cirrhosis caused by chronic HCV infection may reach deeper levels. In contrast, in the non-viral liver cancer group, relatively preserved liver reserve function in many cases may account for the lower frequency of hepatic encephalopathy.

Conclusions:

The results of this study show that the manifestation of hepatic encephalopathy among liver cancer patients is partially dependent on the etiological classification of the cancer. Hepatic encephalopathy occurred with the highest frequency in HCV-related liver cancer, at a moderate level in HBV-related cancer, and at the lowest level in non-viral cancer. Therefore, when developing clinical monitoring and treatment plans for liver cancer, it is essential to consider not only the cancer stage but also the etiology

Keyword(s) : Encephalopathy, HCC, HCC etiology

2355 - A Machine Learning Based Screening Tool for Population Level Screening of MASLD to identify outlier patients current tools miss

Richmond Research Institute, Rri, London-United Kingdom¹ Richmond Pharmacology, , London-United Kingdom² University College London, , London-United Kingdom³ King's College London, , London-United Kingdom⁴

Background / Hypothesis: Metabolic associated steatotic liver disease (MASLD) is the most common cause of liver disease, 25% of the population have

MASLD, of concern is 1 in 5 (20%) of these patients have silent steatohepatitis, of whom 20% develop cirrhosis. Body Mass Index (BMI) has a 0.75 AUROC in predicting MASLD, with limitations related to high muscle/high BMI and low muscle/low BMI patients. We hypothesised that a machine learning (ML) based screening tool requiring anthropometric measurements and age can achieve comparable predictive performance, enabling a low-cost, easily accessible and truly non-invasive screening tool for population-level screening.

Materials and Methods: An observational study of 1912 healthy volunteers aged 18-90 years was conducted NCT04873258. The data collected consists of demographics, anthropometrics, bioimpedance vector analysis (BIVA) and laboratory bloods. FibroScan was performed as a pragmatic gold standard for diagnosing MASLD with thresholds of ≥ 290 dB/m or ≥ 7.6 kPa defining fatty liver or early but significant fibrosis. We developed the models to predict MASLD cases using LASSO logistic regression (LR), elastic net LR, Random Forest (RF) and XGBoost. The initial models were trained using all available features, followed by model re-training using anthropometric variables and age alone. The predictive performance was evaluated and SHAP analysis was carried out to determine feature importance.

Results: All models were able to achieve > 0.87 AUROC. Utilising all variables, the RF model performed best, achieving an AUROC of 0.892 [95% CI 0.859-0.917] and sensitivity of 0.862 [95% CI 0.790-0.906]. The top 10 features in this model were waist-to-height ratio, waist circumference, BMI, weight, age, GGT, ALT, body fat percentage, visceral fat type II and AST. When feature set was simplified to anthropometric variables and age, it surpassed the predictive value of BMI alone for MASLD (AUROC 0.75) with a AUROC of 0.864 [95% CI 0.828-0.892]; sensitivity = 0.899 [95% CI 0.826-0.935]).

Conclusions: We present a non-invasive and low-cost ML screening tool to identify patients with MASLD with a performance comparable to established non-invasive MASLD screening methods. This low-cost model offers a significant potential for large-scale population screening in the community without the need for blood tests and may better identify outlier patients which are missed by current tools. Once identified, patients can undergo screening to determine their risk

E-POSTER ABSTRACTS

of, or the presence of, liver fibrosis and underlying steatohepatitis – the target for most new drug treatments.

2356 - Mechanism research of α Amyrin targeting Sirt1 PGC 1 α PPAR α axis to regulate fatty acid metabolism reprogramming against liver fibrosis

Xuemei Wang¹, Guanyue Su², Feilin Ge³, Zujiang Yu⁴, Zhigang Ren⁵, Hongxia Liang⁶

The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases, State Key Laboratory Of Antiviral Drugs, Zhengzhou-China¹ The First Affiliated Hospital Of Zhengzhou University, Department Of Liver Disease, State Key Laboratory Of Antiviral Drugs, Zhengzhou-China² The First Affiliated Hospital Of Zhengzhou University, State Key Laboratory Of Antiviral Drugs, Zhengzhou-China³ The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases, Zhengzhou-China⁴ Fifth Medical Center Of Chinese PLA General Hospital, Department Of Liver Disease, Zhengzhou-China⁵ The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases, State Key Laboratory Of Antiviral Drugs, Pingyuan Laboratory, Zhengzhou-China⁶

Background / Hypothesis:

Liver fibrosis remains one of the serious public health problems worldwide at present. Unfortunately, there is no first-line small molecule drug recommended by clinical guidelines for liver fibrosis currently. Therefore, the development of innovative targeted small molecule drugs is urgent. Previous studies have shown that the natural small molecule α -Amyrin has significant anti-inflammatory effects. However, whether it has anti-cirrhotic effects is unclear. In this study, the anti-fibrosis effect of α -Amyrin was evaluated for the first time at the basic research level, and both its mechanism and active compounds were researched.

Materials and Methods:

In this study, we use an in vitro model of fibrosis in human hepatic stellate LX-2 cells induced with TGF- β 1 and an in vivo mouse model with CCl₄ to evaluate the anti-fibrosis potential of α -Amyrin using multiple approaches. Employing multi-omics and molecular biology techniques to investigate the mechanism of α -Amyrin counteracting hepatic fibrosis. The interaction targets of α -Amyrin were examined through molecular docking, molecular dynamics simulations and surface

plasmon resonance. The anti-hepatic fibrosis mechanism of α -Amyrin was further validated using both in vitro and in vivo PPAR α knockout or inhibition models.

Results:

In vivo, α -Amyrin significantly inhibited the formation of hepatic Pseudolobules and suppressed hepatic inflammation compared with the model control group. In vitro, α -Amyrin significantly down-regulated the expression levels of well-established markers of liver fibrosis. The results of transcriptomics and metabolomics provided clues to the mechanisms of the PPAR α pathway and fatty acid metabolism. Further experimental validation of these mechanisms was conducted. In vitro and in vivo, α -Amyrin significantly promoted fatty acid oxidation levels which is consistent with up-regulation of PPAR α pathway involved in this process, including Sirt1, PPAR α , PGC-1 α , CPT1A, ACOX1, and its downstream targets. Moreover, α -Amyrin markedly enhanced PPAR α nuclear translocation and facilitated the Sirt1-PGC-1 α interaction. Molecular docking, dynamics simulations, and surface plasmon resonance confirmed direct binding of α -Amyrin to PPAR α . Critically, the anti-hepatic fibrosis effect of α -Amyrin was significantly compromised in both the in vivo PPAR α inhibitor model and the in vitro PPAR α knockout model.

Conclusions:

The possible mechanism of α -Amyrin's anti-fibrosis effect is to target the PPAR α axis to promote the reprogramming of fatty acid oxidation metabolism, which in turn exerts an anti-inflammatory effect and reverses the inflammation-fibrosis pathological process. The above results are expected to provide an innovative strategy for the development of small molecule drugs targeting liver fibrosis.

2357 - Pediatric Seronegative Autoimmune Hepatitis has a comparable clinical and laboratory profile to Seropositive Disease

Aditya Soni¹, Rajeev Khanna², Seema Alam¹, Vikrant Sood¹, Bikrant Bihari Lal¹, Archana Rastogi³

Institute Of Liver And Biliary Sciences, Pediatric Hepatology, New Delhi-India¹ Institute Of Liver And Biliary Sciences, New Delhi, Pediatric Hepatology, New Delhi-India² Institute Of Liver And Biliary Sciences, Pathology, New Delhi-India³

Background / Hypothesis: Seronegative autoimmune

E-POSTER ABSTRACTS

hepatitis (SN-AIH) represent a distinct subset of autoimmune liver disease in which children present with typical clinical and histological features of AIH but lack conventional autoantibodies. Limited pediatric data exist regarding their histological spectrum and long-term outcomes.

Materials and Methods: Retrospective analysis of prospectively collected data with a diagnosis of AIH presenting between January 2011 to July 2025 was done. Diagnosis of SN-AIH was based on characteristic clinical features, raised aminotransferases, compatible histology, elevated IgG, and exclusion of other causes of liver disease. For children enrolled before 2017, seronegative status was defined by the absence of traditional antibodies (ANA, SMA, LKM), while those enrolled during or after 2017, this was defined additionally by the absence of extended antibody testing (SLA/LP, LC1 and p-ANCA) at presentation or at follow-up. SN-AIH was compared with seropositive AIH (SP-AIH) for clinical, laboratory and histological profile, and outcome in terms of difficult-to-treat AIH and survival with native liver.

Results: Out of 232 patients, 66 (28.4%) were labelled as seronegative AIH. SN-AIH was comparable to SP-AIH in terms of gender, age at diagnosis and presentation. All the laboratory parameters were comparable except for higher bilirubin in the SN-AIH cohort (mean bilirubin: 11.5 ± 9.8 versus 8.7 ± 8.5 mg/dL, $p=0.030$). Mean simplified score in the SN-AIH cohort was lower than the SP-AIH (mean 5.5 ± 0.7 versus 7.4 ± 1.0 , $p<0.001$). Histologically, both the SN-AIH and SP-AIH were comparable with the most commonly demonstrated findings being lymphoplasmacytic infiltrates, interface hepatitis, lobular inflammation and pseudo-rosetting. Cholestasis, ductular reaction and duct damage are also comparable. Mean fibrosis score was higher in the SP-AIH cohort (3.0 ± 2.0 versus 2.2 ± 2.0 , $p=0.005$), however the mean liver stiffness measurements were comparable between the 2 cohorts (Table 1). At the end of 12 months, 30 patients lost to follow-up. Of the 202 children, 9 required liver transplantation and 28 died. 30 patients had difficult to treat AIH – 5 belonged to SN-AIH group. Both the survival with native liver and difficult-to-treat AIH were comparable between 2 groups ($p=NS$).

Conclusions: Seronegative AIH in children, though lacking conventional autoantibodies, demonstrates classical histological features and favorable response to standard immunosuppressive therapy. Histology plays

a crucial role in diagnosis, and early recognition is essential to prevent disease progression. Long-term outcomes are similar to seropositive AIH.

Keyword(s) : Seronegative AIH, Sn-AIH, children, Histology

2358 - Serum HBV RNA as a Marker of Occult HBV Infection in Patients with Hepatocellular Carcinoma

Aziza Khikmatullaeva¹, Nargiz Ibadullaeva¹, Nargiza Mirrakhimova¹

Research Institute Of Virology, Scientific Department, Tashkent-Uzbekistan¹

Background / Hypothesis: In recent years, particular attention has been paid to the phenomenon of occult HBV infection, which is characterized by the absence of HBsAg in the blood serum despite the presence of HBV DNA in liver tissue. Biopsy-based determination of HBV DNA is informative but an invasive method. In this regard, for non-invasive assessment of viral activity, the serum marker HBV RNA is increasingly used, which allows determination of the etiological structure of HCC and detection of occult forms of infection, influencing prognosis and therapeutic strategy.

Materials and Methods: We examined 75 patients with a confirmed diagnosis of HCC, in whom serological and molecular markers of HBV (HBsAg and HBV DNA) and HCV (anti-HCV and HCV RNA) were determined. As a result of the analysis, two main groups of patients were identified. The first group included 21 patients with the presence of anti-HCV and HCV RNA and negative HBsAg. The second group included 54 patients who had neither HBsAg nor anti-HCV. Detection of HBV RNA was performed using the "ROSSamed HBV-RNA" kit (LLC ROSSA, Uzbekistan).

Results: Among patients with anti-HCV and HCV RNA and negative HBsAg, HBV replication confirmed by the presence of HBV RNA was detected in 2 (9.5%) individuals. This finding demonstrates the presence of HBV replication in patients with HCV infection. Based on these data, it can be assumed that these patients may have an occult form of HBV infection - a condition in which viral activity persists despite negative serological HBsAg results. These results indicate latent HBV replication in patients with HCV infection. In 3 (5.6%) patients without serological markers of HBV and

E-POSTER ABSTRACTS

HCV (negative HBsAg and anti-HCV), HBV RNA was detected, indicating the presence of occult HBV infection - a diagnostically challenging condition in which the virus persists without obvious signs in standard serological screening.

Conclusions: The data obtained indicate that the determination of HBV RNA in serum can serve as an informative non-invasive marker of occult HBV infection in patients with HCC. This approach allows detection of hidden forms of HBV infection without the need for liver biopsy, which is particularly important for patients who do not consent to invasive procedures. Comprehensive use of serological and molecular methods, including HBV RNA, may contribute

2362 - Gallstone Disease in Pediatric Wilson Disease Prevalence Risk Factors and Outcome

Aditya Soni¹, Rajeev Khanna², Seema Alam¹, Vikrant Sood¹, Bikrant Bihari Lal¹, Shalini Thapar³

Institute Of Liver And Biliary Sciences, Pediatric Hepatology, New Delhi-India¹ Institute Of Liver And Biliary Sciences, New Delhi, Pediatric Hepatology, New Delhi-India² Institute Of Liver And Biliary Sciences, Radiodiagnosis, New Delhi-India³

Background / Hypothesis: Gallstone disease (GSD), including gallstones and biliary sludge, is increasingly recognized in children with Wilson disease (WD), but pediatric data on prevalence, risk factors, and early evolution are limited. This study aimed to quantify the burden of GSD at diagnosis and during follow-up in a pediatric WD cohort, identify independent correlates, and evaluate early course and management outcomes.

Materials and Methods: We performed a retrospective analysis of prospectively collected data from 152 children with WD managed at ILBS between January 2011 and July 2025. WD diagnosis was based on a Leipzig score ≥ 4 and/or detection of one homozygous or ≥ 2 compound heterozygous pathogenic ATP7B mutations. GSD was defined ultrasonographically as gallstones (echogenic foci with acoustic shadowing) or biliary sludge (low-amplitude homogeneous echogenicity layering along the posterior gallbladder wall without acoustic shadowing, with or without mobility). The primary objective was to determine the prevalence of GSD at diagnosis. Secondary objectives

included assessing the natural history of GSD, incidence of new gallstones or sludge among those stone-free at baseline, and outcomes of symptomatic and asymptomatic GSD during follow-up. Statistical analysis was performed using SPSS version 26, with $p < 0.05$ considered significant.

Results: Of the 152 children with WD (mean age 8.5 years), 51 (33.6%) had GSD at diagnosis - 33 (65%) had sludge and 13 (25%) had stone. In the univariate analysis, younger age ($p=0.04$), higher bilirubin ($p=0.012$), lower SAP ($p=0.025$), lower Hb ($p<0.001$) and higher reticulocyte count ($p<0.001$), and presence of hemolysis ($p<0.001$) were associated with GSD. On multivariate analysis, hemolysis was independently associated with baseline GSD (adjusted odds ratio [aOR] 2.42; 95% CI 1.00–5.84; $p=0.049$), while older age was inversely associated (aOR 0.85 per year; 95% CI 0.73–0.98; $p=0.028$). Total bilirubin (log-transformed) showed a positive, non-significant trend (aOR 1.33; 95% CI 0.94–1.89; $p=0.105$). Over a median follow-up of 8 (6–24) months, 64.5% sludge persisted, 22.6% progressed to stone formation 12.9% resolved. Baseline stones showed increase in number and size in 30.8%, resolution in 15.4%, persistence in 53.8%. 5 children developed incident stones over a mean follow-up of 90 months. Of the 20 children with gallstones, 1 patient developed Mirizzi syndrome requiring cholecystectomy, while remaining 19 remained asymptomatic.

Conclusions: One-third of children with Wilson disease have gallstone disease at diagnosis, associated with younger age and hemolysis. Routine baseline and follow-up ultrasonography is warranted, particularly in hemolytic phenotype. Most of gallstones and biliary sludge remained asymptomatic.

Keyword(s) : Gall stone, Wilson disease, sludge

2363 - An Innovative Digital Oncology Platform for Enhanced Precision Management of Hepatocellular Carcinoma in China

Cheng Huang¹, Jiabin Cai¹, Dian Wang², Cunying Pu², Jit Thye Kee², Huichuan Sun¹

Department Of Hepatobiliary Surgery And Liver Transplantation, Comprehensive Treatment Center For Hepatobiliary Cancer, Liver Cancer Institute And Z, Department Of Hepatobiliary Surgery And Liver Transplantation, Shanghai-China¹ Roche Diagnostics (Shanghai) Ltd. Shanghai, China, Roche Information Solution China, Shanghai-China²

E-POSTER ABSTRACTS

Background and Aims:

Hepatocellular carcinoma (HCC) imposes a severe burden in China, ranking as the fourth most common malignant tumor and the second leading cause of cancer-related death, characterized by late diagnosis, complex comorbidities, and highly heterogeneous treatment responses. Multi-Disciplinary Treatment (MDT) and real-world data utilization are critical for improving outcomes, yet traditional workflows are limited by fragmented data and inefficient analysis. We hypothesized that a comprehensive digital oncology platform could enhance multidisciplinary consultation efficiency, enable prognosis-oriented clinical data mining, and support personalized treatment strategies for patients with HCC.

Methods:

A digital oncology platform (Oncology Hub, OH) was designed and implemented by both Roche and Zhongshan hospital to integrate clinical data across the entire care pathway of HCC, including diagnosis, treatment, and follow-up. The clinical data was derived from 2,465 HCC patients who sought medical care between 2020 and 2022 and underwent corresponding follow-up. Advanced analytics and large language model-based digital tools were applied to mine longitudinal real-world data, identify prognostic patterns aligned with clinical needs, and retrieve historical cohorts of clinically similar patients to inform treatment planning and efficacy prediction. System performance was evaluated in terms of consultation efficiency, data processing speed, and clinical decision support capability.

Results:

The Oncology Hub (OH) significantly boosted MDT efficiency in complex HCC cases by accelerating data aggregation and preparation up to 12-fold and enhancing expert collaboration, leading to an expected >500% increase in MDT discussions productivity. The data analysis could be done from OH platform, based on different treatment strategy achieved relatively disease-free survival(DFS) across all stages including I.II.III stages (CNLC). Prognosis-oriented data mining allowed clinicians to clarify the evolution of treatment decision-making, with decision focus shifting from "patient-based" (considering comorbidities in stage I) to "tumor-based" (assessing risk levels in stages II/III). Adjuvant therapy equalized survival for high-risk patients to the standard level in stages III although this

benefit waned in stage III. By leveraging a digital large language model, the system identified historically similar patients from the database to enable evidence-based and stage-specific treatment strategy selection. This improved clinical efficiency, decision confidence, and personalized care for HCC patients across all stages.

Conclusion:

The Oncology Hub (OH) which integrates automated data capture, advanced analytics, and large language model, demonstrates significant potential in providing enhanced clinical benefits in HCC management.

2365 - Cholangioscopy Guided Diagnosis of Acquired Biliary Web in a Pediatric Patient A Case Report

Darryl John Pasamba¹, Romel John Sazon¹, Mark Anthony De Lusong³
Philippine General Hospital, Gastroenterology, Manila-Philippines¹

Background / Hypothesis:

Biliary webs are one of the rare causes of biliary obstruction in the pediatric population and are usually congenital. Choledocholithiasis contributes to web formation via prolonged biliary stasis and chronic inflammation. Endoscopic retrograde cholangiopancreatography (ERCP) with biliary dilation and cholangioscopy offers a minimally invasive therapeutic option for biliary web formation. We report a case of obstructive jaundice from acquired biliary webs from large common bile duct stone diagnosed with cholangioscopy and successfully managed with ERCP and biliary dilation

Materials and Methods:

A 13-year-old male, previously healthy, presented with right upper quadrant abdominal pain and generalized jaundice. MRCP was done showing intraluminal filling defect in distal common bile duct measuring 1.7 x 1.2 x 1.3 cm with noted gallbladder hydrops and gallbladder sludge. ERCP was performed with cholangiogram that showed markedly dilated left and right intrahepatic ducts (16mm), common hepatic duct (30mm) and common bile duct (18 mm), with a circumferential band-like constriction in the distal CBD, located 15mm from the ampulla. Spyglass cholangioscope was used to

E-POSTER ABSTRACTS

directly visualize the constriction, which appeared to be a circumferential stenosis with smooth mucosa and without obvious mass. Saline irrigation and aspiration ensured adequate visualization. Using a 12-15mm CRE balloon, the sphincter of oddi and the distal CBD constriction were dilated to 12mm (3atm) for 3 minutes, until the balloon waists were obliterated. Spontaneous passage of black bile, sludge, and stone fragments was noted. Both IHDs were cannulated and balloon sweeps were done extracting some biliary sludge. Occlusion cholangiogram no longer showed any filling defects in the biliary tree. The patient was monitored clinically and biochemically post-procedure.

Results:

ERCP confirmed the presence of a distal biliary web, with upstream bile duct dilatation, likely acquired from a large obstructing choledocholithiasis. Balloon dilation resulted in disruption of the biliary web with direct visualization using cholangioscopy, allowing biliary drainage and improved ductal patency. The patient showed clinical improvement after the ERCP, with relief of obstruction and abdominal pain. Follow-up evaluation showed resolution of jaundice and decrease of liver enzymes and bilirubin levels to normal range.

Conclusions:

This case presents acquired biliary web as a rare but important cause of biliary obstruction in pediatric patients with large choledocholithiasis. Cholangioscopy is crucial in identifying a benign circumferential biliary web. ERCP with biliary dilation is a minimally invasive approach for both diagnosis and treatment, potentially avoiding surgical

Keyword(s) : biliary web, obstructive jaundice, choledocholithiasis, cholangioscopy

2366 - Sex Disparities in Hepatocellular Carcinoma in a Korean Nationwide Cohort

Do Seon Song¹, Ji Won Han¹, Gwang Hyeon Choi², Jeayeon Park³, Su Jong Yu³

The Catholic University Of Korea, Internal Medicine, Suwon-South Korea¹ Seoul National University Bundang Hospital, Internal Medicine, Seongnam-South Korea² Seoul National University, Internal Medicine, Seoul-South Korea³

Background

Hepatocellular carcinoma (HCC) is a malignancy with a well-established male predominance, with incidence rates two to three times higher in men than in women. However, sex-related disparities in HCC have not been

well characterized in Asian populations

Methods

This study included patients newly diagnosed with HCC between 2008 and 2020 from the Korea Central Cancer Registry. Exclusion criteria were age <18 years, missing data, and combined HCC and cholangiocarcinoma. Tumor stage was classified according to the modified Union for International Cancer Control (mUICC) staging system.

Results

A total of 19,729 patients with HCC were included, of whom 15,595 (79.0%) were men. HCC in men peaked in their 50s and declined thereafter, whereas in women, the number of cases increased with age. The male-to-female (M:F) ratio was highest in patients aged 40–59 years (6.0:1), followed by 60s (3.7:1) and ≥70 years (2.4:1), indicating a decreasing male predominance with age.

By etiology, the M:F ratio was 2.7 for HBV, 1.4 for HCV, 22.0 for alcohol-related HCC, and 2.2 for other causes, with the most pronounced male predominance in alcohol-related cases. From 2008 to 2020, the proportion of women with alcohol-related HCC increased from 3.6% to 5.6% ($P < 0.05$), while no significant sex-based changes were observed in other etiologies ($P > 0.05$).

At diagnosis, the proportion of women decreased with advancing stage: 28.2% in stage I, 23.2% in stage II, 18.2% in stage III, and 14.9% in stage IV ($P < 0.001$), suggesting later-stage diagnosis in men.

In stage I, treatment patterns did not differ by sex.

However, in stage II, men were more likely to undergo surgical resection (35.2% vs. 28.2%). In stage IVa, systemic therapy was more common in men (17.4% vs. 12.6%), whereas more women remained untreated (43.2% vs. 36.1%). In stage IVb, men more frequently received transarterial therapy (24.4% vs. 17.7%) and systemic therapy (26.4% vs. 22.6%), while untreated rates were higher among women (50.9% vs. 41.0%).

These findings indicate that men were more likely to receive active treatment, especially in advanced stages. In total patients, women had better survival ($P < 0.001$); however, no difference was observed when analyzed by stage.

Conclusion

The incidence of HCC differs by sex across age groups and underlying etiologies, with the most pronounced disparity observed in alcohol-related liver disease. Notably, the proportion of women developing alcohol-related HCC has been gradually increasing. Following diagnosis, men tend to receive more active treatment compared to women. Recognizing these sex-based

E-POSTER ABSTRACTS

differences in HCC is essential to guide strategies aimed at improving outcomes

Keyword(s) : Hepatocellular carcinoma, Sex, stage, treatment

2367 - Hepatic arterial infusion chemotherapy sequential transarterial embolization combined with lenvatinib and tislelizumab in patients with high risk unresectable hepatocellular carcinoma an update analysis of a phase 2 trial

Jian-hong Zhong¹, Jia-yong Su¹, Zhu-jian Deng¹, Lu-nan Qi¹, Zhu-shun Chen¹, Zhi-ming Zhang¹, Bang-de Xiang¹, Liang Ma¹

Guangxi Medical University Cancer Hospital, Department Of Hepatobiliary Surgery, Nanning-China¹

Background / Hypothesis: Several studies have confirmed the efficacy of hepatic arterial infusion chemotherapy (HAIC) combined with lenvatinib and anti-PD-1 therapy in unresectable hepatocellular carcinoma (HCC). This phase 2 trial aims to evaluate the safety and efficacy of HAIC followed by transarterial embolization (TAE) combined with lenvatinib and tislelizumab (an anti-PD-1) as a first-line treatment in patients with high-risk unresectable HCC.

Materials and Methods: This is a single-arm, open-label, phase 2 trial (NCT05532319). Patients with high-risk unresectable HCC (CNLC stage Ib, II, and III) were enrolled and received at least one cycle of HAIC followed by TAE (every 4 weeks) combined with lenvatinib and tislelizumab (200 mg intravenously every 3 weeks). The primary endpoint was the progression-free survival (PFS) rate at six months per RECIST 1.1. Secondary endpoints included objective response rate (ORR), the proportion of patients who underwent curative treatments after partial response (including hepatectomy, ablation, radiotherapy, and liver transplantation), significant tumor necrosis on pathological examination (defined as >70% necrosis of the resected tumor), recurrence-free survival, overall survival and safety. Tumor necrosis was analyzed in patients who received completed hepatectomy.

Results: A total of 64 patients were enrolled and received the study treatment between November 2022 to September 2025. Follow-up was updated as of September 2025. The six-month and twelve-month progression-free survival rates were 84.8% and 55.0%, respectively, with a median progression-free survival of

13.0 months. The objective response rate was 65.6% (42/64) per RECIST 1.1 and 84.4% (54/64) per mRECIST. Following partial response, 31 patients (48.4%) underwent curative treatment, including 20 (31.3%) with R0 hepatic resection, 8 (12.5%) with radiotherapy, 2 (3.1%) with radiofrequency ablation, and 1 (1.6%) with liver transplantation. The median recurrence-free survival was not reached. Other 3 (4.7%) patients received palliative radiotherapy. Based on postoperative histopathological assessment, all patients who underwent complete hepatectomy achieved a major pathologic response ($\geq 70\%$) in their tumors, with 50.0% (10/20) attaining a pathologic complete response. Although the median overall survival was not reached, 19 patients (29.7%) died due to tumor progression (n=15), persistent duodenal ulcer perforation (n=1), continuous hematemesis caused by liver cirrhosis (n=1), liver failure resulting from multiple treatments (n=1), or cerebral hemorrhage of unknown etiology (n=1). Most treatment-related adverse events were grade 1 or 2, including epigastric pain, low-grade fever, transient liver function impairment, and thrombocytopenia.

Conclusions: HAIC sequential TAE combined with lenvatinib and tislelizumab was well tolerated and demonstrated promising survival efficacy in patients with high-risk unresectable HCC.

2370 - Comparison of surgical resection percutaneous ablation and transarterial chemoembolization for hepatocellular carcinoma in patients with recompensated cirrhosis a multicenter retrospective cohort study

Can Zhang¹, Nijin Wu², Hang Zheng³, Qiqi Liu⁴, Ping Lü¹, Mingyue Wang¹, Xinke Wang¹, Tianru Zhang¹, Ping He¹, Zhen Zhang⁵, Qiang Zhu¹, Yuemin Feng¹
Shandong Provincial Hospital Affiliated To Shandong First Medical University, Department Of Gastroenterology, Jinan-China¹ The First Affiliated Hospital Of Wenzhou Medical University, Department Of Infectious Diseases, Wenzhou-China² The First Affiliated Hospital Of Wenzhou Medical University, Department Of Gastroenterology, Wenzhou-China³ Shandong Provincial Hospital, Cheeloo College Of Medicine, Shandong University, Department Of Gastroenterology, Jinan-China⁴ The First Affiliated Hospital Of Shandong First Medical University & Shandong Provincial Qianfoshan Hospital, Department Of Gastroenterology, Jinan-China⁵

E-POSTER ABSTRACTS

Background / Hypothesis: The concept of recompensation cirrhosis was introduced by the Baveno VII consensus in 2021 and was later recognized in the European Association for the Study of Liver (EASL) guidelines in 2023. However, few studies have focused on the treatment strategies for hepatocellular carcinoma (HCC) in patients with recompensated cirrhosis. This study aims to compare the clinical efficacy and safety of curative treatments, including surgical resection and percutaneous ablation, versus palliative treatment (transarterial chemoembolization, TACE) in HCC patients with recompensated cirrhosis.

Materials and Methods: This multicenter retrospective cohort study including 135 patients from three hospitals: 102 in the curative treatment (58 with surgical resection and 44 with percutaneous ablation) group and 33 in the palliative treatment (TACE) group. Overall survival (OS), progression-free survival (PFS), and treatment-related complications were evaluated and compared. Inverse probability of treatment weighting (IPTW) and subgroup analyses were performed.

Results: Patients in the radical treatment group were more frequently with hepatitis B-related HCC, solitary tumor nodule, smaller in diameter, and earlier tumor stage. After adjustment using IPTW, the baseline characteristics between the two groups were effectively balanced. The 5-year OS rates were 68.3% in the curative treatment group and 60.1% in the palliative treatment group, while the 5-year PFS rates were 51.0% and 58.1%, respectively. No statistically significant differences in OS or PFS were observed between the two groups ($p=0.39$, $p=0.22$). Subgroup analysis demonstrated that the better PFS of curative treatment was more pronounced in patients with lower tumor burden (tumor diameter <3 cm, BCLC stage 0/A, single lesion), better hepatic functional reserve (favorable Child-Pugh score), and stable recompensation status (duration ≥ 5 years). Within the curative treatment group, a comparison between surgical resection and percutaneous ablation therapy showed comparable OS ($p=0.83$), while PFS was significantly better in the surgical resection group than percutaneous ablation group ($p=0.002$). The curative treatment group had a significantly higher incidence of multiple adverse reactions, including liver dysfunction, electrolyte disturbances, and hypoproteinemia, compared to the palliative treatment group.

Conclusions: For HCC patients with recompensated

cirrhosis, the OS were comparable between curative treatments (surgery/ablation) and palliative treatment (TACE). Patients with low tumor burden, well-preserved liver function, and stable recompensation status may achieve better PFS after curative treatments.

Keyword(s) : hepatocellular carcinoma, recompensated cirrhosis, surgical resection, ablation, transarterial chemoembolization

2371 - Prevalence and Significance of Portal Tract Histological Changes in Metabolic Dysfunction-Associated Steatohepatitis

Archana Rastogi¹, Neeti Nagar¹, Chhagan Bihari¹, Rakhi Maiwal², Shiv Sarin²
Institute Of Liver & Biliary Sciences, Pathology, New Delhi-India¹ Institute Of Liver & Biliary Sciences, Hepatology, New Delhi-India²

Background / Hypothesis:

Metabolic dysfunction associated steatohepatitis (MASH) is a leading cause of advanced liver fibrosis globally. The diagnosis of MASH relies on the assessment of histological features of steatosis, ballooning, lobular inflammation, and fibrosis. The NASH Clinical Research Network histological scoring system, the most widely used scoring, is an unweighted composite score of individual grades for steatosis, lobular inflammation, and ballooning. Despite evidence that portal inflammation correlates with fibrosis progression, it is not included in the score, and the prevalence and significance of portal-based features in MASH remain unclear.

To study the prevalence of portal tract changes, including portal inflammation, interface hepatitis, ductular reaction, bile duct damage, plasma cell infiltration, and their correlation with fibrosis in liver biopsies from patients with MASH.

Materials and Methods:

This retrospective cross-sectional study analyzed 505 liver biopsies (>15 mm) from patients with clinically and histopathologically confirmed MASH. Histological scoring was performed using NAS-CRN. Fibrosis stage 3 and 4 were further sub-staged as 3A, 3B, 3C and 4A, 4B, 4C (Laennec cirrhosis substaging), respectively. Portal inflammation, ductular reaction (CK7 immunohistochemistry), interface hepatitis, and plasma cells were semi-quantitatively graded. Fibrosis in Sirius red-stained, whole-slide scanned digitized tissue

E-POSTER ABSTRACTS

sections was quantified using image analysis. Hepatic progenitor cells were quantified using ImageJ software on CK7-immunostained digitized slides.

Results:

The mean patient age was 45.1 ± 12.5 years, and 65% of the patients were male. Cirrhosis was present in 28.7% of cases, and fibrosis F2–F4 were observed in 69.1%. Portal inflammation was present in 69.3%, of which 53.7% showed mild inflammation. Moderate-severe portal inflammation ($p=0.000$), plasma cells ($p=0.000$) and interface activity ($p=0.002$), significant ductular reaction ($p=0.000$), duct damage ($p=0.000$) were significantly associated with advanced fibrosis stages (F3–F4). HPC (≥ 150) showed significant association with advance fibrosis stages ($p<0.005$). Portal inflammation demonstrated significant correlation with ductular reaction ($p<0.000$), interface activity ($p<0.000$), plasma cell infiltration ($p<0.000$), bile duct damage ($p=0.002$), progenitor cells ($p<0.005$), and fibrosis fraction ($p<0.000$).

Conclusions:

This study confirms that portal inflammation and portal-based histological changes are strongly associated with advanced fibrosis in MASH. The significant correlations between portal inflammation and ductular reaction, interface activity, plasma cells, and HPC expansion suggest a multifactorial role of portal-based changes in disease progression. These findings support the need to incorporate portal inflammation into histological scoring for MASH and to routinely document the severity of portal-based features in the histopathology reports.

Keyword(s) : MASH, Histological scoring, portal inflammation, fibrosis, portal features, quantification

2372 - Refractory Cytomegalovirus Colitis Complicating Ulcerative Colitis After Liver Transplantation The Role of Serial Intestinal Ultrasound

Sylwan Rahardja¹, Shu Wen Tay¹

Singapore General Hospital, Gastroenterology, Singapore-Singapore¹

Background / Hypothesis:

Cytomegalovirus (CMV) is a significant opportunistic pathogen in immunocompromised patients and may complicate colitis in individuals with inflammatory

bowel disease (IBD). In transplant recipients, CMV infection is associated with increased morbidity, and timely diagnosis and antiviral therapy are essential to optimize outcomes.

Materials and Methods:

We report a case of a 23-year-old man with extensive ulcerative colitis (UC) who underwent liver transplantation for Child–Pugh B cirrhosis secondary to autoimmune hepatitis and primary sclerosing cholangitis. The donor was CMV-positive, and the recipient was CMV-negative. At transplantation, UC was in remission on subcutaneous adalimumab. Post-transplant immunosuppression included prednisolone 2.5 mg once daily and tacrolimus (Advagraf®) 8 mg once daily, with valganciclovir 900 mg once daily as CMV prophylaxis.

Results:

Colonoscopy demonstrated diffuse colonic bleeding with scattered deep, punched-out ulcers, most prominent in the left colon. Intestinal ultrasound (IUS) showed active left-sided colitis from the proximal to mid-sigmoid colon. Histology revealed Nancy Histological Index (NHI) grade 4 active chronic inflammation, with CMV inclusions (9/HPF). Antiviral therapy was initiated for 3 weeks. IUS performed 2 days after treatment initiation showed improvement in bowel wall thickness.

Despite initial therapy, repeat colonoscopy showed worsening ulceration and inflammation, with a marked increase in CMV inclusions (up to 60/HPF). Intravenous ganciclovir was restarted, while baseline immunosuppression was maintained. Follow-up IUS after 1 week demonstrated worsening pancolitis, left-predominant. Repeat colonoscopy at 3 weeks showed pancolitis with luminal bleeding and ulcers (UCEIS E1V2B2), and histology again confirmed NHI grade 4 disease with persistent CMV (1–4/HPF).

Antiviral therapy was changed to intravenous foscarnet to complete a total of 6 weeks. UC therapy was switched to intravenous ustekinumab induction. Two-week follow-up IUS demonstrated marked improvement in bowel wall thickening. Colonoscopy confirmed mucosal healing with residual small erosions (UCEIS E1V2B0), and histology was negative for CMV. Maintenance subcutaneous ustekinumab was continued.

E-POSTER ABSTRACTS

Conclusions:

This case highlights the complexity of managing refractory CMV colitis in post-transplant UC. Serial IUS provided an objective, non-invasive modality to monitor inflammatory activity, detect treatment failure, and assess response to antiviral escalation. IUS findings closely correlated with endoscopic and histological outcomes, supporting its role in guiding timely therapeutic decisions in complex immunocompromised patients.

2373 - One step in hospital HCV screening using a qualitative dual detection immunoassay for HCV core antigen and antibodies (Elecys HCV Duo) initial implementation and performance

Rihwa Om¹, Shunsuke Sato¹, Takuya Genda¹
Juntendo University Shizuoka Hospital,
Gastroenterology & Hepatology, Shizuoka-Japan¹

Background / Hypothesis: Hepatitis C virus (HCV) infection remains a global health concern. Although the World Health Organization (WHO) proposed a strategy to eliminate HCV by 2030, Japan faces challenges owing to limited access and insufficient support for high-risk populations. Previously, HCV diagnoses required a two-step process, delaying results and increasing costs. In 2024, Japan introduced the Elecys HCV Duo immunoassay, which enables the qualitative dual detection of HCV core antigen (HCV Ag) and antibodies against HCV (anti-HCV). This study aimed to evaluate its effectiveness in identifying patients with an active HCV infection.

Materials and Methods: A retrospective analysis was conducted on 13,045 patients who underwent HCV screening using the Elecys HCV Duo immunoassay.

Results: Of these, 244 were positive for HCV Duo. All 14 patients positive for HCV Ag and anti-HCV had active infection, as confirmed by HCV-RNA testing. Five HCV Ag-positive but anti-HCV-negative patients were identified as false positives. In contrast, five anti-HCV-positive but HCV Ag-negative patients had active infections with detectable HCV-RNA. A low viral load and possible antibody interference were identified as potential reasons for false-negative HCV Ag results.

Conclusions: The Elecys HCV Duo immunoassay effectively simplified HCV diagnosis and facilitated early detection and treatment initiation. Although

false-negative HCV Ag results occurred, the assay ensured linkage to care for patients with both HCV Ag and anti-HCV positivity. These advancements may contribute to enhanced HCV care and support national elimination efforts.

Keyword(s) : HCV, screening, HCV Duo, HCV core antigen

2376 - PNPLA3 I148M and E434K Variants drive Lipid Dysregulation in Pre diabetes and Diabetics

Abhishak Gupta¹, Manjeet Yadav¹, Israr Ansari¹,
Dheeraj Kapoor², Nirmal K Ganguly¹
Artemis Hospitals, Education And Research, New Delhi-India¹ Artemis Hospitals, Endocrinology, Gurugram-India²

Background: The PNPLA3 gene, encoding adiponutrin, is a key regulator of hepatic lipid turnover and metabolic homeostasis. Two key single nucleotide polymorphisms (SNPs), I148M (rs738409) and E434K (rs2294918), have emerged as important modulators of lipid accumulation and insulin sensitivity. E434K may have a protective effect, whereas I148M is a known risk allele for metabolic disease and hepatic steatosis. The aim of this study is to examine the PNPLA3 I148M and E434K variations affect lipid metabolism in patients with pre-diabetes and type 2 diabetes.

Methods: Patients with prediabetes and type 2 diabetes (n=391) participated in a case-control genetic association study. PNPLA3 variants I148M and E434K were genotyped by direct sequencing and PCR-RFLP. Liver enzymes, insulin resistance indicators, and serum lipid profiles (triglycerides, HDL-C, LDL-C, and total cholesterol) were assessed. The statistical t-test and hardy Weinberg equilibrium were also carried out.

Results: The total patients had hypertriglyceridemia of 46.9% and hypercholesterolemia of 58.6%. We observed that the 'G' carrier was 39.6 and 42.6%, and the genotype frequencies of I148M were CC (48.4 and 36.9%), CG (24 and 40.9%), and GG (27.6 and 22.3%) in Pre- and T2DM, respectively. The genotype frequencies of E434K in the groups were 45 and 58.6%, 48.8 and 30%, and 6.1 and 11.4% for GG, GA, and AA genotypes, respectively. The patients mean levels of HDL, LDL, VLDL, triglycerides, and total cholesterol were 210±42 mg/dl, 194.6±49.8 mg/dl, 59.6±16.2 mg/dl, 122.8±36.4 mg/dl, and 45.8±17.0 mg/dl, respectively. Higher levels of HDL (71.5 vs 40.1 mg/dl, p<0.03), LDL (133.8 vs 68 mg/dl, P<0.005), VLDL (57.3 vs 25.9 mg/dl, P<0.001), triglycerides (224.8 vs 108 mg/dl, p<0.01), and total cholesterol (223.6 vs 138 mg/dl, P<0.01) were all significantly correlated with CG/GG genotype but not

E-POSTER ABSTRACTS

GA/GG.

Conclusion: The PNPLA3 variants I148M and E434K are strong inducers of lipid dysregulation that may accelerate the onset of diabetes.

Keyword(s) : Diabetes, Dyslipidemia, Variants

2379 - Exploring The Inflammatory Cancer Transformation From MASLD To Hepatocellular Carcinoma Using Multi Omics And Machine Learning

Yunzhi Zhang¹, Hanbo Ma¹, Xi Zhang¹, Yunlin Zong¹, Yunlong Yao¹, Shuo Huang¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease has become a leading cause of hepatocellular carcinoma, yet the key mechanisms driving the transition from steatosis/inflammation to cancer remain unclear. This study hypothesized that integrating multi-omics data with machine learning could systematically uncover the driving molecules and signaling pathways during MASLD-related inflammatory-cancer transformation.

Materials and Methods:

We collected tissue and blood samples from patients with metabolic dysfunction-associated steatotic liver disease, metabolic dysfunction-associated steatohepatitis, and hepatocellular carcinoma. Transcriptomic, proteomic, and metabolomic profiling were performed. Machine learning algorithms, including Random Forest and Support Vector Machine, were employed to construct classification models and identify core biomarkers through network analysis.

Results:

Integrated multi-omics analysis identified crucial dynamic changes in genes, proteins, and metabolites during the progression from MASLD to HCC. The machine learning model successfully distinguished different disease stages with a prediction accuracy of 89.5%. Further analysis revealed that immunometabolic reprogramming and specific inflammatory pathways play a central role in the inflammatory-cancer transformation.

Conclusions:

This study systematically elucidates the key molecular

mechanisms underlying the progression from MASLD to hepatocellular carcinoma through multi-omics and machine learning approaches, providing potential biomarkers and a theoretical basis for early warning and targeted intervention.

Keyword(s) : Metabolic dysfunction-associated steatotic liver disease; Hepatocellular carcinoma; Multi-omics; Machine learning; Inflammation-cancer transformation

2380 - The Unexpected Twist Distal Esophageal Obstruction After Rubber Band Ligation in a 51 Year Old Woman with Decompensated Liver Cirrhosis

Leamsi Gay Arpon¹

East Avenue Medical Center, Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Rubber band ligation (RBL) is the standard endoscopic therapy for esophageal varices in patients with cirrhosis and is widely regarded as safe and effective. Rarely, complications such as distal esophageal obstruction may occur, leading to acute dysphagia, vomiting, and hematemesis, with resultant morbidity. Early recognition is crucial, particularly in patients with advanced liver disease.

Case Presentation:

We report the case of a 51-year-old woman with decompensated liver cirrhosis who underwent elective RBL for distal esophageal varices. Within 24 hours of the procedure, she developed sudden-onset dysphagia, retrosternal pain, repeated vomiting, hypersalivation, and an episode of hematemesis. Imaging studies excluded esophageal perforation and mediastinal complications. Urgent upper gastrointestinal endoscopy revealed distal esophageal obstruction caused by post-ligation edema and necrotic mucosal tissue, with superficial oozing consistent with recent hematemesis.

Results:

The patient was managed conservatively with intravenous fluids, a proton pump inhibitor, a somatostatin analog, and close clinical monitoring. Her symptoms gradually improved over 4–5 days. Follow-up endoscopy demonstrated sloughing of necrotic

E-POSTER ABSTRACTS

tissue with complete restoration of distal esophageal patency. She subsequently resumed oral intake and was discharged without recurrence of symptoms or further complications.

Discussion:

Distal esophageal obstruction is an uncommon but potentially serious complication of RBL. Proposed risk factors include advanced cirrhosis, fragile esophageal mucosa, multiple bands applied during a single session, and pre-existing esophagitis. Hematemesis may occur secondary to mucosal necrosis and edema at the banding site. Prompt recognition, urgent endoscopic evaluation, and supportive care are generally sufficient to achieve recovery, thereby avoiding invasive interventions and preventing progression to severe outcomes such as perforation or stricture formation.

Conclusions:

Although RBL remains the cornerstone of management for esophageal varices, clinicians should remain vigilant for rare complications such as distal esophageal obstruction with hematemesis, particularly in patients with decompensated cirrhosis. Timely endoscopic evaluation and supportive care typically result in favorable outcomes, underscoring the importance of careful post-procedure monitoring.

Keyword(s) : Distal esophageal obstruction, rubber band ligation, decompensated cirrhosis, MASLD, hepatitis, esophageal varices

2382 - A Novel VExUS Based Model Integrating Renal Venous Congestion and Mesenteric Hemodynamics for Noninvasive Risk Stratification of High Risk Esophageal Varices in Cirrhosis

Zhen Tian¹, Fei Wang¹, Litao Ruan¹

The First Affiliated Hospital Of Xi'an Jiaotong University, Ultrasound Department-hepatobiliary And Gastrointestinal Ultrasound Section, Xi'an-China¹

Background / Hypothesis:

Accurate noninvasive identification of high-risk esophageal varices remains a critical challenge in cirrhosis management. This study aimed to develop and validate a predictive model based on venous excess ultrasound (VExUS) parameters that reflect dynamic portal hypertensive changes, specifically integrating renal venous congestion and superior mesenteric artery (SMA) hemodynamics.

Materials and Methods:

In this retrospective study, 161 patients with liver cirrhosis were analyzed. Patients were classified into a high-risk group (n=78, requiring endoscopic band ligation ± pharmacotherapy) or a low-risk group (n=83, managed conservatively) based on endoscopic findings as the reference standard. VExUS parameters (renal venous Doppler patterns and SMA peak systolic velocity [PSV]) and liver function markers were assessed. A multivariate logistic regression model was constructed.

Results:

The combined model (renal venous congestion + SMA-PSV + ALT) demonstrated excellent discriminatory performance, with an area under the receiver operating characteristic curve (AUC) of 0.931 (95% CI: 0.892–0.970). This significantly outperformed any single parameter, including renal venous congestion alone (AUC 0.841, 95% CI: 0.775–0.907; all p-values <0.01).

Conclusions:

This novel VExUS-based model provides a highly accurate and completely noninvasive tool for stratifying the risk of high-risk esophageal varices. It holds strong potential to refine clinical decision-making and reduce reliance on routine screening endoscopy in patients with cirrhosis.

2383 - Multikingdom and functional gut microbiota markers for cholangiocarcinoma

Zhigang Ren¹, Benchen Rao¹, Zujiang Yu¹

The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases, Zhengzhou-China¹

Background / Hypothesis:

While the association between gut microbiota and cholangiocarcinoma (CCA) has been explored, existing research has been limited to bacterial components. The alterations in non-bacterial members (fungi, archaea, and viruses) and their functional characteristics in CCA remain unclear. This study aimed to comprehensively characterize the multi-kingdom gut microbiota and functional profiles in CCA patients and develop a non-invasive diagnostic model.

Materials and Methods:

We performed metagenomic sequencing on 700 fecal

E-POSTER ABSTRACTS

samples collected from three distinct regions in China, comprising 289 CCA patients, 312 healthy controls, and 99 hepatocellular carcinoma (HCC) patients. Multi-kingdom microbial composition and functional profiles were analyzed. We integrated multiple machine learning algorithms to generate 117 distinct modeling schemes for constructing and screening the optimal CCA diagnostic model. The model was validated across three independent cohorts and tested for specificity against HCC.

Results:

Extensive alterations were identified in CCA patients across multi-kingdom and functional layers, including 198 archaeal, 154 bacterial, 78 fungal, and 120 viral species, as well as 278 genes, 99 pathways, and 151 carbohydrate-active enzymes (CAZymes). A panel of 21 multi-kingdom and functional markers demonstrated superior diagnostic accuracy with an average AUC of 91% across three validation cohorts, outperforming any single-kingdom model. The model exhibited high specificity in distinguishing CCA from HCC, achieving an AUC of 99.74% with a false positive rate of 11.11%.

Conclusions:

This study represents the first comprehensive characterization of multi-kingdom gut microbiome and functional markers in cholangiocarcinoma. Gut multi-kingdom and functional microbial signatures represent a powerful and promising tool for the non-invasive diagnosis of cholangiocarcinoma.

Keyword(s) : cholangiocarcinoma, gut microbiota, Multikingdom microbiota, metagenome, diagnostic model, liver cancer

2384 - Key T Cell Characteristics Associated with Suboptimal Treatment Responses in Pediatric Chronic Hepatitis B

Xueqi Hong ¹, Jia Liu ², Ce Shi ², Yuxi Ning ³, Ruiyang Yuan ³, Min Zhang ², Yanwei Zhong ²

Beijing Huairou Hospital, Beijing Huairou Hospital, Beijing-China ¹ The Fifth Medical Center Of Chinese PLA General Hospital, The Fifth Medical Center Of Chinese PLA General Hospital, Beijing-China ² Hebei North University, Hebei North University, Zhangjiakou-China ³

Background / Hypothesis:

Adult studies have demonstrated that T cell-mediated immune dysfunction is a key mechanism for suboptimal antiviral treatment outcomes, however, the underlying immunological mechanisms driving poor treatment responses in pediatric patients with chronic

hepatitis B (CHB) remain largely unclear. This study aimed to systematically characterize the composition of T cell subsets, gene expression profiles, and functional pathway differences between pediatric CHB patients who achieved HBsAg seroconversion and those who did not following antiviral treatment using single-cell RNA sequencing (scRNA-seq).

Materials and Methods:

8 pediatric patients who received IFN- α and NAs combination therapy was enrolled. Patients were stratified into the seroconversion group and non-seroconversion group based on post-treatment HBsAg seroconversion status. Peripheral blood mononuclear cells (PBMCs) were isolated from peripheral blood samples and subjected to scRNA-seq using the 10 $\times$ Genomics platform. Seurat software was utilized for cell clustering, expression matrix filtering, and cell subset annotation. The Cluster Profiler R package was employed for differential gene expression (DGE) analysis and Gene Ontology (GO)/ Kyoto Encyclopedia of Genes and Genomes (KEGG) functional enrichment analysis to compare T cell subset composition and gene expression profiles between the two groups.

Results:

scRNA-seq identified 11 distinct T cell subsets, including CD4⁺ effector memory T cells, CD4⁺ naive T cells, CD4⁺ regulatory T cells (Tregs), CD8⁺ cytotoxic T cells, and CD8⁺ naive T cells. The proportions of CD4⁺ effector memory T cells ($p < 0.01$) and CD8⁺ T cells ($p < 0.05$) were significantly higher in the seroconversion group compared with the non-seroconversion group, accompanied by marked expansion of T cells with memory and effector functions. A total of 14 differentially expressed genes (DEGs) were highly expressed in the seroconversion group. Functional enrichment analysis demonstrated that these DEGs were predominantly enriched in pathways related to viral response, type I interferon signaling, and immune defense responses.

Conclusions:

The variability in antiviral treatment response among pediatric patients is closely associated with differences in T cell subset composition and functional pathway activation. Our study further identifies expansion of memory/effector T cells and high expression of viral response pathway-related genes as pediatric-specific immune correlates of HBsAg seroconversion. These

E-POSTER ABSTRACTS

findings provide novel molecular and cellular targets for predicting treatment efficacy and optimizing antiviral therapeutic strategies in pediatric CHB.

2387 - A Comprehensive Ultrasound Model Integrating Gastrointestinal and Hemodynamic Parameters for Non Invasive Risk Stratification of Esophageal Varices

Zhen Tian¹, Fei Wang¹, Litao Ruan¹

The First Affiliated Hospital Of Xi'an Jiaotong University, Ultrasound Department-hepatobiliary And Gastrointestinal Ultrasound Section, Xi'an-China¹

Background / Hypothesis:

To reduce unnecessary endoscopies in cirrhosis, better non-invasive tools are needed. We aimed to develop and validate a comprehensive ultrasound model, incorporating parameters of Acute Gastrointestinal Injury (AGI) and splanchnic hemodynamics, for predicting high-risk esophageal varices (HRV).

Materials and Methods:

In this retrospective study of 155 cirrhotic patients, we performed a standardized ultrasound protocol assessing gastrointestinal metrics (bowel diameter, wall thickness, motility) and hemodynamic parameters (superior mesenteric artery PSV). Using endoscopic findings as the reference standard, a multivariable logistic regression model was built to predict HRV.

Results:

The ultrasound-derived AGI score was significantly elevated in patients with HRV requiring intervention versus those without (3.04 ± 2.06 vs. 0.67 ± 1.16 , $p < 0.001$). The final composite model (AGI score + Child-Pugh + hemodynamic parameter) demonstrated excellent diagnostic accuracy with an AUC of 0.935 (95% CI: 0.898–0.973), outperforming individual components.

Conclusions:

This physiology-based, multimodal ultrasound assessment offers a highly accurate and non-invasive method for HRV prediction. It holds promise as a triage tool to guide more efficient and selective use of screening endoscopy.

2388 - Serum ATX Predicts Posthepatectomy Recurrence in HBV Related HCC

Jia Liu¹, Wenwen Yuan¹, Ce Shi¹, Zixin Guo¹, Zhenyu Zhu¹, Yanwei Zhong¹

The Fifth Medical Center Of Chinese PLA General Hospital, The Fifth Medical Center Of Chinese PLA General Hospital, Beijing-China¹

Background / Hypothesis:

Hepatitis B virus-related hepatocellular carcinoma (HBV-HCC) is a leading cause of cancer-related death in the Asia-Pacific region, and posthepatectomy recurrence remains a major clinical challenge. Autotaxin (ATX), a secreted glycoprotein, contributes to tumor progression, but its predictive value for posthepatectomy recurrence in HBV-HCC patients remains undefined. This study aimed to explore the association between serum ATX levels and posthepatectomy recurrence in HBV-HCC patients, and to evaluate the predictive efficacy of ATX combined with tumor morphological features.

Materials and Methods:

A total of 120 HBV-HCC patients who underwent hepatectomy were enrolled. Based on the final recurrence outcome, patients were stratified into two subgroups: the recurrence group and the non-recurrence group. Serum ATX levels were measured in all patients. Univariate and multivariate logistic regression analyses were performed to identify independent risk factors for posthepatectomy recurrence. Receiver operating characteristic (ROC) curve analysis was used to assess the predictive value of serum ATX alone and the combined biomarker panel.

Results:

Serum ATX levels were significantly higher in the recurrence group than in the non-recurrence group ($p < 0.05$). Univariate analysis showed that maximum tumor diameter, number of tumors, and serum ATX level were correlated with posthepatectomy recurrence. Multivariate logistic regression analysis confirmed that number of tumors, maximum tumor diameter, and serum ATX level were independent predictors of posthepatectomy recurrence. ROC curve analysis indicated that serum ATX alone had an area under the curve (AUC) of 0.680 (95%CI: 0.610–0.714)

E-POSTER ABSTRACTS

for predicting posthepatectomy recurrence. the combined detection of ATX, maximum tumor diameter, and number of tumors yielded an AUC of 0.881 (95%CI: 0.802–0.936), with significantly enhanced predictive performance.

Conclusions:

Serum ATX level, maximum tumor diameter, and number of tumors are valuable predictors for posthepatectomy recurrence in HBV-HCC patients, and their combined use can achieve superior predictive efficacy.

2391 - Apilarnil Alleviates Potassium Dichromate Induced Hepatotoxicity in Rats by Modulating the Ferroptosis Pathway (GPx4 TFRC)

Mehmet Yildiz¹, Engin Altinkaya¹, Mehmet Ekici², Mustafa Özkaraca³, Esra Bulut Atalay⁴, Mustafa Tosun⁵, Hilmi Ataseven¹

Sivas Cumhuriyet University Faculty Of Medicine, Gastroenterology, Sivas-Türkiye¹ Sivas Cumhuriyet University Faculty Of Veterinary Medicine, Physiology, Sivas-Türkiye² Sivas Cumhuriyet University, Faculty Of Veterinary Medicine, Pathology, Sivas-Türkiye³ Sivas Cumhuriyet University Faculty Of Science, Biochemistry, Sivas-Türkiye⁴ Tokat State Hospital Gastroenterology Clinic, Gastroenterology, Tokat-Türkiye⁵

Background / Hypothesis: Potassium dichromate ($K_2Cr_2O_7$) is an industrial and environmental toxin that induces potent oxidative stress and hepatocellular injury. Apilarnil is a bee product rich in bioactive components, such as proteins and steroid hormones. The aim of this study was to investigate the hepatoprotective efficacy of Apilarnil against $K_2Cr_2O_7$ -induced acute liver injury and to evaluate its regulatory role on the ferroptotic cell death pathway [Glutathione Peroxidase 4 (GPx4) and Transferrin Receptor (TFRC)].

Materials and Methods: Rats were randomized into four groups. The Control and toxicity ($K_2Cr_2O_7$) groups received saline, while the treatment groups underwent Apilarnil pre-treatment (400 and 800 mg/kg) via oral gavage for 14 days. On day 15, hepatotoxicity was induced by a single intraperitoneal injection of $K_2Cr_2O_7$ (15 mg/kg) in all groups except the control, which received saline. Blood and liver tissues were harvested 48 hours post-injection. Serum AST, ALT, ALP, and total bilirubin levels were measured using an autoanalyzer. Histopathological alterations, including necrosis,

hydropic degeneration, and periportal inflammatory infiltration, were evaluated using Hematoxylin-Eosin (H&E) staining. Additionally, to investigate the role of the ferroptotic pathway in tissue injury, GPx4 and TFRC expressions were assessed via immunofluorescence analysis.

The study protocol was approved by the Local Ethics Committee for Animal Experiments of Sivas Cumhuriyet University (Date: 01.09.2025, Decision No: 65202830-050.04.04-84).

Results: $K_2Cr_2O_7$ administration caused a significant increase in serum AST, ALT, and Total Bilirubin levels compared to the control group, along with extensive hepatocellular necrosis. The absence of significant differences in ALP levels confirmed the hepatocellular rather than cholestatic nature of the injury.

Immunofluorescence analysis of liver tissues revealed that the expression of the anti-ferroptotic enzyme GPx4 was suppressed, while TFRC levels, indicative of iron uptake, were upregulated in the toxic group. Apilarnil pre-treatment significantly attenuated serum enzyme elevations and histopathological damage scores. Notably, Apilarnil regulated the ferroptotic process by preserving GPx4 expression and suppressing the upregulation of TFRC.

Conclusions: To the best of our knowledge, this is the first study to demonstrate the hepatoprotective efficacy of Apilarnil against $K_2Cr_2O_7$ toxicity. The protective mechanism is attributed not only to its general antioxidant effects but also to its modulation of the ferroptosis pathway (GPx4/TFRC axis) in liver tissue. These findings suggest that Apilarnil may serve as a potential therapeutic agent against chemical-induced liver injury and as a promising candidate for ferroptosis-targeted therapies in preclinical studies.

Keyword(s) : Apilarnil, Ferroptosis, Potassium dichromate, Hepatotoxicity, GPx4, TFRC

2392 - Plug Assisted Retrograded Transvenous Obliteration for Gastric Varices Treatment

Seok Hyun Kim¹, Byung Seok Lee¹, Hyuk Soo Eun¹, Woo Sun Rou¹, Hong Jae Jeon¹, Eaum Seok Lee¹ Chungnam National University Hospital, Internal Medicine, Daejeon City-South Korea¹

Background / Hypothesis:

This study, with longer follow-up period than our previous study, aimed to further investigate the effectiveness and safety of vascular plug-assisted retrograde vein occlusion in the gastric varices.

E-POSTER ABSTRACTS

Materials and Methods:

A retrospective study was conducted on 81 patients who underwent PARTO for gastric varices from January 2018, to June 2025.

Results:

The patients were 49 men and 32 women, with ages ranging from 35 to 90 years old. The cause of cirrhosis was alcohol in 37 patients, HBV in 19 patients, unknown cause in 14 patients, metabolic dysfunction associated steatotic liver disease in 5 patients and HCV in 4 patients. There was one patient with alcohol and HBV, and one patient with GIST metastasis

Of 81 patients in whom PARTO was attempted, the procedure was unsuccessful in three patients presenting with gastric variceal bleeding because the catheter could not be advanced to the gastric varices. The PARTO procedure was performed on 42 patients who were hospitalized due to gastric variceal bleeding, and 39 patients who did not have gastric variceal bleeding but underwent the procedure for prevention of future bleeding.

Of the 42 patients with gastric variceal bleeding, PARTO was technically successful in 39 patients, whereas clinical hemostasis with PARTO was achieved in 33 patients. Death within 7 days after PARTO occurred in 6 patients due to gastric variceal bleeding.

Prophylactic PARTO was successfully performed in 39 patients at high risk for future gastric variceal bleeding and there was no gastric varicose bleeding during follow-up.

Conclusions: With a longer follow-up period than our previous study, the present study demonstrates that PARTO is a relatively safe and effective option for both primary and prophylactic management of gastric variceal bleeding.

Keyword(s) : Gastric varices, PARTO, cirrhosis

2393 - Lipopolysaccharide Inhibits Autophagy and Promotes Inflammatory Responses via p38 MAPK Induced Proteasomal Degradation of Atg13 in Hepatic Stellate Cells

Zhen Tian¹, Fei Wang¹, Litao Ruan¹

The First Affiliated Hospital Of Xi'an Jiaotong University, Ultrasound Department-hepatobiliary And

Gastrointestinal Ultrasound Section, Xi'an-China¹

Background / Hypothesis:

Inflammation is central to acute-on-chronic liver failure (ACLF). Hepatic stellate cells (HSCs) are now recognized as inflammatory contributors. While autophagy regulates inflammation, the role of the ubiquitin-proteasome system (UPS) in HSC inflammation during ACLF is unknown. We investigated how LPS, a key driver of ACLF, regulates inflammation in HSCs, focusing on the interplay between UPS and autophagy via the essential autophagic protein Atg13.

Materials and Methods:

Clinical data and liver tissues from ACLF patients were analyzed. In vitro, human LX-2 HSCs were stimulated with LPS. Key techniques included qRT-PCR, Western blot, ELISA, co-immunoprecipitation, and siRNA knockdown of Atg13 to assess inflammatory responses, protein interactions, ubiquitination, and signaling pathways (p38 MAPK).

Results:

In ACLF patients, serum LPS levels correlated with disease severity, and p38 MAPK was overexpressed in liver tissue. In vitro, LPS activated p38 MAPK and triggered inflammatory cytokine (e.g., IL-1 β) secretion in LX-2 cells. This was accompanied by inhibited autophagy and decreased Atg13 protein expression. Knockdown of Atg13 mimicked and exacerbated LPS effects, suppressing autophagy and promoting inflammation. Mechanistically, LPS induced p38 MAPK-dependent polyubiquitination and proteasomal degradation of Atg13.

Conclusions:

LPS promotes HSC inflammation via a novel p38 MAPK/UPS axis that targets Atg13 for degradation, thereby inhibiting autophagy. This cross-talk between major degradation pathways positions Atg13 as a critical mediator. Targeting Atg13 stability or proteasome activity in HSCs may represent a novel therapeutic strategy for mitigating inflammation in ACLF.

Interferon-alpha Hospital, Oncology, Ulaanbaatar-Mongolia ¹ Second General Hospital, Surgical Oncology, Ulaanbaatar-Mongolia ² Mnums, Infectious Diseases, Ulaanbaatar-Mongolia ³

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is a highly prevalent disease in Mongolia, most commonly associated with chronic infections from hepatitis B virus (HBV), hepatitis C virus (HCV), and hepatitis D virus (HDV).

Bevacizumab (Avastin), a VEGF inhibitor, is widely used as a targeted therapy for HCC. This study reviewed medical records from 21 patients to compare treatment outcomes with bevacizumab—measured by the number of treatment courses, which reflects long-term tolerance and duration—across different types of viral infections, genders, and age groups. A higher number of courses was interpreted as indicating better treatment outcomes. The data were sourced from HCC patient records at Interferon Alpha Hospital in 2025.

Materials and Methods:

Information on age, gender, viral status (HBV, HCV, HDV), and the number of bevacizumab treatment courses was extracted from PDF records of 21 patients. Age data were missing for some patients, so analyses involving age were limited to 18 patients. Patients were grouped by viral infection as follows: HBV only, HCV only, HBV + HCV, and HBV + HDV.

Statistical Methods

Average number of treatment courses was calculated for each subgroup using the pandas library in Python. A correlation coefficient was computed to evaluate the relationship between age and the number of courses. Subgroups analyzed included viral infection type (four categories), gender (male/female), and age (<50 years, 50–60 years, >60 years).

Results:

A total of 21 patients were included, with an overall average of 6.95 treatment courses (range: 1–19). There were 13 males (average: 7.15 courses) and 8 females (average: 6.62 courses). The average age was 60.3 years (range: 36–75 years).

Males demonstrated a slightly higher average of 7.15 courses (13 patients) compared to females at 6.62 courses (8 patients). The difference was small but favored males.

Patients over 60 years of age had the highest average at 9.43 courses (7 patients). Those aged 50–60 years.

Conclusion: Bevacizumab treatment demonstrated higher efficacy in patients with HCV only infection, in males, and in those over 60 years of age.

research should involve larger-scale studies and incorporate additional analyses of biochemical markers, such as alpha-fetoprotein (AFP), to further validate these findings.

2397 - Immune Profiling Reveals Distinct Cytokine Signatures in Autoimmune Hepatitis Flares

Xi Zhang¹, Yunlong Yao¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China ¹

Background / Hypothesis:

Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease characterized by immune-mediated hepatocyte injury. Despite effective immunosuppressive therapy, disease flares are common and their immunological underpinnings remain poorly defined. We hypothesized that patients experiencing an AIH flare exhibit a distinct cytokine profile compared to patients in remission and healthy individuals, reflecting an exaggerated T helper 17 (Th17) cell-mediated immune response.

Materials and Methods:

We conducted a case-control study involving 30 AIH patients in active flare, 30 AIH patients in remission, and 30 healthy controls. Serum cytokine levels (including interleukin-17 (IL-17), IL-10, interferon-gamma (IFN- γ), and tumor necrosis factor-alpha (TNF- α)) were quantified using multiplex ELISA. Clinical disease activity was assessed by serum alanine aminotransferase (ALT) levels and Ishak histological activity index on liver biopsy. Group comparisons were made using ANOVA and correlations were evaluated with Pearson's coefficient.

Results:

Patients in AIH flare demonstrated a distinct cytokine signature. Mean serum IL-17 levels were significantly elevated during flares (24.5 ± 5.2 pg/mL) compared to remission (8.7 ± 3.1 pg/mL) and controls (5.4 ± 2.0 pg/mL; $P < 0.001$). Conversely, the anti-inflammatory cytokine IL-10 was markedly lower in flares (3.1 ± 1.0 pg/mL) versus remission (9.8 ± 2.5 pg/mL; $P = 0.002$). IFN- γ and TNF- α levels were also higher in flares than in remission ($P < 0.01$ for both). IL-17 levels correlated positively with ALT ($r = 0.62$, $P < 0.001$) and histological activity, whereas IL-10 levels showed an inverse correlation ($r = -0.45$, $P = 0.008$). No significant differences in cytokine levels were observed between remission-phase patients and healthy controls.

E-POSTER ABSTRACTS

Conclusions:

AIH flares are associated with a heightened pro-inflammatory Th17-dominant cytokine milieu and reduced anti-inflammatory signals. This distinct immunological profile suggests that Th17-associated cytokines (particularly IL-17) play a key role in AIH flares, and highlights IL-17 as a potential biomarker of disease activity and a target for novel therapeutic interventions to prevent or mitigate flares.

2399 - Trends in Cholangiocarcinoma Mortality and Incidence in Asia 2000–2023 Insights from Joinpoint Analysis

Jing Chen¹, Dong Ji², Haitao Zhao³, George Lau⁴
Chinese University Of Hong Kong, Jc School Of Public Health And Primary Care, Hong Kong-Hong Kong SAR, China¹ Fifth Medical Center Of Chinese PLA General Hospital, Senior Department Of Hepatology, Beijing-China² Peking Union Medical College Hospital, Department Of Liver Surgery, Beijing-China³ Humanity And Health Medical Group, Humanity And Health Clinical Trial Center, Hong Kong-Hong Kong SAR, China⁴

Background / Hypothesis:

Cholangiocarcinoma (CCA) is a highly lethal cancer across Asia, where early detection remains uncommon and most patients present with advanced disease. This study evaluates long-term trends in CCA mortality, incidence, annual percent change (APC), average annual percent change (AAPC), and mortality-to-incidence ratio (MIR) from 2000–2023 to identify regional gaps in early detection and guide biomarker development priorities.

Materials and Methods:

Age-standardized mortality and incidence rates by sex and region were obtained from the Institute for Health Metrics and Evaluation (IHME). Temporal patterns were assessed using Joinpoint regression (version 5.4.0) to estimate APC and AAPC. MIR trends were used as a proxy for survival relative to underlying incidence.

Results:

In South Asia (SA), CCA mortality and incidence generally increased between 2000 and 2023. Among women, mortality rose during 2000–2007 (APC 1.82%,

95% CI 1.45–2.23) and accelerated during 2020–2023 (APC 2.87%, 95% CI 1.65–4.34). Men experienced a rise from 2000–2010 (APC 2.11%, 95% CI 1.69–2.71), a temporary decline from 2010–2015 (APC –1.56%, 95% CI –3.81 to –0.36), and renewed increases thereafter (2015–2023 APC 2.08%, 95% CI 1.52–3.08). Incidence trends paralleled mortality. Critically, the MIR in SA remained >1 across the study period, indicating that deaths consistently exceeded diagnoses—strong evidence of late-stage detection, limited diagnostic access, and poor survival.

In Southeast Asia, East Asia, and Oceania (SEAEAO), CCA mortality and incidence declined from 2000 to ~2020, followed by modest increases. Mortality declined among women from 2000–2008 (APC –1.66%, 95% CI –1.89 to –1.36) and among men from 2000–2007 (APC –0.92%, 95% CI –1.21 to –0.64), with fluctuating trends thereafter and slight increases during 2020–2023. Incidence trends mirrored mortality. The MIR decreased from ~0.9 to 0.7, reflecting improved survival, earlier detection, or more effective care compared with SA.

Conclusions:

CCA remains a substantial and uneven burden across Asia. The persistently high MIR in South Asia, contrasted with improving MIR in SEAEAO, highlights major disparities in early diagnosis and treatment. These findings underscore an urgent need for robust, affordable early-detection biomarkers, particularly for resource-limited settings. Emerging liquid biopsy approaches, including circulating tumor DNA, methylation signatures, fragmentation patterns, and multi-omics classifier panels, offer promising avenues to detect CCA at earlier, more treatable stages. Integrating such biomarkers into regional screening strategies, coupled with strengthened diagnostic and treatment capacity, is essential to reduce CCA mortality across Asia.

Keyword(s) : Cholangiocarcinoma; Joinpoint Analysis; annual percent change; average annual percent change; mortality-to-incidence ratio

2400 - Rituximab Achieves High Remission Rates in Steroid Refractory Autoimmune Hepatitis A Controlled Pilot Trial

Yunlong Yao¹, Xi Zhang¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

A subset of autoimmune hepatitis (AIH) patients fail to

E-POSTER ABSTRACTS

achieve remission with standard corticosteroid and azathioprine therapy, highlighting the need for alternative treatments. B-cell driven autoimmunity is implicated in AIH pathogenesis, suggesting that B-cell depletion therapy could induce remission in refractory cases. We hypothesized that adding rituximab (anti-CD20 monoclonal antibody) to the treatment regimen would improve remission rates in patients with steroid-refractory AIH compared to optimized standard immunosuppressive therapy alone.

Materials and Methods:

In a prospective controlled trial, 50 patients with biopsy-proven AIH who remained active (ALT > 3×ULN, interface hepatitis on biopsy) despite ≥6 months of standard therapy were enrolled. Participants were randomized 1:1 to receive rituximab (two 1,000 mg infusions two weeks apart, alongside ongoing low-dose prednisone) or to intensified standard care (optimized doses of corticosteroids plus introduction or dose escalation of mycophenolate mofetil). The primary endpoint was biochemical remission at 6 months (normalization of ALT and IgG levels). Secondary endpoints included histological improvement, steroid dose reduction, and adverse events.

Results:

At 6 months, the rituximab group achieved a significantly higher remission rate compared to standard care (68% vs 32%, $P = 0.01$). ALT levels normalized in 17 of 25 (68%) rituximab-treated patients, versus 8 of 25 (32%) control patients. Mean serum IgG declined by 35% in the rituximab group, indicating reduced immunoglobulin production, compared to a 10% decline in controls ($P = 0.004$). Histological activity improved by ≥2 points (Ishak score) in 12 rituximab patients (48%) versus 5 controls (20%, $P = 0.05$). Furthermore, 60% of patients in the rituximab arm were able to taper off steroids completely by 6 months, compared to 20% in the control arm ($P = 0.02$). No severe infections or infusion reactions were observed; adverse event rates were comparable between groups.

Conclusions:

B-cell depletion with rituximab markedly improves biochemical and histological remission rates in steroid-refractory AIH and facilitates steroid sparing. These findings support rituximab as an effective and well-tolerated second-line therapy in difficult-to-treat AIH, warranting larger randomized trials to confirm long-

term efficacy and safety.

2401 - A Model Incorporating Serum N Terminal Propeptide of Type III Collagen and Platelet Count Predicts Advanced Fibrosis in Chronic Hepatitis B

Xue Bai¹, Jie Li¹

Nanjing Drum Tower Hospital, Affiliated Hospital Of Medical School, Nanjing University, Department Of Infectious Disease, Nanjing-China¹

Background / Hypothesis:

Accurate non-invasive identification of advanced fibrosis (≥S3) is crucial for improving outcomes in chronic hepatitis B (CHB) patients. Serum N-Terminal Propeptide of Type III Collagen (Pro-C3), a marker of collagen synthesis, has shown promise. This study aimed to develop and validate a novel serum-based model incorporating Pro-C3 and routine clinical parameters for diagnosing CHB-related advanced fibrosis (≥S3).

Materials and Methods:

This retrospective study enrolled 324 treatment-naïve CHB patients who underwent liver biopsy from two centers. Patients from center 1 (n=227) formed the training cohort, and those from center 2 (n=97) formed the validation cohort. Baseline clinical characteristics, serum Pro-C3 (ELISA), liver stiffness measurement (LSM), APRI, and FIB-4 were collected. Histological fibrosis staging used the Scheuer system (S0-S4), with ≥S3 defined as advanced fibrosis. Univariate and multivariate logistic regression were performed to identify independent predictors and construct a predictive model. The model's diagnostic performance was evaluated using the area under the receiver operating characteristic curve (AUC), sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), decision curve analysis (DCA), and calibration curves. Its robustness was tested across various patient subgroups.

Results:

In the overall cohort (n=324), 83 patients (25.6%) had ≥S3 fibrosis. In multivariate analysis, Pro-C3 (OR: 1.04, 95% CI: 1.02-1.05, $P < 0.01$) and platelet count (PLT) (OR: 0.99, 95% CI: 0.98-1.00, $P = 0.04$) were independent predictors. The derived model was: $\text{Logit } P = -1.190 + 0.038 \times (\text{Pro-C3}) - 0.007 \times (\text{PLT})$. In the training cohort, this Pro-C3 and PLT model achieved an AUC of 0.80 (95% CI: 0.74-0.85) for diagnosing ≥S3 fibrosis, with a

E-POSTER ABSTRACTS

PPV of 59.5% and NPV of 88.1%. Its performance was superior to FIB-4 (AUC: 0.67, $P < 0.01$) and APRI (AUC: 0.71, $P = 0.02$), and comparable to Pro-C3 alone (AUC: 0.78, $P = 0.17$). The model was validated in the external cohort with an AUC of 0.84 (95% CI: 0.75-0.91). DCA indicated greater net clinical benefit, and calibration curves showed good agreement between predicted and observed probabilities. The model maintained diagnostic efficacy (AUCs > 0.70) across all tested subgroups, including different genders, ages, ALT levels, HBeAg statuses, and HBV DNA levels.

Conclusions:

The novel serum model combining Pro-C3 and PLT demonstrates good and robust diagnostic performance for identifying CHB-related advanced fibrosis and cirrhosis ($\geq S3$), offering a convenient and accurate non-invasive tool for clinical decision-making.

Keyword(s) : Chronic hepatitis B; Advanced liver fibrosis; N-Terminal propeptide of type III collagen; Platelet.

2402 - Association Between Three Month Average Blood Glucose Levels and Hepatic Steatosis and Liver Fibrosis

Oyunselenge Baatarmunkh¹, Erkhemtugs Zagdaa¹, Tserendulam Dorjsuren¹, Delgermurun Batkhurel¹, Erdenebayar Gonchig¹, Amarsanaa Jazag¹, Enkhtuya Damba¹, Batzaya Sodnomjamts¹
Happy Veritas Hospital, National University Of Medical Science, Ulaanbaatar-Mongolia¹

Background / Hypothesis:

Background: Hepatic steatosis is closely associated with metabolic syndrome and is one of the leading causes of chronic liver disease worldwide. Diabetes mellitus and insulin resistance are major risk factors for the development and progression of fatty liver disease. Glycated hemoglobin (HbA1c), reflecting average blood glucose levels over the previous three months, is widely used in clinical practice. Recently, increasing attention has been paid to the association between HbA1c levels and liver steatosis and fibrosis. This study aimed to evaluate the association between HbA1c levels and hepatic steatosis and liver fibrosis.

Methods: This study included 211 adults aged 28–77 years who underwent both HbA1c testing and liver steatosis and fibrosis assessment at Happy Veritas Hospital between 2024 and 2025. HbA1c levels were measured in whole blood using a fully automated COBAS-6000 biochemical analyzer. Hepatic steatosis

and fibrosis were assessed using the FibroTouch liver scan device. Steatosis was classified as normal, mild (S1), moderate (S2), or severe (S3), and fibrosis stages were categorized from F1 to F4. HbA1c levels were defined as normal, prediabetes, or diabetes. Statistical analysis was performed using SPSS version 25.

Results: A total of 211 adults participated in the study, with a mean age of 52.4 ± 10.4 years; 189 (47.7%) were female and 207 (52.3%) were male. The mean HbA1c level was $6.27 \pm 1.15\%$. HbA1c showed a moderate and statistically significant correlation with hepatic steatosis ($r = 0.359$, $p < 0.001$) and a weak but significant correlation with liver fibrosis ($r = 0.187$, $p = 0.007$). Body mass index was strongly correlated with hepatic steatosis ($r = 0.564$, $p < 0.001$), while age was associated with liver fibrosis ($r = 0.230$, $p = 0.001$).

Conclusion: Higher HbA1c levels are significantly associated with hepatic steatosis and liver fibrosis. HbA1c may serve as a useful biomarker for evaluating fatty liver disease. Further studies are required to clarify its clinical significance.

Keyword(s) : HbA1c, hepatic steatosis, liver fibrosis, BMI

2403 - Optimizing Community Based Hepatitis C Screening Strategies Package of Point of care Testing Reflex Testing and Big Data Based Risk Concentration

Qiran Zhang¹, Yiqi Yu¹, Hong Ren², Feng Sun¹, Sen Wang¹, Wenhong Zhang¹
Huashan Hospital, Fudan University, National Medical Center For Infectious Diseases, Shanghai-China¹
Shanghai Municipal Center For Disease Control And Prevention, Department Of Viral Hepatitis Control And Prevention, Shanghai-China²

Background / Hypothesis: Remarkable efforts have been made in hepatitis C virus (HCV) management in China. The Centers for Disease Control and Prevention (CDC) has established effective screening and linkage-to-care procedures for high-risk populations. However, whether universal HCV screening should be implemented in the general population and how it can be practically carried out and linked to care in large-scale community settings remain controversial. This study aims to evaluate the feasibility of universal HCV screening in community-based settings and explore strategies to optimize screening efficiency.

Materials and Methods: The study was conducted in two phases. Phase 1 was integrated into annual routine

E-POSTER ABSTRACTS

health examinations in communities across four provinces. All participants underwent rapid anti-HCV testing using either point-of-care testing (POCT) from fingertip blood or residual blood from other laboratory tests. Those who tested positive received HCV RNA testing via either callback or reflex testing using residual samples. All RNA-positive samples were genotyped. Building on the findings of Phase 1, Phase 2 was conducted in Shanghai in collaboration with the local CDC. A big data approach was used to pre-concentrate individuals at higher risk within the community.

Results: In Phase 1, 21598 participants were screened, with 20 (0.093%) testing anti-HCV positive. HCV RNA testing was successfully performed in 11 of these cases (4 from reflex testing, 7 from call-back and sample retake, 9 lost in call-back process), identifying 6 RNA-positive infections (genotypes: 1b in 3, 2a in 2, and 2b in 1). In Phase 2, after big data-based risk concentration, 8280 participants were screened, with 67(0.81%) individuals testing anti-HCV positive. Reflex RNA testing was performed in 61 cases with adequate samples, confirming 6 active HCV infections.

Conclusions: Utilizing residual blood from routine health examinations for POCT-based anti-HCV screening and reflex HCV RNA testing is feasible for large-scale community screening. Using fingertip blood for POCT HCV antibody screening is also economical and can be considered as a home-lab testing in the future, but the rate of linkage-to-care need improvement. A strategy incorporating big data to concentrate the target population can improve screening efficiency and positivity rates. However, further optimization is needed to enhance the precision of risk stratification and to distinguish between active infections and previously treated cases, thereby avoiding redundant resource use.

Keyword(s) : Hepatitis C virus, community-based screening, big data, point-of-care testing, reflex testing

2405 - Predictors of Relapse After Immunosuppressive Therapy Withdrawal in Autoimmune Hepatitis

Yunlong Yao¹, Xi Zhang¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Although prolonged immunosuppressive therapy can induce clinical remission in autoimmune hepatitis (AIH),

many patients relapse after drug withdrawal. Identifying patients who can maintain long-term remission off therapy remains a clinical challenge. We hypothesized that certain baseline and treatment-related factors predict the risk of relapse upon cessation of therapy, enabling better selection of patients for safe drug withdrawal.

Materials and Methods:

We performed a retrospective cohort study of 120 AIH patients (80% female, mean age 45) who achieved complete remission (normalized liver enzymes and IgG levels, and resolution of interface hepatitis on biopsy) and subsequently discontinued immunosuppressive therapy after a minimum of 2 years of treatment. Patients were followed for a median of 30 months (range 12–60) after withdrawal. Relapse was defined as re-elevation of ALT > 3×ULN or recurrence of histologic AIH requiring treatment resumption. Clinical, biochemical, and histological variables at the time of withdrawal (including age, sex, treatment duration, liver histology, autoantibody titers, IgG level, and presence of cirrhosis) were analyzed. Kaplan-Meier relapse-free survival was calculated, and predictors of relapse were identified using Cox proportional hazards modeling.

Results:

During follow-up, 72 of 120 patients (60%) experienced a relapse after therapy withdrawal, most within the first year (median time to relapse 8 months). In contrast, 48 patients (40%) remained in sustained remission off treatment at last follow-up. Patients who relapsed had a shorter duration of prior therapy (median 30 vs 48 months in non-relapsers, $P = 0.003$) and were more likely to have had cirrhosis at initial diagnosis (35% vs 10%, $P = 0.001$). The presence of residual portal inflammation on the remission biopsy was also associated with relapse (seen in 50% of relapsers vs 15% of non-relapsers, $P = 0.002$). Multivariate Cox analysis identified treatment duration <36 months (HR 2.9, 95%CI 1.5–5.6) and baseline cirrhosis (HR 3.8, 95%CI 1.8–8.0) as independent predictors of relapse ($P < 0.01$). Age, sex, and autoantibody titers were not significant predictors. Patients without these risk factors had a 70% probability of remaining relapse-free at 2 years off therapy.

Conclusions:

A majority of AIH patients relapse after stopping therapy, but extended treatment duration and absence of cirrhosis significantly increase the likelihood of sustained remission. These findings suggest that only patients with favorable prognostic factors (longer

E-POSTER ABSTRACTS

remission duration and no cirrhosis or residual inflammation) should be considered for therapy withdrawal, and highlight the need for individualized decisions to balance the risks of relapse against long-term medication exposure.

Keyword(s) : Autoimmune hepatitis; remission; relapse; withdrawal; predictors

2407 - Comparison of Bevacizumab Treatment Outcomes (Measured by Number of Courses) with Biopsy Characteristics

Ariunzaya Munkhchuluun¹, Enkhbold Chinbold²,
Agiimaa Buyanbaatar¹, Erdenebayar Gonchig³,
Bolortsetseg Batdelger¹
Interferon-alpha Hospital, Oncology, Ulaanbaatar-Mongolia¹ Second General Hospital, Oncology, Ulaanbaatar-Mongolia² Glu, Oncology, Ulaanbaatar-Mongolia³

Background / Hypothesis:

The objective of this study was to identify which biopsy indicators—specifically the degree of differentiation, tumor type, and pT stage—show the strongest correlation with the duration of tolerance to Bevacizumab (Avastin) treatment, as measured by the number of treatment courses administered.

Materials and Methods:

Biopsy results from 21 patients were compiled along with the corresponding number of Bevacizumab courses received. Patients were categorized based on degree of differentiation, tumor type (e.g., trabecular, solid, mixed), and tumor stage (T1, T2, T3, T4). The average number of courses was then calculated for each category.

Results:

- Degree of Differentiation:
- Well-differentiated: No patients in the dataset.
- Moderately differentiated: 7 patients, average 10.14 courses, highest 19 courses. This group showed the highest overall results.
- Poorly differentiated/trabecular: 8 patients, average 4.63 courses, highest 13 courses. This group had, on average, 2.2 times fewer courses than the moderately differentiated group.
- Tumor Stage:
- T1: 2 patients, average 4.00 courses, highest 7 and 5 courses. Relatively low number of courses.

- T2: 9 patients, average 9.67 courses, highest including 19, 19, 14, and 11 courses. This stage showed very high results.

- T3: 4 patients, average 4.25 courses, highest 9 and 5 courses. Moderate results.

- T4: 3 patients, average 7.00 courses, highest 13 and 19 courses. High results, though based on few cases.

- Other Characteristics:

- With cholangiocarcinoma component (mixed HCC-CCC with neuroendocrine features): 1 patient, 2 courses. Very low number of courses.

- Neuroendocrine differentiation present: 1 patient, 2 courses. Worst results observed.

Statistical Results (n=21)

- Moderately differentiated: average 10.14 courses (p < 0.01, t-test comparing G2 vs. others).

- Poorly differentiated/trabecular: average 4.63 courses.

- T2 stage: average 9.67 courses (p < 0.05).

- T3–T4 stages combined: average 5.29 courses.

Top 5 Patients with the Highest Number of Courses

1. 19 courses: Patient 01 – HCC pT2NxMx (moderately differentiated).
2. 19 courses: Patient 02 – HCC moderately differentiated pT4NxMx.
3. 14 courses: Patient 03 – HCC pT3N0Mx (moderately differentiated).
4. 13 courses: Patient 04 – Poorly differentiated HCC pT4NxMx.
5. 11 courses: Patient 05 – HCC pT3bNxMx (moderately differentiated).

Conclusions: The best and longest-lasting outcomes for Bevacizumab treatment, as measured by the number of courses tolerated, were seen in patients with the following biopsy characteristics:

1. Moderately differentiated hepatocellular carcinoma (HCC) – average of 10.1 courses.
2. T2 stage HCC – average of 9.7 courses.
3. The combination of moderately differentiated and T2 stage – yielding the highest individual numbers of courses (19, 19, 14, and 11).

Keyword(s) : Bevasizumab

2408 - ASSOCIATION BETWEEN SERUM IRON LEVELS AND HEPATIC STEATOSIS

Tserendulam Dorjsuren¹, Delgermurun Batkhurel¹,
Oyunselenge Baatarmunkh¹, Erkhemtugs Zagdaa¹,
Batzaya Sodnomjamts¹, Erdenebayar Gonchig²,
Enkhtuya Damba², Amarsanaa Jazag²
Mnums, School Of Medicine, Ulaanbaatar-Mongolia¹

E-POSTER ABSTRACTS

Masld, Happy Veritas Hospital, Ulaanbaatar-Mongolia ²

Background / Hypothesis: Evidence from multiple studies suggests that excessive hepatic iron accumulation may exert hepatotoxic effects. Therefore, maintaining iron homeostasis in the body may be particularly important for liver health, especially in the context of nonalcoholic fatty liver disease. NAFLD can progress to hepatic fibrosis, cirrhosis, and ultimately hepatocellular carcinoma. The mechanisms underlying the development of nonalcoholic fatty liver disease have not yet been fully elucidated. Therefore, the aim of this study was to examine the association between serum iron levels and the risk of hepatic steatosis.

Materials and Methods: Between January 2024 and 2025, a total of 396 individuals with concurrent measurements of serum iron levels and hepatic steatosis at "Happy Veritas" Hospital were selected and included in this study. Serum iron levels were determined using a Cobas 6000 fully automated biochemical analyzer, and the degree of hepatic steatosis was assessed using a FibroTouch Liver Scan device. Hepatic steatosis measured by FibroTouch liver scan was classified as follows: 0–240 dB/m was considered normal, 240–265 dB/m as S1, 265–295 dB/m as S2, and values above 295 dB/m as S3. Serum iron levels of 11–25 $\mu\text{mol/L}$ were defined as normal, values below 11 $\mu\text{mol/L}$ as low, and values above 25 $\mu\text{mol/L}$ as elevated. Data were analyzed using SPSS version 25.

Results: A total of 396 adults with concurrent measurements of serum iron levels and hepatic steatosis were included in this study. Of these, 189 (47.7%) were female and 207 (52.27%) were male. Among females, the mean age was 50.54 ± 10.84 years (range 27–74 years). Serum iron levels ranged from 2.68 to 49.93 $\mu\text{mol/L}$, with a mean of 16.19 ± 7.53 $\mu\text{mol/L}$. The mean hepatic steatosis value was 250.78 ± 43.39 dB/m (range 163–371 dB/m). Among males, the mean age was 43.27 ± 11.15 years (range 18–81 years). The mean serum iron level was 19.91 ± 8.15 $\mu\text{mol/L}$ (range 6.13–53.00 $\mu\text{mol/L}$). The mean hepatic steatosis value was 275.45 ± 51.4 dB/m (range 181–396 dB/m). The correlation between serum iron and hepatic steatosis was not significant in females ($r = 0.028$, $p = 0.69$) and showed a weak, non-significant correlation in males ($r = 0.08$, $p = 0.31$).

Conclusions: When examining the association between iron status and hepatic steatosis, it is necessary to take into account other disease and dietary factors. In

particular, among women, iron levels may vary substantially due to menstrual status, parity, and pregnancy, and these factors should be carefully considered. In future studies, incorporating additional iron-related parameters such as ferritin, transferrin, and total iron-binding capacity would provide more comprehensive information.

2409 - Deep Learning Assisted Ultrasound Improves Early Hepatocellular Carcinoma Detection in Cirrhosis

Yunlong Yao¹, Xi Zhang¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China ¹

Background / Hypothesis:

Ultrasound surveillance for hepatocellular carcinoma (HCC) in cirrhosis suffers from limited sensitivity, especially for small or early-stage tumors. Missed early HCC can delay curative treatments. Recent advances in artificial intelligence (AI) suggest that deep learning image analysis could enhance tumor detection on ultrasound. We hypothesized that a deep learning-assisted ultrasound system would improve the accuracy of HCC detection in at-risk cirrhotic patients compared to standard radiologist interpretation alone.

Materials and Methods:

We developed a convolutional neural network (CNN) model trained on a dataset of 5,000 ultrasound images (including 1,200 images with pathologically confirmed HCC lesions ≤ 2 cm and 3,800 non-tumor images from cirrhotic livers). The CNN was validated on an independent test set of 200 patients undergoing HCC screening ultrasound (including 50 with small HCC nodules undetectable by prior conventional ultrasound). In a reader study, three blinded radiologists interpreted the ultrasound images with and without AI assistance. Sensitivity, specificity, and area under the ROC curve (AUC) for HCC detection were compared between standard reading and AI-assisted reading. Statistical significance was assessed using McNemar's test for paired proportions and DeLong's test for AUC.

Results:

The deep learning model achieved an AUC of 0.93 in detecting HCC nodules ≤ 2 cm on the test set. AI-assisted interpretation significantly increased sensitivity for small HCC from 68% (radiologists alone) to 85%

E-POSTER ABSTRACTS

with AI support ($P = 0.01$), with a modest reduction in specificity from 95% to 90% ($P = 0.04$) due to a few false positives. Overall AUC improved from 0.81 (unassisted) to 0.90 (AI-assisted, $P = 0.03$). Notably, 10 out of 15 early HCC lesions missed by all three radiologists on initial review were correctly flagged by the AI system. Integration of the AI tool slightly increased reading time by 10% on average, but radiologists reported improved confidence in their interpretations with AI support.

Conclusions:

Deep learning-assisted ultrasound significantly improves the detection of early-stage HCC in cirrhotic patients, increasing sensitivity for lesions that are often missed by human readers. Implementing AI support in HCC surveillance could lead to earlier tumor detection and better patient outcomes, though careful management of false positives and workflow integration will be important for clinical adoption.

2411 - A Machine Learning Model Predicts Hepatic Decompensation Risk in Compensated Cirrhosis

Yunlong Yao¹, Xi Zhang¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Patients with compensated cirrhosis are at variable risk of progressing to hepatic decompensation (development of ascites, variceal hemorrhage, or encephalopathy), but existing clinical scoring systems (e.g., MELD, Child-Pugh) have limited ability to predict individual risk of decompensation. Machine learning (ML) approaches can analyze complex clinical data to improve risk stratification. We hypothesized that an ML-based model using routine clinical parameters could more accurately predict 1-year decompensation in compensated cirrhosis compared to traditional risk scores.

Materials and Methods:

A retrospective analysis was performed on a cohort of 800 patients with compensated cirrhosis (no prior decompensation) from a tertiary center database. Baseline clinical and laboratory variables (demographics, liver function tests, platelets, liver stiffness by elastography, presence of varices on endoscopy, etc.) were collected. Patients were followed for 12 months for occurrence of first decompensation

event. A random forest ML model was trained on 600 patients and internally validated on 200 patients. Model performance (AUC, sensitivity, specificity) for predicting decompensation at 1 year was compared with MELD and Child-Pugh scores. Feature importance analysis identified key predictors within the ML model.

Results:

Within 1 year, 120 of 800 patients (15%) developed a decompensation event (ascites most commonly). The ML model demonstrated superior predictive accuracy: in the validation set, the random forest achieved an AUC of 0.88 (95% CI 0.82–0.94) for predicting 1-year decompensation, compared to AUC 0.72 for MELD and 0.70 for Child-Pugh scores ($P < 0.01$ for both comparisons). At an optimized risk threshold, the ML model's sensitivity was 80% and specificity 85%, versus 60% and 75% for MELD. Key predictors identified by the model included serum albumin, platelet count, liver stiffness, and INR. Patients stratified as high-risk by the ML model had a 30% observed decompensation rate, versus 5% in low-risk patients (HR 6.5, $P < 0.001$). Calibration analysis showed good agreement between predicted and observed risk.

Conclusions:

A machine learning model using standard clinical data outperformed conventional scores in predicting short-term decompensation risk in compensated cirrhosis. Such an ML-based risk stratification tool could help clinicians identify high-risk patients for closer monitoring or early intervention (e.g., preemptive beta-blockers or transplant evaluation), while sparing low-risk patients from unnecessary invasive surveillance. Prospective validation and integration into clinical workflows are warranted to realize its potential in personalized cirrhosis care.

2412 - Influence of clinical stages of decompensated cirrhosis on optimal portal pressure decrease to control ascites while minimizing hepatic encephalopathy after TIPS

Ping Lv¹

Shandong Provincial Hospital Affiliated To Shandong First Medical University, Gastroenterology, Jinan-China

¹

Background / Hypothesis:

Transjugular intrahepatic portosystemic shunt (TIPS) reduces the portal pressure gradient (PPG), which

E-POSTER ABSTRACTS

raises two major clinical concerns: how to effectively prevent rebleeding and how to avoid inducing hepatic encephalopathy (HE) due to excessive shunting. For patients with decompensated cirrhosis presenting with both bleeding and ascites, even within the same range of PPG reduction, they may be more susceptible to post-TIPS complications such as HE. This highlights the need for a more nuanced understanding of how an individual's clinical stage of decompensated cirrhosis and baseline liver function influence the outcomes of TIPS procedures.

Materials and Methods:

This retrospective study included 162 patients with cirrhotic variceal bleeding complicated by ascites who were subjected to TIPS at Shandong Provincial Hospital between February 2015 and February 2025. The primary endpoint of this study was all-cause rebleeding. The secondary endpoints were the occurrence of all-cause overt hepatic encephalopathy (OHE), ascites, and portal hypertension complications (PHC).

Results:

To validate different PPG values as targets for hemorrhage prevention, all patients were stratified based on post TIPS PPG. A significant difference in rebleeding was observed between the $<14\text{mmHg}$ and $\geq 14\text{mmHg}$ groups (18.27% vs. 43.10%, $p = 0.012$; sHR = 0.476, 95% CI 0.267–0.847; Gray's test $p = 0.018$). However, no significant differences were found for ascites recurrence, OHE, or PHC, respectively). Meanwhile, a significant difference in OHE was observed between the $<12\text{mmHg}$ group and the $\geq 12\text{mmHg}$ group ($p = 0.037$, sHR = 1.767, 95% CI 1.034–3.019, Gray's test $p = 0.036$), whereas no significant differences were found for rebleeding, ascites recurrence, or PHC. Among patients with Child-Pugh B cirrhosis, a significant difference in the rate of rebleeding was observed between the group with a portal pressure gradient (PPG) $< 14\text{ mmHg}$ and the group with PPG $\geq 14\text{mmHg}$ (18.39% vs. 44.89%, $p = 0.022$, HR = 0.481, 95% CI 0.257–0.900, Gray's test $p = 0.039$). It is noteworthy that when the postprandial glucose increment (PPG) was $< 12\text{mmHg}$, no significant difference was observed in the incidence of OHE between the two groups (37.50% vs 25.00%, $p = 0.140$, sHR = 1.577, 95% CI 0.855–2.908, Gray's test $p = 0.140$). These results remained robust after propensity score matching (PSM) and inverse probability of treatment weighting (IPTW).

2413 - Breath Volatile Organic Compounds and Machine Learning Enable Non Invasive Detection of Early MAFLD

Xi Zhang¹, Yunlong Yao¹, Jiawei Ran¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD, also known as NAFLD) often goes undiagnosed until advanced stages, as current screening relies on liver enzymes and imaging that can miss early disease. Exhaled breath contains volatile organic compounds (VOCs) reflective of systemic metabolism and oxidative stress, which might serve as non-invasive biomarkers for early liver fat accumulation. We hypothesized that a VOC signature in breath, analyzed with machine learning, can distinguish early MAFLD patients from healthy individuals with high accuracy.

Materials and Methods:

We conducted a cross-sectional study of exhaled breath analysis in 100 subjects: 60 with MRI-confirmed early-stage MAFLD (liver fat fraction 5–15%, normal ALT) and 40 age- and BMI-matched healthy controls without fatty liver. Breath samples were collected using a standardized device and analyzed by gas chromatography–mass spectrometry to identify VOC profiles. Concentrations of key VOCs (e.g., ethane, pentane, isoprene, acetone and others) were quantified. A machine learning classification model (support vector machine with radial kernel) was trained (70% of data) and tested (30% hold-out) to differentiate MAFLD vs control based on VOC patterns. Model performance was evaluated by area under the ROC curve (AUC), sensitivity, and specificity. Important VOC predictors were identified using model feature weights.

Results:

Breath VOC analysis identified a distinct metabolic signature in MAFLD patients. The ML model achieved an AUC of 0.94 (95% CI 0.88–0.99) for detecting MAFLD in the test set. At the optimal probability threshold, sensitivity was 90% and specificity 85% for early MAFLD detection. MAFLD patients showed significantly higher breath levels of ethane and pentane (by 2-fold, $P < 0.001$), consistent with increased lipid peroxidation,

E-POSTER ABSTRACTS

and lower isoprene (−30%, $P = 0.01$) compared to controls. The top VOC contributors to the model were ethane, acetone, and isoprene. A simplified 3-VOC panel (ethane, acetone, and 2-butanone) still classified MAFLD with AUC 0.88.

Conclusions:

Exhaled breath VOC profiling combined with machine learning provides a promising non-invasive approach for early detection of MAFLD, outperforming traditional liver enzyme screening in sensitivity. The VOC signature of early fatty liver reflects underlying metabolic and oxidative changes, offering a potential breath test for population screening. Further validation in larger cohorts and standardization of breath collection will be important before clinical implementation of this technology for liver disease screening.

Keyword(s) : metabolic fatty liver; MAFLD; biomarkers; breath analysis; machine learning

2414 - COMBINED ASSESSMENT OF FERRITIN AFP AND PIVKA II IN THE DIAGNOSIS OF HEPATOCELLULAR CARCINOMA

Delgermurun Batkhurel¹, Tserendulam Dorjsuren¹, Oyunselenge Baatarmunkh¹, Erkhemtugs Zagdaa¹, Batzaya Sodnomjamts¹, Erdenebayar Gonchig², Enkhtuya Damba², Amarsanaa Jazag²
Happy Veritas Hospital, Mongolian National University Of Medical Science, Ulaanbaatar City-Mongolia¹
Happy Veritas Hospital, Happy Veritas Hospital, Ulaanbaatar City-Mongolia²

Background: Hepatocellular carcinoma (HCC) remains one of the leading causes of cancer-related mortality worldwide, largely due to diagnosis at advanced stages. Alpha-fetoprotein (AFP) is widely used for surveillance and screening of HCC; however, its sensitivity is insufficient when used alone. Protein induced by vitamin K absence or antagonist-II (PIVKA-II) has been reported to improve diagnostic sensitivity when combined with AFP. Serum ferritin is a marker of hepatic inflammation and iron storage, and several studies have reported elevated ferritin levels in patients with HCC. The combined assessment of ferritin, AFP, and PIVKA-II may therefore represent an important laboratory indicator in the diagnosis of HCC. This study aimed to evaluate and compare these three biomarkers.

Materials and Methods: Among 8,000 adult patients who underwent PIVKA-II and AFP testing at Happy

Veritas Hospital between 2024 and 2025, 194 individuals who also had serum ferritin measured were included. Participants were aged 21–73 years and included 134 males (69.1%) and 60 females (30.9%). Serum ferritin, AFP, and PIVKA-II levels were measured using a fully automated Maglumi immunological analyzer. Participants were classified into normal and elevated ferritin groups. Biomarker levels and age were analyzed and expressed as mean $\pm$ standard deviation. HCC risk categories were defined using internationally accepted cutoff values: AFP >10 and >400 ng/mL; PIVKA-II 50–149 and ≥ 150 mAU/mL; and ferritin >400 and >1000 ng/mL. The influence of age and sex on biomarker patterns was evaluated. A p-value <0.05 was considered statistically significant.

Results: Elevated ferritin levels were associated with increased AFP and PIVKA-II levels, with a stronger association observed in male participants. In males, a 2.45-fold increase in ferritin corresponded to a 2.14-fold increase in AFP and a threefold increase in PIVKA-II. Among participants with ferritin levels of 400–1000 ng/mL, 72.8% were classified as high risk for HCC, while 22.8% of those with ferritin levels >1000 ng/mL were categorized as high risk. In female participants, ferritin elevation was more strongly associated with increasing age, whereas PIVKA-II levels were mostly within the normal range. Combined elevation of biomarkers consistently overlapped with high-risk HCC classifications.

Conclusions: Although ferritin is not a tumor-specific marker, its combined use with AFP and PIVKA-II improves HCC risk assessment. A multi-biomarker approach may enhance early identification of high-risk individuals and strengthen surveillance and screening strategies.

2415 - Fenofibrate Add On Therapy Improves Biochemical Response in Primary Biliary Cholangitis Patients with Incomplete UDCA Response

Xi Zhang¹, Yunlong Yao¹, Yunzhi Zhang¹
Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Up to 30–40% of primary biliary cholangitis (PBC) patients have an incomplete biochemical response to first-line therapy with ursodeoxycholic acid (UDCA),

E-POSTER ABSTRACTS

leaving them at higher risk for disease progression. Fenofibrate, a peroxisome proliferator-activated receptor- α (PPAR- α) agonist, has shown potential to improve cholestatic markers in PBC. We hypothesized that adding fenofibrate to UDCA in patients with suboptimal response would enhance biochemical response rates and improve cholestatic liver enzymes compared to UDCA alone.

Materials and Methods:

We conducted a 12-month multicenter randomized controlled trial in 80 PBC patients who had an incomplete response to at least 1 year of UDCA (alkaline phosphatase (ALP) $> 1.5\times$ upper limit of normal (ULN) or bilirubin $> 1\times$ ULN). Participants were randomized to receive fenofibrate (160 mg daily) plus continued UDCA (13–15 mg/kg/day) ($n = 40$) or UDCA alone ($n = 40$). The primary endpoint was a biochemical response at 12 months, defined as ALP $< 1.5\times$ ULN and normal bilirubin. Secondary outcomes included absolute change in ALP, gamma-glutamyl transferase (GGT), immunoglobulin M (IgM) levels, liver stiffness by FibroScan, symptom changes (pruritus and fatigue scores), and safety parameters (renal function, transaminases).

Results:

Fenofibrate add-on therapy significantly improved biochemical response rates. At 12 months, 60% of patients in the UDCA+fenofibrate group achieved the primary biochemical response (ALP $< 1.5\times$ ULN, normal bilirubin) compared to 25% in the UDCA-only group ($P = 0.002$). Mean ALP levels decreased by 45% from baseline in the combination group (from 280 to 154 U/L), versus a 20% decrease in the UDCA group (from 290 to 232 U/L, $P < 0.001$ between groups). GGT and IgM levels also declined more in the fenofibrate group (GGT -50% vs -15% ; IgM -30% vs -5% , $P < 0.01$). Liver stiffness improved modestly in the combination arm (median -1.8 kPa) while remaining unchanged with UDCA alone. Symptomatically, 50% of fenofibrate-treated patients reported improvement in pruritus, compared to 20% with UDCA ($P = 0.03$). Fenofibrate was well tolerated; no significant hepatotoxicity was observed, though mild reversible increases in serum creatinine occurred in 10% of patients on fenofibrate.

Conclusions:

In PBC patients with incomplete UDCA response, add-on fenofibrate therapy markedly improves cholestatic biochemical indices, with a higher rate of achieving ALP and bilirubin treatment targets and greater reductions in ALP, GGT, and IgM levels compared to UDCA alone.

These results support the use of fenofibrate as an effective adjunct therapy in UDCA-unresponsive PBC to potentially reduce disease progression.

2416 - Oral Vancomycin Therapy in Primary Sclerosing Cholangitis A Pilot Study Demonstrates Biochemical Improvement

Xi Zhang¹, Yunlong Yao¹

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹

Background / Hypothesis:

Primary sclerosing cholangitis (PSC) is a chronic, immune-mediated cholangiopathy with no established medical therapy proven to alter its course. Mounting evidence suggests a role of the gut microbiota and immune dysregulation in PSC pathogenesis. Oral vancomycin, a minimally absorbed antibiotic, has shown promise in small pediatric studies, potentially by modulating the gut-liver immune axis. We hypothesized that oral vancomycin therapy in adults with PSC would improve cholestatic liver enzyme levels and reduce inflammation compared to placebo.

Materials and Methods:

We conducted a 6-month single-center pilot randomized controlled trial in 40 adults with PSC (median age 38, 70% male). Patients were randomized 1:1 to oral vancomycin (125 mg four times daily, $n = 20$) or placebo ($n = 20$), stratified by presence of inflammatory bowel disease. All patients were on stable ursodiol doses or no UDCA for ≥ 3 months prior to enrollment. Primary outcome was change in serum alkaline phosphatase (ALP) at 6 months. Secondary outcomes included changes in bilirubin, liver aminotransferases, symptom scores (pruritus and fatigue), inflammatory markers (CRP), and adverse events. Between-group differences were assessed using t-tests or Mann-Whitney U as appropriate.

Results:

Vancomycin therapy was associated with significant biochemical improvement. Mean ALP declined by 40% in the vancomycin group (from 320 ± 150 to 190 ± 100 U/L), compared to a 5% decline in the placebo group (310 ± 130 to 295 ± 140 U/L; $P = 0.01$ for between-group ALP change). 30% of vancomycin-treated patients achieved a $\geq 50\%$ ALP reduction vs. 0% of placebo ($P = 0.008$). Total bilirubin remained stable in the vancomycin group but slightly increased in placebo

E-POSTER ABSTRACTS

(+0.3 mg/dL, $P = 0.15$). There were trends toward improved fatigue scores in the vancomycin arm (median improvement 2 points vs. 0 in placebo, $P = 0.08$) and lower CRP (-2.5 mg/L vs. $+0.5$ mg/L, $P = 0.04$). Pruritus improved in 4 of 10 symptomatic vancomycin patients, versus 1 of 9 in placebo (non-significant). No serious adverse events occurred; 3 patients on vancomycin reported mild nausea, and 2 had transient diarrhea, but no *C. difficile* infections were observed.

Conclusions:

In this pilot trial, oral vancomycin therapy in PSC was associated with significant reductions in ALP and signals of clinical improvement compared to placebo over 6 months. These findings support the concept of microbiota-targeted therapy in PSC.

Keyword(s) : primary sclerosing cholangitis; gut microbiota; vancomycin; cholestatic liver disease; trial

2417 - Clinical Course and Short Term Outcomes of Acute Hepatitis B in a Tertiary Liver Transplant Center

Oğuzhan Acet¹, Sümeyra İstek¹, Dilara Yaman¹, Şükrü Dirik¹, Arda Kaya¹, Melike Yaşar Duman², Tansu Yamazhan¹

Ege University Faculty Of Medicine, Department Of Infectious Disease And Clinical Microbiology, İzmir-Türkiye¹ Ege University Faculty Of Medicine, Department Of Medical Microbiology, İzmir-²

Background / Hypothesis:

Acute hepatitis B is generally a self-limited infection in adults. However, a subset of patients may develop severe clinical conditions such as acute liver failure and liver transplantation. This study aimed to evaluate the clinical characteristics and short-term follow-up outcomes of patients diagnosed with acute hepatitis B and to identify factors that may be associated with severe disease and mortality.

Materials and Methods:

Between January 2020-December 2024, patients with anti-HBc IgM positivity identified in electronic medical records at a tertiary university hospital were screened. Cases with immunosuppression-related flare and missing follow-up data were excluded. Demographic data, clinical and laboratory findings, and initiation of nucleos(t)ide analogue (NA) therapy were recorded. Virological follow-up included HBsAg and anti-HBs results. Non-normally distributed continuous variables were compared using the Mann-Whitney U test, and

categorical variables were compared using the chi-square test or Fisher's exact test. A p value <0.05 was considered statistically significant.

Results:

A total of 97 patients were included; the median age was 56.5 years [IQR: 39.8–70.3], and 66% were male. The need for liver transplantation was 3.1% ($n=3$). Seven patients (7.2%) had acute exacerbation of chronic hepatitis B (AECHBV) presentation. The distribution of demographic and clinical characteristics is presented in Table 1.

Among hospitalized patients, AST/ALT, baseline/peak total/direct bilirubin, INR/peak INR were higher, whereas albumin was lower; MELD and MELD-Na scores were significantly higher (all $p \leq 0.009$, most $p < 0.001$). In patients admitted to the ICU, platelet counts were lower ($p=0.007$), while bilirubin, INR/peak INR, and MELD/MELD-Na scores were higher (most $p < 0.001$). In addition, encephalopathy and immunosuppression were significantly associated with ICU admission ($p=0.019$ and $p=0.035$, respectively). Patients with HBsAg loss were younger ($p=0.001$) and had higher AST/ALT levels ($p \leq 0.001$); platelet counts were also higher ($p=0.016$). No significant differences were observed between HBsAg loss and bilirubin, INR, or MELD scores ($p > 0.05$). Anti-HBs positivity at months 3, 6, and 12 was strongly associated with HBsAg loss ($p \leq 0.013$) (Tables 2 and 3).

Both patients who died were identified as having AECHBV. Among these patients, 5 (71.2%) required hospitalization, 3 (42.8%) required transplantation, and 1 (14.2%) achieved HBsAg loss.

Conclusions:

Acute hepatitis B in adults is usually benign; however, hospitalization and ICU admission rates were high in our tertiary referral center with a liver transplantation program. These findings identify patients who may require closer monitoring and earlier supportive care, suggest predictors of serological recovery, and underscore earlier recognition and closer follow-up AECHBV cases for organ failure.

Keyword(s) : acute hepatitis b, liver transplantation, hospitalization, intensive care unit

2419 - Generalized Pustular Psoriasis Complicated by Metabolic Dysfunction Associated Fatty Liver Disease and Immunosuppressive Therapy-Associated Transaminitis Highlighting the Skin-Liver Inflammatory Axis

Adinda Amalia¹, C. Rinaldi Lesmana¹

E-POSTER ABSTRACTS

Division Of Hepatobiliary, faculty Of Medicine
Universitas Indonesia/ Dr.cipto Mangunkusumo
General National Hospital, Internal Medicine, Jakarta-
Indonesia ¹

Background / Hypothesis:

Generalized pustular psoriasis (GPP) is a severe systemic inflammatory disease driven by innate immune dysregulation, including activation of the interleukin-36(IL-36) pathway. Increasing evidence supports a bidirectional interaction between chronic cutaneous inflammation and metabolic liver disease. In patients with metabolic dysfunction-associated fatty liver disease (MAFLD), systemic immunosuppressive therapy may increase susceptibility to transaminitis, even in young and non-obese individuals.

Case Presentation:

A 27-year-old woman with long-standing psoriasis vulgaris complicated by GPP and psoriatic arthritis presented with recurrent flares. She had a prior history of overweight but was normoweight at presentation. After inadequate response to topical therapy and cyclosporine, low-dose methotrexate was initiated with gradual escalation. The patient showed marked clinical improvement with complete resolution of pustulation and a 61% reduction in Psoriasis Area and Severity Index. During treatment under immunosuppressive therapy, serial monitoring demonstrated persistent alanine aminotransferase elevation up to 2.1× the upper limit of normal. Viral hepatitis markers were negative. Abdominal ultrasonography showed fatty liver, and FibroScan confirmed hepatic steatosis (controlled attenuation parameter 281 dB/m) with low liver stiffness (4.5 kPa), consistent with MAFLD without advanced fibrosis. Hepatology evaluation considered the transaminitis multifactorial in the setting of MAFLD and exposure to multiple immunosuppressive agents, and recommended cautious continuation of systemic therapy with close biochemical surveillance.

Discussion:

IL-36, a key cytokine axis in GPP, amplifies neutrophilic inflammation via downstream NF-κB/MAPK signaling and induces broader cytokine cascades, supporting systemic inflammatory spillover beyond the skin. In MAFLD, a pro-inflammatory hepatic milieu and metabolic stress may lower the threshold for hepatocellular injury, increasing vulnerability to drug-associated transaminitis. In this case, liver enzyme elevation occurred despite young age, current normoweight status, and absence of advanced fibrosis, suggesting that host inflammatory and metabolic

susceptibility—potentially influenced by IL-36-linked systemic inflammation may be as important as cumulative drug exposure in determining hepatic tolerance. This phenotype differs from primary autoimmune hepatitis and is more consistent with innate immune-primed liver vulnerability on a MAFLD background.

Conclusions:

Severe GPP may contribute to hepatic vulnerability through an IL-36-linked skin–liver inflammatory axis, while MAFLD may act as a susceptible substrate for immunosuppressive therapy–associated transaminitis in young normoweight patients. Coordinated hepatology follow-up and proactive liver monitoring are essential when prescribing systemic immunosuppression in GPP.

Keyword(s) : Generalized pustular psoriasis; metabolic dysfunction–associated fatty liver disease; transaminitis; immunosuppressive therapy; skin–liver inflammatory axis; interleukin-36.

2420 - Autoimmune Hepatitis–Primary Biliary Cholangitis Overlap Syndrome Clinical Characteristics and Comparative Outcomes

Yunlong Yao ¹, Xi Zhang ¹

Beijing University Of Chinese Medicine, School Of
Traditional Chinese Medicine, Beijing-China ¹

Background / Hypothesis:

A subset of patients exhibit features of both autoimmune hepatitis (AIH) and primary biliary cholangitis (PBC), known as AIH-PBC overlap syndrome. These patients often require combined immunosuppressive and ursodeoxycholic acid therapy, but their long-term outcomes relative to isolated AIH or PBC remain unclear. We hypothesized that overlap syndrome patients present with more advanced disease but, with appropriate dual therapy, can achieve similar biochemical control and long-term outcomes as single-diagnosis AIH or PBC patients.

Materials and Methods:

We retrospectively studied 50 patients with AIH-PBC overlap (meeting accepted diagnostic criteria, e.g. Paris criteria) from three centers, and compared them with 100 matched AIH-only and 100 PBC-only patients. Baseline features (including presence of cirrhosis) were recorded. All overlap patients received both UDCA and corticosteroid-based immunosuppression. Biochemical remission at 1 and 2 years was evaluated (criteria:

E-POSTER ABSTRACTS

normalization of ALT and IgG for AIH, ALP $<1.5 \times \text{ULN}$ and normal bilirubin for PBC, both required for overlap). Liver-related outcomes (development of cirrhosis, liver transplant, or liver-related death) were compared over median 8-year follow-up.

Results:

Overlap patients had more aggressive initial disease. At diagnosis, 40% of overlap patients had cirrhosis, vs 15% of AIH-only and 20% of PBC-only ($P < 0.01$). Baseline ALT and ALP were significantly higher in overlap than in AIH or PBC ($P < 0.01$). Despite this, overlap patients achieved biochemical remission rates by 2 years comparable to isolated AIH or PBC: 65% of overlap patients met combined remission criteria, vs 70% of AIH patients (ALT normalization) and 60% of PBC patients (ALP target) ($P = 0.6$). Long-term outcomes were also similar. Ten-year transplant-free survival was ~87% in overlap, 88% in AIH, and 90% in PBC (no significant difference). Rates of liver transplantation (~10% in each cohort) and liver-related mortality (~8–10%) did not differ between groups. Overlap patients did have a higher prevalence of other concomitant autoimmune diseases (30% vs ~10% in AIH, $P = 0.005$).

Conclusions:

AIH-PBC overlap syndrome presents with more advanced liver disease and higher inflammatory/cholestatic markers at baseline, but with appropriate combined immunosuppressive (steroids plus UDCA) therapy, these patients can achieve remission and long-term outcomes comparable to isolated AIH or PBC. Early recognition and aggressive dual treatment of overlap syndrome is critical, as it appears to mitigate the initially severe disease course and leads to outcomes similar to single-diagnosis autoimmune liver conditions.

Keyword(s) : overlap syndrome; autoimmune hepatitis; primary biliary cholangitis; outcomes; cirrhosis

2421 - When Etiologies Intersect Concomitant Hepatitis B Reactivation Hepatic Tuberculosis and Cholelithiasis in a Filipino Male Presenting with Jaundice

Adrian Bugayong¹, Eda Jo Amatong¹

Veterans Memorial Medical Center, Department Of Internal Medicine, Section Of Gastroenterology, Quezon City-Philippines¹

BACKGROUND / HYPOTHESIS:

Hepatic lesions in patients with chronic hepatitis B (CHB) are frequently presumed malignant due to high risk to develop hepatocellular carcinoma, however, infectious etiologies including hepatic tuberculosis (TB) can mimic neoplastic lesions posing diagnostic challenges. We explore a case of a patient presenting with jaundice arising from concomitant hepatitis B reactivation, hepatic TB, and choledocholithiasis further complicating clinical picture, emphasizing the need for thorough assessment and a multidisciplinary approach for targeted treatment.

MATERIALS AND METHODS:

Patient: 58 y/o male with CHB since 1996, not on antiviral treatment, monitored with annual liver function tests; with prior undetectable HBV DNA and fatty liver on ultrasound.

Clinical presentation: 2-month history of jaundice, anorexia, weight loss, RUQ discomfort, and body weakness.

Laboratory: Serum AST, ALT, Bilirubin and ALP, hepatitis serologies, HBV DNA, tumor markers (AFP, CA 19-9), coagulation profile, albumin, and platelet counts.

Imaging: Abdominal ultrasound and triphasic contrast-enhanced CT of the liver.

Procedures: ERCP, percutaneous liver biopsy.

Molecular test: GeneXpert MTB/RIF assay.

Treatment: Antiviral therapy (Tenofovir Disoproxil Fumarate), CBD stone extraction (via ERCP), Anti TB Therapy, Supportive care for liver cirrhosis.

RESULTS:

Laboratory findings: Marked direct hyperbilirubinemia ($10.4 \times \text{ULN}$), elevated AST and ALT ($>3 \times \text{ULN}$), hypoalbuminemia; normal ALP, platelets, INR, AFP and CA19-9; HBsAg(+), HBeAg(-), AntiHBe(+), Anti HBS(-), AntiHBc Total(+) (consistent with HBeAg Negative Chronic Hepatitis B) and HBV DNA: 48,824 IU/ml (from previously undetectable indicating reactivation).

Imaging: Liver cirrhosis with a right lobe hepatic mass (6.2cm $\times$ 4.8cm $\times$ 5.8 cm), intrahepatic bile duct dilatation, and common bile duct stones.

ERCP: Choledocholithiasis confirmed and removed via sphincterotomy and basket destruction and extraction, resulted in partial resolution of jaundice and decrease in AST, ALT, bilirubin trends.

Liver biopsy: Nodular parenchyma with fibrosis and hyalinization; no malignancy or granulomas.

GeneXpert: Positive for Mycobacterium Tuberculosis, rifampicin resistance detected

Clinical course: Initiation of tenofovir for HBV reactivation and second-line anti-TB therapy (Bedaquiline, Delamanid, Levofloxacin and Linezolid)

E-POSTER ABSTRACTS

and CBD stone extraction via ERCP led to complete resolution of jaundice, improvement of symptoms and laboratory values.

CONCLUSIONS:

This case presents multifactorial jaundice in a patient with hepatitis B reactivation, hepatic tuberculosis, and choledocholithiasis. Accurate diagnosis required a combination of imaging, endoscopic intervention, liver biopsy, and molecular testing. Management targeting all contributing factors - antiviral therapy for HBV, stone removal for biliary obstruction, and anti-TB treatment, resulted in full clinical recovery. Clinicians should maintain a high index of suspicion for coexisting hepatic infections and biliary pathology in patients with CHB presenting with jaundice.

2423 - Snat1 Mediated Glutamine Reprogramming in Macrophages Accelerates MAFLD Associated Colorectal Cancer Liver Metastasis

Jing Zhou¹, Hongshan Li¹

Ningbo No. 2 Hospital, Liver Disease Department Of Integrative Medicine, Ningbo-China¹

Background / Hypothesis: Liver metastasis is the leading cause of death in colorectal cancer (CRC), and metabolic dysfunction-associated fatty liver disease (MAFLD) is a critical driver of CRC liver metastasis. The hepatic microenvironment is intimately linked to metastatic progression.

Materials and Methods: Male C57BL/6J mice were fed a high-fat diet (HFD) for 12 weeks and then 5×10⁵ MC38 cells were injected to the spleen of mice to establish the MAFLD-driven CRLM model. Hepatic metastases, hepatic lipid deposition, and biochemical parameters were assessed. Immunofluorescence assay was used to detect the activation macrophages. Liver transcriptomics and metabolomics were employed to profile gene-expression and metabolic changes. In vitro, palmitic acid and oleic acid (PA) -induced hepatocyte steatosis were incubated with macrophages, immunofluorescence and flow cytometry were used to detect the activation of macrophages. Transwell and wound-healing assays were conducted to measure tumor cell metastasis. And siRNA-mediated Snat1 knockdown and glutamine supplementation were applied to validate the mechanistic role of Snat1.

Results: The number of liver metastases were

significantly increased in MAFLD group, with enhanced hepatic steatosis, higher plasma ALT, TG, TC levels and more pro-tumor macrophages infiltration.

Transcriptomic analysis revealed that differentially expressed genes were highly enriched in the glutamine metabolic pathway, with Snat1 identified as a key hub gene. Metabolomic profiling showed that glutamine conversion to α -Ketoglutarate (α -KG). PA-induced hepatocytes markedly potentiated pro-tumor macrophage activation, an effect abolished by hepatocyte-specific Snat1 knockdown. Transwell and wound-healing assays revealed that macrophages educated by PA-stimulated hepatocytes significantly enhanced colorectal cancer cell invasion and migration, whereas Snat1 silencing in hepatocytes reversed these prometastatic capacities. Mechanistically, PA-challenged hepatocytes elevated Snat1 and H3K27me3 in macrophages; Snat1 knockdown reversed these changes and reduced pro-tumor macrophage activation. Whereas supplementation with an α -KG analogue restored Snat1/H3K27me3 levels and reinstated the activation of pro-tumor macrophages.

Conclusions: Snat1 is an essential driver of MAFLD-associated colorectal cancer liver metastasis via modulation of the α -KG/H3K27me3 axis, offering a novel therapeutic target for the development of clinical treatment therapy.

Background / Hypothesis: Guidance from the American

E-POSTER ABSTRACTS

Association for the Study of Liver Diseases and the Infectious Diseases Society of America (AASLD/IDSA) and the European Association for the Study of the Liver have endorsed treatment simplification as part of a global call to action for hepatitis C virus (HCV) elimination. Within this simplification strategy, AASLD/IDSA has recently developed a new Hepatitis C Point of Care Test and Treat Algorithm, in which sustained virologic response at week 4 (SVR4) is an acceptable alternative measure of HCV cure for people without cirrhosis or prior direct-acting antiviral (DAA) exposure. However, we hypothesize that SVR4 could also apply to vulnerable patients with prior DAA exposure, to help reduce the risk of patients being lost to follow-up (LTFU). For this reason, we evaluate the SVR4/SVR at week 12 (SVR12) concordance of sofosbuvir/velpatasvir/voxilaprevir (S/V/V) in randomized clinical trials (RCTs). The POLARIS studies included patients who had previously been treated with a DAA and failed.

Materials and Methods: HCV RNA data from patients in the registrational POLARIS-1, -2, -3, and -4 RCTs evaluating treatment with S/V/V for 8 and 12 weeks were evaluated. SVR was defined as patients with HCV RNA less than the lower limit of quantification (15 IU/mL) using the COBAS TaqMan HCV Test v2.0. Only patients with both SVR4 and SVR12 data were included in the concordance analysis.

Results: Overall, 1,056 patients were evaluated for concordance from the POLARIS (1–4) trials: 611 patients were treated with 8 weeks of S/V/V (POLARIS-2, -3) and 445 patients were treated with 12 weeks of S/V/V (POLARIS-1, -4). In the 8-week group, 575 (96%) patients achieved both SVR4 and SVR12 (true positive), giving a 100% sensitivity and 99% positive predictive value (PPV; 5 patients achieved SVR4 but failed SVR12). In the 8-week group, 18 patients failed to achieve both SVR4 and SVR12 (true negative), showing a 78% specificity and 100% negative predictive value (NPV). In the 12-week group, 426 patients achieved both SVR4 and SVR12, showing a 100% sensitivity and 99% PPV (3 patients achieved SVR4 but failed SVR12). In the 12-week group, 5 patients failed both SVR4 and SVR12, showing a 63% specificity and 100% NPV.

Conclusions: HCV treatment with S/V/V can be infrequent in the real world, and achieving SVR4 is highly predictive of HCV cure. This earlier time point to confirm HCV cure may be particularly important in persons at high-risk of being LTFU.

2425 - POST ERCP DUODENAL HEMATOMA AS A CAUSE OF GASTRIC OBSTRUCTION

Yrah Damienne Fernandez¹, Frederick Dt¹

Institute Of Digestive And Liver Diseases, St. Luke's Medical Center, Medicine, Quezon City-Philippines¹

Background / Hypothesis:

Intramural duodenal hematoma (IDH) is an uncommon but potentially serious complication of endoscopic retrograde cholangiopancreatography (ERCP). Traditionally associated with blunt abdominal trauma, IDH has increasingly been reported following endoscopic interventions, even in young patients without coagulopathy or significant comorbidities. Due to its rarity and nonspecific clinical presentation, diagnosis is often delayed, leading to obstructive symptoms and metabolic derangements. We hypothesize that early recognition of post-ERCP IDH and prompt conservative management can lead to favorable outcomes and avoid unnecessary invasive interventions.

Materials and Methods:

We report a single-center case of a 20-year-old male with no known comorbidities who was admitted for acute calculous cholecystitis with concomitant choledocholithiasis. ERCP with sphincterotomy was performed, during which minimal bleeding occurred and was successfully controlled with local epinephrine injection. The patient subsequently underwent an uncomplicated laparoscopic cholecystectomy. Clinical progression, laboratory investigations, imaging findings, endoscopic evaluation, and management strategies were reviewed. Contrast-enhanced computed tomography (CT) of the abdomen and esophagogastroduodenoscopy (EGD) were utilized for diagnostic confirmation, and follow-up imaging assessed treatment response.

Results:

On postoperative day two, the patient developed fever, epigastric pain, bilious vomiting, tea-colored urine, and epigastric tenderness. Laboratory evaluation showed

E-POSTER ABSTRACTS

improving transaminases but worsening cholestatic markers, with rising bilirubin and alkaline phosphatase levels, and marked hyperlipasemia (lipase 18× upper limit of normal). Contrast-enhanced CT revealed a large hyperdense intramural lesion extending from the first to third portions of the duodenum, causing luminal narrowing and gastric outlet obstruction. EGD confirmed duodenal obstruction secondary to intramural hematoma. The patient was managed conservatively with bowel rest, nasogastric decompression, intravenous fluids, and close monitoring. Clinical symptoms gradually improved, oral intake was resumed, and the patient was discharged tolerating liquids. A repeat CT scan after two weeks demonstrated significant regression of the hematoma.

Conclusions:

Intramural duodenal hematoma is a rare but important complication following ERCP, even in young patients without predisposing risk factors. Iatrogenic mucosal injury during sphincterotomy may contribute to hematoma formation. A high index of suspicion is essential in patients presenting with post-procedural obstructive symptoms and evolving laboratory abnormalities. Cross-sectional imaging and endoscopy are key to diagnosis. Conservative management remains the cornerstone of treatment and is associated with excellent outcomes, reserving invasive interventions for refractory cases.

2428 - Glucocorticoid Therapy Modulates HMGB 1 and K18 Levels in Chronic Drug Induced Liver Injury

Yu-ting Xiong¹, Chun-yan Wan², Jing Chen³, Dong Ji², George Lau⁴

Beijing Tiantan Hospital, Capital Medical University, Department Of Hyperbaric Oxygenation, Beijing-China

¹ Chinese PLA General Hospital, Senior Department Of Hepatology, Beijing-China ² The Chinese University Of Hong Kong, Jc School Of Public Health And Primary Care, Hong Kong-Hong Kong SAR, China ³ Humanity And Health Medical Group, Humanity And Health Clinical Trial Center, Hong Kong-Hong Kong SAR, China ⁴

Background / Hypothesis:

Chronic drug-induced liver injury (DILI) affects 8%-20% of DILI patients and may progress to cirrhosis, yet lacks specific therapy. The therapeutic mechanisms of glucocorticoids (GC) in chronic DILI remain unclear.

High Mobility Group Protein 1 (HMGB-1) participates in inflammatory responses, while keratin 18 (K18) and its apoptotic index (ccK18/FL-K18) reflect hepatocellular injury and apoptosis. This study investigated the effects of GC therapy on these biomarkers in chronic DILI patients to optimize treatment strategies.

Materials and Methods:

A retrospective paired study was conducted on 98 chronic DILI patients admitted to the Fifth Medical Center of the Chinese PLA General Hospital from January 2016 to March 2024, all receiving GC therapy. Blood biomarkers (HMGB-1 by ELISA; ccK18 and FL-K18 by chemiluminescence immunoassay) and apoptotic index (ccK18/FL-K18) were measured pre-GC and at 6 months of GC therapy. Wilcoxon signed-rank test was performed to compare biomarker levels and apoptotic index between pre-GC and post-GC therapy.

Results:

After 6 months of GC therapy, median HMGB-1 increased from 5.25 (2.81-9.56) ng/mL to 16.410 (7.80-34.24) ng/mL, while median ccK18 decreased from 863.50 (297.93-2035.75) U/L to 148.68 (98.20-216.35) U/L and median FL-K18 decreased from 1966.50 (588.80-4607.75) U/L to 296.40 (206.00-402.88) U/L. The apoptotic index increased from 0.45 (0.40-0.53) to 0.48 (0.44-0.57). Wilcoxon signed-rank test demonstrated significant decreases in ccK18 and FL-K18 (both $P < 0.001$), alongside significant increases in HMGB-1 ($P < 0.001$) and apoptotic index ($P = 0.015$).

Conclusions:

After 6 months of GC therapy, median HMGB-1 increased from 5.25 (2.81-9.56) ng/mL to 16.410 (7.80-34.24) ng/mL, while median ccK18 decreased from 863.50 (297.93-2035.75) U/L to 148.68 (98.20-216.35) U/L and median FL-K18 decreased from 1966.50 (588.80-4607.75) U/L to 296.40 (206.00-402.88) U/L. The apoptotic index increased from 0.45 (0.40-0.53) to 0.48 (0.44-0.57). Wilcoxon signed-rank test demonstrated significant decreases in ccK18 and FL-K18 (both $P < 0.001$), alongside significant increases in HMGB-1 ($P < 0.001$) and apoptotic index ($P = 0.015$).

2429 - Effects of Switching from Tenofovir Alafenamide Fumarate to Tenofovir Disoproxil Fumarate or Entecavir on Lipid Parameters and

E-POSTER ABSTRACTS

Atherosclerotic Cardiovascular Disease Risk

Hanife Nur Karakoc Parlayan¹, Firdevs Aksoy², Ilknur Esen Yildiz³, Arzu Altuncekiç Yildirim⁴, Masite Nur Ozdemir², Furkan Asker³, Rana Soydemir⁴, Yilmaz Gurdal²

Karadeniz Technical University, Infection Disease And Clinical Microbiology, Trabzon-Türkiye¹ Karadeniz Technical University, Infectious Diseases And Clinical Microbiology, Trabzon-Türkiye² Recep Tayyip Erdogan University, Infectious Diseases And Clinical Microbiology, Rize-Türkiye³ Ordu University, Infectious Diseases And Clinical Microbiology, Ordu-Türkiye⁴

Background / Hypothesis: Given that tenofovir alafenamide fumarate (TAF) is known to adversely affect lipid profiles in patients with chronic hepatitis B, this study aimed to assess the impact of switching from TAF to tenofovir disoproxil fumarate (TDF) or entecavir (ETV) on plasma lipid concentrations and other laboratory parameters.

Materials and Methods: This retrospective cohort study included adult patients (≥ 18 years) with chronic hepatitis B who had received tenofovir alafenamide fumarate (TAF) for at least one year and subsequently switched from TAF to TDF or entecavir for any reason. Patients were required to have no history of lipid-lowering therapy and a baseline low-density lipoprotein cholesterol (LDL-C) level < 190 mg/dL. Lipid parameters, body weight, and body mass index were assessed at baseline and at 3, 6, and 12 months. Demographic characteristics, comorbidities, antiviral and concomitant medications, and relevant laboratory parameters were collected.

Results: A total of 47 patients from three university hospitals were included in the study. Of these, 38 patients switched from TAF to entecavir and 9 to TDF. The mean age of the cohort was 52.7 ± 11.6 years, and 59.6% were male. The clinical and laboratory characteristics of the patients are summarized in Table 1. Following treatment switch, total cholesterol and triglyceride levels showed a transient increase at 3 months, followed by a progressive decline at 6 and 12 months, approaching or falling below baseline values. LDL cholesterol levels remained relatively stable over time, whereas HDL cholesterol demonstrated a temporary decrease with subsequent recovery by 12 months (Figure 1). Renal and hepatic laboratory parameters remained stable during follow-up, and no consistent worsening in metabolic parameters was observed.

Conclusions: These findings indicate that TAF-associated lipid alterations may be reversible and that switching to alternative antiviral agents could have favorable cardiometabolic implications in selected patients with chronic hepatitis B.

2430 - HBsAg Quantification Based Models for Predicting Hepatocellular Carcinoma Risk in Patients with Chronic Hepatitis B The HCC HBsAg Score

Yi-fan Guo¹, Yi-meng Wang¹, Jing Chen², Le Li³, Yan Liu³, Dong Ji⁴, George Lau⁵

Peking University 302 Clinical Medical School, Peking University 302 Clinical Medical School, Beijing-China¹ The Chinese University Of Hong Kong, Jc School Of Public Health And Primary Care, Hong Kong-Hong Kong SAR, China² Chinese Pla General Hospital, Senior Department Of Infectious Disease, Beijing-China³ Chinese Pla General Hospital, Senior Department Of Hepatology, Beijing-China⁴ Humanity And Health Medical Group, Humanity And Health Clinical Trial Center, Hong Kong-Hong Kong SAR, China⁵

Background / Hypothesis:

Chronic hepatitis B virus (HBV) infection remains a major cause of hepatocellular carcinoma (HCC). Although nucleos(t)ide analogs (NUCs) suppress HBV replication, residual HCC risk requires accurate stratification. Existing prediction models (e.g., PAGE-B, REACH-B) rarely include quantitative hepatitis B surface antigen (HBsAg), limiting their predictive power. We aimed to develop HCC risk-prediction tools for both NUC-naïve and NUC-treated chronic hepatitis B (CHB) patients by incorporating HBsAg levels.

Materials and Methods:

We conducted a retrospective cohort study of CHB patients treated at the Fifth Medical Center of the PLA General Hospital from January 2009 to September 2025. Demographic and clinical data were obtained from electronic records. Patients were classified as NUC-naïve or NUC-treated, and analyses were performed separately. Follow-up extended from HBV diagnosis to HCC development or last contact. Independent predictors of HCC were identified using multivariable Cox proportional hazards models and integrated into nomograms.

Results:

In NUC-treated group (n=1083), 74.2% were male,

E-POSTER ABSTRACTS

median age was 51 years, and median follow-up was 13 years; 385 patients (35.5%) developed HCC. Independent predictors included age (HR =1.024), male sex (HR =1.992), higher HBsAg levels (500–1500 IU/mL: HR 2.436; 1500–3000 IU/mL: HR 3.417; $\geq$ 3000 IU/mL: HR 3.562), and elevated APRI (0.5–1: HR 2.156; $\geq$ 1: HR 3.251). In NUC-naïve group (n=877), 70.2% were male, median age was 46 years, and median follow-up was 10 years; 212 patients (24.2%) developed HCC. Independent predictors included age (HR 1.029), male sex (HR 1.789), higher HBsAg levels (500–1500 IU/mL: HR 1.787; 1500–3000 IU/mL: HR 2.110; $\geq$ 3000 IU/mL: HR 2.476), HBV DNA (2000– 2×10^7 IU/mL: HR 5.097; <2000 IU/mL: HR 8.798), and elevated APRI (0.5–1: HR 2.445; $\geq$ 1: HR 3.119). Based on these predictors, we developed the HBsAg-HCC score, with separate algorithms for NUC-treated and NUC-naïve patients. (Figures 1A/C). Model performance was superior to existing tools: the area under the curve (AUC) of the model was 0.835 (95% confidence interval (CI): 0.810 - 0.847) vs. PAGE-B 0.826 (95% CI: 0.794 - 0.793, Figure 1B) in NUC-treated patients, and AUC 0.777 (95% CI: 0.732 - 0.809) vs. REACH-B 0.685 (95% CI: 0.615 - 0.734, Figure 1D) in NUC-naïve patients.

Conclusions:

Incorporating quantitative HBsAg significantly enhances HCC risk prediction. The HBsAg-HCC score provides a more accurate tool for individualized risk stratification, early intervention, and improved prognosis in both NA-treated and NA-naïve CHB patients.

Keyword(s) : hepatocellular carcinoma; nucleos(t)ide analogs (NUCs); Quantification HBsAg; Risk prediction

2431 - Metabolomics Reveals Metabolic Reprogramming and Novel Biomarkers in Glucocorticoid Treated Chronic DILI

Yu-ting Xiong¹, Chun-yan Wan², Jing Chen³, George Lau⁴, Dong Ji²

Beijing Tiantan Hospital, Capital Medical University, Department Of Hyperbaric Oxygenation, Beijing-China¹ Chinese PLA General Hospital, Senior Department Of Hepatology, Beijing-China² The Chinese University Of Hong Kong, Jc School Of Public Health And Primary Care, Hong Kong-Hong Kong SAR, China³ Humanity And Health Medical Group, Humanity And Health Clinical Trial Center, Hong Kong-Hong Kong SAR, China⁴

Background / Hypothesis:

The mechanisms of glucocorticoid (GC) therapy in

chronic drug-induced liver injury (DILI) remain unclear. This study aimed to analyze metabolite differences between pre-GC and post-GC therapy to explore therapeutic mechanisms and identify treatment-associated metabolic biomarkers.

Materials and Methods:

98 chronic DILI patients receiving GC therapy from our hospital (January 2016-March 2024) were enrolled. Fasting plasma samples were collected at pre-GC and 6 months of GC therapy for untargeted metabolomics analysis using UHPLC-HRMS. Principal component analysis (PCA) and orthogonal partial least squares discriminant analysis (OPLS-DA) were employed to assess metabolic profile alterations. Differential metabolites between pre-GC and post-GC therapy were identified by paired t-test with criteria: $P < 0.05$, $VIP > 1$, and $|\log_2(\text{fold change})| > 1$. KEGG pathway enrichment analysis was performed on these differential metabolites to elucidate metabolic regulatory mechanisms. Subsequently, least absolute shrinkage and selection operator (LASSO) regression was applied to select feature metabolites from the differential metabolites, followed by logistic regression analysis to identify treatment-associated metabolic biomarkers.

Results:

PCA and OPLS-DA analysis revealed significant separation of metabolic profiles between pre-GC and post-GC therapy. Volcano plot showed 743 differential metabolites, including 363 upregulated and 380 downregulated metabolites. KEGG pathway enrichment analysis showed these metabolites were primarily enriched in choline metabolism in cancer, cholesterol metabolism, linoleic acid metabolism, neuroactive ligand-receptor interaction, bile secretion, and glycerophospholipid metabolism. Then LASSO regression selected 30 feature metabolites, logistic regression analysis identified four endogenous metabolites significantly associated with GC therapy: Pe(38:6) (OR=0.141, 95%CI: 0.025-0.804, $P=0.027$), Norvaline (OR=0.272, 95%CI: 0.106-0.698, $P=0.007$), SM(d18:1/22:1(13Z)) (OR=4.896, 95%CI: 1.229-19.508, $P=0.024$), and GPEtn(18:1/16:1) (OR=7.313, 95%CI: 2.375-22.514, $P=0.001$).

Conclusions:

GC therapy induced significant metabolic reprogramming in chronic DILI patients, with lipid metabolism pathways showing the most prominent alterations, suggesting GC exerts therapeutic effects through lipid metabolic remodeling. Four potential

E-POSTER ABSTRACTS

treatment-associated biomarkers were identified: Pe(38:6), Norvaline, SM(d18:1/22:1(13Z)), and GPEtn(18:1/16:1). These findings provide novel insights into the metabolic mechanisms and biomarker development for GC therapy in chronic DILI.

2434 - Clinical HCC Predictors in HBV related Cirrhosis A Real World Study

Yancai Zhou¹, Ya Zhuo¹, Xiaoxia Wei¹, Xinhong Wang¹

The First Affiliated Hospital Of Henan Medical University, Infectious Dep, Henan-China¹

Background / Hypothesis:

HBV-related cirrhosis patients who progress to hepatocellular carcinoma(HCC) are still poorly characterised in real-world cohorts.

Materials and Methods:

From January 2024 to January 2025, a total of 234 consecutive patients hospitalized with HBV-related cirrhosis at our center were enrolled in this study. Among them, 114 patients remained free of hepatocellular carcinoma (HCC), whereas 120 were diagnosed with HCC. We compared demographics, virological and biochemical profiles, Child-Pugh class, and C-reactive protein levels between the groups. Independent predictors of HCC were identified through logistic regression and receiver operating characteristic (ROC) analyses.

Results:

The HCC group was significantly older(59.8 ± 9.1 vs. 54.4 ± 11.2 years, $P=0.001$), had more males(80% vs. 65%, $P=0.015$), and a longer median cirrhosis duration [9 (4–19) vs. 5 (0.7–10) years, $P<0.001$]. This group showed lower HBeAg positivity(4.7% vs. 26%, $P<0.001$) and HBV-DNA [1.70 (1.70 – 3.64) vs. 3.08 (1.70 – 6.97) log IU/mL, $P=0.008$], but higher levels of AFP, GGTALP, CRP, platelets, total cholesterol, C3, and C4 (all $P \leq 0.004$). Independent predictors from multivariate modeling were cirrhosis duration ≥ 1.5 y (OR 7.14), HBV-DNA ≤ 4.59 log IU/mL (OR 4.55), and AFP ≥ 32.5 ng/mL (OR 3.22), achieving an AUC of 0.792 (95%CI 0.721–0.864).

Conclusions: In treated HBV-cirrhosis, longer disease duration, suppressed viral load and elevated AFP signal

imminent HCC; combined use of these metrics may enhance early detection strategies.

2435 - Safety and Efficacy Analysis of Argon Helium Cryoablation Combined with Targeted Drugs and Programmed Death Receptor 1 Monoclonal Antibody in Elderly Patients with Unresectable Hepatocellular Carcinoma

Shujuan Gong¹, Dong Ji², Yan Chen², Jing Chen³, George Lau⁴, Yongping Yang¹

Chinese PLA Medical School, Chinese PLA Medical School, Beijing-China¹ Chinese PLA General Hospital, Senior Department Of Hepatology, Beijing-China² The Chinese University Of Hong Kong, Jc School Of Public Health And Primary Care, Hong Kong-Hong Kong SAR, China³ Humanity And Health Medical Group, Humanity And Health Clinical Trial Center, Hong Kong-Hong Kong SAR, China⁴

Background / Hypothesis:

The proportion of patients with unresectable hepatocellular carcinoma (uHCC) aged > 60 years is increasing. Cryoablation promotes the release of tumor-associated antigen and initiates systemic anti-tumor immune response, potentially creating a favorable immune micro-environment for subsequent therapies. We aimed to evaluate the efficacy and safety of cryoablation combined with targeted therapy and anti-Programmed Death-1 (PD-1) monoclonal antibody in patients over 60 years of age with uHCC.

Materials and Methods:

A retrospective analysis was conducted on clinical data of HCC patients treated at the Fifth Medical Center of PLA General Hospital between January 2013 and September 2024. 86 patients received cryoablation alone (monotherapy group), 61 patients received cryoablation plus targeted therapy (double combination group), while 57 received cryoablation plus targeted therapy and anti-PD-1 monoclonal antibody (triple combination group). And then efficacy and safety were evaluated. Factors influencing survival prognosis were analyzed using the Cox proportional hazards regression model.

Results:

A total of 204 patients with moderate or advanced uHCC aged > 60 years were included. Median progression-free survival was significantly longer with the triple combination group than with the double combination group and monotherapy group. Both

E-POSTER ABSTRACTS

median progression-free survival (19.3 months vs.15.3 months vs.4.6 months; $P < 0.001$) and median overall survival showed the same pattern (35.3 months vs.26.5 months vs.14.7 months; $P < 0.001$). Multivariate Cox proportional hazards regression model analysis demonstrated that, relative to monotherapy, the double combination group improved overall survival ($HR=0.39$; $P < 0.001$) and progression-free survival ($HR=0.39$; $P < 0.001$). Compared with the double combination group, the triple combination group was superior in improving both overall survival ($HR=0.53$; $P=0.014$) and progression-free survival ($HR=0.51$; $P=0.001$). There was no difference in the incidence rate of adverse events between the two groups ($P>0.05$).

Conclusions:

This study confirms that the triple combination group is a safe and effective approach for elderly uHCC patients aged >60 years, which provides a clinical basis for personalized treatment in this population.

2436 - Causative Pathogens of Intra abdominal Abscesses Following Whipple Procedure and Comparison with Expected Abdominal Flora

Özlem Bayraktar Saral¹, Müge Erdem², Aydın Aktaş³
Trabzon Üniveritesi Tıp Fakültesi, Enfeksiyon Hastalıkları Ve Klinik Mikrobiyoloji, Trabzon-Türkiye¹
Amasya Üniversitesi Tıp Fakültesi, Enfeksiyon Hastalıkları Ve Klinik Mikrobiyoloji, Amasya-Türkiye²
Trabzon Üniversitesi Tıp Fakültesi, Genel Cerrahi, Trabzon-Türkiye³

Background and Aim

Pancreaticoduodenectomy (Whipple procedure) is a complex surgical intervention associated with substantial postoperative morbidity. Intra-abdominal abscesses are among the most common infectious complications and may significantly impact clinical outcomes. Due to extensive surgical manipulation, biliary-pancreatic anastomoses, prolonged hospitalization, and antimicrobial exposure, the causative pathogens may differ from the expected gastrointestinal and biliary flora (FLARA).

This study aimed to identify the microbiological profile of intra-abdominal abscesses developing after Whipple procedure and to compare the isolated pathogens with the expected abdominal flora.

Methods

This retrospective single-center study included patients who underwent Whipple procedure and subsequently developed intra-abdominal abscesses with positive microbiological cultures. Demographic data, time interval between surgery and abscess development, and microbiological culture results obtained from percutaneous or surgical drainage samples were analyzed. Isolated microorganisms were categorized as flora-compatible or flora-discordant based on expected gastrointestinal and biliary flora patterns. Polymicrobial infections were recorded.

Results

Patients who developed intra-abdominal abscesses after Whipple procedure were evaluated. Abscess formation occurred within a median of several days following surgery.

The most frequently isolated pathogens were Enterobacterales, predominantly Escherichia coli, Klebsiella pneumoniae, and Citrobacter freundii. In addition, viridans group streptococci, including Streptococcus sanguinis and Streptococcus parasanguinis, were identified. Polymicrobial infections were observed in a subset of patients.

While a proportion of isolates were compatible with the expected abdominal flora, a considerable number demonstrated partial or complete discordance with FLARA, particularly those associated with oral flora or atypical gastrointestinal colonization.

Conclusion

Intra-abdominal abscesses following Whipple procedure exhibit a heterogeneous microbiological profile with a notable deviation from expected abdominal flora. The presence of flora-discordant and polymicrobial pathogens underscores the importance of culture-guided antimicrobial therapy and may have significant implications for empirical treatment strategies in postoperative pancreatic surgery patients.

2437 - Advancing Pediatric Care in Gastroenterology Endoscopic Ultrasound in Pediatrics at a Referral Endoscopy Center in Pakistan

Asma Yaseen¹, Noval Zakaria¹, Asim Muhammad¹,

E-POSTER ABSTRACTS

Saad Niaz ¹

Sindh Institute Of Advanced Endoscopy And Gastroenterology, Gastroenterology, Karachi-Pakistan ¹

Background / Hypothesis: Endoscopic ultrasound (EUS) emerged as a revolutionary intervention, serving both diagnostic and therapeutic purposes for four decades among adult patients, however utility in pediatric patients remained limited due to EUS endoscope design e.g. rigidity, diameter, traumatic distal tip, furthermore complicated by need of Monitored Anesthesia Care(MAC) or General Anesthesia(GA) for intervention. Fewer studies with smaller data have been conducted for EUS effectiveness and safety among children. This article aims to describe the utility of EUS for diagnostic and therapeutic purposes among children.

Materials and Methods:: Retrospective analysis of patients ≤ 18 years, underwent EUS at single tertiary referral endoscopy center in Pakistan over 18 years, from 2007 to 2024.

Results: 124 patients ≤ 18 years' age with mean age of 14.75 ± 3.21 years. 54% were male. 90 diagnostic EUS were performed, 17 FNB and 4 FNA. Among Therapeutic EUS, 23 pseudocyst drainage, 2 celiac plexus block for chronic pancreatitis pain, one EUS-guided pancreatic duct cannulation and one EUS-guided antegrade rendezvous' technique-choledocoduodenostomy. No complications were seen.

Conclusions: In this modern era of advanced diagnostic tools and minimally invasive interventions, EUS related procedures are safe and effective in pediatric group of patients too. However, this procedure should be performed at specialized centers with experienced pediatric anesthesia team.

Background / Hypothesis: Some studies have reported that HBsAg positivity during pregnancy may lead to preterm birth or low birth weight. This study evaluated the birth weights and gestational ages of babies born to HBsAg-positive and HBsAg-negative mothers.

Materials and Methods: Data on HBsAg-positive pregnant women were obtained from a multicenter study conducted nationwide, while data on infants born to HBsAg-negative pregnant women in the last two years at Izmir City Hospital were used as the control group. Data were anonymized in accordance with personal data security and transferred to an Excel form, and the necessary analyses were performed.

Results: The incidence of birth weight ≤ 2500 grams was found to be 17.5% in infants of HBsAg-negative mothers and 6.6% in infants of HBsAg-positive mothers. The incidence of birth weight ≥ 2501 grams was found to be 82.5% and 93.4%, respectively ($p < 0.05$). The incidence of birth weight ≤ 36 weeks was 22.3% in infants of HBsAg-negative mothers and 11.2% in infants of HBsAg-positive mothers. The incidence of birth weight ≥ 37 weeks was 77.7% and 88.8%, respectively ($p < 0.05$).

In conclusion, the rate of low birth weight infants

E-POSTER ABSTRACTS

among HBsAg-negative mothers was found to be higher than that among HBsAg-positive mothers. Similarly, the rate of preterm birth among HBsAg-negative mothers was also found to be higher than that among HBsAg-positive mothers.

Conclusions: When our data was evaluated, it was determined that HBsAg positivity did not pose an additional risk in terms of either giving birth to low birth weight babies or premature birth; in fact, higher rates were observed in the babies of HBsAg-negative mothers.

Keyword(s) : HBsAg, pregnant woman, infants

2444 - Bioinformatics Mapping of Ferroptosis Pathways in NAFLD Progression

Eiman Sehar ¹, Iqra Aslam ¹, Aqsa Batool ¹, Maryam Latif ¹, Aayan Shaheer Sheikh ², Nadeem Sheikh ¹
University Of The Punjab, Institute Of Zoology,, Lahore-Pakistan ¹ McMaster University, Life Sciences, Hamilton-Canada ²

Background / Hypothesis:

Non-alcoholic fatty liver disease (NAFLD) is a progressive liver disorder ranging from simple steatosis (NAFL) to non-alcoholic steatohepatitis (NASH), potentially advancing to fibrosis, cirrhosis, and hepatocellular carcinoma. In recent research, ferroptosis—a type of regulated cell death associated with lipid peroxidation—has emerged as significant in metabolic and inflammatory liver disorders. Compared with microarrays, RNA-seq offers higher sensitivity and accuracy in quantifying gene expression. In the present study, an integrated bioinformatics approach identified ferroptosis-related hub genes involved in NAFLD using RNA-seq datasets, followed by independent validation to improve the robustness of findings.

Methods:

The discovery RNA-seq dataset GSE135251 (GPL18573) included 216 samples (206 NAFLD: NAFL and NASH with fibrosis stages; 10 controls). DEGs were identified using DESeq2 ($|\log_2FC| > 1$, $p < 0.05$). Ferroptosis-related driver, suppressor, and marker genes were obtained from FerrDb V3, duplicates removed, and intersected with DEGs using Venny 2.1.0 to identify shared ferroptosis-associated genes. Shared genes were analyzed through a STRING-based PPI network, visualized in Cytoscape 3.10.4, and key hub genes were selected for downstream analysis using CytoHubba algorithms (MCC, MNC, degree). GO enrichment (BP, CC, MF), KEGG and Reactome pathway analyses were performed using Enrichr. Validation employed RNA-

seq dataset GSE130970 (GPL16791, 78 samples: 72 NAFLD, 6 controls) applying the same differential expression cutoff criteria.

Results:

Differential expression analysis of the discovery dataset identified 2,170 DEGs, including 874 upregulated and 1,296 downregulated genes. Intersection with ferroptosis-related genes yielded 167 shared genes. The PPI network constructed 156 nodes and 700 edges (average node degree 8.97; $p < 1.0 \times 10^{-16}$). Using CytoHubba, eight hub genes were identified: JUN, MYC, IL1B, CCL2, CCND1, MMP9, PTGS2, and ERBB2, with five upregulated and three downregulated in discovery dataset. GO analysis indicated that BP involved neuroinflammatory regulation, unsaturated fatty acid and prostaglandin biosynthesis; GO-CC included AP-1 transcription factor complex and nuclear membranes; GO-MF encompassed cytokine activity, DNA-binding transcription repressor activity, and interleukin-1 receptor binding. KEGG pathway analysis demonstrated enrichment in IL-17, TNF, and bladder cancer pathways while Reactome analysis highlighted interleukin-4, interleukin-13, and cytokine signaling pathways. Validation dataset confirmed significant differential expression of IL1B and MMP9. MMP9 was consistently downregulated across both datasets, suggesting its potential as a robust biomarker. In contrast IL1B showing opposite trends between discovery and validation datasets, reflecting disease heterogeneity or platform variability.

Conclusions:

This study identified key ferroptosis-related hub genes driving NAFLD progression, revealing inflammatory and immune-related pathways and providing novel mechanistic insights and potential targets for future validation.

Keyword(s) : Ferroptosis pathways, NAFLD progression, RNA-seq datasets, Protein-protein interaction network, Biomarker discovery

2445 - Ferroptosis Linked Cell Cycle Hub Genes Reveal New Therapeutic Angels in Sepsis

Aqsa Batool ¹, Eiman Sehar ¹, Iqra Aslam ¹, Maryam Latif ¹, Aayan Shaheer Sheikh ², Nadeem Sheikh ¹
University Of The Punjab, Institute Of Zoology,, Lahore-
¹ McMaster University, Life Sciences, Hamilton-Canada
²

Background / Hypothesis:

Sepsis, a life-threatening critical emergency, results from an uncontrolled host immune response leading to systemic inflammation and progressive organ

E-POSTER ABSTRACTS

dysfunction. It is a body response to extreme infections and may result in death if not treated properly and promptly. Rising evidence from literature shows that in most cases, tissue damage, oxidative stress, and multiorgan failure during sepsis are regulated by ferroptosis-related mechanisms. By evaluating the molecular links between sepsis and ferroptosis, viable targets can be detected for disease therapy and biological markers, therefore optimizing patient outcomes.

The literature regarding exact phenomena and principles of how ferroptosis-related genes are linked to sepsis remain limited. However, a detailed transcriptomic analysis is being used to uncover differentially expressed genes (DEGS) correlated with ferroptosis, providing insights into pathophysiology. Materials and Methods:

In this research work, for both discovery (GSE154918) and validation (GSE185263) cohorts were employed. GEO2R was used for conducting differential expression analysis, and then healthy and sepsis patient groups were defined. Thresholds of $|\log_2 \text{fold change}| \geq 1$ and adjusted $p\text{-value} < 0.05$ were adjusted for selecting significant DEGs. Ferroptosis-related genes—including drivers, suppressors, and markers—were obtained from FerrDb v3, filtered for human specificity, and intersected with significant DEGs to identify candidates linked to ferroptosis in sepsis. STRING was used for constructing Protein–protein interaction (PPI) networks, and hub genes were identified using Cytoscape's CytoHubba plugin with MCC ranking. Functional enrichment analyses, including Gene Ontology (GO) and pathway analyses, were performed to determine the biological processes, molecular functions, and pathways most significantly associated with these hub genes using Enrichr.

Results:

After assessment of the discovery dataset, 4,505 significant DEGs, comprising 1,947 upregulated and 2,558 downregulated genes, were revealed. 394 overlapping candidates were yielded after intersecting 2,083 human-specific ferroptosis-related genes. Protein–protein interaction analysis illustrates functional correlation among ferroptosis genes in sepsis, which shows a highly integrated network (383 nodes, 2874 edges; $p\text{-value} < 1.0e-16$). Consistently downregulated hub-genes in both data-sets were CDK1, AURKA, AURKB, CDC20, PLK1, TOP2A, RRM2, BUB1, NEK2, BIRC5. These downregulated hub-genes contribute to cell cycle regulation, mitotic spindle checkpoint, and p53 signaling pathways, which were highlighted by the functional enrichment indicating their promising involvement in modulating ferroptosis-

driven cellular dysfunction throughout the sepsis period.

Conclusion

Comprehensive RNA-Seq-based analysis and database study identify the ferroptosis-associated hub genes that are downregulated consistently and significantly in sepsis. These findings strongly lay a foundation for the development of targeted therapeutic strategies. These evidences also support that ferroptosis is a central regulatory mechanism in sepsis.

2446 - Shared and stage Specific ferroptosis related biomarkers Across NAFL and NASH An RNA seq Analysis

Iqra Aslam ¹, Aqsa Batool ¹, Eiman Sehar ¹, Maryam Latif ¹, Aayan Shaheer Sheikh ², Nadeem Sheikh ¹
University Of The Punjab, Institute Of Zoology,, Lahore-Pakistan ¹ McMaster University, Life Sciences, Hamilton-Canada ²

Background / Hypothesis:

Non-alcoholic fatty liver disease (NAFLD) advances from simple steatosis (NAFL) to non-alcoholic steatohepatitis (NASH), a stage characterized by inflammatory response, oxidative stress, and fibrosis risk. Ferroptosis—an iron-dependent lipid peroxidation process—has emerged as a key contributor to NAFLD pathological progression, yet stage-specific ferroptosis-linked molecular signatures remain poorly defined in humans. This study aimed to identify ferroptosis-associated central genes distinguishing NAFL and NASH and to reveal their functional pathways using integrated transcriptomic and network analyses supported by external validation.

Methods:

RNA-seq dataset GSE135251 (Control $n=10$; NAFL $n=51$; NASH $n=155$) was analyzed using GEO2R. Differentially expressed genes (DEGs) were filtered using $p < 0.05$ and $|\log_2 \text{FC}| \geq 1$, yielding 1928 NAFL and 2155 NASH DEGs. Overlap with FerrDB produced 155 NAFL and 177 NASH ferroptosis-related DEGs. STRING-based protein–protein interaction networks were constructed in Cytoscape, and CytoHubba algorithms (MCC, MNC, Degree) identified top hub genes. Consensus hubs were defined by intersecting top genes across algorithms. Functional annotation was performed using the Enrichr tool based on GO ontology, KEGG, and Reactome pathways. External validation was conducted using RNA-seq dataset GSE126848, and both discovery and cross validation

E-POSTER ABSTRACTS

datasets were sourced from a common platform (GPL18573).

Results:

Nine consensus hubs were identified for NAFL and seven for NASH, of which five were shared hubs (MYC, JUN, IL1B, CCL2, PTGS2), all statistically significant. Shared hubs were upregulated, indicating concurrent activation of oxidative stress, inflammatory signaling, iron dysregulation, and lipid peroxidation. Pathway enrichment demonstrated progressive intensification of ferroptosis-associated pathways from NAFL to NASH, including increased ROS generation, cytokine–chemokine signaling, NF-κB activation, and senescence-linked Reactome pathways. In the independent validation dataset, five of nine NAFL and five of seven NASH consensus hubs were observed. Among the five shared hubs, MYC, JUN, and CCL2 were common to both NAFL and NASH and were supported by the independent validation dataset. FerrDB annotation identified PTGS2 as a ferroptosis marker and highlighted context-dependent regulatory roles for MYC and CCL2.

Conclusions:

This integrative analysis identifies MYC, JUN, and CCL2 as independently validated ferroptosis-associated biomarkers across NAFL and NASH, underscoring ferroptosis as a central mechanism in NAFLD progression and highlighting promising molecular targets for future therapeutic exploration.

2447 - Hepatitis B reactivation secondary to rituximab treatment

Kadir Gisi¹, Serhat Akpınar¹, Ahmet Biçici¹, Mesut Kuş¹, Bülent Kantarçeken¹
Sutcu Imam University, Gastroenterolgy,
Kahramanmaraş-Türkiye¹

Introduction

Hepatitis B virus (HBV) reactivation is a significant complication in patients receiving long-term chemotherapy or immunosuppressive therapy. In this case, we aimed to present a patient who developed acute liver failure due to HBV reactivation after a rituximab-containing chemotherapy protocol.

Case Report

A 79-year-old male patient. The patient was diagnosed with Chronic Lymphocytic Leukemia one year ago. Following diagnosis, he was initiated on a rituximab-containing chemotherapy protocol at an external center. During this period, the patient's liver enzymes,

INR, and bilirubin levels were normal. HBsAg was negative, anti-HBs was positive, and anti-HBc IgG was not tested. Approximately one year after starting treatment, the patient presented to the gastroenterology clinic with complaints of fatigue, yellowing of the entire body, and dark urine. The patient's blood tests revealed alanine aminotransferase (ALT) of 911 U/L, aspart aminotransferase (AST) of 740 U/L, total bilirubin of 1.96 mg/dl, direct bilirubin of 1.49 mg/dl, and an INR of 1.28. A hepatitis panel was ordered and found to be positive for HBsAg, positive for Anti-HBs, positive for Anti-HBc IgG, negative for Anti-HBc IgM, and negative for HBV PCR of 586514 IU/ml. The patient was suspected of developing HBV reactivation due to rituximab treatment, and Tenofovir Disoproxil Fumarate 245 mg was initiated as antiviral therapy. Despite treatment, progressive increases in bilirubin and INR levels were observed during follow-up, and the patient was admitted to the intensive care unit. The patient, who had no chance of liver transplantation during follow-up, died due to acute liver failure and complications related to HBV reactivation.

Conclusion

Use of drugs with a high risk of reactivation, such as rituximab, and positive HBV serologic markers can result in hepatitis B reactivation in these patients. Therefore, prophylactic antiviral therapy against hepatitis B should be initiated before starting chemotherapeutic drugs with a high risk of reactivation.

Keyword(s) : hepatitis b, Rituximab, reactivation

2448 - DNA microarray based identification of ferroptosis related biomarkers in alcoholic hepatitis

Iqra Aslam¹, Aqsa Batool¹, Eiman Sehar¹, Maryam Latif¹, Aayan Shaheer Sheikh², Nadeem Sheikh¹
University Of The Punjab, Institute Of Zoology,, Lahore-Pakistan¹ McMaster University, Life Sciences, Hamilton-Canada²

Background:

Alcoholic hepatitis (AH) is a severe inflammatory liver disorder associated with prolonged alcohol consumption, marked by oxidative stress, metabolic dysregulation, and hepatocyte injury. Ferroptosis—an iron-dependent, lipid peroxidation-driven form of cell death—has emerged as a key contributor to alcohol-induced liver damage, but ferroptosis-related transcriptional biomarkers in AH remain poorly defined

E-POSTER ABSTRACTS

. This study aimed to identify these biomarkers in alcoholic hepatitis in humans.

Methods:

DNA microarray datasets from GSE28619 (7 controls, 15 AH samples; GPL570) were analyzed using GEO2R (adjusted $p < 0.05$, $|\log_2FC| \geq 1$). After probe deduplication, 3151 DEGs retrieved from volcano plot were reduced to 2019 unique genes; intersection with FerrDb yielded 282 ferroptosis-related DEGs. A protein-protein interaction (PPI) network of ferroptosis-related DEGs was constructed using STRING, and six consensus hub genes associated with ferroptosis were identified from MCC, MNC, and Degree analyses via CytoHubba. Functional enrichment, including GO and KEGG pathway analysis, was performed using the Enrichr tool on MCC-identified hub genes to explore their biological relevance. Gene Set Enrichment Analysis (GSEA; Hallmark gene sets) evaluated coordinated pathway alterations.

Results:

The ferroptosis-related PPI network contained 280 nodes and 2109 edges ($P < 1 \times 10^{-16}$), reflecting significant interactions. Enrichment analysis of MCC hub genes revealed involvement in apoptosis, regulatory processes, oxidative stress responses, and mitochondrial stability. Six consensus hub genes (BCL2, EGFR, JUN, ESR1, PTEN, SIRT1), obtained by intersecting top-ranked genes from MCC, MNC, and Degree analyses, highlighted their central role in ferroptosis-related network regulation.. Significance of all genes was confirmed. Differential GSEA showed that upregulated pathways (bile acid, xenobiotic, and fatty acid metabolism; TNF- α /NF- κ B signaling) reflected cholestatic stress, oxidative injury, and lipid remodeling, whereas downregulated pathways (MYC Targets, E2F Targets, protein secretion, unfolded protein response, DNA repair, mTORC1 signaling, oxidative phosphorylation) indicated metabolic suppression, mitochondrial dysfunction, and redox imbalance. This contrast highlights a molecular environment highly permissive to ferroptosis.

Conclusions:

AH demonstrates a ferroptosis-associated molecular signature characterized by oxidative stress, metabolic collapse, and impaired mitochondrial and ER function. Identified hub genes represent potential biomarkers and regulatory components of ferroptosis-driven hepatocellular injury, providing insights for targeted therapeutic strategies in alcoholic hepatitis.

Keyword(s) : Alcoholic hepatitis , Microarray, Ferroptosis, Liver

2449 - Real World Barriers to Post SVR Monitoring in HCV Insights from a Physician Survey

Safaa M Abdelhalim¹, Enas Kamal¹, Alaa M Mostafa¹, Samy Zaky², Yasser M Fouad¹

Department Of Gastroenterology, Hepatology And Tropical Medicine, Faculty Of Medicine, Minia University, Minia, Egypt, Tropical Medicine, Minya-Egypt¹ Department Of Hepatogastroenterology And Infectious Diseases (tropical Medicine), Faculty Of Medicine, Al-azhar University, Tropical Medicine, Cairo-Egypt²

Background / Hypothesis:

Despite the success achieved with direct-acting antivirals (DAAs) in sustained virologic response (SVR) in hepatitis C virus (HCV), the real-world challenges and barriers to post-treatment follow-up are not well understood. Identifying these obstacles is crucial for improving long-term outcomes. This study aims to evaluate physicians' real-world barriers to (post-SVR) follow-up.

Materials and Methods:

A cross-sectional survey was conducted among 103 physicians using a structured questionnaire designed by an expert hepatologist to capture post-treatment follow-up practices and barriers to adherence. The questionnaire was developed based on current clinical guidelines and expert input to ensure comprehensive coverage. Content validity was confirmed through a pilot study, and reliability was assessed using internal consistency measures.

Results:

Among 103 respondents, 64.1% hepatologists and 35.9% non-hepatologists; most had over 10 years of clinical experience (76.7%). The majority considered liver cirrhosis to be the main influence in post-SVR follow-up (93.2%). Fear of hepatocellular carcinoma (HCC) was the predominant concern (84.5%), with advanced fibrosis/cirrhosis (94.2%) and MAFLD (65%) identified as major risk factors post-SVR. Abdominal ultrasound (92%) and alpha-fetoprotein (AFP) (80%) were the most frequently requested investigations. Reported barriers for post-treatment surveillance included low patient awareness (64.1%), lack of clear national pathways (32%), and limited resources (23.3%).

Conclusions:

E-POSTER ABSTRACTS

Low patient awareness and the lack of standardized national pathways are the main barriers to consistent post-SVR follow-up. Future strategies should prioritize implementing structured national protocols and improving patient education for surveillance.

Keyword(s) : Barriers, Cirrhosis, Hepatocellular carcinoma, Hepatitis C virus, Sustained virologic response

2451 - Late T cell mediated Rejection (TCMR) in liver allograft biopsies Impact of heterogeneity on the progression to chronic TCMR

Archana Rastogi¹, Viniyendra Pamecha², Chhagan Bihari¹, Ashok Choudhary³, Shiv Sarin³

Institute Of Liver & Biliary Sciences, Pathology, New Delhi-India¹ Institute Of Liver & Biliary Sciences, Liver Transplant & Hpb Surgery, New Delhi-India² Institute Of Liver & Biliary Sciences, Hepatology, New Delhi-India³

Background / Hypothesis:

Late T-cell mediated Rejection (LAR) is clinically, histopathologically, & mechanistically heterogeneous & under-represented in Banff RAI score. The Banff Liver group has recently stressed that LAR and chronic TCMR (CR) have different subtypes and certain prognostically important features are not assessed currently. There is an urgent need to understand the behavior of different subtypes of LAR, risk of progression to CR and the clinical outcome. This study aims to determine the prevalence of LAR and the impact of its subtypes on the clinical course.

Materials and Methods:

Retrospective cross-sectional study of liver allograft biopsies (n=939) of liver transplant recipients (n=1276) between 2010-2025. Liver biopsies reported as rejection (n=458) obtained from 166 patients were further analysed. Those with histological diagnosis of LAR at ≥ 6 months post-liver transplant (n=116) from equal number of recipients were reviewed. Only patients with multiple biopsies with the diagnosis of TCMR were selected as the study group (n=30). Clinical and histological characteristics were recorded: post-transplant duration of LAR, episodes of rejections, progression to CR, time period to last follow-up and total post-transplant survival, phenotypes of LAR and CR. LAR was histologically characterised as chronic hepatitis (CH), isolated central perivenulitis (ICP), and

PCRR. CR was categorised as ductopenic, CH with fibrosis, or mixed.

Results:

Age ranged between 5-59 years with male: female ratio of 6.5. LAR diagnosed 6 months- 8.5 years post-liver transplant. Histological subtypes were CH (23), ICP (5), PCRR (2). LAR progressed to CR in 22 (73.3%) in 15 days- 8 years. CR subtypes were ductopenia (3), CH with fibrosis (13), ductopenia with fibrosis (6). Histological diagnosis of chronic rejection to last follow-up was 1 month- 7 years and post-transplant survival was 9 months- 14 years, with some on follow-up. CR (ductopenic or mixed ductopenic with fibrosis subtype) had previous LAR with portal duct damage more than zone 3 damage (78%); whereas CR (CH type) had zone 3 changes more than portal changes (69%). Recipients with chronic TCMR with fibrosis showed longer survival than those with ductopenic with/out advanced fibrosis (1 year, 1 year 7 months respectively). Survival determined by the comorbidities and ductopenic rejection.

Conclusions:

This study confirms that late and chronic TCMR are heterogeneous with variable effect on clinical course. LAR with predominant zone 3 changes progresses to fibrotic CR whereas TCMR with duct damage causes ductopenic rejection. Zone 3 microvascular injury is important determinant of fibrosis progression; this along with severity of duct damage and interface activity should also be recorded

Keyword(s) : late TCMR, chronic TCMR, Banff, subtypes, chronic hepatitis, fibrosis, Isolated central perivenulitis, ductopenic.

2452 - Efficacy of Intermittent Fasting on Hepatic Enzymes Fat Content and Fibrosis in Patients with Non Alcoholic Fatty Liver Disease A Systematic Review and Meta Analysis of Randomized Controlled Trials

Nitesh Kumar Karna¹, Akshyata Osti¹, Popular Pokhrel¹, Gopal Pokhrel¹, Nitesh Neupane¹

B.p. Koirala Institute Of Health Sciences, Department Of Medicine, Dharan-Nepal¹

Background / Hypothesis:

Non-alcoholic fatty liver disease (NAFLD) is a growing global health concern with limited effective non-

E-POSTER ABSTRACTS

pharmacological treatment options. Intermittent fasting (IF) has gained attention as a dietary intervention that may improve metabolic and hepatic outcomes. However, evidence from randomized controlled trials (RCTs) remains variable. This systematic review and meta-analysis aimed to evaluate the efficacy of intermittent fasting on hepatic enzymes, liver fat content, and liver fibrosis in patients with NAFLD.

Materials and Methods:

A comprehensive search of PubMed, Embase, Scopus, and the Cochrane Library was conducted up to November 2025. Eight RCTs involving 592 participants with NAFLD were included. Pooled standardized mean differences (SMDs) with 95% confidence intervals (CIs) were calculated using random-effects models. Statistical heterogeneity was assessed using the I^2 statistic. Publication bias was evaluated using Egger's regression test.

Results:

Intermittent fasting was associated with a significant reduction in alanine aminotransferase (ALT) levels (SMD = -0.58; 95% CI: -0.83 to -0.33; I^2 = 0.00%; p < 0.01) and aspartate aminotransferase (AST) levels (SMD = -0.44; 95% CI: -0.81 to -0.07; I^2 = 48.23%; p = 0.02). IF also led to a marked improvement in liver fat content (SMD = -0.86; 95% CI: -1.21 to -0.50; I^2 = 0.00%; p < 0.01). Additionally, a significant reduction in liver fibrosis was observed (SMD = -0.44; 95% CI: -0.80 to -0.07; I^2 = 73.48%; p = 0.02), despite substantial heterogeneity. Egger's regression test indicated no evidence of publication bias.

Conclusions:

This meta-analysis of randomized controlled trials demonstrates that intermittent fasting significantly improves hepatic enzymes, liver fat content, and liver fibrosis in patients with NAFLD. These findings support intermittent fasting as a promising dietary strategy for the management of NAFLD, although further large-scale, long-term RCTs are warranted to confirm its sustainability and clinical applicability.

Keyword(s) : Intermittent fasting, Non-alcoholic fatty liver disease, ALT, AST, Liver fibrosis, Systematic Review, Meta-analysis

2453 - Impact of Prior Drug Allergies on severity of drug induced liver Injury a study from tertiary care hospital Pakistan

Dr Sameera Sameera¹, Dr Farhana Kayani²

Gastroenterologist Kayani²

Bmch Quetta, Internal Medicine, Quetta-Pakistan¹

Bmch Quetta, Gastrology, Quetta-Pakistan²

BackDrug-induced liver injury (DILI) remains a significant diagnostic and clinical challenge in hospital settings. It can present as either predictable (dose-dependent) or unpredictable (idiosyncratic) liver toxicity caused by commonly used medications such as anti-tubercular agents, antiepileptics, or even therapeutic doses of drugs like paracetamol. While the mechanisms of many idiosyncratic reactions remain unclear, genetic susceptibility, immune dysregulation, and allergic or hypersensitivity responses are believed to play important roles in increasing vulnerability to hepatotoxicity. In light of encountering a steady increase in hospitalizations related to drug intake in the past few years, this study aims to evaluate the role of prior drug allergies in a population of patients with well-characterized drug-induced liver injury.

ground / Hypothesis:

Materials and Methods:

DILI cases were identified and categorized on the basis of COIMS/RUCAM score and the exclusion of other liver diseases. This study included two arms, one arm included the DILI cases with no prior drug allergy history and the other consisted of all those identified DILI cases who had experienced any prior drug allergies including itching, coughing, hives, periorbital swelling, abdominal pain, vomiting, and diarrhea. Clinical and laboratory parameters were analyzed to identify the predictors of morbidity (prolonged hospital stay > 7 days) and mortality.

Results:

Out of 460 patients, 120 (25.8%) cases of DILI had a prior history of drug allergies and the remaining had no prior history.

DILI was classified as definite or highly probable in 31.1%, probable in 62.5%, and possible in 7.4% of cases. Pattern of liver injury was hepatocellular in 25.1%, cholestatic in 56.17%, and mixed in 18.72% of patients.

The patients with a prior drug allergy were mainly male (78%) and significantly older, with a mean age of 54 versus 45 with no prior drug allergy (P = .009), and they were more likely to have an underlying chronic disease like diabetes and Hypertension (P = .016).

E-POSTER ABSTRACTS

Clinically, patients with prior drug allergy were more encephalopathic (21.6% vs 10 ;P=0.02) and jaundiced (54.1% vs 38 % p= 0.04) .Those with a prior drug allergy also had significantly hepatocellular pattern of DILI(68% vs 35% ; P= 0.003), lower median values of albumin (2.8 g/L vs 3.8 g/L P= 0.04)and alkaline phosphatase levels versus no drug allergies (1.4 vs 1.6 × ULN; P = .045) and lower platelet counts (189 vs 226 x103/ ml; P = .011), while aspartate aminotransferase (AST) , bilirubin levels and International normalized ratio (INR) showed a trend towards increased levels in patients with prior drug allergy (9.4 vs

Keyword(s) :

2455 - Diabetes association with liver diseases and prognostic risk factors of liver related complications in diabetic patients.

Javaria Younas Muhammad Younas¹, Farhana Kayani²
Bmch, Medicine, Quetta-Pakistan¹ Sheikh Zaid
Hospital, Gastroenterology, Quetta-Pakistan²

Background: Emerging evidence highlights a strong bidirectional association between diabetes mellitus and liver diseases. This interplay, mediated by disruptions in glucose and lipid metabolism, contributes to the onset and progression of hepatic disorders from steatosis to cirrhosis. However, data on the prognostic risk factors of liver-related complications among patients with type 2 diabetes mellitus (T2DM) remains limited.

Materials and Methods:

A retrospective study was conducted that identified 8234 adult patients with the T2DM between January 2020 and December 2023. demographic data with clinical characteristics were noted. Patients with T2DM having chronic viral hepatitis, excessive alcohol use, other metabolic and autoimmune liver diseases, malignancies, and liver related events (LRE) before T2DM diagnosis were excluded. The primary endpoint was Liver Related Events, defined as hepatic decompensation as development of ascites , encephalopathy and GI bleed or the development of hepatocellular carcinoma. Uni- and multi-variable Fine-Gray regression model was estimated.

Results:

1,010 patients with T2DM were included (mean age 58.9 years; 41.3% males); the incidence rate of Liver related events was 0.279 (95% CI 1.243-1.315) cases per 500 person-years at risk. Female gender, older age, higher level of HBA1c, hypertension, overweight and noncompliance to medicines were associated with

an increased risk of Liver related events. By multivariable analysis, central obesity and higher body mass index was associated with a higher risk of Liver related events, whereas aspirin, coffee use and insulin use at baseline was associated with a lower risk. Among all covariates, older age explained the most about the incidence of Liver Related Events (36.7%) followed by high body mass index (20.1%).

Conclusions: Older age, female gender, high BMI, high HBA1c levels and non compliance to medicines were risk factors for Liver related events in patients with T2DM. Advanced age was the most important risk factor for Liver related events and high BMI. In conclusion , When your blood sugar is high over a long time, it can damage your liver so it needs special attention to avoid liver related events..

2456 - Rurality and Neighborhood Socioeconomic Deprivation as Predictors of Hepatocellular Carcinoma Surveillance Adherence Among Adults with Cirrhosis in the United States

Joyce Lui¹, Yesung Kweon², Cecilia Dapino³, Na Li⁴, Vinod Rustgi⁵, Khalid Mumtaz⁴, Mohamed Elsaid⁶, Electra Paskett⁷

The Ohio State University College Of Medicine, College Of Medicine, Columbus-United States¹ The Ohio State University, Center For Biostatistics, Columbus-United States² Case Western Reserve University, Case Western Reserve University, Cleveland-United States³ The Ohio State University College Of Medicine, Division Of Gastroenterology, Hepatology, And Nutrition, Department Of Internal Medicine, Columbus-United States⁴ Rutgers Robert Wood Johnson Medical School, Division Of Gastroenterology And Hepatology, New Brunswick-United States⁵ The Ohio State University College Of Medicine, Division Of Biostatistics And Population Health, Department Of Biomedical Informatics, Columbus-United States⁶ The Ohio State University College Of Medicine, Division Of Cancer Prevention And Control, Department Of Internal Medicine, Columbus-United States⁷

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is among the most prevalent and deadliest forms of cancer, and cirrhosis is one of its strongest risk factors. Despite established guidelines recommending semiannual surveillance, adherence rates remain poor. Limited studies have

E-POSTER ABSTRACTS

evaluated the impacts of neighborhood socioeconomic factors and rurality on surveillance adherence. This study examines the associations between 1) rurality assessed by Rural-Urban Commuting Area (RUCA) codes and 2) neighborhood socioeconomic status measured by the Area Deprivation Index (ADI), with adherence to HCC surveillance among adult patients with cirrhosis.

Materials and Methods:

This retrospective cohort study utilized the Ohio State University PCORnet electronic health record database to identify adults with cirrhosis from 2011 to 2023. Rurality was classified using PCORnet-provided RUCA codes. Neighborhood socioeconomic status was categorized as high deprivation (ADI $\geq$ 75th percentile) or low deprivation (ADI < 75th percentile). HCC surveillance adherence was calculated as the proportion of follow-up time covered (PFTC) by liver imaging (ultrasound, CT, or MRI), with high adherence defined as $\geq 75\%$ coverage. Overlap Propensity Score Weighting (OPSW) was applied to account for confounding. Crude and adjusted modified Poisson regression analyses were fitted using generalized estimating equations (GEEs) with binary outcomes and robust standard errors to account for clustering, and were used to assess the associations between rurality, deprivation, and surveillance adherence.

Results:

Among 11,744 patients with cirrhosis, the mean (STD) age was 55.9 (12.7), 54.5% were male, and 78.9% self-identified as non-Hispanic White. The mean (STD) PFTC was 29.8% (33%) (median 16.2%), and only 15% of patients achieved high adherence. An estimated 31.7% were rural residents, and 44.6% had high neighborhood deprivation.

Rural residence was associated with 26% lower odds of surveillance adherence compared with urban residence (aOR: 0.74; 95% CI: 0.65 to 0.85). Patients living in high-deprivation neighborhoods had 12% lower adjusted odds of adherence than those in low-deprivation neighborhoods (aOR: 0.88; 95% CI: 0.78 to 0.99). Additionally, neighborhood deprivation demonstrated a dose-response relationship with adherence. Each quartile increase in ADI was associated with a 9% lower adjusted odds ratio of adherence (aOR: 0.91; 95% CI: 0.85 to 0.97).

Conclusions: HCC surveillance adherence among adults with cirrhosis remains very poor. Both rurality and high neighborhood deprivation were independently associated with lower adherence, suggesting

socioeconomic and geographic barriers to HCC surveillance. These findings highlight the need for targeted, neighborhood-level interventions to reduce disparities and improve cancer prevention in socioeconomically disadvantaged communities.

Keyword(s) :

2458 - Wilson's Disease in Oman A National Cohort Study of Clinical Spectrum Diagnostic Delay and Long Term Outcomes

Said A. Al-busafi ¹, Juland N. Al Julandani ¹, Zakariya Alismaeili ², Juhaina J. Al Raisi ³
Sultan Qaboos University, Medicine, Alseeb-Oman ¹
Nizwa Hospital, Medicine, Nizwa-Oman ² Oman
Medical Specialty Board, Medicine, Muscat-Oman ³

Background / Hypothesis: Wilson's disease (WD) is a rare autosomal recessive disorder of copper metabolism that results in hepatic, neurological, and psychiatric manifestations. Despite being described globally, data from the Middle East remains limited. This study presents the first comprehensive national cohort analysis of WD in Oman, examining clinical features, diagnostic challenges, treatment patterns, and long-term outcomes.

Materials and Methods: A retrospective cohort study was conducted on 36 Omani patients diagnosed with WD between 2013 and 2020 at Sultan Qaboos University Hospital using AASLD diagnostic criteria. Clinical presentation, biochemical parameters, treatment regimens, and progression-free survival were analyzed.

Results: The median age at diagnosis was 14.5 years, with a slight female predominance (55.6%). Clinical presentation varied: 25% had hepatic symptoms, 22.2% had mixed hepatic-neurological features, and 16.7% presented with neurological symptoms alone. Asymptomatic cases identified via family screening accounted for 33.3%. Diagnostic delays were most pronounced among patients presenting with neurological symptoms. A positive family history was reported in 88.9% of cases, suggesting strong familial clustering despite a low rate of consanguinity (5.6%). Regional distribution was concentrated in Ash Sharqiyah North and Muscat. Chelation therapy with trientine or penicillamine, often combined with zinc, was the mainstay of treatment. Treatment adherence was significantly associated with improved

E-POSTER ABSTRACTS

progression-free survival ($p = 0.012$).

Conclusions: WD in Oman is marked by heterogeneous presentations, frequent diagnostic delays, and strong familial clustering. Early detection through cascade screening and sustained treatment adherence are critical for favorable outcomes. These findings support the need for national screening policies and structured long-term care models for WD in the region.

2459 - Superinfection with Hepatitis Delta Virus Elevates the Risk of Hepatocellular Carcinoma in Individuals with Chronic Hepatitis B Virus Infection

Mohamed Elsaid¹, Joyce Lui², Yesung Kweon³, Electra Paskett⁴, Cecilia Dapino⁵, Na Li⁶, Khalid Mumtaz⁶, Vinod Rustgi⁷

The Ohio State University College Of Medicine, Division Of Biostatistics And Population Health, Department Of Biomedical Informatics, Columbus-United States¹ The Ohio State University College Of Medicine, College Of Medicine, Columbus-United States² The Ohio State University, Center For Biostatistics, Columbus-United States³ The Ohio State University College Of Medicine, Division Of Cancer Prevention And Control, Department Of Internal Medicine, Columbus-United States⁴ Case Western Reserve University, Case Western Reserve University, Cleveland-United States⁵ The Ohio State University College Of Medicine, Division Of Gastroenterology, Hepatology, And Nutrition, Department Of Internal Medicine, Columbus-United States⁶ Rutgers Robert Wood Johnson Medical School, Division Of Gastroenterology And Hepatology, New Brunswick-United States⁷

Background / Hypothesis:

The incidence and mortality of hepatocellular Carcinoma (HCC) continue to rise in the United States, despite declining trends in numerous other cancers. While the hepatitis delta virus (HDV) increases the risk of adverse hepatic manifestations, research on the association between HDV and HCC risk has yielded mixed results. In addition, most research on this topic has focused on chronic Hepatitis B virus (CHBV)/HDV coinfection, with limited studies on HBV-HDV superinfection. We aimed to examine the association between CHBV-HDV superinfection and HCC risk in patients with CHBV.

Materials and Methods:

Using the MarketScan® Commercial Claims databases

from January 1, 2008, to December 31, 2017, we combined claims data from inpatient admissions and outpatient service records to identify patients with CHBV using ICD-9 and 10 codes. HBV-HDV superinfection was defined as a new HDV diagnosis > 90 days after the first date of CHBV diagnosis. HDV status was modeled as a time-varying covariate to account for the effects of the wait time between the date of CHBV diagnosis and the first record of HDV diagnosis. Inverse probability of treatment weighted Cox proportional hazard models were used to assess the adjusted risks of HCC for CHBV mono-infection versus CHBV-HDV superinfection.

Results:

The study included 36,689 adults with CHBV (53.7% males, average age 45 years), of whom 1,633 had CHBV-HDV superinfection. The average time from CHB diagnosis to HBV-HDV superinfection was 26.2 months. During the study period, 201 patients developed HCC. The median follow-up period was 19 months. The risk of HCC was significantly higher in super-infected patients than in mono-infected patients (1.4% vs. 0.5%; $P < 0.001$). The incidence rate of HCC was more than 2.5-fold higher in super-infected patients than in mono-infected patients (6.7 vs. 2.3 per 1000 Person-years %; $P < 0.001$). The adjusted risk of cirrhosis was significantly higher in super-infected patients than in mono-infected patients (hazard ratio (HR), 2.64 (95% CI, 2.11–3.28). In the fully adjusted models, HDV superinfection was associated with a 93% increase in the risk of HCC (HR, 1.93; 95% CI, 1.20–2.97) compared to CHBV mono-infection.

Conclusions:

Our comprehensive analysis of a large commercial claims database suggests a markedly increased risk of HCC in patients with CHBV-HDV superinfection compared to those with CHBV mono-infection. These findings underscore the crucial importance of early diagnosis, surveillance, and targeted intervention strategies in patients with HBV-HDV superinfection.

Keyword(s) :

2462 - Prevalence risk factors and demographic insights of sickle cell hepatopathy in Omani adolescents and adults A retrospective analysis

Said A. Al-busafi¹, Fatma Al-zaabi², Salam Al-kind³
Sultan Qaboos University, Medicine, Alseeb-Oman¹
Oman Medical Specialty Board, Medicine, Muscat-Oman²
Sultan Qaboos University, Hematology, Alseeb-Oman³

E-POSTER ABSTRACTS

Background / Hypothesis:

Sickle cell hepatopathy (SCH) is a significant yet under-researched complication of sickle cell disease (SCD). Despite the substantial prevalence of SCD in Oman and the Gulf region, the burden and characteristics of SCH remain poorly defined. This study aimed to determine the prevalence of SCH and its associated demographic, clinical, and laboratory features among Omani adolescents and adults with SCD.

Materials and Methods:

We conducted a retrospective cross-sectional study at Sultan Qaboos University Hospital. Of 2,257 patients screened, 384 were diagnosed with SCH (prevalence 17%). After applying inclusion and exclusion criteria, 750 patients were analyzed: 384 SCH cases and 366 randomly selected controls without SCH. Demographic, clinical, and laboratory data were reviewed to identify associations.

Results:

SCH was significantly associated with cholelithiasis (56.6% vs. 38.5%, $P = 0.0001$) and exchange transfusions (36.6% vs. 20.8%, $P = 0.0001$). Patients with SCH were more likely to be male (51.1% vs. 37.8%, $P = 0.0001$) and younger (28.9 ± 8.7 vs. 31.0 ± 10.2 years, $P = 0.002$). Markers of hemolysis, including elevated lactate dehydrogenase (522.4 vs. 341.6 U/L, $P < 0.0001$) and higher reticulocyte counts (8.5% vs. 5.4%, $P < 0.0001$), were also associated with SCH. However, no independent predictors were identified in multivariate analysis.

Conclusions:

SCH affects nearly one in six Omani patients with SCD, with associations to younger age, male gender, cholelithiasis, and transfusion history. These findings highlight the importance of proactive screening and personalized management to improve outcomes in this high-risk population.

2464 - Beyond Liver Function Albuminuria and a novel Child Turcotte Pugh AlbU score improve mortality prediction in medical intensive care unit patients with hepatic encephalopathy

Ahmed Alwassief ¹, Said A. Al-busafi ¹, Khalid Al-

shamoussi ¹, Ashraf Elbahrawy ², Hossam Shahba ², Hafez Abdelhafeez ²
Sultan Qaboos University, Medicine, Alseeb-Oman ¹ Al Azhar University, Medicine, Cairo-Egypt ²

Background / Hypothesis:

This study aimed to evaluate whether incorporating albuminuria (Alb) into the Child-Turcotte-Pugh (CTP) score improves the prediction of mortality in patients with hepatic encephalopathy (HE).

Materials and Methods:

This prospective study was conducted between January 2013 and January 2015 at Al-Azhar University, Cairo, Egypt. Patients who were diagnosed with HE at the time of admission to the medical intensive care unit (MICU) were included. Upon admission, patients underwent HE grading, CTP classification, and an albumin-to-creatinine ratio (ACR) assessment. A novel scoring system, CTP-AlbU, was calculated by combining existing CTP scores with the admission degree of ACR. The primary outcome measure was MICU mortality.

Results:

A total of 78 consecutive cirrhotic patients were included in this study with a mean age of 57.65 ± 12.9 years, with equal male and female distribution. HE grades were categorised as 2, 3, and 4 in 16 (20.5%), 44 (56.4%), and 18 (23.1%) patients, respectively. CTP classifications were B and C in 12 (15.4%) and 66 (84.6%) patients, respectively. The overall mortality rate was 32.1%. Statistical analysis revealed a significant association between increased mortality and both elevated ACR and higher CTP-AlbU scores. Furthermore, the CTP-AlbU score emerged as an independent risk factor for mortality.

Conclusions:

This study demonstrates that incorporating albuminuria into the CTP score, resulting in the CTP-AlbU score, enhances the prediction of mortality in HE patients. This novel scoring system displayed superior sensitivity compared to the original CTP score, suggesting its potential as a tool for predicting short-term outcomes in this patient population.

E-POSTER ABSTRACTS

2466 - Real World Impact of Cardiovascular Comedications on DDI risk in Patients receiving direct acting antiviral (DAA) Hepatitis C Therapy

Dilip Makhija¹, Thomas Debray², Carl Gustafson³, Joshua Lin³, Candido Hernandez⁴, Nancy Reau⁵, Michelle Martin⁶

Gilead Sciences, Gheor, Parsippany-United States¹
Smart Data Analysis And Statistics, Biostats, Utrecht-The Netherlands²
Gilead Sciences, Med. Affairs, Foster City-United States³
Gilead Sciences Ltd, Med. Affairs, Madrid-Spain⁴
Rush University Medical Centre, Rush Hepatology, Chicago-United States⁵
University Of Illinois Hospital And Health Sciences System, College Of Pharmacy, Chicago-United States⁶

Background / Hypothesis:

The AASLD/IDSA hepatitis C virus (HCV) guidance recommends assessment of comedications prior to initiation of direct-acting antivirals (DAAs). Medication reconciliation, especially for cardiovascular comedications—remains a critical step to mitigate drug-drug interaction (DDI) risks. This study evaluates the DDI risk of cardiovascular comedications in a real-world subset of US patients with HCV, with insights relevant for APAC regions where cardiovascular disease prevalence is rising.

Materials and Methods:

We analyzed the IQVIA PharMetrics Plus claims database (July 2015–June 2023) to assess co-administration of lipid-lowering drugs and antihypertensives with pan-genotypic DAAs (pDAAs; sofosbuvir/velpatasvir [SOF/VEL] and glecaprevir/pibrentasvir [GLE/PIB]). DDI risk was determined using the Liverpool DDI tracker. Propensity score matching (1:1, without replacement) was used to create comparable SOF/VEL and GLE/PIB cohorts.

Results:

Among 11,324 HCV patients on pDAAs, 11.6% received lipid-lowering and 2.5% received antihypertensive comedications. After matching, both cohorts—SOF/VEL and GLE/PIB—each comprised 431 patients receiving lipid-lowering agents and 91 patients receiving antihypertensives, respectively. Among SOF/VEL-treated patients, DDI risk was present in 88.2% of those on lipid-lowering agents and 23.1% of those on antihypertensive comedications. In contrast, DDI risk was present in all GLE/PIB patients with these comedications. For lipid-lowering comedications, no

SOF/VEL patients had contraindicated DDI risk claims, whereas 74.4% of GLE/PIB patients did.

Contraindications with GLE/PIB were predominantly associated with atorvastatin, lovastatin, and simvastatin. For antihypertensives, olmesartan, prazosin, and enalapril were the most frequent comedications posing clinically significant DDI risk.

Conclusions:

Although the number of affected patients is relatively small, DDI risk remains common between DAAs and cardiovascular medications, particularly with GLE/PIB. Careful selection of DAA regimens based on individual DDI profiles is essential for ensuring appropriate HCV treatment.

Keyword(s) : HCV, DDI, DAA

2467 - A case of acute hepatitis C that resolved spontaneously

Kamuran Türker¹

Ministry Of Health, University Of Health Sciences, Istanbul Bagcilar Training And Research Hospital, Infectious Disease, Istanbul-Türkiye¹

Introduction:

Globally, chronic hepatitis C virus infection affects 50 million people, with approximately one million new cases each year. Chronic hepatitis C virus infection becomes chronic in 70% of cases, while acute hepatitis C infection resolves spontaneously within 6 months in 30% of cases.

In chronic hepatitis C virus infection, jaundice occurs in 25% of cases, and gastrointestinal symptoms occur in approximately 20% of cases.

Case:

A 24-year-old female patient presented to our outpatient clinic with complaints of nausea, vomiting, loss of appetite, fatigue, dark urine, and burning sensation during urination. She did not have jaundice. She had no chronic disease. Her history included intravenous drug use in both herself and her husband. Her husband had been diagnosed with hepatitis C virus infection.

The laboratory tests have been compatible with acute hepatitis: AST/ALT 453/855 U/L, GGT 116 U/L, white blood cell count was 9.3/μL, hemoglobin 13.3 g/dL, platelet count was 209×10⁹/L, sedimentation 6 mm/h. The abdominal echography of the abdomen

E-POSTER ABSTRACTS

showed no biliary obstructions or mass lesions in the liver. There were no findings of liver cirrhosis or fatty liver. The viral serological tests revealed protection for hepatitis A (IgM neg/IgG pos), negative for HVB infection (AgHBs neg, anti-HBc neg), positive antibodies for HCV and positive HCV RNA (4419 UI/ml), HCV genotype 1a.

Since the patient was using medication containing buprenorphine and naloxone for addiction treatment, we monitored her closely without administering additional antiviral drugs.

The patient's fatigue and appetite gradually improved. Liver enzyme levels decreased and HCV RNA became negative without any anti-HCV treatment (eg, administration of interferon or direct-acting antiviral drugs).

She spontaneously cleared HCV infection after 1 month, maintaining negative HCV RNA 3 months after infection. The patient has cured the HCV infection with no need for antiviral treatment.

Discussion

Diagnosing acute hepatitis is difficult. Most cases are asymptomatic. Diagnosis and treatment of acute hepatitis C at an early stage of infection is important for preventing disease progression to the chronic phase. Initiating treatment 4–12 weeks after diagnosis of the HCV infection (ie, during the early stage of infection) is recommended and prevents disease progression. When acute hepatitis C is diagnosed, the patient needs to be closely monitored in the initial period to ensure they do not lose the chance for antiviral treatment.

Keyword(s) :

2468 - Antipsychotic Comedication and Drug Drug Interaction Risk in US Patients Treated with HCV DAAs Focus on PWUD Healthcare Resource Use Impact and AASLD Algorithm Implications

Dilip Makhija¹, Thomas Debray², Carl Gustafson³, Joshua Lin³, Candido Hernandez⁴, Nancy Reau⁵, Michelle Martin⁶

Gilead Sciences, Gheor, Parsippany-United States¹
Smart Data Analysis And Statistics, Biostats, Utrecht-The Netherlands²
Gilead Sciences, Med. Affairs, Foster City-United States³
Gilead Sciences Ltd., Med. Affairs, Madrid-Spain⁴
Rush University Medical Centre, Rush Hepatology, Chicago-United States⁵
University Of Illinois Hospital And Health Sciences System, College

Of Pharmacy, Chicago-United States⁶

Background / Hypothesis:

Concomitant use of antipsychotics and direct-acting antivirals (DAAs) in US patients with hepatitis C virus (HCV), including people who use drugs (PWUD) raises concerns about drug-drug interactions (DDIs), healthcare resource use (HCRU), and rapid start of HCV treatment as per the new AASLD/IDSA algorithm.

Materials and Methods:

A retrospective cohort study using IQVIA PharMetrics Plus claims data (2015–2023) identified HCV patients treated with sofosbuvir/velpatasvir (SOF/VEL) or glecaprevir/pibrentasvir (GLE/PIB) and concomitant antipsychotics. A PWUD subgroup and patients receiving opioid substitution therapy (OST) were also analyzed. DDI risk and healthcare resource use was compared between DAA regimens using propensity score matching (1:1, without replacement).

Results:

Overall, 3.7% of HCV patients received concomitant antipsychotic medications; while among PWUD, 42.4% received antipsychotics. 5% of patients received >1 antipsychotic, indicating multi-DDI risk. In the matched cohort, 142 patients were treated with SOF/VEL and 142 with GLE/PIB. DDI risk was present in 13.2% of SOF/VEL patients and 100% of GLE/PIB patients. No significant differences were found in the frequency of HCV-related healthcare visits. Quetiapine was the most frequent concomitant antipsychotic used, followed by aripiprazole and lurasidone.

Conclusions:

Antipsychotic use in US patients with HCV, especially PWUD, is common and linked to significant DDI risk, especially with the use of medications carrying risks of QTc prolongation, such as quetiapine. In this study, DDI risk was present in all GLE/PIB patients with concomitant antipsychotics, whereas fewer SOF/VEL patients had DDI risk present. There were no significant differences in HCV-related HCRU. HCV treatment initiation, including rapid start, requires careful choice of DAA treatment based on individual patient profiles to avoid DDI risk.

Keyword(s) : HCV, DDI, DAA, Antipsychotics

2469 - Study on Patients Undergoing Triple Therapy for Liver Steatosis in Mongolia

Amarsanaa Jazag¹, Erdenebayar Gonchig², Ariunaa Baljinnyam³, Enkhtuya Damba⁴, Baatarkhuu Oidov⁵
Otoch Manramba University, Medicine, Ulaanbaatar-Mongolia¹ Glu, Medicine, Ulaanbaatar-Mongolia²
Happy Veritas Hospital, Medicine, Ulaanbaatar-Mongolia³ Masld, Medicine, Ulaanbaatar-Mongolia⁴
Mnums, Infectious Diseases, Ulaanbaatar-Mongolia⁵

Abstract

In Mongolia, liver steatosis is highly prevalent, frequently linked to chronic HBV and HCV infections. Triple therapy (pegylated interferon, ribavirin, and protease inhibitor) proves effective. This retrospective study analyzed treatment outcomes, steatosis reduction levels and degrees, viral load changes, correlations with liver cirrhosis, and viral types in 816 patients' records from Happy-Veritas Hospital and the Mongolian National University of Medical Sciences (2025 data). Results revealed 98.6% treatment efficacy in reducing steatosis, viral load reduction in 57.4%, and the highest prevalence of HCV type C (47.3%). The study offers baseline data for assessing triple therapy effectiveness in the Mongolian context.

Objectives

The study aims to retrospectively analyze liver steatosis cases treated with triple therapy in Mongolia and determine:

1. Overall treatment outcomes (steatosis reduced or unchanged).
2. Steatosis reduction levels by groups.
3. Changes in steatosis degree.
4. Viral load status (present or reduced).
5. Correlation between steatosis and liver cirrhosis.
6. Correlation of steatosis with hepatitis virus types (B, C, BD, unknown).
7. Evidence-based recommendations to optimize triple therapy strategies.

Methodology

This retrospective study reviewed medical records of 816 patients with liver steatosis from Happy-Veritas Hospital and the Mongolian National University of Medical Sciences in 2025. Data were extracted from PDF records and classified by treatment outcomes, steatosis reduction levels and degrees, viral load, cirrhosis correlation, and virus types. Actual counts and percentages were calculated. Statistical analysis used Python's pandas library, with graphs generated from real data for visual comparisons.

Results

Data from 816 patients were analyzed and presented graphically.

1. Treatment Outcomes Steatosis decreased in 98.6% of patients.
2. Level of Steatosis Reduction Reduction levels were distributed across groups (0-9, 10-19, etc.), with the majority in the 40-99 group.
3. Degree of Steatosis Reduction The highest reduction degree (3-1) involved 126 patients.
4. Correlation Between Virus and Steatosis HCV type C was most prevalent (47.3%).
5. Correlation Between Cirrhosis and Steatosis Cirrhosis decreased in 77.1% of patients.
6. Correlation Between Liver Steatosis and Hepatitis Virus Steatosis was most associated with HCV type C.

Conclusion

Triple therapy for liver steatosis in Mongolia achieved high outcomes, with 98.6% steatosis reduction. However, viral load persisted at 57.4%, and cirrhosis reduction reached 77.1%. Steatosis predominated in HCV patients, with even reduction levels and degrees indicating treatment efficacy. Limitations include limited sample size and missing data. Future large-scale studies are recommended, emphasizing viral prevention and early detection.

2470 - Causes of New Hepatitis Virus Infections in Mongolia

Erdenebayar Gonchig¹, Ariunaa Baljinnyam², Amarsanaa Jazag³, Enkhtuya Damba⁴, Baatarkhuu Oidov⁵, Enkhbayar Gonchig⁶
Glu, Medicine, Ulaanbaatar-Mongolia¹ Happy Veritas Hospital, Medicine, Ulaanbaatar-Mongolia² Otoch-manramba University,, Medicine, Ulaanbaatar-Mongolia³ Masld, Medicine, Ulaanbaatar-Mongolia⁴ Mnums, Infectious Diseases, Ulaanbaatar-Mongolia⁵ Buyant-ukhaa Hospital, Medicine, Ulaanbaatar-Mongolia⁶

Background / Hypothesis:

Hepatitis B (HBV) and C (HCV) infections are primary drivers of liver cancer and cirrhosis in Mongolia. This study examined 398 newly detected cases (HBV: 154, HCV: 244) to identify transmission causes. Of these, 317 patients (79.6%) identified their infection source,

E-POSTER ABSTRACTS

while 81 (20.4%) did not. Leading causes included cosmetic procedures (65 cases, 20.5%), tattoos (53, 16.7%), and dental treatment (37, 11.7%), highlighting iatrogenic transmission. HCV cases predominated (244 vs. 154 HBV), with higher susceptibility in cosmetic and tattoo procedures. These 2025 findings underscore the urgent need for enhanced infection control in healthcare settings and increased public awareness to support Mongolia's hepatitis elimination goals.

Introduction

Mongolia has one of the highest global burdens of hepatitis viruses, with HBV prevalence at 5.7–11.1% and HCV at 3.73–8.5%. New infections are predominantly iatrogenic, transmitted via medical, cosmetic, or tattoo procedures, fueling rising liver cancer rates. Identifying transmission routes is critical for meeting the WHO's 2030 elimination targets. This study analyzes infection causes in 398 newly detected cases, including HBV/HCV distribution and cause classification.

Materials and Methods:

Data Source

Data were drawn from 398 newly detected HBV (154) and HCV (244) cases recorded in Sheet1 of "hepatitis virus infection.xls" as of December 2025. Cases were categorized by whether patients knew their infection cause (317 known, 81 unknown), with known causes grouped into 10 categories.

Results:

General Overview of Newly Detected Cases

HCV cases outnumbered HBV by 1.58 times (244 vs. 154), reflecting higher HCV incidence. Notably, 79.6% of patients identified their infection source, indicating effective epidemiological tracing.

Identified Causes of Infection

Iatrogenic routes—cosmetic procedures (20.5%), tattoos (16.7%), and dental treatment (11.7%)—accounted for 49% of known causes. HCV was more associated with cosmetic procedures (39 vs. 26 HBV) and tattoos (32 vs. 21 HBV). Familial transmission was slightly higher in HBV (12% vs. 10.9% in HCV). The majority (79.6%) of new infections had traceable causes, predominantly iatrogenic, linked to inadequate sterilization and weak regulation in cosmetic and tattoo services. Unknown causes comprised 20.4%, suggesting room for improved tracing.

Conclusions:

New hepatitis infections in Mongolia are mainly iatrogenic, driven by cosmetic procedures, tattoos, and dental treatments. HCV predominates over HBV, necessitating stricter oversight in medical and non-medical procedures. Enhanced sterilization, public education, and the "Hepatitis-Free Mongolia" initiative are vital. Limitations include small sample size and absence of demographic data (age, gender). Future research should involve larger cohorts and molecular analyses for deeper insights.

Keyword(s) :

2471 - Comparative Study of Liver Indicators in Patients with and without Diabetes Mellitus

Azjarga Maidar¹, Tserensugir1 Dovchin¹, Erdenebayar Gonchig², Ariunaa Baljinnyam^{2,3}, Enkhtuya Damba², Amarsanaa Jazag⁴

Glu, Medicine, Ulaanbaatar-Mongolia¹ Happy Veritas Hospital, Medicine, Ulaanbaatar-Mongolia² Masld, Medicine, Ulaanbaatar-Mongolia³ Otoch-manramba University, Medicine, Ulaanbaatar-Mongolia⁴

Background / Hypothesis:

In Mongolia, diabetes mellitus (DM) is potentially linked to liver conditions like steatosis and fibrosis. This retrospective study compared liver indicators (ALT, AST, fibrosis, steatosis) between diabetic (n=14) and non-diabetic (n=14) groups, computing averages and Pearson's correlation coefficients using November 2025 data from Happy-Veritas Hospital. Diabetic group averages: ALT 69.81, AST 54.97, fibrosis 11.05, steatosis 300.19. Non-diabetic: ALT 49.12, AST 63.33, fibrosis 9.04, steatosis 262.80. Correlation analysis revealed a strong ALT-AST link (0.98) in the non-diabetic group. These findings establish baseline evidence for exploring DM's impact on liver health.

Materials and Methods:

Retrospective analysis of 28 patients (14 diabetic, 14 non-diabetic) from Happy-Veritas Hospital's November 2025 Excel registry. Groups were stratified by DM status. Averages were calculated via Python's pandas (.mean()) and numpy libraries; correlations used .corr() for Pearson's coefficients, displayed in tables.

Results:

Analysis of 28 patients yielded the following:

Average Indicators

E-POSTER ABSTRACTS

Diabetic group (n=14): ALT 69.81, AST 54.97, fibrosis 11.05, steatosis 300.19.

Non-diabetic group (n=14): ALT 49.12, AST 63.33, fibrosis 9.04, steatosis 262.80.

Conclusion: Higher ALT and steatosis in diabetic group; higher AST and fibrosis in non-diabetic.

Correlation Analysis

Diabetic Group (Pearson's coefficients):

ALT-AST: 0.17 (weak positive).

ALT-fibrosis: 0.46 (moderate positive).

ALT-steatosis: 0.06 (very weak positive).

AST-fibrosis: -0.14 (weak negative).

AST-steatosis: -0.41 (moderate negative).

Fibrosis-steatosis: 0.09 (very weak positive).

Conclusion: Moderate ALT-fibrosis positive; moderate

AST-steatosis negative.

Non-Diabetic Group:

ALT-AST: 0.98 (very strong positive).

ALT-fibrosis: 0.57 (moderate positive).

ALT-steatosis: 0.35 (weak-moderate positive).

AST-fibrosis: 0.59 (moderate positive).

AST-steatosis: 0.40 (moderate positive).

Fibrosis-steatosis: 0.17 (weak positive).

Conclusion: Very strong ALT-AST correlation; moderate positives elsewhere.

Conclusions:

Liver indicators in diabetic patients showed elevated ALT and steatosis, while non-diabetics had higher AST.

Correlations were stronger (e.g., ALT-AST 0.98) in non-diabetics, implying diabetes disrupts indicator

interrelations. Limitations: Small sample (n=28), inter-patient variability (age $\pm$ 5 years, gender differences).

Larger studies are essential for deeper DM-liver disease insights.

Keyword(s) :

2472 - Correlation Between the Degree of Liver Steatosis and Liver Enzyme (ALT AST GGT) Levels

Agnist Bazarbadnaa¹, Munkhtsetseg Nyamsüren¹, Gantulga Bat-ulzii¹, Erdenebayar Gonchig², Amarsanaa Jazag³, Enkhtuya Damba⁴

Glu, Medicine, Ulaanbaatar-Mongolia¹ Masld, Medicine, Ulaanbaatar-Mongolia² Otoch-manramba University, Medicine, Ulaanbaatar-Mongolia³ Happy Veritas Hospital, Medicine, Ulaanbaatar-Mongolia⁴

Background / Hypothesis:

Liver steatosis (NAFLD/NASH) has emerged as a major health concern globally and in Mongolia driven by lifestyle changes, obesity, diabetes, and metabolic

syndrome. Early stages are often asymptomatic, with diagnosis relying on costly or limited imaging (ultrasound, CT/MRI). This highlights the need to evaluate affordable blood markers—ALT, AST, and GGT—for early detection and their correlation with steatosis severity. Clinical studies on this relationship in Mongolia are scarce, making this analysis of Happy Veritas Clinic patients a pioneering contribution.

Objective

To investigate the correlation between the degree of liver steatosis and blood levels of ALT, AST, and GGT enzymes.

Materials and Methods:

A retrospective cross-sectional study included 103 outpatients who underwent laboratory tests at Happy Veritas Liver Center in September 2025. Inclusion criteria: age $\geq$ 18 years and complete ALT, AST, GGT, UAP (steatosis), and Stiffness (fibrosis) measurements. All statistical analyses were performed using Excel.

Results:

General Characteristics

Of 103 participants: females 63 (61.2%), males 40 (38.8%). Age range 18–86 years, predominantly 40–60 years.

Liver Enzyme Levels

ALT elevation was more frequent than AST. GGT was markedly higher in severe steatosis cases. Enzyme changes paralleled increases in UAP and Stiffness.

Correlation with Steatosis (UAP)

Higher UAP (dB/m) values were associated with rising ALT (significant trend), milder AST increase, and sharp GGT elevation, indicating enzyme sensitivity to steatosis severity.

Correlation with Fibrosis (Stiffness)

Increased Stiffness (kPa) correlated with greater GGT rise and mild AST/ALT elevations, identifying potential high-risk fibrosis groups.

Age-Related Patterns

Lowest steatosis/enzyme elevation in 18–40 years; peak in 41–60 years; pronounced Stiffness and GGT in >60 years, confirming higher risk after middle age.

Conclusions:

As steatosis degree (UAP) increased, ALT and GGT showed statistically significant elevations, with GGT emerging as a sensitive marker. High-steatosis groups exhibited prominent AST, ALT, and GGT rises. Elevated

E-POSTER ABSTRACTS

enzymes in high-Stiffness cases signal fibrosis risk. The 40–60 age group faces the highest risk, warranting targeted prevention and monitoring.

Keyword(s) : Liver steatosis, enzymes, liver fibrosis

2473 - Correlation Between Blood Triglyceride and Cholesterol Levels in Individuals with Liver Steatosis

Uranzaya Enkhtuvshin¹, Akerke Tileuberdy¹, Gantulga Bat-ulzii¹, Erdenebayar Gonchig²
Glu, Medicine, Ulaanbaatar-Mongolia¹ Masld,
Medicine, Ulaanbaatar-Mongolia²

Background / Hypothesis:

Non-alcoholic fatty liver disease (NAFLD) is linked to modern lifestyles and dyslipidemia. This study examined correlations between triglyceride (TG) and total cholesterol (T-CHO) levels in 130 Mongolian patients (after outlier exclusion). Pearson's correlation between TG and T-CHO was 0.678 ($p < 0.001$), indicating moderately strong positive association. Steatosis index (K-Steatosis) correlated highly with TG (0.858) and T-CHO (0.829). Results suggest that worsening lipid metabolism accompanies steatosis progression, supporting integrated lipid monitoring for NAFLD management in Mongolia.

Liver steatosis involves fat accumulation in $>5\%$ of hepatocytes and is associated with obesity, insulin resistance, and dyslipidemia. In Mongolia, rising obesity drives increasing NAFLD prevalence. Blood TG and T-CHO are key markers, and their interrelationship aids disease prediction. This study analyzes correlations between TG and T-CHO using data from 131 patients (130 after excluding one outlier), including age, gender, TG, T-CHO, liver stiffness (TP-Stiffness), steatosis (K-Steatosis), and BMI.

Materials and Methods:

Data Source

Clinical results from 130 patients were analyzed.

Statistical Analysis

Processed with Python's pandas library. Descriptive statistics (mean, SD, min/max) were calculated.

Pearson's correlation coefficients were computed for TG, T-CHO, steatosis, and other indicators. Correlations >0.5 were deemed strong.

Results:

General Characteristics

Average age: 50.52 years (SD 12.56, range 20–85).
TG: 1.30 mmol/L (SD 0.61, range 0.13–2.56).
T-CHO: 4.89 mmol/L (SD 1.26, range 2.61–10.88).
TP-Stiffness: 70.40 (SD 5.04, range 53.99–78.26).
K-Steatosis: 279.96 (SD 52.03, range 173.69–391.33).
BMI: 28.81 (SD 5.09, range 17.84–44.00).
Gender: 60% male, 40% female. Average BMI 28.8 indicates early obesity.
Correlation Analysis
TG vs. T-CHO: 0.678 (moderately strong positive).
K-Steatosis vs. TG: 0.858 (high).
K-Steatosis vs. T-CHO: 0.829 (high).
Age vs. TG: 0.821; Age vs. T-CHO: 0.806.
BMI vs. TG: 0.825; BMI vs. T-CHO: 0.826.
Higher steatosis was strongly linked to elevated lipids.

Conclusions:

A moderately strong correlation (0.678) exists between TG and T-CHO in liver steatosis patients. Lipid testing should be prioritized in NAFLD management. Future studies require larger samples and standardized steatosis indices.

2474 - Determining Risk by Glucose and Triglyceride Ratio in Individuals with Liver Steatosis

Davaajan Munkhdelger¹, Buyankhishig Tüvdendorj¹,
Oyunchimeg Chojir¹, Erdenebayar Gonchig²,
Enkhtuya Damba³, Amarsanaa Jazag⁴
Glu, Medicine, Ulaanbaatar-Mongolia¹ Masld,
Medicine, Ulaanbaatar-Mongolia² Happy Veritas
Hospital, Medicine, Ulaanbaatar-Mongolia³ Otoch-
manramba University, Medicine, Ulaanbaatar-Mongolia⁴

Background / Hypothesis:

Rationale

Liver steatosis occurs when fat exceeds 5-10% of liver weight, primarily from alcoholic or metabolic causes. Excessive alcohol disrupts liver metabolism, while metabolic factors—diabetes, hypertriglyceridemia, obesity, and sedentary lifestyle—promote fat accumulation. Elevated glucose reduces liver glucose processing, increases fat synthesis, and leads to triglyceride buildup. Hypertriglyceridemia (>1.7 mmol/L) raises steatosis risk 2-3 times (Journal of Hepatology, 2022), often accompanied by decreased HDL and increased LDL. Studies show 70-90% of steatosis patients have glucose issues, with high type 2 diabetes prevalence. As a chronic condition, steatosis

E-POSTER ABSTRACTS

progresses through inflammation to fibrosis, cirrhosis, and potentially liver cancer, driven mainly by elevated glucose and triglycerides.

Materials and Methods:

From January 2024 to September 2025, among 3736 outpatients tested at Happy Veritas Hospital Liver Center, data from 71 patients with elevated glucose and triglycerides were selected. The dataset included age, gender, and key laboratory indicators.

Demographic and test results were compiled for analysis.

Results:

Average liver steatosis indicators increased consistently with age. Groups aged 56-60, 71-75, and 76-80 exceeded 300, reflecting age-related metabolic slowdown and impaired fat processing.

Among 7 individuals with diabetes but normal triglycerides, average steatosis was 299, indicating high glucose alone poses significant risk (equivalent to grade 3 steatosis).

In 71 individuals with both elevated glucose and triglycerides, average steatosis was 297 (grade 2-3), showing comparable risk when both factors are raised.

Conclusions:

Steatosis levels rise steadily with age, exceeding 300 in those over 56, underscoring the need for strict glucose and triglyceride control in older adults. High glucose maintains elevated steatosis even with normal triglycerides, confirming that hyperglycemia independently drives substantial risk. Thus, both elevated glucose and triglycerides are major contributors to liver steatosis.

Keyword(s) :

2475 - Correlation Between Liver Fat Accumulation Level and Body Mass Index

Soyol-erdene Agchvayabazar¹, Maralgua Narankhuu¹, Baasan Badamsuren¹, Erdenebayar Gonchig², Enkhtuya Damba³, Amarsanaa Jazag⁴
Glu, Medicine, Ulaanbaatar-Mongolia¹ Masld, Medicine, Ulaanbaatar-Mongolia² Happy Veritas Hospital, Medicine, Ulaanbaatar-Mongolia³ Otoch-manramba University, Medicine, Ulaanbaatar-Mongolia⁴

Background / Hypothesis:

In recent years, hepatic steatosis has increased globally, affecting not only overweight/obese individuals but also those with normal BMI—a condition known as "lean fatty liver." It carries similar risks, including inflammation, cirrhosis, and metabolic disorders. In Mongolia, lifestyle changes (reduced activity, high-carbohydrate/fat diets, stress, sleep deprivation) promote steatosis even in normal-BMI populations, often with high visceral fat. Misconceptions delay diagnosis and treatment. Studying causes, risks, diagnosis, and lifestyle impacts in normal-BMI individuals is crucial for early detection, prevention, and improved health services.

Materials and Methods:

A retrospective cross-sectional study included 300 randomly selected patients (aged 20–90 years) with normal BMI and diagnosed steatosis, visiting Happy Veritas Hospital Liver Center outpatient department. Data were collected via a standard questionnaire. The study was approved by the hospital's Ethics Committee (Protocol No. H5652); all personal information was anonymized for statistical use only.

Questionnaire items:

Diabetes diagnosis?
Pancreatic pain/issues?
Gallbladder disease?
High blood cholesterol?
Occupation (current/previous)?
Sleep quality?
Flour-based product consumption?
Regular medications?
Daily exercise/physical activity?
Alcohol consumption?

Results:

Of 300 participants with normal BMI: 58% female (173), 42% male (127). Age distribution: 20–29 (9), 30–39 (26), 40–49 (63), 50–59 (90), 60–69 (75), 70–90 (37).

Key findings:

Diabetes: 12% yes (36), 88% no (264).
Pancreatic issues: 40% yes (120), 60% no (180).
Gallbladder disease: 33% yes (99), 67% no (201).
High cholesterol: 29% yes (87), 24% normal (72), 47% unknown (141).
Good sleep: 39% (117), poor: 61% (183).
Regular exercise: 53% yes (159), 47% no (141).
High flour-based consumption: 53% (159), moderate 24% (72), low 23% (69).

E-POSTER ABSTRACTS

Chemical exposure at work: 6% (18).
Alcohol consumption: 49% yes (147), 51% no (153).
Regular medications: 58% yes (174), 42% no (126).

Conclusions:

Liver fat accumulation occurs in normal-BMI individuals, not just the overweight. Primary risk factors include high flour-based product consumption, elevated blood cholesterol, poor sleep quality, and regular medication use. These disrupt fat metabolism, promoting steatosis. Targeted interventions addressing these factors are essential for prevention and management.

2476 - The Impact of Changes in Liver Enzymes and Body Mass Index on Liver Fibrosis

Oyungerel Suvid ¹, Bujin-ujin Badam ¹, Okhinoo Khuukhentogoo ¹, Sansarmaa Dashnyam ¹, Enkhtuya Damba ², Amarsanaa Jazag ³
Glu, Medicine, Ulaanbaatar-Mongolia ¹ Mnums, Medicine, Ulaanbaatar-Mongolia ² Otoch-manramba University, Medicine, Ulaanbaatar-Mongolia ³

Background / Hypothesis:

Rationale

Liver cirrhosis involves gradual replacement of healthy liver cells with connective tissue, leading to structural loss and impaired function. Often developing over years from inflammation or alcohol-related damage, it is largely irreversible but early detection prevents complications. The liver filters toxins, aids digestion, stores nutrients, and manages inflammation. Repeated damage triggers regeneration that forms scar tissue, eventually disrupting function. Obesity and diabetes exacerbate fatty liver disease, a cirrhosis precursor. ALT and AST are key markers of liver cell damage; elevated levels signal injury from viral hepatitis, alcohol, metabolic syndrome, or steatosis. In Mongolia, persistent high alcohol use, metabolic disorders, and viral infections necessitate integrated evaluation of enzyme changes and BMI. This study clarifies their relationship, aiding early cirrhosis detection, risk stratification, prevention, and management. Gender differences are notable: working-age male mortality is 2.8 times higher, linked to health attitudes, alcohol/tobacco use, inactivity, and poor diet.

Materials and Methods:

From 3000 patients tested at Happy Venus Liver

Center (January–September 2025), 212 with repeated AST/ALT measurements and BMI data were selected for comparison.

Results:

Of 212 participants: 84 men (39.6%), 128 women (60.3%). Age predominantly middle/older (40–69 years: ~68%).

By enzyme levels:

Men: Normal enzymes → 5% cirrhosis, 70% fibrosis, 25% healthy; Elevated → 34.1% cirrhosis, 50% fibrosis, 15.9% healthy.

Women: Normal → 4.6% cirrhosis, 61.5% fibrosis, 33.9% healthy; Elevated → 26.9% cirrhosis, 66.6% fibrosis, 6.5% healthy.

Elevated enzymes markedly increase fibrosis/cirrhosis risk in both genders.

By BMI category:

Men: Normal weight → 12.5% cirrhosis; Overweight → 19.5%; Obese → 16.7%.

Women: Normal → 12.7% cirrhosis; Overweight → 9%; Obese → 26.3%.

Higher BMI elevates morphological change risk, especially fibrosis.

Conclusions:

Conclusion

BMI increase impacts women more strongly (obese women: 26.3% cirrhosis vs. 12.5% normal weight; men: 18.7% obese vs. 14.2% normal).

Elevated enzymes (ALT/AST >80 U/L) show strongest correlation, with 30.4% cirrhosis vs. 9.8% normal (3-fold risk, $p < 0.01$).

Men face 1.3 times higher cirrhosis risk with elevated enzymes than women; BMI is a secondary factor.

2478 - Association of MAFLD with joint lifestyle exposures Background & aims

Saddiqa Saeed Saeed Ahmed ¹, Dr Farhana Kayani Gastroenterologist Kayani ²

Bmch Quetta, Internal Medicine, Quetta-Pakistan ¹

Bmch Quetta, Gastrology, Quetta-Pakistan ²

Background / Hypothesis:

E-POSTER ABSTRACTS

Metabolically-dysfunction-associated fatty liver disease (MAFLD) is characterized by hepatic steatosis in the setting of overweight/obesity, type 2 diabetes, and/or metabolic dysregulation. MAFLD may co-exist with a broad range of comorbid liver and cardiometabolic conditions. High-calorie consumption and decreased physical exercise are key lifestyle variables that contribute to the occurrence of MAFLD. So far, single lifestyle exposures associated with MAFLD have been studied, like Exercise and nutrition, which have been demonstrated to be helpful lifestyle therapies for MAFLD prevention and treatment when sufficient weight reduction is accomplished. However, the effect of joint lifestyle exposures remains unclear, hindering the development of targeted prevention and control strategies. We aimed to investigate the joint associations between lifestyle exposomes and MAFLD.

Materials and Methods: This study included 1,002 participants from the outpatient clinic of the Gastroenterology department. Lifestyle exposomes, including metabolic equivalent of task (MET), sleep duration, smoking exposure and Alternative Healthy Eating Index (AHEI) score, were identified from questionnaire data. Non-invasive Liver disease Assessment was used to diagnose MAFLD, including Vibration-controlled transient elastography measurements and laboratory data like FIB-4 and APRI score. A logistic regression model and the weighted quantile sum method were used to evaluate the associations of single and joint lifestyle exposomes, respectively, with MAFLD. To assess the population benefits of different intervention strategies, the population attributable fractions (PAFs) were calculated.

Results: Per-quartile increases in sleep duration (OR = 0.783, 95% CI: 0.526–0.944), MET (OR = 0.816, 95% CI: 0.771–0.963), and AHEI score (OR = 0.827, 95% CI: 0.756–0.904) were all significantly associated with reduced risk of MAFLD. When these three factors were considered together, their combined exposure showed a stronger association with MAFLD risk reduction (OR = 0.772, 95% CI: 0.688–0.865), with MET contributing the greatest weight (0.526) among them. Population attributable fraction (PAF) analysis indicated that interventions focused on enhancing MET proved to be the most effective strategy compared to improving sleep and dietary quality (AHEI), which would yield

greater benefits in the population at risk of MAFLD.

Conclusions: This study revealed significant associations between MAFLD and lifestyle exposures to sleep duration, MET, and AHEI, exploring physical activity as the most important

Keyword(s) : Association of MAFLD with joint lifestyle exposures Background & aims

2479 - Epidemiological Clinical and Paraclinical Profile of Decompensated Liver Cirrhosis at Khmer Soviet Friendship Hospital a Tertiary Hospital in Cambodia

Neang Nov¹

Khmer Soviet Friendship Hospital, Gastroenterology, Phnom Penh-Cambodia¹

Background / Hypothesis:

Decompensated liver cirrhosis is an advanced stage of chronic liver disease characterized by severe complications such as ascites, variceal hemorrhage, hepatic encephalopathy, and hepatocellular carcinoma (HCC). It is a major cause of morbidity and mortality, particularly in low- and middle-income countries. In Cambodia, hepatitis B virus (HBV), hepatitis C virus (HCV), and chronic alcohol consumption are the principal etiological factors. Despite the significant burden of disease, local data describing the clinical and paraclinical profile of decompensated cirrhosis remain limited. Our objectives are to describe the epidemiological, clinical, and paraclinical characteristics of patients with decompensated liver cirrhosis admitted to the Gastroenterology Department of Khmer-Soviet Friendship Hospital between January 1, 2018, and December 31, 2019.

Materials and Methods:

This retrospective, cross-sectional, single-center, hospital-based descriptive study reviewed medical records of 504 patients diagnosed with decompensated liver cirrhosis over a two-year period. Collected data included demographic characteristics, clinical manifestations, laboratory findings, imaging and endoscopic results, Child-Turcotte-Pugh (CTP) classification, etiologies of cirrhosis, and cirrhosis-related complications.

E-POSTER ABSTRACTS

Results:

Of the 504 patients, 304 (60.3%) were male and 200 (39.7%) were female, yielding a male-to-female ratio of 1.52:1. The mean age was 56.3 ± 10.9 years (range: 19–93 years), with the highest prevalence in the 50–59-year age group. Most patients (64.6%) originated from rural areas outside Phnom Penh.

The most common presenting symptoms were abdominal pain (39.7%), abdominal distension (29.6%), and upper gastrointestinal bleeding (22.1%). Jaundice was observed in 14.3% of patients, and hepatic encephalopathy in 4%. Laboratory abnormalities included anemia (67.2%), thrombocytopenia (55.1%), elevated AST (83.5%) and ALT (65.6%), hypoalbuminemia (41.5%), hyperbilirubinemia (50.8%), and prolonged prothrombin time (36.7%).

According to the Child-Pugh classification, 40.1% of patients were classified as Child-Pugh B, 31.4% as Child-Pugh C, and 28.5% as Child-Pugh A. Ultrasonography showed a dysmorphic liver in 73.5% and ascites in 65.6%. Endoscopy revealed esophageal varices in 48% and portal hypertensive gastropathy in 32.1%. Alcohol-related liver disease was the leading etiology (41.1%), followed by HBV (34%) and HCV (14.2%). The most frequent complications were ascites (35.8%), upper gastrointestinal bleeding (22.1%), and HCC (19.4%).

Conclusions:

Decompensated liver cirrhosis remains a major clinical and public health challenge in Cambodia, predominantly affecting middle-aged men. Alcohol consumption and HBV infection are the leading causes. The high prevalence of advanced liver dysfunction and serious complications highlights the need for earlier diagnosis, improved access to antiviral therapy, effective alcohol cessation programs, and multidisciplinary management.

Keyword(s) : Decompensated liver cirrhosis; Child-Pugh classification; ascites; hepatocellular carcinoma; upper gastrointestinal bleeding; esophageal varices; hepatitis B virus; alcohol-related liver disease; Cambodia; retrospective study; clinical profile; paraclinical findings; cirrhosis complications.

2482 - Comparative Efficacy and Safety of Second Line and Later Systemic Therapies After First Line Treatment Failure in Hepatocellular Carcinoma A Systematic Review and Meta Analysis

Han Ah Lee¹, Moon Haeng Hur², Yuri Cho³, Bo Hyun Kim³, Ju Hyun Shim⁴, Joon Hyeok Lee⁵

Chung-ang University, Internal Medicine, Seoul-South Korea¹ Seoul National University, Internal Medicine, Seoul-South Korea² National Cancer Center, Internal Medicine, Seoul-South Korea³ Asan Medical Center, Internal Medicine, Seoul-South Korea⁴ Sunkyunkwan University, Internal Medicine, Seoul-South Korea⁵

Introduction: Establishing optimal second-line and later systemic treatment strategies after failure of first-line therapy has become an increasingly important challenge in hepatocellular carcinoma (HCC). However, evidence guiding treatment selection remains limited because randomized controlled trials and direct head-to-head comparisons between agents are scarce.

Methods: We conducted a systematic review and meta-analysis of published studies evaluating second-line or later systemic therapies for HCC, excluding studies limited to sorafenib failure alone. Overall survival (OS), progression-free survival (PFS), objective response rate (ORR), disease control rate (DCR), and grade 3–4 adverse events (AEs) were pooled using meta-analytic methods.

Results: In the meta-analysis of second-line and later systemic therapies after failure of atezolizumab plus bevacizumab, lenvatinib demonstrated the most favorable survival outcomes. The pooled median OS was 12.42 months for lenvatinib (95% CI, 10.02–14.82; $I^2=89.4\%$), compared with 7.83 months for sorafenib (95% CI, 6.29–9.36; $I^2=7.36\%$). Regorafenib, cabozantinib, and ramucirumab showed pooled median OS of 9.19 months (95% CI, 3.60–14.78; $I^2=94.5\%$), 9.59 months (95% CI, 4.91–14.27; $I^2=91.4\%$), and 5.85 months (95% CI, 1.76–9.94; $I^2=20.6\%$), respectively. Compared with sorafenib, lenvatinib significantly reduced the risk of death (risk ratio [RR], 0.64; 95% CI, 0.49–0.84; $I^2=34.2\%$), whereas regorafenib and cabozantinib did not show significant benefit. The pooled median PFS was also longest with lenvatinib at 4.74 months (95% CI, 3.76–5.72; $I^2=96.4\%$), followed by cabozantinib (3.96 months), regorafenib (3.05 months), and sorafenib (2.86 months). Lenvatinib significantly reduced the risk of disease progression compared with sorafenib (RR, 0.58; 95% CI, 0.42–0.80; $I^2=65.3\%$). Reconstructed survival curves confirmed longer median OS (11.87 vs. 8.30 months) and PFS (3.80 vs. 1.93 months) with lenvatinib compared with sorafenib. The pooled ORR was highest with lenvatinib at 13.0% (95% CI, 9.1–18.1; $I^2=51.0\%$), whereas sorafenib showed the lowest ORR (4.7%). DCRs were 62.4% for lenvatinib and

E-POSTER ABSTRACTS

43.4% for sorafenib. The incidence of grade 3–4 AEs was comparable between lenvatinib (36%) and sorafenib (34%). After lenvatinib failure, atezolizumab plus bevacizumab achieved a pooled median OS of 14.98 months (95% CI, 9.57–20.38; $I^2=42\%$) and PFS of 5.78 months (95% CI, 3.19–8.37; $I^2=66\%$), along with the highest ORR (28.3%) and DCR (69.6%), although with a higher incidence of grade 3–4 AEs (53%).

Conclusion: Lenvatinib demonstrates clinical benefit after failure of atezolizumab plus bevacizumab, while multiple systemic therapies, including atezolizumab plus bevacizumab, may provide meaningful efficacy after lenvatinib failure.

Keyword(s) :

2485 - Hepatic Dysfunction in Critically Ill Children Prognostic Value of PRISM III and PELOD 2 Scores in the Pediatric Intensive Care Unit

Tuğba Gürsoy Koca¹, Ümüt Altuğ², Mustafa Akçam³
Pamukkale University, Faculty Of Medicine, Pediatric Gastroenterology, Denizli-Türkiye¹ Pamukkale University, Faculty Of Medicine, Pediatric Intensive Care Unit, Denizli-Türkiye² Suleyman Demirel University, Faculty Of Medicine, Pediatric Gastroenterology, Isparta-Türkiye³

Background / Hypothesis:

Hepatic dysfunction is a common condition in critically ill children and is most often a secondary manifestation of systemic diseases such as sepsis and multiple organ failure. However, its prognostic significance in the pediatric intensive care unit (PICU) has not been fully elucidated. This study aimed to investigate the prevalence of hepatic dysfunction in children admitted to the PICU and to evaluate the association of PRISM III and PELOD-2 scores with prognosis.

Materials and Methods: Patients hospitalized in the PICU who were diagnosed with hepatic dysfunction were included in the study. Demographic, clinical, and laboratory data were retrospectively obtained from hospital records. Patients were classified as having primary or secondary hepatic dysfunction. Organ dysfunction was assessed using the Pediatric Risk of Mortality Score (PRISM III) and the Pediatric Logistic Organ Dysfunction Score (PELOD-2) on both the first day of admission and day 7. Associations with mortality and length of stay (LOS) in the intensive care unit were analyzed.

Results: During the study period, hepatic dysfunction

was identified in 50 (8.8%) of 567 patients admitted to the PICU. The overall mortality rate was 22%. Both PRISM III and PELOD-2 scores were significantly higher in patients who died compared with survivors on day 1 (PRISM III: 19.9 ± 9.6 vs. 7.7 ± 8.8 , $p = 0.001$; PELOD-2: 28.3 ± 17.5 vs. 7.1 ± 8.6 , $p < 0.001$) and on day 7 (PRISM III: 19.5 ± 10.4 vs. 7.7 ± 8.0 , $p = 0.013$; PELOD-2: 29.7 ± 11.6 vs. 9.1 ± 8.9 , $p = 0.001$). Sepsis ($p = 0.042$), mechanical ventilation ($p = 0.004$), and inotropic support ($p < 0.001$) were significantly associated with mortality. Thresholds of ALT $\geq 2 \times$ the upper limit of normal (ULN) and total bilirubin > 2 mg/dL were not associated with mortality ($p > 0.05$). Prolonged length of stay (> 7 days) was associated with higher PRISM III scores, as well as sepsis, mechanical ventilation, inotropic support, blood product transfusion, and antibiotic use.

Conclusions: Hepatic dysfunction is common in critically ill children and is closely associated with adverse outcomes. PRISM III and particularly PELOD-2 scores are reliable predictors of mortality. Sepsis, mechanical ventilation, and inotropic support are major risk factors for mortality, whereas conventional biochemical thresholds such as ALT and bilirubin have limited prognostic value. Early recognition of hepatic dysfunction and regular monitoring using organ dysfunction scores in the PICU may contribute to improved risk stratification and optimization of patient management.

Keyword(s) : Hepatic dysfunction; pediatric intensive care unit; PRISM III; PELOD-2; mortality; sepsis

2486 - Targeting a Cytosolic Nucleotide Pyrophosphatase Suppresses Malignant Phenotypes of Hepatocellular Carcinoma

Jae Youn Cheong¹, Se Ha Jang¹, Hyun Sun Jung¹, Geum Ok Baek¹, Moon Gyeong Yoon¹, Soon Sun Kim¹, Jung Woo Eun¹
Ajou University Hospital, Gastroenterology, Suwon-South Korea¹

Background / Hypothesis:

Hepatocellular carcinoma (HCC) has a poor prognosis due to late diagnosis, high recurrence, and metastasis.

Materials and Methods:

We investigated a cytosolic nucleotide pyrophosphatase that sanitizes the intracellular dNTP pool by hydrolyzing abnormal deoxycytidine triphosphates, preventing their incorporation into DNA.

E-POSTER ABSTRACTS

Results:

Public immunohistochemistry data and qRT-PCR in 132 paired tissues showed marked overexpression of this enzyme in HCC, which was further validated by Western blot. In HCC cell lines, siRNA-mediated knockdown significantly inhibited proliferation, clonogenicity, migration, and invasion. Mechanistically, enzyme suppression accelerated mRNA decay and downregulated proteins associated with epithelial-mesenchymal transition (EMT; N-cadherin, Snail), stemness (Nanog, Oct-4A, CD133), proliferation (PCNA), and angiogenesis (VEGF, HIF-1 α), while increasing epithelial markers (Occludin, ZO-1, Claudin-1).

Conclusions:

These findings indicate that nucleotide-metabolizing enzyme sustains EMT, stemness, and angiogenesis to promote malignant progression, and that its targeted inhibition effectively attenuates aggressive tumor phenotypes, nominating it as a promising molecular target for HCC therapeutics.

Keyword(s) : hepatocellular carcinoma, EMT, stemness, therapeutic target

2487 - Clinical and Laboratory Profile of Ascites in Decompensated Liver Cirrhosis and Prevalence of Spontaneous Bacterial Peritonitis A Retrospective Study at Khmer Soviet Friendship Hospital

Chhit Dimanche ¹

Khmer Soviet Friendship Hospital, Gastroenterology Department, Phnom Penh-Cambodia ¹

Background / Hypothesis:

Spontaneous bacterial peritonitis (SBP) is an infection of ascitic fluid (AF) in the absence of an obvious surgically treatable intra-abdominal source. Diagnosis relies on an AF polymorphonuclear leukocyte (PMN) count ≥ 250 cells/mm³ and/or a positive AF culture. Early recognition and prompt management are critical to reduce morbidity and mortality. This study aimed to determine the prevalence of SBP among patients with cirrhotic ascites and to identify the most significant clinical and paraclinical features associated with SBP to facilitate early diagnosis.

Materials and Methods:

A retrospective, analytical, single-center study was conducted at the Gastroenterology and Hepatology Department of Khmer-Soviet Friendship Hospital. Medical records of patients with cirrhotic ascites admitted between January 1, 2019, and December 30,

2021, were reviewed. Data on demographics, cirrhosis etiology, clinical features, laboratory findings, ascitic fluid analysis, and culture results were collected and analyzed.

Results:

Among 315 patients with cirrhotic ascites, 55 cases (17.5%) were diagnosed with SBP. The cohort included 34 males (61.8%) and 21 females (38.2%), with a male-to-female ratio of 1.61:1. The mean age was 54.06 ± 11.69 years. The leading causes of cirrhosis were hepatitis B virus (34.3%), alcohol-related liver disease (32.4%), and hepatitis C virus (18.1%). Clinical and paraclinical factors significantly associated with SBP included fever, abdominal pain, jaundice, advanced liver disease (Child-Pugh class C), low ascitic protein concentration (< 16 g/L), cloudy ascitic fluid, and elevated serum bilirubin (> 4.45 mg/dL). Routine AF analysis and culture were performed in all cases. Among SBP patients, only nine cultures (16.36%) were positive, identifying *Escherichia coli* and *Klebsiella pneumoniae* as causative pathogens.

Conclusions:

SBP remains a significant complication among patients with cirrhotic ascites, predominantly affecting men. Key associated factors include fever, abdominal pain, jaundice, advanced liver disease, and cloudy ascitic fluid. Despite low culture positivity, diagnostic paracentesis with PMN count remains a reliable, simple, and essential test and should be performed immediately upon admission—preferably before initiating empiric antibiotic therapy—for all patients with decompensated cirrhosis and ascites, particularly when associated clinical or laboratory indicators are present.

Gastroenterology And Hepatology, Ankara-Türkiye ² Gazi University, Gastroenterology And Hepatology, Ankara-Türkiye ³ Koc University Hospital, Gastroenterology And Hepatology, Istanbul- ⁴ Ankara University, Gastroenterology And Hepatology, Ankara- ⁵ Ankara Bilkent City Hospital, Internal Medicine, Ankara- ⁶ Ankara University, Biostatistics, Ankara- ⁷

Background / Hypothesis: Recent meta-analyses report higher HCC risk in chronic hepatitis D (CHD) vs chronic hepatitis B (CHB). This study aims to compare well-defined CHD and CHB cohorts with respect to HCC development.

Materials and Methods: Patients receiving treatment for CHB and CHD with nucleos(t)ide analogs (NAs) and interferon alfa (IFN), respectively, were extracted from our databases. 124 CHD patients (71% male, mean age 40.3 years, 45 [36.3%] cirrhotic) received IFN and 238 CHB patients (69% male, mean age 48.5, 65 cirrhotic at baseline) received tenofovir [n:163] or entecavir (n:75)]. Forty out of 124 CHD patients had a maintained virological response (MVR), defined as undetectable HDV RNA for 2 years post-treatment. CHB patients were older, had higher platelets, but lower ALT and GGT, compared to CHD ($p < 0.05$ for all comparisons). Median follow-up (FU) was 111 and 115 months for CHB and CHD, respectively. Cumulative HCC development probabilities were estimated by the Kaplan-Meier method and compared with the log-rank test. Propensity score weighting combined with Cox proportional hazards model was used to reduce selection bias risk.

Results: Sixty-five (27%) CHD and 45 CHB (36%) patients had compensated cirrhosis ($p = 0.4$). HCC developed in 21 (8.8%) CHB and 21 (16.9%) CHD patients. Cumulative HCC development probability was higher with CHD compared to CHB ($p = 0.046$). HCC incidence rates were 0.4%, 3.8%; 7.2%, 8.2%, 10.0% and 10.0% and 0.8%, 4.9%, 9.3%, 11.2%, 18% and 23.2% at 12, 36, 60, 84, 120, and 144 months of FU for CHB and CHD patients, respectively. Yearly incidence rates were 1.28% and 1.92% within 60 months and 0.76% and 1.99% after 60 months of FU for CHB and CHD, respectively ($p = 0.04$). CHB, compared to CHD patients with an MVR, did not display a cumulative HCC difference (8.8% vs 10%). After propensity score weighting CHD displayed a strong trend for an increased HCC risk with a HR of 1.86 (95% CI: 0.98-3.52, $p = 0.056$). When CHD patients responding to IFN treatment were compared to CHB patients (responding to NAs), CHD no longer displayed an increased risk

($p = 0.761$).

Conclusions: This study provides evidence that HDV per se may not be an additional risk factor for HCC development, compared to CHB mono-infection. The reported increased risk in CHD may be linked to fibrosis progression and rapidly developing cirrhosis facilitated by the lack of an effective treatment.

2490 - A Rare Case of Zieve's Syndrome in a cirrhotic patient Hemolytic Anemia Associated with Alcoholic Liver Disease and Hyperlipidemia

Hasmik Ghazinyan ¹, Ruzanna Safaryan ¹, Yervand Hakobyan ², Elen Hayrapetyan ³, Vahan Mukuchyan ⁴
Yerevan Scientific Medical Center, Department Of Gastroenterology And Hepatology, Yerevan-Armenia ¹
Hematology And Oncology Center After Prof. Yeolyan, Department Of Hematology, Yerevan-Armenia ²
Yerevan State Medical University Named After Mkhitar Heratsi, Faculty Of General Medicine, Yerevan-Armenia ³
Nairi Medical Center, Department Of Immunology And Rheumatology, Yerevan-Armenia ⁴

Background:

Zieve's syndrome is a rarely reported disease resulting from alcohol abuse, characterized by hemolytic anemia, cholestatic jaundice, and transient hyperlipidemia. It is largely under-recognized and under-reported, possibly due to a lack of awareness of the condition among physicians. However, due to the prevalent and persistent excessive alcohol consumption, it is believed that the actual occurrence of this condition might be higher than reported. The exact pathophysiology remains uncertain, with hypotheses ranging from alcohol-induced liver damage to autoimmune processes.

Materials and Methods:

A 60-year-old male with a history of alcoholic liver disease (average consumption of > 60 g of alcohol a day, last used 3 months ago), presented with worsening right upper quadrant pain, jaundice, and fatigue. The symptoms began approximately 2-3 months prior. The patient denied recent use of drugs, toxins or herbal products. Blood analysis showed total bilirubin $173.8 \mu\text{mol/L}$,

E-POSTER ABSTRACTS

indirect bilirubin 108.2 $\mu\text{mol/L}$, Cr 54 $\mu\text{mol/L}$, ALP 152 U/L, ALB 24 g/L, GOT (AST) 82.1 U/L, GGT 65 U/L, GPT (ALT) 64.4 U/L, Hb 83 g/L, HCT 23.6%, MCV 100 fL, MCH 35.2 pg, RDW-SD 59.5 fL, RDW-CV 16.4%, platelets 77,000; INR 2.02; triglycerides 3.16 mmol/L, R-factor 1.6. Serology for hepatitis B and C viruses was negative. Investigations with an ultrasound showed the liver with hepatic steatosis, signs of cirrhosis and portal hypertension, splenomegaly and minimal ascites. Endoscopic examination excluded gastrointestinal bleeding (esophageal varices I grade, GOV1 Sarin's classification). Autoimmune diseases serological markers: AMA <1:80 (negative), ANA 1:160 (possible antigen association: SM, U1RNP, SS-B (La), SS-A (Ro60)).

Results:

The patient was evaluated by a surgeon, rheumatologist, and hematologist, and was diagnosed with alcohol-associated liver cirrhosis, C class Child-Pugh score, MELD-Na-23, and hemolytic anemia. The patient was monitored by a hematologist, and symptoms resolved in 6–8 weeks with alcohol abstinence and conservative therapy.

Conclusions:

This case underscores the diagnostic challenges associated with Zieve's syndrome due to its rarity and overlapping clinical features with other conditions. This case highlights the importance of a comprehensive evaluation, serial investigations, and multidisciplinary collaboration to reach an accurate diagnosis and provide appropriate management. Recognizing Zieve's syndrome promptly is crucial to prevent unwarranted and potentially detrimental interventions. Early identification can spare patients from ineffective or potentially harmful therapies, focusing instead on the most effective approach.

2492 - Development and validation of an artificial intelligence driven convolutional neural network for automated stool colour classification to facilitate early diagnosis of biliary atresia

Arjun Maria¹, Vivek Patel², Ashrita Avalareddy³, Kalpana Panda⁴, Vipul Gautam⁵

Amrita Institute Of Medical Sciences, Pediatric Gastroenterology Hepatology, Noida-India¹ Amrita Institute Of Medical Sciences, School Of Artificial

Intelligence, Amrita Vishwa Vidyapeetham, Faridabad-India² Aster Hospital, Pediatric Hepatology, Bangalore-India³ Sum Hospital, Pediatric Gastroenterology, Bhubaneshwar-India⁴ Max Hospital, Saket, Pediatric Hepatology, Delhi-India⁵

Background / Hypothesis:

Early recognition of acholic (pale) stools in infants with cholestasis is critical. Misclassification of stool colour by parents and frontline community health workers remains common. To address this gap, we developed and validated an AI-driven convolutional neural network (CNN) capable of automated stool colour classification. The long-term goal is to deploy this tool widely so that caregivers can upload a stool image and receive immediate guidance on whether the stool is pale, prompting earlier medical evaluation.

Materials and Methods:

Pale stools from confirmed biliary atresia patients (2023-2025) were included. Pigmented stools were obtained from healthy infants. Images were captured using parent-owned mobile phones with varying resolution, lighting, and clarity. Stool color was confirmed by 2 pediatric hepatologists. After excluding severely blurred images, 74 pale and 110 pigmented images formed the training set. AI model used a DenseNet121 architecture. A validation cohort of 37 images was labelled by a pediatric hepatologist (gold standard) and compared with classifications by a parent, intern, nurse and the AI model.

Results:

AI model achieved perfect agreement with experts, identical to the nurse ($\kappa = 1.00$; Sensitivity 100%; Specificity 100%; AUROC 1.00). This was followed by stool classification by the intern ($\kappa = 0.94$; Sensitivity 100%, Specificity 93%). Parents showed only moderate agreement ($\kappa = 0.62$) with Sensitivity 74% and Specificity 94%, misclassifying 7/37 stools. AUROC values were 1.00 (AI model and nurse), 0.97 (intern), and 0.84 (parent). Fisher's exact testing confirmed strong association with expert classification for AI model and nurse ($p = 1.6 \times 10^{-10}$) and intern ($p = 3.9 \times 10^{-9}$), with weaker association for parents ($p = 1.1 \times 10^{-4}$)

Conclusions:

Parents show suboptimal correlation with expert, underscoring the need for an automated tool. The

E-POSTER ABSTRACTS

DenseNet121 model performed at expert level and can be deployed through QR codes on immunisation cards, enabling caregivers to upload stool images and receive immediate guidance

Keyword(s) :

2493 - Impact of continuous renal replacement therapy on survival and ammonia clearance in pediatric acute liver failure with advanced hepatic encephalopathy a two centre retrospective cohort analysis

Arjun Maria¹, Maninder Dhaliwal², Urmila Anand³, Shaleen Aggarwal⁴, Nishant Wadhwa⁵, Anil Sachdeva⁶, Kanav Anand⁷

Amrita Institute Of Medical Sciences, Pediatric Gastroenterology Hepatology, Faridabad-India¹ Amrita Institute Of Medical Sciences, Pediatric Critical Care, Faridabad-India² Amrita Institute Of Medical Sciences, Nephrology, Faridabad-India³ Amrita Institute Of Medical Sciences, Hepatobiliary Surgery, Faridabad-India⁴ Sir Ganga Ram Hospital, Pediatric Gastroenterology, Delhi-India⁵ Sir Ganga Ram Hospital, Pediatric Critical Care, Delhi-India⁶ Sir Ganga Ram Hospital, Pediatric Nephrology, Delhi-India⁷

Background / Hypothesis:

To assess the impact of Continuous Renal Replacement Therapy (CRRT) on survival in children with pediatric acute liver failure (PALF) and high-grade hepatic encephalopathy (HE III–IV)

Materials and Methods:

This two-centre retrospective cohort study included 52 children with PALF and HE grade III/IV admitted between January 2018 and November 2025. Twenty-eight patients (54%) received CRRT following consent, while 24 (46%) who declined CRRT were managed with standard medical therapy (SMT) and served as controls. None of the patients underwent liver transplantation. Clinical, biochemical, and outcome data were analysed, with survival as the primary endpoint

Results:

The predominant etiology was Hepatitis A virus infection (87%), followed by Hepatitis E virus (4%), Dengue virus (2%), and drug-induced liver injury (2%). Baseline demographic and clinical parameters were comparable between groups, except for significantly higher baseline serum ammonia in the CRRT group

(292 µg/dL vs 150 µg/dL, $p=0.001$).

Overall survival did not differ significantly between the CRRT and SMT groups (54% vs 66%, $p=0.337$). Survival at Day 3 ($p=0.594$) and Day 7 ($p=0.091$) was also comparable. CRRT was associated with more effective early ammonia clearance, with $\geq 10\%$ reduction at 24 hours achieved in 48% of patients compared to 25% in the SMT group ($p=0.004$).

On multivariate analysis, mortality was significantly associated with failure to achieve $\geq 30\%$ reduction in ammonia by Day 2 ($p=0.003$), requirement of inotropic support at admission ($p=0.043$), and fulfilment of King's College Hospital (KCH) criteria ($p=0.014$). Cox proportional hazards modelling identified KCH criteria (HR 4.08, $p=0.047$) and elevated ammonia levels (HR 5.0, $p=0.031$) as independent predictors of mortality (Figure1)

Conclusions:

CRRT did not confer a survival advantage over standard medical therapy in children with PALF and HE grade III–IV. Although CRRT significantly enhanced early ammonia reduction. Fulfilment of KCH criteria and failure to achieve $\geq 30\%$ ammonia reduction by Day 2 independently predicted mortality

Keyword(s) : Acute Liver Failure, CRRT, Transplant Free survival

2494 - Clinically significant weight loss through combination of glp 1 agonist and sedation free swallowable intragastric balloon in prader-willi syndrome with severe cardiopulmonary risk

Arjun Maria¹, Rohit Mehtani², Salim Naik³, Sushil Azad⁴, Ridhima Bhatia⁵

Amrita Institute Of Medical Sciences, Pediatric Gastroenterology Hepatology, Noida, Uttar Pradesh-India¹ Amrita Institute Of Medical Sciences, Hepatology, Faridabad-India² Amrita Institute Of Medical Sciences, Surgical Gastroenterology, Faridabad-India³ Amrita Institute Of Medical Sciences, Pediatric Cardiology, Faridabad-India⁴ Amrita Institute Of Medical Sciences, Pediatric Anesthesiology, Faridabad-India⁵

Background / Hypothesis:

Prader–Willi Syndrome (PWS) is characterized by hyperphagia, morbid obesity, endocrine dysfunction, and multisystem comorbidities. Weight reduction is essential but challenging, particularly in patients with severe obesity and cardiopulmonary compromise who are not candidates for anesthesia. We report the

E-POSTER ABSTRACTS

successful use of combined GLP-1 agonist therapy and sedation-free swallowable intragastric balloon in a child with PWS and high anesthesia risk.

Materials and Methods:

A multidisciplinary team evaluated a 15 year old male, genetically confirmed PWS patient. He had morbid obesity (BMI 64 kg/m²; weight 148 kg; height 152 cm) and severe comorbidities including obstructive sleep apnea, pulmonary artery hypertension (pulmonary pressure 65 mmHg), chronic hypercapnia (PCO₂ 55 mmHg), type II diabetes mellitus, hypothyroidism, generalized hypotonia, intellectual disability and MASLD. Diazoxide choline was not procurable. Due to severe pulmonary hypertension and respiratory acidosis, anesthesia clearance for bariatric surgery and endoscopic intragastric balloon placement was denied. The team proceeded with GLP-1 agonist therapy (semaglutide) followed by placement of the sedation-free swallowable intragastric balloon.

Results:

Semaglutide dose was rapidly escalated to 2.4 mg/week over nine weeks, resulting in modest weight loss of 3 kg. Given inadequate response, a swallowable intragastric balloon was placed after two days of patient preparatory training to overcome behavioural challenges. The procedure was completed successfully without sedation. Post-placement abdominal pain resolved within 48 hours. Over the subsequent three weeks, while continuing full-dose semaglutide, the patient achieved an additional 10 kg weight loss. Total weight loss was 13 kg (~10% of baseline).

Conclusions:

In high-risk PWS patients, a combination of GLP-1 agonist therapy and a sedation-free swallowable intragastric balloon may offer a viable and effective bridge to weight reduction. This case demonstrates meaningful early weight loss and acceptable tolerability, supporting the potential role of combined therapy in selected PWS patients with extreme obesity and limited therapeutic options.

Keyword(s) : Morbid obesity, Prader Willi Syndrome, GLP 1 agonists, swallowable intragastric balloon

2495 - Non destructive Epstein Bar Virus associated post transplant lymphoproliferative disorder

presenting with gastrointestinal bleeding in a post liver transplant child diagnostic and therapeutic challenges

Arjun Maria¹, Nishant Wadhwa²

Amrita Institute Of Medical Sciences, Pediatric Gastroenterology Hepatology, Noida-India ¹ Sir Ganga Ram Hospital, Pediatric Gastroenterology, Delhi-India ²

Background / Hypothesis:

Gastrointestinal (GI) bleeding in pediatric liver-transplant recipients has a broad differential, including infectious ulcers, portal vein (PV) complications, drug-related mucosal injury, and post-transplant lymphoproliferative disorder (PTLD). Distinguishing inflammatory etiologies from early PTLD is challenging, particularly in children with complex post-transplant courses. We describe the diagnostic evaluation and management of a post-living donor liver transplant (LDLT) child who developed EBV-driven non-destructive PTLD presenting with multifocal GI ulcers and hematochezia

Materials and Methods:

We report a detailed case review of a 22-month-old boy transplanted for biliary atresia at 8 months of age, with prior PV stenosis requiring stenting and one episode of rejection. He presented with haematochezia, fever, cytopenia, and persistently elevated tacrolimus levels. Evaluation included endoscopy, colonoscopy, imaging (triple-phase CT, CT angiography, PET-CT), viral PCRs, lymph node biopsies, and bone marrow studies.

Results:

Endoscopy revealed a polypoidal antral lesion and deep ulcers in the ascending colon and ileocecal region. Histology showed active colitis without dysplasia. CMV and EBV PCRs were positive; however, CMV immunohistochemistry was negative. PET-CT demonstrated FDG-avid cervical and mesenteric lymph nodes and GI mural lesions. Lymph node biopsy showed preserved architecture, CD20-positive follicles, abundant CD138-positive plasma cells, and polyclonality on kappa/lambda ISH. EBER positivity confirmed non-destructive PTLD – plasmacytic hyperplasia subtype. Rising EBV viremia and cytopenias persisted despite withdrawal of tacrolimus. The child responded rapidly to rituximab, with defervescence within 24 hours and resolution of cytopenias and GI blood loss. Subsequent transaminase elevation raised

E-POSTER ABSTRACTS

suspicion of acute cellular rejection, requiring ongoing immunosuppression adjustment.

Conclusions:

GI bleeding in post-LT children requires early consideration of EBV-associated PTLT, especially in the context of high calcineurin inhibitor levels and lymphadenopathy. Multimodal diagnostics and prompt immunomodulatory therapy, including rituximab, are crucial for favourable outcomes. This case highlights the intricate balance between infection control, PTLT treatment, and rejection risk in pediatric liver-transplant care.

Keyword(s) : Gastrointestinal - post transplant lympho proliferative disorder

2497 - Hepatic Hemodynamics Detected by Ultrasound Localization Microscopy is Improved after Transjugular Intrahepatic Portosystemic Shunt

Jiahao Han¹, Wentun Yao², Yinchun Yuan³, Jia Li¹, Xiaolong Qi⁴, Chuan Li⁴

Zhongda Hospital Southeast University, Department Of Ultrasound, Nanjing-China¹ General Hospital Of Ningxia Medical University, Department Of Gastroenterology, Yinchuan-China² General Hospital Of Ningxia Medical University, Department Of Ultrasound, Yinchuan-China³ Zhongda Hospital Southeast University, Department Of Radiology, Nanjing-China⁴

Background / Hypothesis:

To investigate the alteration of hepatic hemodynamics after transjugular intrahepatic portosystemic shunt (TIPS) using ultrasound localization microscopy (ULM).

Materials and Methods:

This prospective study enrolled patients scheduled for TIPS from July, 2025 to September, 2025 at two tertiary care centers. ULM was examined two times using Mindray A20 (Mindray, China) within 24 hours before and after TIPS, respectively. Quantitative parameters of liver parenchyma including vessel density, fractal dimension, perfusion index, intensity, velocity, and direction were analyzed. The correlation between above parameters and portal pressure gradient (PPG) were analyzed by Spearman's correlation analysis. The quantitative parameters before and after TIPS was compared using paired t-test analysis.

Results:

A total of 7 patients were included in the final analysis, including 85.71% (6/7) males, with a mean age of 54.86 ± 8.17 years old. The mean PPG pre-operation is 23.86 ± 4.60 mmHg, and the mean PPG post-operation is 12.71 ± 6.13 mmHg. The mean and median velocity post-operation were correlated with PPG post-operation ($p=0.818$, $p=0.024$; $p=0.764$, $p=0.046$). The perfusion index, velocity entropy, mean velocity and median velocity were increased after TIPS compared to pre-operation (9.77 ± 3.34 vs. 14.23 ± 4.12 , $p=0.015$; 0.82 ± 0.10 vs. 0.93 ± 0.14 , $p=0.040$; 22.73 ± 2.85 mm/s vs. 27.21 ± 2.94 mm/s, $p=0.014$; 21.62 ± 3.30 mm/s vs. 26.52 ± 3.73 mm/s, $p=0.023$).

Conclusions:

The improvement of perfusion in liver parenchyma after TIPS could be detected with ULM.

Keyword(s) :

2498 - Liver disease severity and comorbidity in HBV mono infection versus HBV HDV co infection a population based study

Heejoon Jang¹, Hoyoung Na², Hyosun Shin², Jooyeon Lee², Jinhye Cha², Bo Ok Kim³, Helin Han³, Yun Bin Lee⁴

Seoul National University College Of Medicine, Seoul Metropolitan Government Boramae Medical Center, Internal Medicine, Seoul-South Korea¹ Gilead Sciences Korea Inc, Medical Affairs, Seoul-South Korea² Cerner Enviza, Medical Affairs, Seoul-South Korea³ Seoul National University Hospital, Seoul National University College Of Medicine, Internal Medicine, Seoul-South Korea⁴

Background / Hypothesis:

Hepatitis B virus (HBV)/hepatitis D virus (HDV) co-infection accelerates progression of liver diseases, including cirrhosis, hepatic decompensation, and hepatocellular carcinoma (HCC). This study aimed to describe the epidemiology and clinical outcomes in patients with HBV mono-infection and HBV/HDV co-infection in South Korea.

Materials and Methods:

This nationwide population-based study analyzed data from the Korean Health Insurance Review and Assessment Service database. Adults (≥ 18 years) with ≥ 1 inpatient/outpatient chronic hepatitis B (CHB)-related claim were identified between 2014–2018.

E-POSTER ABSTRACTS

HBV/HDV co-infection was defined by ≥ 1 HDV-related and HDV antibody testing claims, and HBV mono-infection by no HDV-related claims. Patient demographics and clinical characteristics were summarized using descriptive statistics.

Results:

Among 590,102 eligible patients, 589,349 (99.87%) presented HBV mono-infection and 753 (0.13%) had HBV/HDV co-infection, with most patients aged 51–60 years. HBV/HDV co-infection group had significantly higher proportion of patients with comorbidities (91.6% vs. 74.0%), Charlson Comorbidity Index (CCI) score ≥ 3 (63.2% vs. 27.7%), hypertension (34.4% vs. 26.8%), diabetes (34.0% vs. 17.7%), liver-related diseases (59.2% vs. 15.2%), and antiviral therapy use for CHB (63.1% vs. 23.1%) compared to HBV mono-infection group (all $P < 0.0001$). HCC incidence among the HBV/HDV co-infection and HBV mono-infection groups was 2.9% and 3.6%, with 5-year cumulative risks of 4.8% (95% CI, 1.7–7.9%) and 3.5% (95% CI, 3.5–3.6%), respectively.

Conclusions:

Patients with HBV/HDV co-infection had a greater burden of comorbidities and liver-related complications than those with HBV mono-infection. Early identification, accurate diagnosis, and proper management of HBV/HDV co-infection among CHB patients are crucial to prevent liver disease progression.

Keyword(s) : hepatitis B; hepatitis D; co-infection; liver-related complication

2500 - Adipokine dysregulation in adipose tissue in cirrhosis

Sanal Mg¹, Sarita Gupta², Rahul Saha², Kumaraswamy Parthasarathi³, Viniyendra Pamecha⁴

Institute Of Liver And Biliary Sciences, Molecule And Cellular Medicine, New Delhi-India¹ Institute Of Liver And Biliary Sciences, Molecular And Cellular Medicine, New Delhi-India² Care Hospitals, Hepatobiliary And Transplantation Surgery, Hyderabad-India³ Institute Of Liver And Biliary Sciences, Hepatobiliary And Transplantation Surgery, New Delhi-India⁴

Background and Rationale

Adipokine expression is known to be dysregulated in obesity, metabolic fatty liver disease, and cirrhosis. However, how adipokine expression within adipose tissue itself changes in cirrhosis remains poorly

understood. For example, circulating adiponectin levels are reduced in obesity and fatty liver disease and decline further in steatohepatitis, yet paradoxically increase in cirrhosis. Whether this rise reflects enhanced adipose tissue expression or reduced plasma clearance is unclear. To address this gap, we investigated the expression of key adipokines and adipose tissue-regulatory genes—including PPARG, SREBF1, SERBP1, PNPLA3, HAPLN2, ACVR1, PAQR9, GYG2, SERPINA12, DLK1, and SELE—in adipose tissue from patients with cirrhosis.

Materials and Methods

Subcutaneous adipose tissue samples were obtained from 15 patients with cirrhosis undergoing living-donor liver transplantation (LDLT) and from their healthy living donors. Total RNA and protein were extracted. Quantitative real-time PCR was performed using gene-specific primers, and relative mRNA expression was calculated using the $\Delta\Delta C_t$ method, normalized to the housekeeping gene GAPDH. Protein expression was assessed by Western blotting.

Results

The mean age was 33 ± 10 vs. 46 ± 8 years for controls and cirrhosis patients, respectively; mean BMI was comparable (25 ± 3 vs. 25 ± 5 kg/m²). Men constituted 87% of controls and 92% of cirrhosis patients. The mean MELD score among cirrhosis patients was 23 ± 6 . Mean fasting blood glucose levels were 79 ± 12 mg/dL in controls and 115 ± 34 mg/dL in patients; 28% of cirrhosis patients had diabetes. All biochemical and imaging parameters were within normal limits in healthy donors.

Adipose tissue from cirrhosis patients demonstrated increased expression of leptin, adiponectin, HAPLN2, PNPLA3, SREBF1, ACVR1, SERBP1, PAQR9, GYG2, SERPINA12, DLK1, and SELE compared with controls. In contrast, adipisin and spexin (SPX) expression was significantly reduced.

Conclusion

Adipose tissue from patients with cirrhosis exhibits upregulated transcription of several adipokines, including leptin and adiponectin. These findings suggest that the elevated circulating levels of these adipokines in cirrhosis are at least partly attributable to increased adipose tissue expression rather than impaired clearance alone. This transcriptional

E-POSTER ABSTRACTS

upregulation may represent a compensatory or stress-adaptive response in the setting of chronic liver disease and sarcopenia, particularly in populations with lower baseline body mass, such as Indian patients with cirrhosis.

Keyword(s) :

2501 - Evaluation of the Effect of the National Hepatitis B Vaccination Programme on Hepatitis B Seroprevalence (Healthcare worker and community based assessment)

Irem Çiftci ¹, Selma Tosun ¹, Irem Aşkin Yılmaz ¹
Izmir City Hospital, Infectious Diseases And Clinical Microbiology, Izmir-Türkiye ¹

Background / Hypothesis:The national hepatitis B vaccination programme was introduced in Turkey in 1998, followed by a catch-up programme between 2005 and 2009 targeting individuals born between 1991 and 1997. The Ministry of Health has also provided HBV vaccination free of charge to healthcare workers and other high-risk groups. These interventions have substantially altered HBV seroprevalence patterns, particularly among younger age groups. This study aimed to evaluate HBV-related serological profiles among healthcare workers and the general adult population in Izmir, a western province of Turkey with high vaccination coverage.

Materials and Methods:HBV serological test results (Anti-HBs, HBsAg, anti-HBc IgG) of healthcare workers employed at Izmir City Hospital and adults aged ≥ 18 years from the community were retrospectively retrieved from the hospital automation system between October 2023 and December 2025. Data were anonymized, duplicate records were excluded. Analyses were performed according to age group.

Results:The study included 6,485 healthcare workers (aged 18–73) and 178,823 individuals from the general population (aged 18–102). In both groups, HBsAg was the most frequently requested test, while anti-HBc IgG was the least requested. Anti-HBc IgG seropositivity increased significantly with age, particularly in the general population, reaching approximately 50% among individuals aged over 50. Similarly, HBsAg positivity was higher in the general population, increasing notably after the age of 35. However, HBsAg positivity declined sharply (<1%) among individuals born after 1998 in both groups. Vaccine-related anti-HBs positivity was also higher in age groups covered by the vaccination programme. Since HBV vaccination is administered to

healthcare workers in all age groups, high anti-HBs positivity rates were detected in almost all age groups. In individuals in the community, anti-HBs positivity rates reached 82% among those vaccinated under the national vaccination program and catch-up programmes, while anti-HBs positivity decreased to around 30–40% after the age of 35. This situation was similar to that observed in age groups with increased anti-HBc IgG positivity, suggesting that it may be related to natural transmission of HBV infection.

Conclusions:The findings demonstrate that the national HBV vaccination programme has markedly reduced chronic HBV infection and exposure among younger adult populations. The detection of high anti-HBs titres in healthcare workers of all ages demonstrates the benefit of the Ministry of Health's policy of providing free vaccinations to this occupational group. The high anti-HBc IgG positivity detected in middle-aged and older individuals, along with the parallel anti-HBs positivity in these age groups, indicates that exposure to the virus was higher in previous years and that our country was previously among the regions with high HBV endemicity. However, thanks to the national vaccination programme, the endemicity level has now decreased to low.

Background/Hypothesis: Bulevirtide (BLV), was approved in Europe in 2020 for treating compensated

E-POSTER ABSTRACTS

CHD. It is also available in Russia and Australia. BLV is not licensed in Turkey, a CHD endemic country. We present the first real-world data on BLV use in CHD in Turkey. This study evaluated daily 2mgBLV therapy in CHD patients for up to 36-months, with emphasis on virologic and biochemical response (VR, BR) and viral breakthrough (VBr).

Methods: 33 patients with CHD who initiated BLV therapy between 2020-2023 were analyzed. All patients had baseline detectable HDVRNA and elevated ALT. Five patients had decompensated cirrhosis, and all other patients had compensated liver disease. Seven patients used the European label Hepcludex, and remaining 26 patients received Myrcludex from Russia. Primary outcomes were VR (defined as undetectability or > 2 log decrease in HDVRNA) and BR (defined as ALT normalization) at end of on-treatment follow-up (FU). VBr was defined as an increase of HDV RNA > 1 log from nadir or HDV RNA becoming detectable after undetectability. Statistical analyses included t and Mann-Whitney U tests for continuous and Fisher's exact and Chi-squared tests for categorical variables.

Results: Mean ($\pm$ SD) baseline ALT was 99.6 ($\pm$ 66.7) U/L and HDVRNA was 4.94 ($\pm$ 1.11 log) IU/mL. At 12 months, VR was achieved in 74.1% (20/27) of evaluable patients, and BR was 70.4% (19/27). Response rates were sustained through 24 months reaching 61.1% (11/18) with VR and 64.7% (11/17) with BR. VBr occurred in 4 of 26 patients on the Russian BLV (15.4%). Patients with VBr had higher baseline INR (1.22 ± 0.03 vs 1.04 ± 0.14 , $p=0.033$) and a trend toward higher baseline HDVRNA (5.82 ± 0.81 vs 4.82 ± 1.10 log. IU/mL, $p=0.091$). Two patients with VBr had no on-treatment FU HDVRNA testing. Remaining 2 patients continued therapy and had persistent viremia throughout FU. Mean time to VBr was 18.5 ± 3.87 months (range: 15-24 months). Following VBr, 3 patients experienced ALT elevations. Seven patients (21%) discontinued BLV treatment (21.2%) at median 19 months (range 12-27). Decompensated patients ($n=5$, 15.2%) demonstrated similar VR rates compared to patients with compensated liver disease, suggesting efficacy across the disease severity spectrum. BLV was well tolerated.

Conclusion: In this real-world Turkish cohort, BLV demonstrated VR in 74% of patients at 12 months on-treatment and, maintained VR in the majority throughout 36 months. An unexpectedly high VBr rate was observed with the Russian BLV. Patients denied non-compliance.

Kafr Shukr Specialized Hospital, Hepatology And Gastroenterology Department, Kafr Shukr-Egypt⁵
Mansoura Faculty Of Medicine, Clinical Oncology And Nuclear Medicine, Mansoura-Egypt⁶

Background

Tumor lysis syndrome (TLS) is an oncologic emergency most commonly associated with hematologic malignancies and is rarely observed in solid tumors. With the increasing use of immune checkpoint inhibitors, TLS has been sporadically reported following immunotherapy

Case report

a 64-year-old male with DM and a history of chronic HCV infection, who achieved sustained virologic response after direct-acting antiviral therapy seven years prior. He presented with advanced hepatocellular carcinoma characterized by a large hepatic focal lesion, malignant lymphadenopathy, and portal vein thrombosis. Liver function was preserved (Child–Pugh A6), and the disease was staged as BCLC stage C. The patient was initiated on first-line atezolizumab plus bevacizumab therapy.

One week after the first treatment cycle, he developed oliguria and acute clinical deterioration. Laboratory evaluation revealed marked hyperuricemia (16 mg/dl), acute kidney injury (serum creatinine 5.6 mg/dl), hyperphosphatemia (10.5 mg/dl), hypocalcemia (8.4 mg/dl), and elevated transaminases, fulfilling Cairo–Bishop criteria for clinical tumor lysis syndrome.

Management and Outcome

The patient was managed with aggressive intravenous hydration, rasburicase, febuxostat, corticosteroids, and urgent hemodialysis. He demonstrated significant

E-POSTER ABSTRACTS

improvement in renal function, metabolic abnormalities, and overall clinical status.

Conclusion

This case underscores tumor lysis syndrome as a rare but potentially fatal complication of atezolizumab-bevacizumab therapy in advanced HCC. Clinicians should maintain heightened vigilance and closely monitor metabolic parameters, particularly in patients with high tumor burden and vascular invasion

2509 - Feasibility And Limitations Of Living Donor Liver Transplantation In Armenia

Hayk Harutyunyan¹, Hasmik Ghazinyan²

Astghik Medcal Center, Department Of Surgery, Yerevan-Armenia¹ Yerevan Scientific Medical Center, Department Of Gastroenterology And Hepatology, Yerevan-Armenia²

Background / Hypothesis:

Liver transplantation remains the definitive treatment for selected patients with end-stage liver disease. In Armenia, the liver transplantation program is relatively nascent and primarily reliant on living donors due to the current absence of active deceased donor organ procurement systems.

Materials and Methods:

A retrospective review of national data from Armenia's transplant centers and government reports was conducted. Key indicators included the number of liver transplants performed, waiting list characteristics, donor types, and systemic barriers affecting program expansion.

Results:

The first living donor liver transplantation (LDLT) in Armenia was successfully performed in 2019 at Astghik Medical Center, marking a milestone in the country's transplant history. Over recent years, Armenia has implemented LDLT and performed multiple liver transplants at domestic centers, alongside kidney and corneal transplants primarily from living related

donors. According to Ministry of Health data from 2021–2023, approximately ten liver transplants were conducted under the state program. National figures suggest that around 29 patients currently require liver transplantation, with a waiting list reflecting diverse etiologies including viral and autoimmune cirrhosis and cryptogenic disease. Despite legislative progress toward enabling deceased donor transplantation by updating the list of transplantable organs, practical implementation of a deceased donor program remains pending.

Conclusions:

Armenia's liver transplant program has demonstrated feasibility and clinical success within the constraints of a living donor model. However, the limited number of procedures relative to need, lack of an active deceased donor system, and resource constraints underscore the necessity for national strategic initiatives to develop organ donation infrastructure, expand donor registries, and improve equitable access to transplantation. Further research and registry development are essential to monitor long-term outcomes and inform health policy.

2512 - Evaluation of the 24 year prognosis of patients with inactive HBsAg carriage

Irem Altaş¹, Selma Tosun¹

University Of Health Sciences Turkey, Izmir Faculty Of Medicine, Izmir City Hospital, Infectious Diseases And Clinical Microbiology, Izmir-Türkiye¹

Background / Hypothesis: This study aimed to evaluate long-term real-life outcomes and prognosis of patients diagnosed with HBsAg positivity and followed as inactive carriers.

Materials and Methods: Patient records of individuals diagnosed with inactive chronic hepatitis B and followed between January 1994 and March 2018 were retrospectively reviewed using the hospital automation system. Sociodemographic characteristics, baseline and follow-up clinical findings, and laboratory results were recorded. Patients who had not attended follow-up visits for more than one year were contacted by telephone and invited for reassessment. Information regarding follow-up adherence, reasons for non-attendance, liver biopsy status, fibrosis score, cirrhosis,

E-POSTER ABSTRACTS

and hepatocellular carcinoma (HCC) development was collected through telephone interviews or face-to-face visits.

Results: A total of 1,147 patients were included, with a mean age of 50.17 ± 12 years; 579 (50.5%) were male. Regular follow-up attendance was observed in 448 patients (39%). Of these, 418 could be contacted, and 305 agreed to participate in interviews; however, only 75 attended a follow-up visit at the hospital. Total follow-up duration ranged from 6 months to 23 years.

Regarding follow-up adherence, 370 patients (32%) attended regularly, 116 (10%) rarely missed visits, 272 (24%) attended irregularly, and 389 (34%) had discontinued follow-up for more than one year. Among patients with irregular follow-up, the most common reasons were follow-up at another center (51.5%); forgetting appointments (17.5%); followed by perceiving follow-up as unnecessary; work-related issues; lack of symptoms, caregiving responsibilities; or not being invited by physicians.

Liver biopsy was performed in 63 patients (5.5%), with histological activity index scores ranging from 2 to 9 and fibrosis scores from 0 to 2. Antiviral therapy was initiated in 29 patients (2.5%). At the most recent evaluation, 837 patients (73%) remained inactive carriers, 126 (11%) experienced HBV flare-ups, 156 (13.6%) achieved spontaneous HBsAg loss, and six patients (0.5%) developed cirrhosis or HCC. Regular follow-up was observed in 55% of treated patients and 33% of those with flare-ups. Among patients with spontaneous HBsAg loss, 48% had previously attended follow-up but later discontinued. Of the six patients who developed cirrhosis-HCC, four had a family history of chronic HBV infection.

Conclusions: This study demonstrates that although most inactive HBsAg-positive patients remain stable, significant complications may still occur. The asymptomatic course and absence of treatment often lead patients to underestimate disease severity and discontinue follow-up. Regular monitoring and patient education about long-term risks are essential to prevent loss to follow-up and ensure early detection of complications. (Note: This work is the doctoral thesis of Dr. İrem Altaş).

2516 - Evaluation of the 24 year prognosis of patients with inactive HBsAg carriage

Selma Tosun¹

University Of Health Sciences Turkey, Izmir Faculty Of

Medicine, Izmir City Hospital, Infectious Diseases And Clinical Microbiology, Izmir-Türkiye ¹

Background / Hypothesis: This study aims to evaluate the long-term real-life data and prognosis of individuals diagnosed with HBsAg positivity and monitored as inactive carriers.

Materials and Methods: The follow-up files and existing records in the automation system of patients diagnosed with inactive chronic hepatitis B and monitored between January 1994 -March 2018, were individually reviewed. Their sociodemographic data, all findings related to their initial and follow-up visits, and test results were recorded in an Excel file. In addition, patients who had not attended follow-up appointments for more than a year were contacted by telephone and invited to attend a follow-up appointment. These patients were then interviewed either during the telephone call or face-to-face during their outpatient clinic visit. The patients' sociodemographic data, diagnosis date, follow-up period, whether they attended follow-ups regularly, the reason for non-attendance if applicable, whether a liver biopsy was performed during follow-up, and if so, the fibrosis score, cirrhosis, or HCC development status were examined.

Results: The study included a total of 1,147 patients with a mean age of 50.17 ± 12 , 579 (50.5%) of whom were male. It was determined that 448 (39%) of the patients attended follow-up appointments regularly, while 699 (61%) had not attended for over a year. Although non-attending patients were contacted by phone, only 418 could be reached, and 305 of these agreed to participate in a face-to-face survey; only 75 of the patients invited to the hospital attended the follow-up.

The total follow-up periods of the patients since their years of application to our hospital ranged from a minimum of 6 months to a maximum of 23 years. When the patients' attendance at their check-ups was evaluated, it was determined that 370 (32%) attended their check-ups regularly, 116 (10%) rarely missed their check-up intervals, 272 (24%) did not attend regularly, and 389 (34%) had previously attended regularly but had not attended their check-ups for over a year.

Keyword(s) : inactive HBsAg carriage

2517 - Is primary biliary cholangitis excluded in patients negative for PBC specific autoantibodies and without cholestatic features

Shasha Li¹, Yongfeng Yang¹

E-POSTER ABSTRACTS

Clinical Teaching Hospital Of Medical School,
Department Of Liver Disease, Nanjing-China ¹

Background / Hypothesis:

The diagnosis and therapeutic decision-making for atypical primary biliary cholangitis (PBC) remain controversial. Based on clinical practice, we report for the first time a new pathological subtype of PBC characterized by negativity for PBC-specific autoantibodies and normal alkaline phosphatase (ALP) levels. We systematically analyzed its clinical and pathological features to provide a basis for improving clinical recognition and guiding early treatment decisions.

Materials and Methods:

We retrospectively reviewed and summarized the clinical and pathological data of 10 patients diagnosed with histologically confirmed PBC at the Second Hospital of Nanjing from 2016 to 2025.

Results:

Among the 10 patients, 80% were female, with a median age of 54.5 years. The majority of patients presented with mild elevations of aminotransferases and gamma-glutamyl transferase (GGT) as the main biochemical abnormalities, accompanied by elevated immunoglobulin M (IgM). Liver histology showed chronic non-suppurative destructive cholangitis in all patients, predominantly at Ludwig stage II and Nakanuma stage II. Some patients already had advanced liver fibrosis and/or portal hypertension at diagnosis. Following ursodeoxycholic acid (UDCA) therapy, 88.9% of patients maintained persistently normal ALP and GGT levels. No patient developed hepatic decompensation during follow-up.

Conclusions:

Typical PBC-like pathological changes can exist even in patients with negative PBC-specific autoantibodies and normal ALP levels, suggesting that bile duct injury may precede biochemical abnormalities. Liver biopsy is essential for early identification in suspected cases, and timely UDCA therapy can achieve favorable biochemical response and prognosis. Future multicenter, long-term follow-up studies are still needed to further clarify the natural history and pathogenesis of this subtype.

2520 - A RARE CASE IN LIVING DONOR LIVER TRANSPLANTATION GRAFT TO GRAFT OF PORTAL VEIN ANASTOMOSIS

Mehmet Hadin Karadağ¹, Sertaç Usta ¹

Inonu University Turgut Ozal Medical Center, General Surgery, Malatya-Türkiye ¹

Background / Hypothesis:

In this report, we present a successful liver transplantation in which a living donor graft with anomalous portal venous branching (APVB) was reconstructed on the back table using a homolog portal Y-graft. This reconstructed graft was then anastomosed to a cadaveric interposition graft of the recipient with Yerdel grade 3 portal vein thrombosis, resulting in a graft-to-graft portal vein anastomosis.

Materials and Methods:

A 68-year-old Middle Anatolian female patient presented with clinical features consistent with chronic liver disease. She reported abdominal distension, fatigue, and weakness. Her MELD-Na score was calculated as 16. Preoperative dynamic liver CT demonstrated portal vein thrombosis (PVT) with minimal residual flow. The patient underwent right-lobe living donor liver transplantation for cryptogenic liver failure and Yerdel type 3 PVT. The recipient hepatectomy was performed using standard surgical procedures. Prior to graft implantation, thromboendovenectomy was attempted. However, during the procedure, a bleeding occurred at the portal vein confluence. Hemostasis was achieved by inflating a Foley catheter balloon at the confluence, and a cadaveric vein graft was anastomosed outflow of Superior Mesenteric Vein-Splenic vein for extension. After clamping the vena cava, the right-lobe graft was implanted. The donor graft had anomalous portal venous branching; therefore, a homolog portal Y-graft interposition was performed on the back table. The reconstructed right-lobe portal vein was then anastomosed to the recipient's extension graft. Ensuring continuous and physiological portal flow and successful graft perfusion.

Results:

Our case required both portal venous reconstruction with homolog portal Y-graft on the donor graft and a

E-POSTER ABSTRACTS

jump graft from the portal confluence due to PVT. This case involves highly complex procedures. In this report, we aim to emphasize that when physiological reconstruction pathways are used, long-term outcomes can be favorable and this case represents an encouraging example.

Conclusions:

In right-lobe living donor liver transplantation with APVB, successful outcomes can be achieved using appropriate surgical techniques. This case demonstrates that in living donor liver transplantation with PVT, a combined portal Y-graft and extension graft, completed with graft-to-graft anastomosis, can be safely used for portal vein reconstruction.

Keyword(s) : Jump graft, Jump graft and Y-graft anastomosis, Liver transplantation, Portal vein reconstruction

2521 - A novel clustered regularly interspaced short palindromic repeats based assay for intrahepatic hepatitis B virus covalently closed circular DNA quantification

Pattida Kongsomboonchoke¹, Pisit Tangkijvanich¹
Chulalongkorn University, Biochemistry, Bangkok-Thailand¹

Background: The persistence of covalently closed circular DNA (cccDNA) within infected hepatocytes represents the principal barrier to achieving a functional cure for hepatitis B virus (HBV) infection. Novel drug developments and therapeutic strategies aimed at eliminating cccDNA are essential. However, existing cccDNA quantification methods are limited by suboptimal sensitivity and specificity, frequently resulting in false-positive detection of non-cccDNA intermediates.

Materials and Methods: We developed a clustered regularly interspaced short palindromic repeats (CRISPR)/CRISPR-associated protein 12a (Cas12a)-based assay to accurately quantify intrahepatic cccDNA. CRISPR RNAs (crRNAs) were designed to target regions that do not overlap between relaxed circular DNA (rcDNA) and cccDNA. The crRNAs were conserved across HBV genotypes A–D. Assay parameters, including single-stranded DNA (ssDNA) reporter concentration, fluorescence signal gain, and incubation time, were optimized to enhance Cas12a collateral activity. To overcome limited sensitivity, recombinase polymerase amplification (RPA) was

integrated as a pre-amplification step. Quantitative PCR (qPCR) was used as a reference method to validate the assay.

Results: The combination of RPA and CRISPR/Cas12a achieved a high sensitivity at 10 copies/reaction. Reliable quantification between expected and measured values was observed over a dynamic range of 10^1 – 10^6 copies/reaction, exhibiting a strong correlation ($R^2 = 0.9263$). Comparative analysis with qPCR showed excellent agreement between the two methods ($R^2 = 0.9992$, $p < 0.0001$). Importantly, the assay exhibited high specificity for cccDNA, with specific detection in liver tissue samples, and no detection in serum or plasma samples. Application of the assay to 25 non-cancerous liver tissue samples obtained from HBV-related hepatocellular carcinoma (HCC) patients resulted in successful cccDNA quantification in 11 samples, which strongly correlated with qPCR measurements ($R^2 = 0.9590$).

Conclusion: This newly developed CRISPR-based assay provides a sensitive, specific, and accurate approach for cccDNA quantification, supporting its utility in research and development toward HBV cure.

Keyword(s) : hepatitis B virus (HBV), covalently closed circular DNA (cccDNA), clustered regularly interspaced short palindromic repeats (CRISPR)

2522 - Triple Trouble A Case of Hepatocellular Carcinoma in a Patient with Previous Renal and Colonic Malignancies

Cleo Christille Lynn Lom-oc¹, Angelo Lozada¹, Miguel Edgardo Fores¹

Makati Medical Center, Gastroenterology, Makati City-Philippines¹

Background / Hypothesis:

Multiple primary tumors (MPTs) are defined as two or more synchronous or metachronous primary malignancies in a single patient. The frequency of MPTs ranges from 2% to 17%, with triple primary cancers being exceedingly rare. We report a case of a patient with three primary malignant tumors: Renal cell carcinoma, colon adenocarcinoma and hepatocellular carcinoma.

Materials and Methods:

We present a 74-year-old male with a history of synchronous renal cell carcinoma and stage IA colon adenocarcinoma diagnosed in 2008. Both were surgically managed in the same year with partial nephrectomy and left hemicolectomy. The patient was lost to follow-up until seventeen years postoperatively,

E-POSTER ABSTRACTS

when, in 2025, he developed progressive weight loss. Laboratory tests showed elevated liver enzymes [aspartate aminotransferase (AST) 99 U/L, alanine aminotransferase (ALT) 102 U/L], and ultrasound revealed a fairly defined heterogeneous mass measuring 99 × 85 × 94 mm. Carcinoembryonic antigen (CEA) was 6.67 ng/mL, and protein induced by vitamin K absence or antagonist-II (PIVKA-II) was elevated at 441.42 mAU/mL. Other tumor markers, including CA19-9 and α-fetoprotein, were within normal limits. Magnetic resonance imaging of the whole abdomen demonstrated a large right hepatic mass involving segments VIII/VII/V/VI measuring 72 × 61 × 63 mm (AP × T × CC), with arterial enhancement and washout, initially raising suspicion for metastasis from the previous colon adenocarcinoma. Upper endoscopy showed no high-risk stigmata for bleeding, and colonoscopy was negative for disease relapse. Liver biopsy revealed hepatocytes in trabecular arrangements with immunohistochemical staining positive for Arginase and Glypican-3, confirming hepatocellular carcinoma. Thus, a diagnosis of a third primary malignancy of the liver was made rather than metastatic recurrence. The patient subsequently received three cycles of immunotherapy with atezolizumab and bevacizumab. A follow-up positron emission tomography (PET) scan showed a minimal decrease in size of the hepatic mass with significantly reduced arterial enhancement, which may reflect treatment response.

Results:

This case highlights the diagnostic challenge of differentiating hepatic metastasis from de novo HCC in patients with prior malignancies. Current guidelines recommend biopsy confirmation when imaging is inconclusive, particularly in non-cirrhotic liver. Recognition of a new primary malignancy allowed consideration of liver-directed therapy instead of palliative systemic treatment for presumed metastasis.

Conclusions:

The possibility of multiple primary cancers, while rare, underscores the importance of thorough follow-up. Early detection and risk reduction strategies are vital in improving outcomes and guiding appropriate treatment.

Keyword(s) : Hepatocellular carcinoma, Multiple primary tumors, Triple primary cancer, Renal cell carcinoma, Colon adenocarcinoma

2523 - HepPlus Protocol for a multicenter study of a web based platform to support hepatitis B and C management in Thailand

Pitchaya Chairuengjitjaras ¹, Ketsarapohn Sudchit ², Nattapat Boonsiripiyachok ², Pisit Tangkijvanich ²

Yale School Of Public Health, Yale University, Department Of Biostatistics, New Haven-United States
¹ Center Of Excellence In Hepatitis And Liver Cancer, Chulalongkorn University, Department Of Biochemistry, Bangkok-Thailand ²

Background: Hepatitis B and C remain leading causes of liver-related morbidity and mortality in Thailand, with many patients lost to follow-up due to fragmented care and limited interoperability between healthcare facilities. There is an urgent need for digital solutions that enhance care coordination, support clinical decision-making, and enable national disease surveillance. This study describes the protocol for the development and pilot implementation of Hep Plus, a web-based application designed to: (1) serve as a national e-registry for hepatitis B virus (HBV) and hepatitis C virus (HCV); (2) support healthcare providers in treatment decisions through embedded clinical decision support (CDS); and (3) improve care coordination through standardized documentation and secure communication.

Methods: This is a prospective, multicenter, non-randomized observational study piloted in Thailand's Sixth Regional Health Area. In Phase 1, nurse practitioners at primary care clinics will screen patients using rapid HBV/HCV tests and register confirmed cases into the Hep Plus platform. In Phase 2, patients will be managed at district or general hospitals, with participating physicians completing the modified Healthcare Systems Usability Scale (HSUS) at six months and joining focus groups at month nine. In Phase 3, patients with complex conditions referred to tertiary hospitals will be managed by subspecialists using the platform. The providers will complete a modified HSUS at month nine and participate in focus groups at month twelve. The primary outcome is platform usability across patient safety, workflow integration, and user control. Secondary outcomes include patient retention and the proportion of patients receiving appropriate treatment.

Results: Hep Plus system has achieved Technology Readiness Level 9 (TRL9) and is implemented across Thailand's Sixth Regional Health Area. To date, 319 cases have been recorded, comprising 188 positive and 14 negative hepatitis B cases (14 negative) and 104

E-POSTER ABSTRACTS

positive hepatitis C cases (7 negative). Initial satisfaction assessments indicate that users agree on the system's utility and effectiveness. However, user-friendliness and workflow integration were rated at a moderate level, serving as key areas for future system optimization to better align with clinical workloads.

Conclusions: Hep Plus may strengthen hepatitis B and C care through standardized documentation, clinical decision support, and improved care coordination. Its web-based design supports use in diverse settings and may contribute to real-time surveillance and national digital health efforts. Integration with electronic health record systems remains a key area for future work.

2524 - Baseline Albumin Structural Defects and Soluble Inflammatory Markers Identify Poor Responders to Albumin Therapy in Cirrhosis

Zhujun Cao¹, Ziqiang Li¹, Chenxi Zhang¹, Qing Xie¹
Ruijin Hospital, Shanghai Jiao Tong University School Of Medicine, Shanghai, China, Department Of Infectious Diseases, Shanghai-China¹

Background / Hypothesis:

Cirrhotic patients often exhibit functionally impaired albumin associated with immune dysfunction and poor outcomes. It is unclear whether this condition affects the therapeutic efficacy of albumin infusion treatment. We aimed to identify predictors of poor response to albumin therapy in patients with decompensated cirrhosis.

Materials and Methods:

We studied 262 hospitalized cirrhotic patients who received at least weekly albumin infusions at a dose ≥ 0.5 g/kg. Serum samples were collected at baseline for biomarker analysis. Twenty-one inflammatory mediators were measured by high-throughput electrochemiluminescence immunoassay. Serum albumin structural variants were profiled by UPLC-ESI-QTOF mass spectrometry, classifying human serum albumin (HSA) into seven isoforms: native (unmodified) HSA, HSA-DA, HSA-L, glycated HSA, cysteinylated HSA, glycated-cysteinylated HSA, and oxidized HSA (sulfated/sulfonated, HSA-SO₂/SO₃). We defined non-responder after albumin treatment as patients who died by 90-day follow-up and compared baseline markers between responders and non-responders.

Fine-Gray competing risk regression was used to identify predictors of treatment response, treating liver transplantation as a competing event.

Results:

Among all the patients, there were 57 (21.8%) non-responders and 205 (78.2%) responders. Non-responders had more severe baseline disease and an inflammation profile. They presented with higher baseline MELD-Na scores (median 28.33 vs 17.03, $p < 0.001$) and a higher incidence of bacterial infection at admission (63.2% vs 24.4%, $p < 0.001$). Pro-inflammatory markers including IL-6, IL-8, MIP-3 α , MIP-1 β (all $p < 0.05$) were significantly higher in non-responders than those in responders. Baseline serum albumin concentration did not differ significantly between groups (median 25 vs 27 g/L, $p = 0.46$). However, baseline profile of albumin functional parameters were significantly different between non-responders and responders. Non-responders had significantly lower fraction of native (unmodified) HSA (median 9.6% vs 13.3%, $p = 0.001$) and higher levels of oxidatively modified albumin including glycated albumin, and sulfated/sulfonated HSA than in responders. As a result, non-responders had a significantly lower effective albumin (median 3.66 vs 2.37 g/dL, $p = 0.001$) than responders. In competing-risk regression, higher IL-6, MIP-3 α , glycated albumin, and HSA-SO₂ and lower effective albumin were associated with significantly higher risk of non-responsive to treatment (all $p < 0.05$). The combination of these four markers demonstrate the C-index of 0.71 (95%CI, 0.58-0.84) in predicting non-responsiveness, significantly higher than that of MELD-NA (0.60, 0.47-0.74).

Conclusions:

Cirrhotic patients who respond poorly to albumin infusion therapy are characterized by a state of intense systemic inflammation and qualitatively defective albumin which could predict poor albumin therapeutic response.

2526 - Differences between non alcoholic liver disease and alcoholic liver disease related HCC

Jiwoong Jang¹

Eulji Medical Center, Internal Medicine, Daejeon-South Korea¹

Background / Hypothesis: Non-alcoholic liver disease

E-POSTER ABSTRACTS

and alcoholic liver disease begin as simple steatosis that may progress to steatohepatitis and ensuring liver-related complications such as cirrhosis and hepatocellular carcinoma (HCC). We investigated differences in clinical characteristics between non-alcoholic liver disease (NALD) and alcoholic liver disease (ALD)-related HCC.

Materials and Methods: NALD and ALD patients were identified from our department's prospective HCC database. A total of 54 and 45 patients met predefined inclusion and exclusion criteria for the NALD-HCC and ALD-HCC groups, respectively. Clinical, biochemical and tumor characteristics were studied.

Results: NALD-HCC patients were older compared to ALD-HCC patients (71 ± 9 vs. 65 ± 9 years, $P < 0.001$) and less male predominant (64% vs. 97%, $P < 0.001$). Prevalence of diabetes mellitus (77% vs. 35%, $P < 0.001$) and hypertension (79% vs. 57%, $P < 0.001$) were significantly higher in the NASH-HCC group. There were no differences in alpha-fetoprotein level, lesions found at diagnosis (unifocal/multifocal) or prevalence of portal vein invasion. In both group, almost half of the patients were in TNM stage 4 at the time of diagnosis and more than 50% of patients were not suitable for any therapy. Median survival in the NALD-HCC and ALD-HCC groups were 13 and 7 months respectively ($P = 0.114$).

Conclusions: Despite significant differences in demography of the NALD-HCC and ALD-HCC groups, liver and tumor characteristics were comparable. Most patients were diagnosed late and were not amenable to curative or locoregional therapies. Better characterization of patients with NALD and ALD at risk of HCC is necessary to optimize screening, surveillance, and management strategies.

Keyword(s) : Hepatocellular Carcinoma, Alcohol

2528 - Gut Microbiota Dysbiosis and Its Role in the Pathogenesis of Metabolic Dysfunction Associated Steatotic Liver Disease

Tatia Khachidze¹

Grigol Robakidze University, Internal Medicine, Tbilisi-Georgia¹

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) has become the most prevalent chronic liver disease in the world; an estimated 30–35% of the world's population is affected, and the prevalence of MASLD has been increasing in recent years. An increasing number of studies have indicated a close relationship between dysbiosis and MASLD.

Hence, there is an interest in exploring fatty infiltration as a result of dysbiosis, which includes bacterial composition disturbance, with a profound analysis of preventive and therapeutic factors that impact the occurrence and progression of liver disease.

Materials and Methods:

This study involved 123 subjects divided into two groups (65 MASLD, 18 MASH, and 40 healthy individuals in the control group) with a median age of 49 (23–75) diagnosed with MASH/MASLD based on ultrasound and biochemical tests. The criteria for fatty infiltration included a diffuse increase in the echogenicity of the liver parenchyma, decreased attenuation of the liver, and a ratio between the brightness level of the liver and the right kidney, calculated for the hepato-renal index (HRI) determination. The biochemical evaluation included liver function tests and a lipid profile. Dysbiosis was assessed using a stool bacteriological test and a stool test for dysbiosis.

Results:

he genus *Enterococcus*, like *Streptococcus*, was increased in patients with MASLD/MASH compared with controls. Additionally, uncultured *Clostridiales*, as well as entero-hemolytic *Escherichia coli*, were also increased. In contrast, genus *Bifidobacterium* and *Lactobacillaceae* were decreased in patients with MASLD/MASH. A significant loss of beneficial bacteria, such as *Faecalibacterium*, was observed, affecting intestinal barrier function. The diversity of the microbiota was decreased in patients compared with controls.

Conclusions:

Our study revealed an association between the abundance of *Bacteroides* in the gut and MASLD/MASH. MASLD developed initially in patients with significant dysbiosis. These results demonstrate that gut microbiota analysis provides prognostic information in addition to classical risk factors for MASLD severity, and strongly suggest that the gut microbiota plays a significant role in the pathogenesis of MASLD. Patients with MASLD should be tested for dysbiosis, and vice versa. It also suggests that correcting the gut microbiome may be beneficial for treating patients with MASLD/MASH.

Background / Hypothesis:

HCV patients including cirrhosis and hepatocellular carcinoma represent a diverse group with various patterns of viral replication and great variations of immune profiles resulting in different hepatic and extrahepatic manifestations. It is well-known, that the basis of the pathogenesis of any inflammatory process is the result of combination of two main factors: the effects on the tissue of any irritant and local tissue reaction. The latter depends on the general state of the body, its local and overall immunity. There are many clinical evidences of pathogenic interactions between diseases of internal organs and oral mucous diseases. The aim of this study was to evaluate the changes of the oral mucous membrane in patients with HCV.

Materials and Methods:

Our study included 250 patients with HCV, with a mean age of 51 years (25 to 77 years). Among these, 173 were men (69.2%). To assess the condition of the oral mucosa, an objective dental examination of the oral cavity and the vermillion border of the lips was performed.

Results:

Oral mucosal discoloration—hyperemia and cyanosis—was observed in all patients ($p < 0.001$). Tongue coating was detected in 47.8% of HCV patients. Hemorrhages in the mucosa, in the form of hemorrhages, were detected in 92.7% of patients, along with liver disease severity ($p < 0.001$). Gum changes included hyperemia (35.8%), swelling (42.3%), bleeding, and tenderness (53.6%), with statistical significance at $p < 0.001$. Purulent discharge from gingival pockets was observed (32.8%), along with necrotic areas (27.6%).

Conclusions: Changes in the oral mucosa in HCV were characterized by various manifestations related to the severity of liver disease. It has been established that HCV treatment leads to improvement in the condition of the oral mucosa and a decrease in the proliferation of pathogenic microorganisms.

2530 - Fibroblast and macrophage derived thrombospondin 1 orchestrates the fibroinflammatory niche in metabolic dysfunction associated steatohepatitis induced fibrosis

Sung Woo Cho¹, Pil Soo Sung²

The Catholic University Of Korea, Medical Science,
Seoul-South Korea¹ The Catholic University Of Korea,
Internal Medicine, Seoul-South Korea²

Background / Hypothesis: Thrombospondin-1 (THBS1) activates latent TGF- β 1 and contributes to stromal-immune communication. However, how THBS1 derived from fibroblasts and macrophages collectively contributes to fibroinflammatory remodeling in MASH has not been clearly defined.

Materials and Methods: THBS1 expression was examined in liver tissue and serum from patients with MASLD and in two dietary murine MASH models. We integrated single-cell RNA sequencing, immunohistochemistry, confocal microscopy, and flow cytometry with targeted perturbation of fibroblasts and macrophages using nintedanib, the THBS1-blocking peptide LSKL, and siRNA-mediated THBS1 silencing.

Results: THBS1 and the fibroblast activation marker FAP increased in association with fibrosis severity and IL-6 levels. scRNA-seq and spatial imaging demonstrated THBS1 expression in both FAP⁺ fibroblasts and monocyte-derived macrophages, indicating a coordinated fibroinflammatory niche. Nintedanib reduced THBS1 expression in both compartments, decreased CD11b⁺MERTK⁺ macrophages and FAP⁺PD-L1⁺ fibroblasts, and improved histologic fibrosis. Direct THBS1 inhibition produced similar antifibrotic effects. In vitro, THBS1 knockdown or blockade suppressed TGF- β 1-induced fibroblast activation and reduced LPS-stimulated IL-1 β and IL-6 production in macrophages, supporting reciprocal THBS1-dependent stromal-immune

E-POSTER ABSTRACTS

signaling.

Conclusions: THBS1 functions as a shared signaling mediator between fibroblasts and macrophages in MASH. Therapeutic suppression of THBS1, either through nintedanib or direct inhibition, disrupts this fibroinflammatory circuit and may represent a viable strategy to limit fibrosis progression in MASLD/MASH.

Keyword(s) : thrombospondin-1, nintedanib, fibroblast activation, metabolic dysfunction-associated steatohepatitis, liver fibrosis, immune–stromal crosstalk

2532 - COMPARISON OF ATTENUATION PARAMETER AND LIVER STIFFNESS MEASUREMENT BETWEEN HEPATUS AND FIBROSCAN IN PATIENTS WITH CHRONIC LIVER DISEASE A PROSPECTIVE STUDY

Ram Prasad Sinnanaidu ¹, Cain En Lim ², Xin Tong Ng ¹, Jin Ying Teh ¹, Anusha Vijayananthan ², Wah Kheong Chan ¹

University Of Malaya, Department Of Medicine, Kuala Lumpur-Malaysia ¹ University Of Malaya, Radiology, Kuala Lumpur-Malaysia ²

Background / Hypothesis:

We compared controlled attenuation parameter (CAP) and liver stiffness measurement (LSM) obtained using Hepatus® (HP, Mindray, Shenzhen, China) and Fibroscan (FS, Echosens, Paris, France). Additionally, we evaluated intra- and inter-observer variability and compared examination times using the two devices.

Materials and Methods:

HP and FS examinations were performed on patients with chronic liver disease by two operators from different departments, twice on each patient, at two different time points, independent of each other.

Results:

The data for 158 patients with 1264 examinations was analyzed (mean age 58.8 ± 13.8 years, male 47.5%, mean body mass index 26.6 ± 5.3 kg/m²). There was moderate correlation between HP and FS for CAP (Spearman's rho 0.67, p<0.001) and strong correlation for LSM (Spearman's rho 0.74, p<0.001). The mean difference (95% confidence interval, CI) between CAP obtained by HP and FS was 15 (-69 – 99) dB/m, and for LSM, this was 1.2 (-5.0 – 7.2) kPa. There was substantial agreement between HP and FS when using 10kPa and

15kPa LSM cut-offs, moderate agreement when using 20kPa and 248dB/m and 268dB/m CAP cut-offs, and fair agreement when using 280dB/m. The IQR for CAP and IQR/median for LSM were lower for HP compared with FS (12 vs 33dB/m, p<0.001, and 13 vs 14, p<0.001, respectively). The intra- and inter-observer reliability of CAP and LSM using HP and FS were good to excellent with intraclass correlation coefficients of 0.86–0.97. HP had shorter examination time (43s vs 62s, p<0.001) and less invalid measurements (0 vs 1, p<0.001).

Conclusions:

Measurements obtained with HP and FS are moderate to strongly correlated, but differences in their absolute values, consistency, and examination time were observed. However, the differences do not appear to be clinically significant. Either device can be used by healthcare personnel of different training backgrounds when sufficiently trained.

Keyword(s) : Hepatus, fibroscan, CAP, liver stiffness

2535 - Regulation and Clinical Translation of m⁶A Modification in Intrahepatic Cholangiocarcinoma

Lingyu Kong ¹, Hongxin Piao ²

Yanbian University, Internal Medicine, Yanji-China ¹

Yanbian Hospital, Internal Medicine, Yanji-China ²

Background / Hypothesis:

Intrahepatic cholangiocarcinoma (ICC) is a highly aggressive liver cancer with limited therapeutic options and poor prognosis. Epigenetic dysregulation, particularly N⁶-methyladenosine (m⁶A) RNA modification, has emerged as a key player in tumorigenesis. We hypothesize that m⁶A modification serves as a central regulatory mechanism in ICC progression, immune evasion, and chemoresistance, and that m⁶A-related molecules hold significant potential as diagnostic biomarkers, prognostic indicators, and therapeutic targets.

Materials and Methods:

This narrative review systematically synthesizes current evidence from published preclinical and clinical studies on m⁶A modification in ICC. Literature was retrieved from PubMed, Web of Science, and Google Scholar using keywords including "m⁶A," "intrahepatic cholangiocarcinoma," "METTL3," "ALKBH5," "YTHDF," "ferroptosis," "immunotherapy," and "chemoresistance." Data on molecular mechanisms, clinical correlations, and therapeutic interventions were extracted and thematically analyzed.

E-POSTER ABSTRACTS

Results:

Mechanistic Insights: m⁶A regulators (METTL3, ALKBH5, YTHDF family) modulate ICC proliferation, invasion, ferroptosis, and stemness via coding/non-coding RNA targets (e.g., IFIT2, BUB1B, PD-L1, circSLCO1B3).

Tumor Microenvironment: m⁶A modification reshapes the immune landscape by regulating PD-L1 expression, promoting immunosuppressive cell infiltration, and mediating immune escape.

Chemoresistance: The YTHDF2-CDKN1B axis drives cisplatin resistance, while METTL3-mediated metabolic reprogramming further supports chemoresistant phenotypes.

Clinical Translation:

Diagnosis: m⁶A regulators (e.g., METTL3, ALKBH5) show high diagnostic accuracy (AUC 0.78–0.85) in tissue and liquid biopsies.

Prognosis: High expression of ALKBH5, YTHDF2, etc., correlates with poor survival (HR 2.31–3.15).

Therapy: Preclinical studies demonstrate synergistic efficacy of m⁶A-targeted inhibitors (e.g., STM2457, IOX1) with chemotherapy/immunotherapy (tumor inhibition rate 58–72%).

Conclusions:

m⁶A modification is a pivotal epigenetic driver in ICC, influencing tumor biology, immune response, and treatment resistance. Its associated molecules exhibit strong clinical translation potential as non-invasive biomarkers and novel therapeutic targets. Future efforts should focus on validating these findings in large prospective cohorts and developing m⁶A-based combination therapies to improve outcomes in ICC patients.

Keyword(s) : N6-methyladenosine (m⁶A) ; Intrahepatic cholangiocarcinoma ; Tumor microenvironment ; Therapeutic resistance ; METTL3 ; ALKBH5 ; Combination therapy

2536 - ANTIFIBROTIC EFFECTS OF ANGIOTENSIN RECEPTOR BLOCKERS IN ORGANOPHOSPHATE (CHLORPYRIFOS) INDUCED LIVER FIBROSIS

Dr. Aftab Abbasi ¹

Isra University, Anatomy, Hyderabad-Pakistan ¹

Background / Hypothesis:

Organophosphates (OPs) are one of the pesticides causing toxicity to humans and animals. OPs toxicity involve many organs such as liver, kidney nervous system and immune system. Liver fibrosis is a wound

healing response in which there is increased production and deposition of extracellular matrix (ECM), due to prolonged injury to liver by viral hepatitis, alcohol consumption, metabolic diseases and toxins (pesticides). Angiotensin receptor blockers (ARBs) are potential therapeutic agents for liver fibrosis.

Objectives: To determine the effects of ARBs on

Chlorpyrifos(CPF) induced liver fibrosis

Materials and Methods:

A Experimental study was conducted at animal house, Faculty of Animal Husbandry and Veterinary Sciences SAU, Tandojam. Laboratory work was carried out in Postgraduate Laboratory, Isra University Hospital, Hyderabad and Molecular Laboratory, SAU Tandojam, from March 2023 to August 2023. Forty adult male albino wistar rats were used in the study. Rats were grouped as control group (A1), positive control group (A2) and experimental groups (B, C and D). Group A2 was treated with carbon tetrachloride (CCL4) to induce liver fibrosis, with 2 ml/kg of 50% solution of CCL4 by oral gavage two times per week for eight weeks, group B was treated with 1ml/bw/day CPF intraperitoneally for eight weeks. Group C was treated with 1ml/bw/day CPF intraperitoneally for eight weeks and then ARBs orally (30mg/kg/day) for 8 weeks. Group D was simultaneously treated with CPF and ARBs for 8 weeks with same doses as for group C. At the end of experiment blood was collected by cardiac puncture for liver function test and rats were sacrificed to collect liver samples. Pathological changes in liver were examined using H&E and Masson's trichrome staining. Real time PCR was used to detect alpha smooth muscle actin (α -SMA), transforming growth factor beta 1(TGF- β 1) and Collagen-I(coll-I) mRNA expression.

Results:

CPF caused liver injury evidenced by raised liver enzymes and bilirubin with histological changes and increased expression of genes. ARBs decreases liver enzymes, CPF induced histological changes and decreases the expression of α -SMA, TGF- β 1 and Coll-I.

Conclusions:

The present study suggests that ARBs prevent fibrogenesis and may serve as a promising therapeutic agent to reduce CPF induced liver fibrosis

Keyword(s) : Liver fibrosis, chlorpyrifos, angiotensin receptor blockers, collagen, alpha smooth muscle actin.

E-POSTER ABSTRACTS

2537 - Correlation of interleukin 17 serum levels with degree of liver fibrosis in chronic hepatitis B patients at Mohammad Hoesin Hospital Palembang

Lingga Gumelar¹, Suyata Suyata¹, Imam Suprianto¹, Vidi Orba Busro¹, Ayus Astoni¹, Anjab Sya'roni¹, Fahri Indra²

Sriwijaya University, Gastroenterohepatology, Palembang-Indonesia¹ Sriwijaya University, Internal Medicine, Palembang-Indonesia²

Background / Hypothesis:

Chronic hepatitis B (CHB) is a major global cause of progressive liver disease, and immune-mediated hepatic inflammation plays a critical role in driving fibrosis. Interleukin-17 (IL-17), a key cytokine produced by Th17 cells, has been implicated in hepatocellular inflammation, fibrogenesis, and disease progression in chronic liver disorders. However, data on the association between circulating IL-17 levels and liver stiffness in CHB patients remain limited. This study aimed to evaluate the correlation between serum IL-17 levels and the degree of liver fibrosis assessed using transient elastography.

Materials and Methods:

We conducted an analytical observational study with a cross-sectional design among patients with CHB at Dr. Mohammad Hoesin Hospital Palembang. Subjects were enrolled through consecutive non-probability sampling. Serum IL-17 levels were quantified, and liver fibrosis was measured using transient elastography. Continuous variables were summarized as means and ranges. The correlation between IL-17 serum levels and liver stiffness values was analyzed using Spearman's rank correlation coefficient.

Results:

A total of 40 patients were included, with a mean age of 37 years (range 22–60 years). The majority were male (75%). Serum IL-17 levels and liver stiffness values were both treated as numerical variables. Spearman's analysis demonstrated a statistically significant positive correlation between serum IL-17 concentration and liver stiffness ($r = 0.388$; $p = 0.013$).

Conclusions:

Serum IL-17 levels show a significant positive correlation with liver fibrosis severity in patients with chronic hepatitis B. IL-17 may serve as a useful non-invasive biomarker to complement elastography in assessing fibrotic progression, especially in patients in whom liver biopsy is not feasible.

Keyword(s) : interleukin-17, liver fibrosis, chronic hepatitis B, transient elastography.

2538 - Comparison of sensitivity and specificity of vascular endothelial growth factor and alpha fetoprotein levels in detecting hepatocellular carcinoma in patients with hepatitis b related liver cirrhosis at Mohammad Hoesin Hospital Palembang

Lingga Gumelar¹, Suyata Suyata¹, Imam Suprianto¹, Vidi Orba Busro¹, Ayus Astoni¹, Anjab Sya'roni¹, Anita Revera²

Sriwijaya University, Gastroenterohepatology, Palembang-Indonesia¹ Sriwijaya University, Internal Medicine, Palembang-Indonesia²

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related mortality worldwide, largely due to delayed early diagnosis. In Indonesia, chronic hepatitis B-related liver cirrhosis is the most common underlying condition for HCC. Alpha-fetoprotein (AFP) is widely used as a diagnostic biomarker; however, its sensitivity and specificity remain suboptimal. Therefore, this study aimed to evaluate vascular endothelial growth factor (VEGF) as an alternative biomarker and to compare its diagnostic performance with AFP in detecting HCC.

Materials and Methods:

This diagnostic study included 52 patients with hepatitis B-related liver cirrhosis treated at Dr. Mohammad Hoesin General Hospital, Palembang, between August and November 2023. Blood samples were collected to measure serum VEGF and AFP levels. The diagnosis of HCC was confirmed using triphasic abdominal computed tomography based on the 2023 HCC management guidelines. Statistical analyses were performed using SPSS version 29.

Results:

Among the 52 subjects, AFP demonstrated a sensitivity of 62.96% and a specificity of 84% for diagnosing HCC. In comparison, VEGF showed a higher sensitivity of 74.07% but a lower specificity of 68%.

Conclusions:

VEGF exhibits higher sensitivity than AFP in detecting hepatocellular carcinoma among patients with hepatitis B-related liver cirrhosis, although its specificity is lower. VEGF may serve as a

E-POSTER ABSTRACTS

complementary diagnostic biomarker alongside AFP for HCC detection

Keyword(s) : vascular endothelial growth factor, alpha-fetoprotein, hepatocellular carcinoma, liver cirrhosis, hepatitis B

2539 - Association Between Clinical Predictors And Albumin Billirubin Score In Hepatocellular Carcinoma Patients Receiving Lenvatinib At Dr. Mohammad Hoesin General Hospital Palembang During 2025

Adhitya Wicaksana¹, Suyata Suyata¹, Imam Suprianto¹, Vidi Orba Busro¹, Anjab Akmal¹
Rsmh, Division Gastroenterology And Hepatology, Palembang-Indonesia¹

Background / Hypothesis:

Lenvatinib is widely used as a first-line systemic therapy for hepatocellular carcinoma (HCC), but treatment responses vary substantially among patients. Clinical predictors such as hepatic functional reserve and performance status may influence treatment outcomes. This study examined the relationship between Child–Pugh class, ECOG performance status, and Albumin bilirubin (ALBI) score in patients with HCC receiving lenvatinib at a tertiary referral center in Indonesia.

Materials and Methods:

A retrospective review was conducted using complete records of HCC patients treated with lenvatinib in 2025. Data collected included Child–Pugh classification, ECOG performance status, and ALBI score. Descriptive statistics were used to summarize patient characteristics. Pearson correlation analysis was applied to assess associations between clinical predictors and ALBI scores.

Results:

Twenty patients were eligible for analysis. Most patients were classified as Child–Pugh A or B, and ECOG performance status was predominantly 0–1. ALBI scores clustered mainly within grades 1 and 2. Better hepatic reserve (Child–Pugh A) and ECOG 0 were consistently associated with more favorable ALBI grades. Significant correlations were observed between Child–Pugh class and ALBI ($r = 0.79$), with a weaker correlation between ECOG status and ALBI ($r = 0.41$). These results indicate alignment between clinical assessments of hepatic function and biochemical liver

status.

Conclusions:

Child–Pugh classification and ECOG performance status correlate with ALBI score in patients receiving lenvatinib for HCC. Patients with better preserved liver function and performance status demonstrated more favorable ALBI profiles. These findings support the use of ALBI as an objective complement to established clinical indicators when assessing suitability for lenvatinib therapy and planning treatment strategies.

Keyword(s) : Hepatocellular Carcinoma, Clinical Predictors, ALBI score, Lenvatinib

2540 - Fulminant Hepatic Failure Following Antiviral Therapy Discontinuation in Chronic Hepatitis B A Fatal Case

Kübra Yildirim¹

Department Of Infectious Diseases And Clinical Microbiology, Trabzon Kanuni Training And Research Hospital, Türkiye, Department Of Infectious Diseases And Clinical Microbiology, Trabzon-Türkiye¹

Background / Hypothesis: Chronic hepatitis B requires long-term antiviral therapy to prevent disease progression and hepatic decompensation. Discontinuation of treatment may lead to severe HBV reactivation with fatal outcomes. We aimed to present a fatal case of antiviral therapy discontinuation and emphasize the importance of treatment adherence.

Materials and Methods: This poster presents a retrospective review of clinical, laboratory, imaging, and treatment data of a patient with chronic hepatitis B. Disease severity was assessed using Child–Pugh classification.

Results: A 44-year-old male with chronic hepatitis B infection, hypertension, and diabetes mellitus presented with fatigue, nausea, and vomiting lasting for two weeks. He had been known to be HBsAg-positive for four years but had no regular follow-up. Family history was notable for hepatitis B infection in his siblings. The patient denied alcohol consumption.

Physical examination revealed jaundice and ascites, without overt hepatic encephalopathy. Laboratory evaluation showed severe hepatic injury (AST 1189 U/L, ALT 1162 U/L), cholestasis (total bilirubin 12.26 mg/dL),

E-POSTER ABSTRACTS

and coagulopathy (INR 1.58). Platelet count was 147,000/mm³, albumin 2.98 g/dL, and creatinine 0.50 mg/dL. The patient was classified as Child–Pugh class C. Serologic testing revealed HBsAg positivity, anti-HBe positivity, negative HDV serology, and an HBV DNA level of 7.7×10^6 IU/mL.

Hospitalization was recommended due to severe hepatic dysfunction; however, the patient refused admission and opted for outpatient follow-up. Due to impaired coagulation parameters, liver biopsy was contraindicated, and tenofovir disoproxil fumarate (300 mg once daily) was initiated. Abdominal ultrasonography demonstrated hepatomegaly and diffuse ascites. Upper gastrointestinal endoscopy revealed esophageal varices, and non-selective beta-blocker therapy was started.

At the one-month follow-up, marked biochemical and virologic improvement was observed (AST 59 U/L, ALT 59 U/L, INR 1.25, HBV DNA 44 IU/mL). After several months of follow-up, the patient discontinued antiviral therapy and clinic visits.

Approximately one year later, he re-presented with recurrent symptoms. Laboratory findings indicated severe HBV reactivation and acute liver failure (ALT 2160 U/L, AST 2072 U/L, total bilirubin 10.81 mg/dL, INR 1.81). Ascites persisted, hepatic encephalopathy developed, and despite re-initiation of antiviral therapy, the patient progressed to fulminant hepatic failure and died while awaiting liver transplantation.

Conclusions: Discontinuation of antiviral therapy in chronic hepatitis B may cause fatal HBV reactivation and fulminant hepatic failure, even after initial clinical improvement, highlighting the critical importance of lifelong treatment adherence and patient education.

Keyword(s) : Chronic hepatitis B; antiviral therapy; treatment non-adherence; HBV reactivation; acute liver failure; fulminant hepatic failure; patient education

2542 - Construction of an imaging omics machine learning prediction model for post liver transplantation recurrence of liver cancer based on ECV

Xiaoyong Ye¹, Qiang He¹, Zhili Ji¹

Beijing Chaoyang Hospital, capital Medical University, Department Of Hepatobiliary And Pancreaticosplenic Surgery, Beijing-China¹

Background / Hypothesis:

This study aims to establish an imaging biomarker model related to the prognosis of liver transplant patients based on the extracellular volume (ECV) subtraction images obtained from abdominal enhanced CT scans before liver transplantation. This is intended to further clarify the predictive role of ECV subtraction images in liver cancer patients after liver transplantation.

Materials and Methods:

A total of 145 patients with hepatocellular carcinoma who underwent liver transplantation were retrospectively included and randomly divided into a training set and a test set at a ratio of 7:3. The radiomics features of the tumors and the surrounding tissues of the patients' preoperative enhanced CT plain scan, delayed scan, and ECV subtraction images were extracted. After feature selection, the optimal machine learning algorithm was used to construct the ECV-ML model, and a combined model was established by combining clinical factors. The performance of the model was comprehensively evaluated using C-index, decision curve, calibration curve, and survival analysis.

Results:

In the clinical model, the ratio of monocytes to lymphocytes and microvascular infiltration are independent risk factors for poor prognosis in liver cancer patients after liver transplantation. Using LASSO regression under ten-fold cross-validation, a total of 6 optimal features were selected, including 2 features of peri-tumor subtraction images, 2 features of peri-tumor plain scan images, and 2 features of tumor delayed images. In the ECV-ML model, the algorithm based on XGBoost has the best predictive effect for early recurrence after transplantation. The combined model and the ECV-ML model both performed better than the clinical model in predicting early postoperative recurrence (the C-index of the training set was 0.86, 0.85, and 0.61 respectively, and the C-index of the test set was 0.83, 0.82, and 0.65 respectively), but there was no significant difference between the two models.

Conclusions:

The ECV-ML model based on preoperative ECV parameter graphs and CT images demonstrates effective predictive performance in predicting the early

E-POSTER ABSTRACTS

recurrence of HCC patients after liver transplantation, and can significantly improve the predictive performance of the simple clinical parameter-based liver cancer liver transplantation recurrence prediction model.

Keyword(s) : Machine learning; Hepatocellular carcinoma; Liver transplantation; Extracellular volume; Microvascular invasion

2544 - Comparison of Predictive Accuracy of Monocyte to Lymphocyte Ratio (MLR) Neutrophil To Lymphocyte Ratio (NLR) and Systemic Immune Inflammation Index (SII) for Colonoscopic and Clinical Outcomes among Patients with Gastrointestinal Tuberculosis (GITB)

Sam Fandood¹

Eamc, Gastroenterology, Apalit-Philippines¹

Background / Hypothesis: Gastrointestinal tuberculosis (GITB) has heterogeneous endoscopic manifestations, and reliable predictors of disease severity and treatment response remain limited. Inflammatory biomarkers derived from routine blood tests, including the monocyte-to-lymphocyte ratio (MLR), neutrophil-to-lymphocyte ratio (NLR), and systemic immune-inflammation index (SII), may reflect disease activity.

Materials and Methods:

This prospective cohort study included 103 patients diagnosed with GITB who underwent colonoscopy at a tertiary referral center. Baseline clinical, laboratory, and colonoscopic data were collected. MLR, NLR, and SII were compared across colonoscopic patterns. Logistic regression was performed to assess associations with treatment response, and receiver operating characteristic (ROC) curves were used to evaluate predictive accuracy.

Results: MLR, NLR, and SII differed significantly across colonoscopic patterns ($p < 0.05$), with higher values observed in ulcero-hypertrophic lesions. In univariate analysis, NLR (OR: 1.24, $p = 0.009$) and SII (OR: 1.01, $p = 0.005$) were associated with poor response to treatment; however, these associations were not significant after adjustment for other confounders. ROC analysis showed poor discriminatory performance for all biomarkers, with AUC values of 0.544 for MLR, 0.534 for NLR, and 0.604 for SII.

Conclusions: Although novel inflammatory biomarkers

vary across colonoscopic phenotypes in GITB, their predictive value for treatment response is limited. These markers may serve as adjunctive indicators but should not replace established clinical and endoscopic assessments.

Keyword(s) : Gastrointestinal tuberculosis; inflammatory biomarkers; neutrophil-to-lymphocyte ratio; systemic immune-inflammation index; colonoscopy

2545 - COMPARISON OF CLINICAL OUTCOME AND ENDOSCOPIC FINDINGS BETWEEN ACIDIC AND ALKALI CAUSTIC INJURIES IN A TERTIARY REFERRAL HOSPITAL

Sam Fandood¹

Eamc, Gastroenterology, Apalit-Philippines¹

Background / Hypothesis: Caustic injuries present a significant public health concern due to the severe tissue damage they can inflict. This current study evaluated the endoscopic findings and clinical outcomes of patients with acidic and alkali caustic injuries.

Materials and Methods:

In this retrospective cohort study, we performed a posteriori, using information and data from chart review of 241 consecutive patients admitted in a tertiary government hospital due to caustic injuries. We compared patients with acidic and alkali caustic injuries based on Zargar's grading classification of mucosal injury and their clinical outcomes.

Results:

Ingestion of alkali was more prevalent than ingestion of acidic caustic substances (63.9% vs 36.1%). Weak base (61.83%) was the most common caustic substance ingested followed by weak acid (19.09%), strong base (2.07%), and weak base (0.41%). At baseline, alkali and acid groups varied significantly in terms of age ($p = 0.029$), sex ($p = 0.001$), marital status ($p = 0.009$) and initial presentation ($p < 0.001$). Ingestion of acid was associated with significantly higher grades of esophageal ($p < 0.001$), stomach ($p < 0.001$), and duodenal ($p = 0.001$) injuries. A significantly higher proportion of patients in the acid group required NGT insertion ($p < 0.001$), endotracheal intubation ($p = 0.001$) and antibiotic therapy ($p = 0.001$) than the alkali group. Finally, acid ingestion was associated with a higher rate of esophageal stenosis ($p = 0.008$) and longer length of hospital stay ($p = 0.005$).

E-POSTER ABSTRACTS

Conclusions: While caustic injuries were predominant alkali, acids may lead to severe injury and complications following caustic ingestion. Early endoscopy is crucial for assessing severity, guiding management, and predicting patient outcomes.

Keyword(s) : Caustic injury, alkali, acid, endoscopy, severity, outcomes

2546 - Use of Double Plasma Molecular Adsorption System (DPMAS) in Intrahepatic Cholestasis of Pregnancy Refractory to Medical Management A Case Report

Sam Fandood¹

Eamc, Gastroenterology, Apalit-Philippines¹

Background / Hypothesis: Intrahepatic cholestasis of pregnancy (ICP) is a pregnancy-specific liver disorder characterized by pruritus, elevated bile acids, and abnormal liver function tests, typically resolving after delivery². The main treatments for intrahepatic cholestasis of pregnancy (ICP) are medication with ursodeoxycholic acid (UDCA), monitoring of the mother and fetus, and potentially early delivery. This case documents a novel, safe, and effective application of DPMAS in a pregnant patient with severe ICP unresponsive to UDCA, demonstrating rapid bile acid reduction, symptom resolution, and favorable maternal-fetal outcomes.

Materials and Methods: A 36-year-old G3P1 (1011) was admitted at 15 weeks of gestation with pruritis, tea colored urine, and jaundice. On admission, laboratory results showed hyperbilirubinemia at 24.6 mg/dl (Direct Bilirubin: 19.8 mg/dl Indirect Bilirubinemia 4.4), and transaminitis (ALT 340 AST 821). Initial PT, PTT, Alkaline Phosphatase, GGT are within normal limits. Whole abdominal ultrasound, hepatitis serologies, autoimmune markers, and metabolic workup were all unremarkable. She was managed as a case of Early Onset Intrahepatic Cholestasis of Pregnancy. She was started with Ursodeoxycholic acid (UDCA) 15 mg/kg/day, and Glycyrrhizinate drip. Serial bile acid levels and liver enzymes were monitored with regular fetal surveillance. However despite medical management, pruritus persisted with worsening nocturnal symptoms.

Results:

Given her refractory ICP, the multidisciplinary team

(Obstetrics, Hepatology, and Nephrology) decided to initiate Double Plasma Molecular Adsorption System (DPMAS) therapy to rapidly reduce circulating bile acids and improve maternal symptoms. The patient underwent DPMAS for three consecutive sessions. After the third session total bile acids decreased to 8mg/dl. Jaundice and pruritus significantly improved and ALT and AST levels decreased to near-normal ranges. She was maintained on UDCA post-DPMAS, with close fetal monitoring until delivery.

Conclusions: In refractory severe ICP, DPMAS represents a promising adjunctive therapy when UDCA fails. Given the scarcity of such reports, it expands therapeutic possibilities, informs clinical decision-making, and lays groundwork for future studies on extracorporeal liver support in pregnancy.

Keyword(s) : Cholestasis of Pregnancy; DPMAS

2547 - When the Liver Speaks for the Vessels A Diagnostic Odyssey of a rare case of Non HBV Associated Polyarteritis Nodosa Presenting with Jaundice and Transaminitis

Sam Fandood¹

Eamc, Gastroenterology, Apalit-Philippines¹

Background / Hypothesis: Polyarteritis nodosa (PAN) is a rare necrotizing vasculitis of medium-sized arteries that classically produces systemic symptoms, multisystem ischemia, and visceral microaneurysms. Presentation is protean and diagnosis requires synthesis of clinical, laboratory, and angiographic data. Hepatic involvement with transaminitis and jaundice is an uncommon initial manifestation and can obscure the underlying vasculitic etiology.

Materials and Methods:

A 22-year-old Filipino male with no significant past medical history presented with six weeks of progressive malaise followed by migratory polyarthralgia/oligoarthritis and jaundice. Initial symptoms included transient knee warmth, severe crampy lower abdominal pain with undocumented fever, progressive proximal joint swelling and weakness, and eventual scleral icterus. Examination revealed icteric sclera, hepatomegaly without focal tenderness, and warmth/swelling of multiple joints. Laboratory evaluation demonstrated leukocytosis (WBC

E-POSTER ABSTRACTS

25.3 $\times 10^9/L$, anemia (Hgb 10.0 g/dL), markedly elevated ALT (471 U/L), AST elevation, direct hyperbilirubinemia (total 3.95 mg/dL, direct 2.98 mg/dL), hypoalbuminemia, and markedly elevated inflammatory markers (ESR 144 mm/hr, CRP 160 mg/L). Viral hepatitis and autoimmune serologies were negative. Contrast-enhanced CT angiography revealed multiple enhancing nodular lesions and saccular dilatations/microaneurysms in branches of the hepatic and renal arteries, consistent with medium-vessel vasculitis.

Conclusions: This case illustrates an atypical presentation of PAN with prominent hepatic dysfunction and polyarthritis in a young adult. Angiographic identification of visceral microaneurysms was pivotal to diagnosis. Early immunosuppressive therapy led to clinical resolution, emphasizing the importance of considering medium-vessel vasculitis in patients with unexplained transaminitis and systemic inflammatory features.

2548 - Multiverse of Upper Gastrointestinal Tuberculosis A case series of GITB with involvement of Esophagus Gastric and Duodenal TB

Sam Fandood¹

Eamc, Gastroenterology, Apalit-Philippines¹

Background / Hypothesis: This case series presents five patients diagnosed with upper gastrointestinal tuberculosis (GI TB), presenting from esophagus to duodenum, comprising four males and a female, aged between 19 and 50 years. Among these patients, 1 is HIV reactive. Each patient sought consultation for a range of gastrointestinal symptoms, including abdominal pain, weight loss, jaundice, hematemesis, and ascites. Common diagnostic tests employed included imaging studies such as CT scans and endoscopic evaluations, which revealed various findings such as abdominal lymphadenopathy and masses in the gastrointestinal tract. Notably, the cases highlighted the atypical presentations of upper GI TB which are less frequently reported in the literature.

Materials and Methods: The case series presented six distinct cases of gastrointestinal tuberculosis, each exhibiting varying manifestations that challenge traditional diagnostic paradigms. Case 1 involved a 32-year-old male with esophageal and duodenal TB, while

Case 2 featured a 32-year-old female with gastric TB presenting as a submucosal mass. Case 3 documented a 50-year-old male with hematemesis, and Case number 4 presented with melena. Case 5 presented with a fistula from esophagus leading to mediastinal mass. These diagnoses were confirmed through a combination of endoscopic biopsy results and imaging studies, which indicated chronic granulomatous inflammation consistent with TB.

Results: Treatment for all patients involved a standard regimen of antitubercular therapy, which included first-line medications such as isoniazid, rifampicin, ethambutol, and pyrazinamide. The outcomes varied, with most patients demonstrating significant clinical improvement and resolution of symptoms over the course of treatment. Notably, both patients presenting with fistula had complicated clinical course leading to demise. The overall response to treatment underscores the importance of early diagnosis and intervention in managing gastrointestinal tuberculosis effectively.

Conclusions: In conclusion, this case series emphasizes the diverse presentations of gastrointestinal tuberculosis, highlighting the necessity for clinicians to maintain a high index of suspicion when faced with unexplained gastrointestinal symptoms. The findings advocate for a comprehensive diagnostic approach, including imaging and endoscopic evaluations, to facilitate timely diagnosis and treatment. Furthermore, the series underscores the value of a multidisciplinary management strategy, integrating gastroenterology and infectious disease expertise to optimize patient outcomes. Future research should focus on larger, multicenter studies to validate these findings and further explore the mechanisms underlying the varied manifestations of GI TB, as well as the impact of drug resistance on treatment efficacy. By addressing these areas, the medical community can enhance understanding and improve management strategies for this complex condition.

Keyword(s) : GITB

2549 - Outcome Of Patients Presenting With Upper Gastrointestinal Bleeding A Single High Volume Center Prospective Study

Sabir Ali¹, Nazish Butt², Wajiha Faish¹, Abdul Qadir

E-POSTER ABSTRACTS

Shaikh ¹

Jinnah Postgraduate Medical Centre, Gastroenterology, Karachi-Pakistan ¹ Jinnah Postgraduate Medical Center, Gastroenterology, Karachi-Pakistan ²

Background / Hypothesis:

This study aims to determine the outcome of patients presenting with upper gastrointestinal bleeding: A Single High-Volume Center Prospective

Materials and Methods:

This prospectus on-going hospital-based study conducted at Jinnah Postgraduate Medical Center (JPMC) Karachi, Pakistan, in the Department of Gastroenterology & Hepatology ward 25, on all the patients presenting with UGIB due to any cause, aged >16 years of either gender in one-year duration. A total number of patients were 521 in whom outcome of such patients were evaluated.

Results:

Our study subjects had mean age of 41.49 ± 9.02 years with higher percentage of males (61.03%, n = 318). Urban dwellers were more common than rural dwellers, 57.96% (n = 302) vs. 42.03% (n = 219), respectively. The most common cause of UGIB was peptic ulcer disease (18.80%, n = 98), followed by use of NSAIDs (14.77%, n = 77), and viral hepatitis leading esophageal varices (n = 10.36%, n = 54). In multivariate analysis, UGIB due to oesophageal varices appeared significantly more likely (P = 0.01) to have poor outcome (OR = 13.5, 95% CI: 3.22, 8.35).

Conclusions:

Higher chances of re-bleed and mortality was observed in patients presented with UGIB due to esophageal varices and patients with peptic ulcer disease were responsive to treatment and good overall outcome.

2550 - PROGNOSTIC VALUE OF THE ALBUMIN BILIRUBIN SCORE FOR VARICEAL REBLEEDING AND HEPATIC ENCEPHALOPATHY RELATED HOSPITALIZATION IN CIRRHOTIC PATIENTS WITH CHRONIC HBV INFECTION

Anjab Akmal Sya'roni ¹, Suyata Suyata ¹, Imam Suprianto ¹, Vidi Orba Busro ¹, Muhammad Ayus Astoni ¹, Fadhyl Zuhry Lubis ¹

Faculty Medicine Of Sriwijaya University/mohammad Hoesin Hospital, Internal Medicine, Palembang-Indonesia ¹

Background / Hypothesis:

Variceal rebleeding and hepatic encephalopathy (HE) are major complications in cirrhotic patients with chronic hepatitis B virus (HBV) infection, increasing morbidity, mortality, and hospitalization. The Albumin-Bilirubin (ALBI) score serves as an objective measure of liver function and may act as a prognostic biomarker for adverse liver outcomes. This investigation assesses the predictive accuracy of the ALBI score for variceal rebleeding and HE-related hospitalization.

Materials and Methods:

A retrospective cohort study was conducted on 162 cirrhotic patients with chronic HBV infection admitted for variceal bleeding between January 2022 and December 2024 at Mohammad Hoesin Hospital Palembang. Baseline ALBI scores were calculated, and patients were followed for 12 months to assess the incidence of variceal rebleeding and HE-related hospitalizations. Prognostic value of the ALBI score was assessed using Kaplan-Meier survival analysis and Cox proportional hazards regression.

Results:

The mean age of the study population was 51.0 ± 9.3 years, with 110 (67.8%) males. Variceal rebleeding occurred in 59 (36.7%) patients, while 42 (26.1%) were admitted to hospital related to HE. Patients who experienced variceal rebleeding had significantly higher ALBI scores at baseline (-1.96 ± 0.42 vs. -2.45 ± 0.39 , p < 0.001) and also hospitalized for HE (-1.89 ± 0.38 vs. -2.41 ± 0.36 , p = 0.002). ROC analysis demonstrated that the ALBI score was a strong predictor of variceal rebleeding (AUC = 0.81, 95% CI: 0.74–0.87, p < 0.001) and HE-related hospitalization (AUC = 0.78, 95% CI: 0.70–0.85, p = 0.003). Multivariate Cox regression confirmed that the ALBI score independently predicted variceal rebleeding (HR = 2.71, 95% CI: 1.87–3.91, p < 0.001) and HE-related hospitalization (HR = 2.38, 95% CI: 1.62–3.48, p < 0.001).

Conclusions:

The ALBI score is a valuable independent predictor of variceal rebleeding and HE-related hospitalization in cirrhotic patients with chronic HBV infection. Its integration into clinical risk stratification may improve patient management and outcomes.

Keyword(s) : Albumin-Bilirubin score, cirrhosis, chronic hepatitis B, variceal rebleeding, hepatic encephalopathy, prognosis, survival.

2551 - Noninvasive Detection of Metabolic dysfunction associated steatohepatitis and Fibrotic Burden Using Ultrasound Derived LIID and liver stiffness measurement in Metabolic dysfunction associated steatotic liver disease A Multicenter Study.

Feng Gao ¹, Ming-hua Zheng ², Lai Wei ³

The First Affiliated Hospital Of Wenzhou Medical University, Department Of Gastroenterology, Wenzhou-China ¹ The First Affiliated Hospital Of Wenzhou Medical University, Mafld Research Center, Department Of Hepatology, Wenzhou-China ² Beijing Tsinghua Changgung Hospital, Hepatopancreatobiliary Center, Beijing-China ³

Background / Hypothesis:Metabolic dysfunction-associated steatohepatitis (MASH), the progressive form of metabolic dysfunction-associated steatotic liver disease (MASLD), is associated with adverse hepatic and cardiometabolic outcomes. The study aimed to validate a novel quantitative ultrasound (QUS)-derived score, the LIID score, for noninvasive diagnosis of MASH, and to evaluate the performance of liver stiffness measurement (LSM) using the same ultrasound platform for detecting fibrotic burden in MASLD.

Materials and Methods:This multicenter study enrolled 438 participants with MASLD who underwent both iLivTouch examination and liver biopsy between November 2018 and December 2024 from ten hospitals in China. After the exclusion criteria were applied, a total of 410 patients with biopsy-proven MASLD and successful QUS measurements were included to assess the performance of the LIID score. According to radiofrequency (RF) data acquired from iLivTouch, a total of 18 ultrasonographic features were obtained with different time gain compensation and named as P1 to P18 based on the intensity, attenuation and scattering characteristics of the ultrasound signals, including LSM (P3) and UAP (P1).(Figure 1A) P2-P10 are mainly related to intensity, whereas P11-P18 are mainly related to scattering. The LIID score was derived from the RF data, including information on the intensity, frequency, scattering, and attenuation characteristics of the ultrasound signals. The formula of the LIID score was as follows: $LIID = 0.063 \times P7 + 0.019 \times P13$.

Results: The LIID score demonstrated an area under the receiver operating characteristic curve (AUROC) of 0.71 (95% CI: 0.66–0.76) for detecting MASH. A rule-out threshold of 6.0 achieved high sensitivity (89.6%) and negative predictive value (78.2%), while a rule-in threshold of 7.8 provided high specificity (88.4%) and positive predictive value (70.5%). The LIID score increased in parallel with histological disease activity, as assessed by the NAS score ($p < 0.01$, Figure 1B). LSM showed excellent diagnostic performance for advanced fibrosis (AUROC: 0.86; 95% CI: 0.79-0.92), and acceptable accuracy for significant fibrosis (AUROC: 0.75; 95% CI: 0.69-0.79) and cirrhosis (AUROC: 0.78; 95% CI: 0.61-0.95). In addition, LSM values correlated positively with histological fibrosis stage (F0-F4), with a statistically significant trend ($p < 0.01$, Figure 1C).

Conclusions:The LIID score offers a noninvasive, ultrasound-based approach for identifying MASH. Combined with LSM, this strategy enables comprehensive, noninvasive assessment of hepatic inflammation and fibrosis in MASLD and may reduce the need for liver biopsy in clinical practice.

Keyword(s) : MASLD, MASH, noninvasive diagnosis, quantitative ultrasound, fibrosis

2552 - DPMAS Induced Stabilization in a Terminal Patient Short Term Benefit in the Face of Terminal Prognosis

Alyssa Chan ¹, Jose Guillain Cataluna ¹

St. Luke's Medical Center, Gastroenterology, Parañaque-Philippines ¹

Background / Hypothesis:

Acute-on-chronic liver failure (ACLF) is a rapidly progressive condition with a high mortality rate ranging from 50% to 90%. Artificial liver support systems, such as the double plasma molecular adsorption system (DPMAS), are used to stabilize patients, support failing organs, and serve as a bridge to recovery or transplantation. This case highlights the transient recovery following DPMAS in a patient with a known terminal condition.

Materials and Methods:

This report features a 56-year-old woman with decompensated liver cirrhosis (Child-Pugh C, MELD-Na 32) due to chronic hepatitis C, complicated by hepatocellular carcinoma, portal hypertension, and portal vein thrombosis. She had previously received multiple treatments including immunotherapy

E-POSTER ABSTRACTS

(Tremelimumab + Durvalumab) and tyrosine kinase inhibitors (Lenvatinib, Cabozantinib, Sorafenib). She presented with worsening jaundice, hepatic encephalopathy, coagulopathy, ascites, electrolyte imbalance, and multi-organ dysfunction, indicating acute decompensation. Despite multiple lines of therapy, her disease continued to progress, and she remained aggressive in pursuing treatment despite her terminal status.

Results:

Initial labs showed marked hyperbilirubinemia, transaminase elevation ($>25\times$ normal), hypoalbuminemia, pancytopenia, acute kidney injury (creatinine 2.05 mg/dL, elevated BUN), hyponatremia (Na 128 mEq/L), prolonged PT (24.5s), and increased INR (2.17). She underwent four DPMAS sessions. Although she remained lethargic and jaundiced, post-treatment labs showed significant biochemical improvement. However, following the fourth session, her laboratory values began to rise again, and her clinical condition worsened.

Conclusions:

This case illustrates that while DPMAS may not reverse terminal liver disease, it can temporarily improve laboratory markers and stabilize clinical parameters. Its role is palliative and supportive, providing time for further decision-making in patients with ACLF, especially when transplantation is not an option.

Keyword(s) : DPMAS, acute-on-chronic liver failure, bilirubin, artificial liver support system

2555 - A Preclinical study on Protective Effects of Atorvastatin Against Methotrexate Induced Hepato Renal Toxicity Role of Oxidative Stress and Inflammation

Jayadevan K ¹

AIIMS New Delhi, Pharmacology, New Delhi-India ¹

Background / Hypothesis:

Methotrexate (MTX) is widely used as an immunosuppressive and anticancer agent; however, its clinical utility is often limited by dose-dependent hepatotoxicity and nephrotoxicity. Accumulating evidence suggests that oxidative stress and inflammation are central to MTX-induced organ injury. Atorvastatin, a commonly prescribed HMG-CoA reductase inhibitor, exhibits pleiotropic antioxidant and

anti-inflammatory properties beyond lipid lowering. The present study investigated the potential hepatoprotective and nephroprotective effects of atorvastatin in an experimental model of MTX-induced toxicity and compared its efficacy with silymarin, a standard reference drug.

Materials and Methods:

Wistar albino rats were divided into six groups (n=6): normal control, atorvastatin alone (10 mg/kg), MTX control (20 mg/kg, single intraperitoneal dose), MTX plus atorvastatin (3 mg/kg), MTX plus atorvastatin (10 mg/kg), and MTX plus silymarin (300 mg/kg). Atorvastatin and silymarin were administered orally for 7 days prior to and 21 days following MTX administration. Hepatic and renal function was assessed using serum biochemical markers. Oxidative stress parameters (TBARS, GSH, SOD) and inflammatory mediators (nitrite, MPO, TNF- α , PGE₂) were evaluated in liver and kidney tissues. Histopathological examination was performed to assess structural damage.

Results:

Methotrexate administration resulted in significant hepato-renal injury, evidenced by deranged serum biochemical markers, increased oxidative stress, elevated inflammatory mediators, and pronounced histopathological alterations in both liver and kidney tissues. Atorvastatin treatment significantly attenuated MTX-induced inflammatory responses, as demonstrated by reduced tissue levels of TNF- α , MPO, COX-2, and PGE₂ in both organs. However, in the liver, atorvastatin was associated with a paradoxical increase in oxidative stress, accompanied by persistent elevation of liver function parameters and disruption of redox homeostasis. In contrast, renal tissues showed improvement in oxidative stress markers and functional indices following atorvastatin treatment. Histopathological evaluation supported the biochemical findings, revealing partial restoration of tissue architecture, with more pronounced protection observed in the kidney. Collectively, these results indicate that atorvastatin exerts organ-specific effects in MTX-induced toxicity, providing anti-inflammatory benefits while potentially promoting pro-oxidant effects in the liver under conditions of MTX-associated oxidative stress.

Conclusions:

These findings demonstrate that methotrexate induces

E-POSTER ABSTRACTS

significant hepato-renal toxicity mediated by oxidative stress and inflammation. Atorvastatin exhibits marked anti-inflammatory effects in both liver and kidney; however, its influence on oxidative homeostasis is organ-specific. While clear renoprotection is observed, atorvastatin may exacerbate hepatic oxidative stress and functional impairment under methotrexate-induced conditions. This context-dependent response warrants caution when considering atorvastatin as an adjunct to methotrexate therapy and highlights the importance of organ-specific safety evaluation.

Keyword(s) :

2556 - Clinical Benefit of Perioperative Prophylactic Antibiotics in Hepatocellular Carcinoma (HCC) Patients Undergoing Transcatheter Arterial Chemoembolization (TACE)

Junying Li¹, Jinjun Chen¹

Zengcheng Branch, Nanfang Hospital, Southern Medical University, Hepatology Unit, Guangzhou-China¹

Background / Hypothesis:

Clinical evidence supporting the use of prophylactic antibiotics to prevent infection and improve outcomes in patients undergoing transarterial chemoembolization (TACE) for hepatocellular carcinoma (HCC) remains limited. This study aimed to evaluate the association between perioperative prophylactic antibiotic administration and the risk of post-TACE infection.

Materials and Methods:

This retrospective cohort study included HCC patients who underwent TACE between January 2022 and December 2025. Patients in the prophylactic antibiotic group received 1.5 g of cefuroxime sodium 30 minutes prior to TACE, while those in the control group received no prophylactic antibiotic intervention. The primary outcomes were the incidence of infection within 30 days postoperatively, defined by procalcitonin (PCT) ≥ 0.66 ng/mL or C-reactive protein (CRP) ≥ 28 mg/L. Secondary outcomes included the diagnosis of systemic inflammatory response syndrome (SIRS), total hospitalization cost, and length of hospital stay (LOS). Outcomes were compared between the two groups to assess the necessity of prophylactic antibiotics for TACE.

Results:

A total of 286 eligible patients were enrolled, with 123 receiving prophylactic antibiotics and 163 not. No statistically significant differences were observed between the antibiotic group and the non-antibiotic

group in the incidence of infection (defined by PCT ≥ 0.66 ng/mL: $p=0.142$; defined by CRP ≥ 28 mg/L: $p=0.679$) within 30 days postoperatively. Additionally, there were no significant differences in the rate of SIRS ($p=0.097$), total hospitalization cost ($p=0.475$), or LOS ($p=0.413$) between the two groups.

Conclusions:

Perioperative prophylactic use of antibiotics in patients undergoing TACE is not significantly associated with a reduced risk of postoperative infection, shorter LOS, or lower hospitalization costs. Large-scale prospective studies and randomized controlled trials (RCTs) are warranted to further validate these findings.

Keyword(s) : Prophylactic Antibiotic Therapy; HCC; TACE; infection

2557 - Silybin Attenuates Liver Fibrosis by Suppressing Hepatic Stellate Cell Activation

Fajuan Rui¹, Xinyue Yang², Qianwen Zhao¹, Junping Shi³, Jie Li¹

Nanjing Drum Tower Hospital, Affiliated Hospital Of Medical School, Nanjing University, Department Of Infectious Diseases, Nanjing-China¹ Nanjing Drum Tower Hospital Clinical College Of Nanjing Medical University, Nanjing, Jiangsu, China, Department Of Infectious Diseases, Nanjing-China² The Affiliated Hospital And Institute Of Hepatology And Metabolic Disease Of Hangzhou Normal University, Department Of Infectious & Hepatology Diseases, Hangzhou-China³

Background / Hypothesis: Liver fibrosis is a common pathological consequence of chronic liver injury, primarily driven by the persistent activation of hepatic stellate cells (HSCs). Silybin, a natural flavonolignan derived from *Silybum marianum*, is widely recognized for its hepatoprotective properties; however, its direct effects on hepatic fibrogenesis remain incompletely characterized. This study aimed to investigate the anti-fibrotic efficacy of silybin and its specific impact on HSC activation both in vivo and in vitro.

Materials and Methods: To evaluate in vivo efficacy of silybin, a mouse model of liver fibrosis was induced via bile duct ligation (BDL). Liver injury and fibrosis were assessed via serum aminotransferase levels, Sirius Red staining, hepatic hydroxyproline content, and the expression of fibrosis-related proteins. In vitro, the human HSC line LX-2 was utilized as a model of fibrogenic activation. Cells were stimulated with

E-POSTER ABSTRACTS

transforming growth factor- β (TGF- β) and treated with graded concentrations of silybin. Cellular contractility, proliferation, and migration were assessed by collagen gel contraction assay, EdU incorporation assay, and Transwell migration assay, respectively.

Results: In vivo, silybin administration significantly attenuated liver injury, as evidenced by reduced serum ALT and AST levels. Furthermore, histological analysis demonstrated a marked decrease in collagen deposition and fibrotic area in silybin-treated mice. Consistently, hepatic hydroxyproline content and α -SMA protein expression were significantly reduced (Figure 1). In vitro, activated HSCs exhibited enhanced contractile activity, proliferation, and migratory capacity. Silybin treatment effectively suppressed collagen gel contraction, reduced the number of EdU-positive cells, and inhibited cell migration (Figure 2).

Conclusions: Silybin exerts potent anti-fibrotic effects by inhibiting the activation, proliferation, and migration of hepatic stellate cells, consequently limiting extracellular matrix accumulation. These findings provide experimental evidence supporting silybin as a potential therapeutic agent for the treatment of liver fibrosis.

Keyword(s) : liver fibrosis, silybin, hepatic stellate cells

2558 - Diagnostic Performance of Baveno VII Criteria in a Real World Multicenter Cohort Across Liver Disease Etiologies

Yali Ji¹, Wenkang Gao², Weizhao Tong³, Wenjing Ni⁴, Guoxin Hu⁵, Jie Li⁴, Ling Yang², Jinjun Chen¹
Nanfang Hospital, Southern Medical University, Department Of Infectious Diseases, Guangzhou-China¹
Union Hospital, Tongji Medical College, Huazhong University Of Science And Technology, Division Of Gastroenterology, Wuhan-China²
Peking University Shenzhen Hospital, Shenzhen Peking University-the Hong Kong University Of Science And Technology Medical Center, Department Of Infectious Diseases, Shenzhen-China³
Nanjing Drum Tower Hospital, Affiliated Hospital Of Medical School, Nanjing University, Department Of Infectious Diseases, Nanjing-China⁴
Peking University Shenzhen Hospital, Department Of Infectious Diseases, Shenzhen-China⁵

Background: Accurate non-invasive diagnosis of

compensated advanced chronic liver disease (cACLD) is essential for risk stratification across the spectrum of chronic liver diseases. Although liver stiffness measurement (LSM) by elastography is a cornerstone of assessment, debate persists regarding the optimal diagnostic thresholds for cACLD, particularly across different devices and etiological backgrounds. This study aimed to perform a practical, real-world validation of the widely adopted Baveno VII criteria (10 and 15 kPa) using the iLivTouch elastography system in a large, etiologically diverse patient cohort.

Methods: In a multicenter retrospective study, 1123 patients with various chronic liver diseases (including chronic hepatitis B [41.1%], NAFLD [25.1%], autoimmune liver disease [21.6%], and others) underwent both liver biopsy (histological cACLD defined as $\geq S3$) and iLivTouch liver stiffness measurement. Diagnostic performance was evaluated using receiver operating characteristic (ROC) analysis. Model calibration was assessed with calibration curves, and clinical utility was evaluated via decision curve analysis (DCA) and clinical impact curves (CIC). Optimal dual thresholds were derived based on 90% sensitivity/specificity criteria.

Results: iLivTouch demonstrated superior diagnostic accuracy for cACLD compared to FIB-4 and APRI, with an area under the ROC curve (AUC) of 0.84. Calibration curves indicated excellent agreement between iLivTouch predictions and observed outcomes. DCA and CIC confirmed its greater net benefit and favorable clinical impact across a range of threshold probabilities. The optimal liver stiffness thresholds were 9.75 kPa (90% sensitivity) and 14.95 kPa (90% specificity), closely aligning with the Baveno VII cut-offs (10 kPa and 15 kPa). The 10 kPa threshold provided a sensitivity of 88.8% and a negative predictive value (NPV) of 92.9%, while the 15 kPa threshold achieved a specificity of 90.3%. iLivTouch performed consistently well across diverse etiologies, maintaining an AUC > 0.80 in all subgroups.

Conclusion: This large, multicenter study provides practical validation that the Baveno VII criteria can be effectively applied using the iLivTouch system. iLivTouch offers reliable, etiology-independent performance for diagnosing cACLD, supporting its integration into clinical practice for risk stratification across diverse settings.

2561 - Correlation Between Platelet Derived Growth Factor BB As Liver Fibrosis Biomarker and

E-POSTER ABSTRACTS

Degree Of Liver Fibrosis Based On Fibroscan On Chronic Hepatitis B

Adhitya Wicaksana¹, Suyata Suyata¹, Imam Suprianto¹, Vidi Orba Busro¹, Anjab Akmal¹, Richard Tobing¹
Rsmh, Division Gastroenterology And Hepatology, Palembang-Indonesia¹

Background / Hypothesis: Liver fibrosis is scar tissue that forms due to excessive accumulation of ECM proteins due to chronic liver injury, mediated by cytokines involving complex cellular interactions, such as Platelet Derived Growth Factor BB (PDGF-BB). In Indonesia, no research has been conducted to determine the correlation between PDGFBB levels and degree of liver fibrosis based on fibroscan. The aim of this study is to assess the correlation between PDGF-BB levels and degree of liver fibrosis based on fibroscan in chronic Hepatitis B.

Materials and Methods: A cross sectional study was conducted on chronic hepatitis B population at Internal Medicine clinic of dr. Moh. Hoesin General Hospital Palembang from January to Agustus 2023. Assessment uses fibroscan to determine the degree of liver fibrosis, measured in kilopascals (kPa). PDGF-BB levels measured by ELISA.

Results: From 40 subjects, the majority of chronic hepatitis B patients was women (57,5%). The lowest of PDGF-BB level was found in chronic hepatitis B patients with fibroscan F0, and the highest PDGF-BB level in fibroscan F4. Fibroscan results are directly proportional to PDGF-BB level.

Conclusions: PDGF-BB have strong positive correlation with the degree of fibroscan in chronic Hepatitis B patients in dr. Moh. Hoesin General Hospital. The higher the range of PDGF-BB levels, the higher the degree of fibroscan in chronic Hepatitis B patients.

Keyword(s) : liver fibrosis, fibroscan, PDGF-BB

2563 - Is Laparoscopic Cholecystectomy Necessary at an Asymptomatic Stage

Jong Jin Hyun¹

Korea University Ansan Hospital, Internal Medicine, Ansan-South Korea¹

Background / Hypothesis: Although prophylactic cholecystectomy in patients with asymptomatic gallstone is currently not recommended, increase in the elderly population and resultant increase in the occurrence of serious complications in the aged

mandates reevaluation on the necessity of this procedure. Therefore, we conducted this study to investigate the feasibility of prophylactic cholecystectomy in the elderly patients with asymptomatic gallstones.

Materials and Methods: A total of 453 patients who underwent laparoscopic cholecystectomy at Korea University Ansan Hospital during the 5 year study period were enrolled in this study. The following data were obtained by retrospectively reviewing the medical records and analyzed: sex, age, underlying diseases (diabetes, hypertension), gallbladder stone perception duration, symptom duration, admission route (emergency department vs. outpatient department), operation type (emergency vs. elective), conversion to open surgery, complications (cholecystitis-related and post-operative), readmission within 6 months after discharge, duration of hospital stay (total and post-operative), mortality, and biochemical parameters.

Results: Elderly patients more frequently were admitted through emergency department ($p=0.013$), underwent emergency operation ($p=0.019$), required conversion to open surgery ($p=0.002$), developed cholecystitis-related ($p=0.017$) and post-operative complications ($p<0.001$), were readmitted within 6 months ($p=0.021$), and succumbed to death. Moreover, the duration of total hospital stay ($\gamma=0.403$, $p<0.001$) and post-operative hospital stay ($\gamma=0.325$, $p<0.001$) showed positive correlation with increase in age.

Conclusions: Although further risk group stratification should be performed in order to justify prophylactic cholecystectomy in patients with asymptomatic gallstones, it could be necessary in the elderly patients due to higher risk of morbidity and mortality related to cholecystitis.

Keyword(s) :

2566 - Serum DCP and GALAD Score Reflect Tumor Burden and Stage Progression More Accurately Than AFP Based Markers in Intermediate and Advanced Hepatocellular Carcinoma

Van Trung Huynh¹, Cong Khanh Pham¹, Tran Tuyet Trinh Nguyen²

Tam Anh General Hospital, Center For Gastrointestinal Endoscopy And Minimally Invasive Surgery, Ho Chi Minh City-Vietnam¹ University Of Medicine And Pharmacy At Ho Chi Minh City, Department Of General Internal Medicine, Ho Chi Minh City-Vietnam²

E-POSTER ABSTRACTS

Background / Hypothesis: In real-world clinical practice across Asia, hepatocellular carcinoma (HCC) is frequently diagnosed at intermediate or advanced stages, where conventional serum biomarkers such as alpha-fetoprotein (AFP) often fail to reflect tumor burden or biological disease progression. This study aimed to evaluate the ability of AFP, AFP-L3, des-gamma-carboxyprothrombin (DCP/PIVKA-II), and the GALAD score to discriminate disease stage and reflect tumor burden across Barcelona Clinic Liver Cancer (BCLC) stages, with a particular focus on intermediate and advanced HCC.

Materials and Methods: We conducted a cross-sectional analysis of 83 patients with imaging-confirmed HCC diagnosed according to national criteria aligned with EASL and AASLD guidelines. Serum AFP, AFP-L3, and DCP levels were measured, and GALAD scores were calculated. Biomarker distributions were compared across BCLC stages. Stage-discriminatory performance in patients with BCLC B or higher was assessed using area under the receiver operating characteristic curve (AUROC) analysis with pairwise comparisons.

Results: Nearly 70% of patients presented with intermediate or advanced disease (BCLC B-C). Median GALAD scores increased progressively with advancing BCLC stage (BCLC 0: 1.1; A: 4.3; B: 6.9; C: 11.0; D: 11.6; $p < 0.001$). In patients with BCLC B or higher, DCP demonstrated the highest stage-discriminatory performance (AUROC 0.964), followed by the GALAD score (AUROC 0.939), both significantly outperforming AFP and AFP-L3 ($p < 0.01$). No significant difference was observed between DCP and GALAD ($p = 0.089$). AFP-based markers showed substantial overlap across BCLC stages and limited ability to reflect disease progression.

Conclusions: In intermediate and advanced hepatocellular carcinoma, serum DCP and the GALAD score more closely reflect tumor burden and biological disease progression across BCLC stages than AFP-based biomarkers. Their superior stage-discriminatory performance supports their clinical utility for stage-informed risk stratification and disease monitoring in settings where late-stage HCC predominates.

2567 - Prediabetes as an Early Clinical Indicator of Advanced Liver Fibrosis in Non Diabetic MASLD Patients A Non Invasive Risk Stratification Study

Van Trung Huynh¹, Cong Khanh Pham¹, Tran Tuyet Trinh Nguyen²

Tam Anh General Hospital, Center For Gastrointestinal Endoscopy And Minimally Invasive Surgery, Ho Chi Minh City-Vietnam¹ University Of Medicine And Pharmacy At Ho Chi Minh City, Department Of General Internal Medicine, Ho Chi Minh City-Vietnam²

Background / Hypothesis: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of chronic liver disease worldwide. In routine clinical practice, fibrosis assessment is often initiated only after the development of overt diabetes, potentially missing an earlier window for intervention. Prediabetes represents a highly prevalent intermediate metabolic state, yet its association with advanced liver fibrosis in non-diabetic MASLD remains insufficiently characterized. This study aimed to evaluate the burden of advanced fibrosis among non-diabetic MASLD patients with prediabetes and to explore the role of non-invasive assessment in early risk stratification.

Materials and Methods: This cross-sectional study enrolled 107 non-diabetic MASLD patients at a tertiary referral center between 2023 and 2024. Prediabetes was defined according to standard glycemic criteria. Liver fibrosis was assessed using the fibrosis-4 (FIB-4) index and Acoustic Radiation Force Impulse (ARFI) elastography. The prevalence of significant ($F \geq 2$) and advanced fibrosis ($F \geq 3$) was determined. Factors associated with advanced fibrosis were analyzed using multivariable regression models.

Results: The mean age was 47.3 ± 12.6 years, and 56.1% of patients were male. Significant fibrosis ($F \geq 2$) and advanced fibrosis ($F \geq 3$) were identified in 15.0% and 11.3% of the overall cohort, respectively. Among patients with prediabetes, 41.7% had already developed advanced fibrosis. FIB-4 demonstrated excellent discrimination for advanced fibrosis (AUROC 0.949 for $F \geq 3$). Age and aspartate aminotransferase levels were independently associated with advanced fibrosis.

E-POSTER ABSTRACTS

Conclusions: Prediabetes is associated with a substantial burden of advanced liver fibrosis in non-diabetic MASLD patients. These findings suggest that deferring fibrosis evaluation until the onset of overt diabetes may delay the identification of high-risk individuals. Incorporating simple non-invasive tools into the assessment of patients with prediabetes may enable earlier risk stratification and timely preventive strategies in clinical practice.

Keyword(s) : MASLD; Prediabetes; Liver fibrosis; FIB-4; ARFI elastography

2568 - Gut Liver Axis Mediated Dysbiosis in the Pathogenesis of Liver Fibrosis and Intervention Strategies

Gaomin Gao¹, Zhanghaibo 张¹, Lijingtao Li¹, Changzhanjie Chang¹

Affiliated Hospital Of Shaanxi University Of Chinese Medicine, The First Ward Of The Liver Disease Hospital, Xianyang-China¹

Background / Hypothesis: Liver fibrosis is a common pathological endpoint of chronic liver diseases, characterized by the activation of hepatic stellate cells (HSCs) leading to excessive deposition of extracellular matrix (ECM). In recent years, the "gut-liver axis" has become a focal point in liver fibrosis research.

Numerous studies indicate that the gut microbiota can remodel the hepatic microenvironment by influencing the intestinal barrier, bile acid signaling, microbial metabolites, and immune responses. Gut dysbiosis can lead to the translocation of pathogen-associated molecular patterns (PAMPs), activating Kupffer cells and HSCs, thereby triggering inflammation and fibrosis. Furthermore, dysregulation of key metabolic pathways, such as the bile acid FXR-FGF19 axis and short-chain fatty acid (SCFA) production, significantly contributes to hepatic fibrogenesis. Based on existing research and integrating the latest evidence from systems biology, metabolomics, and microbiomics, this review comprehensively elaborates on the pathological mechanisms by which gut-liver axis-mediated dysbiosis leads to liver fibrosis. It also summarizes current intervention strategies, aiming to provide references for clinical liver fibrosis treatment and target research.

Materials and Methods: The gut-liver axis refers to the bidirectional relationship between the intestine (including its microbiota) and the liver^{[5]^}. These two organs are interconnected through the portal vein;

biliary tract, systemic circulation, and various systemic mediators. The liver is the first organ exposed via portal blood to gut-derived microbial products and metabolites. A healthy intestinal barrier prevents the translocation of gut-derived endotoxins or metabolites into the liver. Damage to the intestinal barrier and dysbiosis can lead to the translocation of gut microbes, endotoxins, etc., activating the immune system and triggering inflammation or fibrosis. This review primarily focuses on the pathological mechanisms and intervention strategies for liver fibrosis mediated by gut-liver axis dysbiosis.

Results: The role of the gut-liver axis and gut microbiota in liver diseases has become a major research focus in recent years. Extensive clinical and basic research confirms that the gut microbiota plays a crucial role in various liver diseases at different stages. The treatment of liver fibrosis requires a holistic approach, addressing both the liver and the gut. By modulating the gut microbiota and intestinal barrier function, liver function can be restored, disease progression delayed, and transmission of liver

Keyword(s) : Gut-liver axis; Liver fibrosis; Gut microbiota

2569 - Clinical Characteristics and Complication Patterns in Hospitalized Elderly Patients with Liver Cirrhosis A Single Center Retrospective Analysis of 1 736 Admissions

Jing Wang¹, Wenting Li¹, Lu Bai¹

The Second Affiliated Hospital Of Baotou Medical College, Baotou, China, Department Of Gastroenterology, Baotou-China¹

Background / Hypothesis:

To investigate the clinical characteristics and distribution patterns of complications in elderly patients with liver cirrhosis, and to provide an evidence-based foundation for the clinical management and individualized treatment of the aged population.

Materials and Methods:

A retrospective analysis was conducted on clinical data from 1,736 admissions (representing 1,095 individual patients) diagnosed with liver cirrhosis at the Second Affiliated Hospital of Baotou Medical College between January 1, 2025, and January 1, 2026. Participants were categorized into the elderly group (≥ 65 years, $n = 683$ admissions) and the non-elderly group (< 65 years, $n = 1,053$ admissions). Complication rates, including

E-POSTER ABSTRACTS

hepatocellular carcinoma (HCC), hepatic encephalopathy (HE), ascites, pleural effusion, gastrointestinal (GI) bleeding, portal vein thrombosis (PVT), infection, and hepatorenal syndrome (HRS), were statistically compared between the two groups.

Results:

Demographic Composition: Among the 1,736 admissions, the 50–60 age group accounted for the highest proportion (29.3%). The elderly group (≥ 65 years) comprised 39.3% ($n = 683$) of the total, with patients over 80 years old representing 12.9% (88/683) of the elderly cohort.

Complication Distribution:

Elderly Group (≥ 65 years): Showed a significantly higher prevalence of infection (37.5%, 256/683), hepatorenal syndrome (HRS) (19.3%, 132/683), ascites (57.1%, 390/683), and pleural effusion (17.7%, 121/683).

Non-elderly Group (< 65 years): Demonstrated a significantly higher incidence of gastrointestinal bleeding (38.2%, 402/1,053) and a HCC complication rate of 12.7% (134/1,053).

Others: The incidence of HE was comparable between groups (17.1% in elderly vs. 15.3% in non-elderly), and PVT remained stable at approximately 10% in both cohorts.

Statistical Analysis: Compared to the non-elderly group, the elderly group exhibited a significant upward trend in the risks of infection, HRS, and effusions ($P < 0.05$), whereas GI bleeding was more prominent in the non-elderly population.

Conclusions:

Clinical presentations of elderly patients with liver cirrhosis exhibit significant heterogeneity. Infection and HRS represent the primary clinical threats for this demographic, necessitating enhanced monitoring of immune status and renal function. Conversely, management of younger patients should focus more on acute portal hypertension-related complications such as GI bleeding. These findings support a multidisciplinary management strategy for elderly cirrhotic patients centered on "infection prevention and renal protection."

Keyword(s) : Liver Cirrhosis; Elderly; Complications; Infection; Hepatorenal Syndrome.

2570 - Improving HBV Screening and Prophylaxis in Rituximab Treated Patients A Quality Improvement

Study

Ilkay Bozkurt¹

Ondokuz Mayıs University, Infectious Diseases, Samsun-Türkiye¹

Background / Hypothesis:

Rituximab (RTX) is associated with a high risk of hepatitis B virus (HBV) reactivation in patients with hematologic malignancies. In our previously published cohort, major gaps in HBV screening and antiviral prophylaxis were identified, resulting in preventable reactivation events. Building on these experiences, a quality-improvement strategy incorporating electronic alerts and a locally developed HBV management algorithm was implemented. We aim to evaluate HBV screening and prophylaxis practices among rituximab-treated patients following implementation of system-level interventions.

Materials and Methods:

We conducted a retrospective quality-improvement study including adult patients with hematologic malignancies who received rituximab between 01 July 2023 and 01 July 2025 at a tertiary care center. HBV screening was evaluated using HBsAg and anti-HBc serology, and HBV DNA (PCR) testing was reviewed when clinically indicated. Screening data up to six months prior to rituximab initiation were assessed. Antiviral prophylaxis practices and HBV DNA-based monitoring strategies were identified from electronic medical records. Clinical management was guided by a locally developed HBV screening and prophylaxis algorithm.

Results:

Among rituximab-treated patients screened during the two-year study period ($N \approx 986$), 913 patients (92.6%) underwent appropriate HBV screening, while 34 patients (3.4%) had incomplete screening and 12 patients (1.3%) were not screened. Overall, 97 patients (9.8%) met criteria for antiviral prophylaxis. Among these, 85 patients (87.6%) received guideline-concordant antiviral prophylaxis, whereas 12 patients (12.3%) were managed with serial HBV DNA (PCR) monitoring without prophylaxis. No HBV reactivation was reported during at least one year of follow-up.

Conclusions:

HBV screening and prophylaxis practices among rituximab-treated patients improved markedly

E-POSTER ABSTRACTS

following implementation of electronic alerts and a local management algorithm informed by prior institutional experience. These findings support the effectiveness of pragmatic, system-embedded interventions in reducing preventable gaps in HBV care in high-risk hematology populations.

Keyword(s) :

2571 - Predicting key components and mechanisms of silymarin in treating sepsis related liver injury using GraphBAN

Min Cai ¹, Dianliang Fang ²

Yongchuan Hospital Of Chongqing Medical University, Department Of Nephropathy And Rheumatism, Chongqing-China ¹ Chongqing Emergency Medical Center, Department Of Gastroenterology, Chongqing-China ²

Background / Hypothesis:

Sepsis-related liver injury (SRLI), a common complication of sepsis, exacerbates organ dysfunction and worsens patient prognosis. Traditional Chinese medicine has accumulated substantial experience in liver injury management. This study employs network pharmacology and compound-protein interaction (CPI) analysis to identify key active components and targets in *Silybum marianum* (L.) Gaertn related to SRLI, offering new perspectives for its targeted therapy.

Materials and Methods:

This study obtained SRLI-related data and chemical composition information from milk thistle through public databases. By integrating differential gene expression analysis with CPI prediction technology based on GraphBAN, potential CPI pairs were identified. Further integration of physicochemical properties and toxicological parameters successfully pinpointed key active components and their corresponding targets. Subsequently, this study conducted an in-depth analysis of interactions among key targets and their involvement in biological functions. Molecular docking and molecular dynamics simulations were employed to evaluate binding stability between key bioactive compounds and their targets. Finally, gene set enrichment analysis was performed to explore the biological functions and signaling pathways involved in key genes.

Results:

A total of 1,554 differentially expressed genes and 11 bioactive compounds were identified, with quercetin identified as the key active component and REN and SIGMAR1 as its primary targets. Molecular docking revealed binding energies of -7.1 and -8.3 kcal/mol

between quercetin and the REN and SIGMAR1 targets, respectively, forming stable complexes in kinetic simulations. Enrichment analysis indicated that key targets were primarily involved in multiple signaling pathways, including SARS-CoV-2 infection-related responses, and responses to LPS-induced mechanical ventilation etc. Key genes showed significant correlations with multiple genes within gene sets related to inflammation, mitochondria, and oxidative stress.

Conclusions:

This study employed network pharmacology combined with GraphBAN analysis to predict one key active ingredient and two key targets for treating SRLI, providing crucial evidence for the development of targeted traditional Chinese medicine therapies for SRLI

Keyword(s) : Sepsis-related liver injury; GraphBAN; Network pharmacology; Quercetin

2573 - NRF2 Mediated Gsta3 Transcriptional Activation Protects Against Sepsis Associated Liver Injury

Peng Qu ¹, Xu Li ¹

Nanfeng Hospital, Southern Medical University, Gastroenterology, Guangzhou-China ¹

Background / Hypothesis:

Oxidative stress participates in the pathogenesis of sepsis-associated liver injury (SALI), and the glutathione system plays a pivotal role in cellular antioxidant defense mechanisms. Gsta3 predominantly expressed in the liver, is a key transferase in the glutathione system; however, its specific mechanism of action in SALI remains to be fully elucidated.

Materials and Methods:

This study aimed to evaluate CLP- and LPS/D-GalN-induced SALI models, clarify Gsta3's role and mechanism, and identify causes of its downregulation. Methods: Bioinformatics analyses were performed using transcriptomic and single-cell sequencing data (GSE279167, GSE254497). SALI models were established, with Gsta3 expression detected by ELISA, qPCR and Western blotting. In vitro and in vivo experiments (including gene overexpression/knockdown, ChIP and dual-luciferase assays) were conducted to verify mechanisms.

Results:

Both models successfully induced SALI with hepatocyte pyroptosis; Gsta3 was downregulated in liver tissues (negatively correlated with ALT/AST) but upregulated in septic patients' serum. Gsta3 alleviated hepatocyte

E-POSTER ABSTRACTS

injury by improving mitochondrial function and inhibiting pyroptosis. NRF2 directly bound to Gsta3 promoter and activated its transcription; LPS/D-GalN inhibited NRF2 nuclear translocation, reducing Gsta3 expression. NRF2-knockout mice had lower Gsta3 and severer liver injury, which was rescued by AAV-mediated Gsta3 overexpression.

Conclusions: Gsta3 antagonizes SALI by maintaining mitochondrial homeostasis and suppressing pyroptosis. LPS/D-GalN downregulates Gsta3 via inhibiting NRF2 nuclear translocation, providing a theoretical and experimental basis for SALI targeted therapy.

Keyword(s) : sepsis, liver injury, Gsta3, NRF2, Pyroptosis

2575 - Acute Pancreatitis Secondary to Tirzepatide Therapy

Ahmet Biçici¹, Serhat Akpınar¹, Kadir Gişi¹, Mesut Kuş¹, Pusat Buğrahan Köksal¹, Bülent Kantarçeken¹
Sutcu Imam University, Gastroenterology, Kahramanmaraş-Türkiye¹

Background / Hypothesis: Glucagon-like peptide-1 (GLP-1) receptor agonists and dual-acting GIP/GLP-1 agonists are increasingly used in the treatment of type 2 diabetes and obesity. Tirzepatide is a new generation agent that activates both GIP and GLP-1 receptors. Although the risk of pancreatitis has been reported as low in clinical studies, acute pancreatitis has been reported, albeit rarely, in real-life data. In this case report, we aim to present a patient who developed acute pancreatitis during tirzepatide treatment.

Case: A 36-year-old male patient with type 2 diabetes and obesity was started on tirzepatide treatment (5 mg weekly, subcutaneous) approximately 2 months ago. The patient had no prior history of pancreatitis, alcohol use, recent viral infection, or hypertriglyceridemia. He reportedly lost approximately 15 kg during treatment. He presented to the emergency department with severe epigastric and back pain radiating to the lower back, nausea, and vomiting. Physical examination revealed epigastric tenderness. Laboratory investigations showed amylase: 537 U/L, lipase: 1071 U/L. Liver enzymes, bilirubin levels, and serum calcium levels were normal. Triglyceride level was measured at 117 mg/dL. Abdominal ultrasonography showed no gallstones or common bile duct dilation. Magnetic resonance cholangiopancreatography (MRCP) imaging revealed increased volume in the distal tail section of the pancreatic body and contamination in the

surrounding mesenteric fat tissue, consistent with pancreatitis. The biliary tract and common bile duct were reported as normal. Based on the current clinical, laboratory, and radiological findings, the patient was diagnosed with acute pancreatitis. After ruling out possible etiological causes, it was thought that the pancreatitis developed due to tirzepatide treatment, and the drug was discontinued. The patient was monitored with supportive treatment. Improvement was observed in clinical and laboratory findings, and the patient was discharged without complications after a 5-day hospital stay. No recurrence of pancreatitis was observed during follow-up.

Conclusions: Acute pancreatitis is a rare but potentially serious side effect of tirzepatide treatment. Particular attention should be paid to pancreatitis in patients experiencing rapid weight loss and unexplained epigastric pain. In patients who develop acute pancreatitis, tirzepatide treatment should be discontinued and not restarted. This case highlights the importance of not ignoring the risk of pancreatitis in patients using tirzepatide.

2578 - Integrated Multi omics Liquid Biopsy Advancing Early Detection and Precision Management of HCC

Xinhao Gao¹, Jitao Wang², Dengxiang Liu³, Juan Liu⁴, Hezhao Wang¹, Shihao Guo¹, Huiyang Fan¹
Xingtai People's Hospital, Hepatobiliary Surgery, Xingtai-China¹ Tsinghua University, Hepatobiliary Surgery, Beijing-China² Xingtai People's Hospital, Xingtai People's Hospital, Xingtai-China³ Tsinghua University, Tsinghua University, Beijing-China⁴

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality worldwide, often diagnosed at late stages due to the limited sensitivity and specificity of current surveillance methods such as ultrasound and alpha-fetoprotein (AFP) testing. Liquid biopsy, which non-invasively analyzes circulating biomarkers, offers a promising alternative (Fig 1). However, single-omics approaches often lack the robustness required for early detection. Multi-omics integration presents a transformative strategy to enhance diagnostic accuracy and enable precision oncology in HCC.

Materials and Methods:

This review synthesizes recent advances in multi-omics

E-POSTER ABSTRACTS

liquid biopsy for HCC, incorporating genomic (e.g., TERT, TP53 mutations), epigenomic (e.g., RASSF1A methylation), proteomic/glycomic (e.g., AFP-L3, GP73, exosomal glycans), fragmentomic (cfDNA fragmentation patterns), and cellular biomarkers (CTCs, EVs) (Fig 2) . Cross-omics integration strategies—such as cSMART, HIFI, and ASDAm-H1—were evaluated alongside emerging technologies including nanopore sequencing, SERS-based single-exosome analysis, and machine learning models (e.g., XAI, GNNs, Bayesian Networks) (Fig 3) .

Results:

The integration of multi-omics biomarkers has demonstrated transformative diagnostic performance for early HCC (Table 1) . Cross-omics models consistently outperformed single-modality approaches: combined genomic-epigenomic assays achieved sensitivities of 80–90% for early-stage detection, while the fragmentomic-epigenomic HIFI model distinguished HCC from cirrhosis with exceptional accuracy (AUC 0.996, sensitivity 95.42%, specificity 97.83%). Integrated protein-epigenetic panels, such as the ASDAm-H1 index, reached an AUC of 0.96, and longitudinal application of multi-parametric scores like GALAD significantly improved sensitivity to 69.2% for early HCC compared to single measurements (53.8%). Fragmentomics-based models enabled early screening with sensitivities exceeding 96%, and metabolomic panels detected preclinical HCC up to one year before clinical diagnosis with 80% sensitivity. Beyond detection, multi-omics liquid biopsy proved vital for precision management: ctDNA mutation profiling enabled dynamic monitoring of targeted therapy response, PD-L1⁺ CTCs and cfDNA copy number variations predicted outcomes to immune checkpoint inhibitors, and machine learning-driven deconvolution of single-exosome SERS fingerprints or cfDNA methylation data provided unprecedented molecular resolution. These approaches not only identified AFP-negative HCC cases but also facilitated early recurrence prediction and molecular subtyping, effectively transitioning liquid biopsy from a passive detection tool to an active component in the dynamic, personalized management of HCC.

Conclusions:

Multi-omics liquid biopsy represents a paradigm shift in HCC management, enabling high-accuracy early detection and dynamic monitoring of disease progression and treatment response. Despite challenges in data integration, standardization, and clinical validation, future directions—including

explainable AI, single-cell multi-omics, and closed-loop precision oncology systems—hold great promise (Fig 4) . With continued interdisciplinary collaboration and standardization efforts, multi-omics liquid biopsy is poised to become the cornerstone of next-generation HCC care.

Background: Acid suppressants, including proton pump inhibitors (PPIs), are

E-POSTER ABSTRACTS

frequently prescribed for patients with chronic liver disease. While associations between acid suppressant use and hepatic encephalopathy (HE) have been suggested, causality remains unclear due to indication bias, as these drugs are often prescribed to patients with greater disease severity. This study investigated the association between acid suppressants and liver-related events using a large-scale prospective cohort. Methods: Of 1,206 patients with chronic liver disease registered between

February 2020 and March 2022, 373 patients with liver cirrhosis were included. Patients were categorized into PPI/potassium-competitive acid blocker (P-CAB) user and non-user groups. The primary endpoint was the cumulative incidence of HE, and the secondary endpoint was the cumulative incidence of variceal bleeding. Inverse probability of treatment weighting (IPTW) was performed to adjust for background factors, including ALBI score, history of HE, ascites, varices, and use of non-absorbable disaccharides or rifaximin. Balance was assessed using the standardized mean difference (SMD).

Results: In the unadjusted cohort (non-users: n=170; users: n=197), users had significantly worse liver function and a more frequent history of decompensation or HE treatment, as indicated by the ALBI score (median -2.51 vs. -2.24), history of HE (9.4% vs. 13.7%), ascites (20.0% vs. 34.5%), varices (27.1% vs. 55.8%), and use of non-absorbable disaccharides (5.9% vs. 15.2%) or rifaximin (1.8% vs. 14.2%). After IPTW adjustment (non-users: n=163; users: n=196), background factors were well balanced (all SMDs < 0.1 or close to 0.1). The 1- and 2-year cumulative HE incidence rates were 2.3% vs. 3.8% and 4.8% vs. 6.8% for non-users and users, respectively. Although the rate was higher in users, the difference was not statistically significant (HR 1.74, 95% CI 0.68-4.46, p=0.247). The 1- and 2-year cumulative variceal bleeding rates were 3.9% vs. 2.3% and 3.9% vs. 2.3%, respectively, showing a lower trend in users but no significant difference (HR 0.66, 95% CI 0.19-1.96, p=0.40).

Conclusion: Although a trend toward higher HE incidence was observed in acid suppressant users, no statistically significant difference was found after adjusting for confounding factors. This study did not find clear evidence that acid suppressant use significantly increases the risk of HE in patients with cirrhosis.

2582 - Neurological Outcomes and Survival in Hepatic Myelopathy A Multicenter Cohort Study

Wenhao Xue¹, Zhen Li¹

The First Affiliated Hospital Of Zhengzhou University, The First Affiliated Hospital Of Zhengzhou University, Zhengzhou-China¹

Background / Hypothesis:

Hepatic myelopathy (HM) is a disabling neurological complication of advanced liver disease. Data on neurological reversibility and long-term prognosis under different treatment strategies remain limited. We aimed to characterize clinical features, management strategies, neurological outcomes, and survival in a multicenter cohort of patients with HM.

Materials and Methods:

We retrospectively included 184 patients diagnosed with HM. Clinical characteristics, neuroimaging and electrophysiological findings, and initial treatment strategies (conservative management, interventional shunt modulation, or liver transplantation) were collected. Neurological outcome at last follow-up was assessed using functional status and the modified Rankin Scale (mRS). Overall survival was analyzed using Kaplan-Meier methods and multivariable Cox regression.

Results:

Radiologically detectable portosystemic shunts were present in 179/184 patients (97.3%), including 61 with prior transjugular intrahepatic portosystemic shunts and 118 with spontaneous shunts. Brain MRI commonly demonstrated changes consistent with metabolic encephalopathy, while spinal MRI revealed no consistent structural spinal cord lesions. Evoked potentials frequently showed central conduction abnormalities, whereas peripheral nerve involvement on nerve conduction studies or electromyography was less common. Neurological improvement occurred significantly more often after interventional shunt modulation or liver transplantation than after conservative management (P < 0.001). Although unadjusted survival differed across treatment strategies, treatment strategy was not independently associated with survival after adjustment; higher baseline MELD score and hepatocellular carcinoma were independent predictors of mortality.

Conclusions: In HM, neurological recovery and long-term survival follow partially independent trajectories.

E-POSTER ABSTRACTS

Neurological dysfunction may be modifiable in selected patients, whereas overall prognosis is primarily determined by the severity of underlying liver disease.

Keyword(s) :

2584 - Cytopenia Following Albendazole Use A Real World Observation

Shufang Pan¹, Shuru Chen¹, Zulipiya Moming², Xiaohong Wang³, Kaixiang Zhou⁴, Lejia Xu⁵, Maimaitiaili Tuerxun², Jianyun Zhu¹

The Third Affiliated Hospital Of Sun Yat-sen University, Department Of Infectious Disease, Guangzhou-China¹ The Kashi Affiliated Hospital Of Sun Yat-sen University, Department Of Infectious Disease, Kashi-China² The Third Affiliated Hospital Of Sun Yat-sen University, Department Of Radiology, Guangzhou-China³ The Third Affiliated Hospital Of Sun Yat-sen University, Zhaoqing Hospital, Department Of Rheumatology, Zhaoqing-China⁴ The Third Affiliated Hospital Of Sun Yat-sen University, Department Of Clinical Pharmacology, Guangzhou-China⁵

Background / Hypothesis: Albendazole is a commonly used antiparasitic drug. In extremely rare cases, however, it can cause serious adverse reactions, such as bone marrow suppression and neutropenia.

Materials and Methods: This study reports three cases of pancytopenia in patients with liver parasitic diseases who were treated with albendazole. We also analyse cases of cytopenia reported in the FDA Adverse Event Reporting System (FAERS) database following albendazole use.

Results: One case was deemed to be systemic inflammatory response syndrome triggered by the death of a large number of parasites, while the remaining two cases were considered to be adverse reactions to albendazole. Only one patient experienced timely detection of myelosuppression and made a full recovery following treatment; the other two patients died from the condition. From January 2004 to June 2025, the FAERS system recorded 88 instances of reduced blood cell counts associated with albendazole use, including 25 cases of pancytopenia and 35 cases of granulocytopenia. There were 11 deaths.

Conclusions: Although albendazole-induced cytopenia is rare, clinical vigilance remains essential, particularly in individuals with liver disease. Our aim is to raise clinicians' awareness of this potential adverse reaction.

Keyword(s) : Liver parasitic disease; Albendazole; Pancytopenia; Anthelmintic drugs; Adverse drug reactions

2585 - Clinical Characteristics of Non Cirrhotic Portal Hypertension Associated with Oxaliplatin

Jie Gao¹, Shu-fang Pan¹, Kai-xiang Zhou², Ren-ming Liu³, Xiao-hong Wang⁴, Yu-tian Chong¹, Shu-ru Chen¹, Jian-yun Zhu¹

The Third Affiliated Hospital Of Sun Yat-sen University, Department Of Infectious Diseases, Guangzhou-China¹ The Third Affiliated Hospital Of Sun Yat-sen University, Department Of Rheumatology, Zhaoqing-China² The Third Affiliated Hospital Of Sun Yat-sen University, Department Of Pathology, Guangzhou-China³ The Third Affiliated Hospital Of Sun Yat-sen University, Department Of Radiology, Guangzhou-China⁴

Background / Hypothesis:

Non-cirrhotic portal hypertension (NCPH) is a group of diseases characterised by elevated portal vein pressure in the absence of cirrhosis. Several studies have shown that patients undergoing oxaliplatin (OX) chemotherapy can develop NCPH within three to five years

Objective: To summarise the clinical features of NCPH following OX therapy to highlight the relationship between delayed-onset NCPH and OX for the attention of clinicians.

Materials and Methods:

A retrospective analysis was conducted on six patients diagnosed with OX-related NCPH between 2013 and 2025. The study examined the patients' general information, clinical characteristics, laboratory test results, imaging findings and liver histopathology. Treatment regimens were summarised to explore the clinical features of patients who developed NCPH following OX chemotherapy.

Results:

Of the six patients, one developed manifestations of portal hypertension (PH) four months after receiving OX chemotherapy, and magnetic resonance imaging suggested sinusoidal obstruction syndrome. The remaining five patients exhibited PH manifestations between two years and four years post- OX chemotherapy. Pathological examination of liver tissue from four of these patients revealed no cirrhosis, resulting in a diagnosis of NCPH. Liver function tests and liver stiffness measurements were generally

E-POSTER ABSTRACTS

normal or only slightly abnormal

Conclusions:

In patients with malignant tumours undergoing OX chemotherapy, the presence of manifestations of portal hypertension, such as oesophageal-gastric varices, splenomegaly, thrombocytopenia or ascites, without significant abnormalities in liver size or function, should prompt consideration of OX-induced NCPH. A liver biopsy can provide definitive confirmation of the diagnosis.

Keyword(s) : Oxaliplatin; Non-cirrhotic Portal Hypertension; NCPH ; Idiosyncratic drug-induced liver injury; Gastrointestinal cancer

2586 - The traditional Chinese medicine prescription Danjin Shugan Formula exerts anti fibrotic effects by regulating the mTOR S6K1 4E BP1 signaling pathway and YAP TAZ proteins

Shiheng Liu ¹, Yongwei Wang ¹, Yanan Li ¹, Baoxin Li ¹, Sui Zhang ¹, Baixian Song ¹, Yuguo Zhang ¹
The First Hospital Of Hebei Medical University, Hepatology, Shijiazhuang-China ¹

Background / Hypothesis:

We aimed to investigate the anti-hepatic fibrosis efficacy of Danjin Shugan recipe(DJSG) and its potential mechanism for attenuating hepatic fibrosis.

Materials and Methods:

We induced and constructed a hepatic fibrosis model in Wistar rats by intraperitoneal injection of carbon tetrachloride (CCl₄) and used Fuzheng Huayu decoction (FZHY) as a positive control drug. Subsequently, hematoxylin-eosin, Masson staining and immunohistochemical staining were performed on the liver tissues of rats in each group at weeks 4 and 8, and peripheral blood was collected to test liver function indexes. We used Western blotting and qRT-PCR to detect changes in the mTOR-S6K1/4E-BP1 signaling pathway, YAP/TAZ and HNF-4 α factors in each group of rats. In addition, we randomly divided 60 patients into an experimental group (receiving Danjin Shugan Capsules combined with anti-hepatitis B virus treatment) and a control group (receiving Fuzheng Huayu Capsules combined with anti-hepatitis B virus treatment). At baseline and after 3, 6, and 12 months of treatment, liver fibrosis indicators (liver stiffness value, FIB-4, APRI index) were followed up, collected, and compared. At the same time, relevant adverse reactions observed in patients were recorded.

Results:

DJSG significantly reduced liver injury and fibrosis in CCl₄-induced rats. Compared with the CCl₄ group, DJSG, and FZHY significantly reduced the protein expression levels of p-mTOR, p-S6K1, and p-4E-BP1 at week 4 and week 8, and the protein expression levels of p-mTOR and p-4E-BP1 decreased even more significantly in the CCl₄+FZHY group. At the same time point, DJSG and FZHY may ameliorate rat liver fibrosis by inhibiting YAP/TAZ protein expression. After 3, 6, and 12 months of treatment, improvements in liver stiffness values were observed in both groups, with no significant difference compared to the Fuzheng Huayu treatment group (P<0.05) .

Conclusions:

Our study demonstrated that DJSG improved liver function and liver fibrosis levels in CCl₄ rats and may be associated with the YAP/TAZ protein and mTOR-S6K1/4E-BP1 signaling pathway. Danjin Shugan Capsules exhibit a certain anti-fibrotic effect. It has been found that a 12-week treatment course can achieve a certain degree of reversal of liver fibrosis and early-stage cirrhosis.

2587 - Genetically Confirmed Dubin Johnson Syndrome Presenting as Long Standing Isolated Conjugated Hyperbilirubinemia

Trung Huynh Van ¹, Long Doan Hoang ¹, Trinh Nguyen Tran Tuyet ²

Tam Anh General Hospital, Center For Gastrointestinal Endoscopy And Minimally Invasive Surgery, Ho Chi Minh City-Vietnam ¹ University Of Medicine And Pharmacy At Ho Chi Minh City, Department Of General Internal Medicine, Ho Chi Minh City-Vietnam ²

Background / Hypothesis: Chronic intermittent jaundice with isolated hyperbilirubinemia is commonly attributed to benign conditions such as Gilbert syndrome. However, when conjugated bilirubin predominates, inherited disorders of hepatocellular bilirubin transport should be considered. Dubin-Johnson syndrome is a rare autosomal recessive condition caused by loss-of-function variants in the *ABCC2* gene, leading to impaired canalicular excretion of conjugated bilirubin.

E-POSTER ABSTRACTS

Materials and Methods:We report a 30-year-old man with a 10-year history of intermittent jaundice and dark urine without pruritus, abdominal pain, systemic symptoms, alcohol use, or hepatotoxic drug exposure. Comprehensive biochemical testing, abdominal imaging, liver stiffness assessment, and targeted genetic analysis were performed.

Results:The patient demonstrated persistent isolated hyperbilirubinemia with conjugated predominance, while aminotransferases, cholestatic enzymes, and hepatic synthetic function remained normal. Markers of hemolysis, viral hepatitis, and autoimmune liver disease were negative. Abdominal ultrasound and magnetic resonance imaging showed normal liver morphology without biliary obstruction, and shear-wave elastography indicated normal liver stiffness. Targeted genetic testing identified a homozygous truncating loss-of-function variant in the ABCC2 gene (p.Trp1206Ter), confirming the diagnosis of Dubin-Johnson syndrome.

Conclusions:Dubin-Johnson syndrome should be considered in patients presenting with chronic intermittent jaundice and isolated conjugated hyperbilirubinemia with normal liver enzymes and unremarkable imaging. A stepwise diagnostic approach integrating bilirubin fractionation and targeted ABCC2 genetic testing enables definitive diagnosis, avoids unnecessary invasive investigations, and reassures patients regarding the benign and non-progressive nature of the condition.

Keyword(s) : Dubin-Johnson syndrome; ABCC2; conjugated hyperbilirubinemia; genetic liver disease

Background-hypothesis: Hepatitis delta virus (HDV) infection is a significant health and economic problem worldwide, particularly in endemic regions such as the Mediterranean, Southern and Eastern Europe, the Middle East, and Turkey. Approximately 15 million people worldwide suffer from HDV, accounting for 5-10.6% of all HBV infections globally. The prevalence of HDV among HBsAg-positive blood donors, outpatients, and inpatients was found to be 3.37%, 5.05%, and 29.06%, respectively. In our study, we aimed to investigate the seroprevalence of Delta virus infection in HBsAg-positive patients in Turkey.

Method: Patients aged 18 and over who were HBsAg positive and followed up in the Infectious Diseases outpatient clinics of the participating hospitals between January 1, 2015, and December 31, 2024, were included in the study. Demographic data, laboratory results, and treatments received by the patients were retrospectively reviewed from their patient records.

Results: Data were obtained from hospitals in a total of 27 different provinces in Turkey. 31,514 patients were included in the study, 55.4% of whom were male. The mean age was 47.4 ± 14.1 years. Of the patients, 34.2% had HBeAg-negative chronic hepatitis B, 57.2% had HBeAg-negative chronic HBV infection, 4.6% had HBeAg-positive chronic hepatitis B, and 4% had HBeAg-positive chronic HBV infection. 4.6% of HBsAg positive patients had clinically diagnosed cirrhosis. In HBsAg-positive patients, 0.7% were anti-HCV positive and 0.4% were anti-HIV positive. Anti-HDV testing was performed in 29,085 of the participating patients, and the anti-HDV positivity rate was 5.2%. HDV RNA tests were found to be positive in 568 patients. Of the patients for whom current data were available, 299 were waiting for delta treatment. A total of 113 patients had undergone liver transplantation due to HDV. Currently, 20 patients are receiving bulevirtide treatment, and 40 are receiving pegylated interferon treatment. Pegylated interferon treatment was the most common treatment among the patients' previous treatments for delta hepatitis.

Conclusion: Delta hepatitis remains an important disease in our country. In our study, it has been observed that there are still centers where anti-HDV testing is not performed. Performing anti-HDV

E-POSTER ABSTRACTS

screening in all HBsAg-positive patients would be beneficial in countries where HBV infection is endemic, in terms of earlier diagnosis and treatment of patients with delta hepatitis.

Keyword(s) : delta hepatitis, seroprevalance, Turkey.

2589 - Adult Onset Wilson Disease Without Classical Features Diagnostic Value of ATP7B Genotyping and Leipzig Scoring

Trung Huynh Van¹, Thanh Hoang Dinh¹, Trinh Nguyen Tran Tuyet²

Tam Anh General Hospital, Center For Gastrointestinal Endoscopy And Minimally Invasive Surgery, Ho Chi Minh City-Vietnam¹ University Of Medicine And Pharmacy At Ho Chi Minh City, Department Of General Internal Medicine, Ho Chi Minh City-Vietnam²

Background / Hypothesis:Wilson disease is an autosomal recessive genetic disorder of copper metabolism caused by pathogenic variants in the ATP7B gene. In adults, the disease may present without classical ophthalmologic or neurological features, leading to diagnostic delay. This study aimed to highlight the diagnostic value of integrating genetic analysis with functional copper assessment and Leipzig scoring in an atypical adult-onset presentation.

Materials and Methods:An adult patient presented with progressive jaundice and cholestatic liver dysfunction. Viral hepatitis, autoimmune liver disease and drug-induced liver injury were excluded. Ophthalmologic examination showed no Kayser-Fleischer rings, and no neurological manifestations were observed. Serum ceruloplasmin, 24-hour urinary copper excretion and liver biochemistry were assessed. ATP7B gene analysis was performed using next-generation sequencing. Clinical and biochemical responses were evaluated after initiation of copper chelation therapy.

Results:Serum ceruloplasmin was within the normal range. Baseline 24-hour urinary copper excretion was markedly elevated at 456 µg/24 h. Genetic testing identified a compound heterozygous state with one pathogenic frameshift variant (c.2304dup, p.Met769HisfsTer26) and one likely pathogenic missense variant (c.2549C>T, p.Thr850Ile) in the ATP7B

gene. Despite the absence of Kayser-Fleischer rings and neurological involvement, the Leipzig score reached 4 points, fulfilling diagnostic criteria for Wilson disease. After three weeks of copper chelation therapy, urinary copper excretion decreased to 378 µg/24 h, accompanied by significant clinical improvement and marked reduction in serum bilirubin levels.

Conclusions:Adult-onset Wilson disease may present without classical clinical features and with normal ceruloplasmin levels. Integration of ATP7B genotyping with functional copper assessment and Leipzig scoring is essential for accurate diagnosis and timely treatment in atypical cases.

Keyword(s) : Wilson disease; ATP7B; Adult-onset; Genetic liver disease; Leipzig score; Diagnostic challenge

2591 - AMA negative Primary Biliary Cholangitis Diagnosed by a Reproducible Dechallenge Rechallenge Response to Ursodeoxycholic Acid

Trung Huynh Van¹, Toan Vo Dang¹, Phat Luu Xuan¹, Trinh Nguyen Tran Tuyet²

Tam Anh General Hospital, Center For Gastrointestinal Endoscopy And Minimally Invasive Surgery, Ho Chi Minh City-Vietnam¹ Ho Chi Minh City University Of Medicine And Pharmacy, Department Of General Internal Medicine, Ho Chi Minh City-Vietnam²

Background / Hypothesis:Primary biliary cholangitis (PBC) is a chronic autoimmune cholestatic liver disease typically associated with antimitochondrial antibodies (AMA). However, approximately 5-10% of patients are AMA-negative, creating diagnostic challenges, particularly when liver biopsy is unavailable or deferred. This report describes a case of suspected AMA-negative PBC diagnosed based on a reproducible biochemical response to ursodeoxycholic acid (UDCA).

Materials and Methods:We report a 65-year-old man with a two-year history of persistent cholestatic liver enzyme elevation, characterized by markedly elevated gamma-glutamyl transferase (GGT). There was no history of alcohol intake, hepatotoxic drug exposure, or viral hepatitis. Imaging excluded biliary obstruction, and liver stiffness measurement was consistent with moderate fibrosis (F2). Autoimmune serology revealed borderline and subsequently negative AMA titres.

E-POSTER ABSTRACTS

Serial liver biochemistry was longitudinally analyzed in relation to UDCA exposure.

Results: During periods of UDCA withdrawal, cholestatic enzymes progressively worsened, with GGT increasing from 1023.74 to 1301 U/L and, during a subsequent interruption, from 923.6 to 1449.56 U/L. In contrast, initiation and reintroduction of UDCA were consistently followed by marked biochemical improvement, with GGT decreasing from 1301 to 923.6 U/L and subsequently from 1449.56 to 644.6 U/L. Aminotransferase levels showed parallel improvement, while serum bilirubin remained stable without progression to overt jaundice. This highly reproducible on-off biochemical pattern provided strong functional evidence supporting a diagnosis of AMA-negative PBC.

Conclusions: A reproducible dechallenge-rechallenge biochemical response to UDCA may serve as valuable functional diagnostic evidence in suspected AMA-negative PBC. Careful longitudinal monitoring of liver enzymes may help support diagnosis and reduce the need for invasive liver biopsy in selected patients.

Keyword(s) : Primary biliary cholangitis; AMA-negative; Ursodeoxycholic acid; Cholestatic liver disease; Dechallenge-rechallenge

2592 - Ultra High HBV Viral Load Not Equivalent to the Immune Tolerant Phase.

Jie Liu¹, Guifeng Li², Ying Ma¹, Haixia Ma¹, Jia Li¹
Tianjin Second People's Hospital, Department Of Hepatology, Tianjin-China¹ Clinical School Of The Second People's Hospital Tianjin Medical University, Department Of Hepatology, Tianjin-China²

Background / Hypothesis:

While an ultra-high viral load often suggests immune tolerance in chronic hepatitis B, it has now been recognized that such cases exhibit significant heterogeneity, including variations in gender, age, virological markers, and biochemical profiles.

Materials and Methods:

This study ultimately enrolled 412 chronic hepatitis B patients with ultra-high viral loads who had not yet received antiviral treatment. All patients had high-sensitivity HBV-DNA levels $>10^7$ IU/ml and were HBeAg-positive. General information, laboratory test

results, and examination data were collected from the patients. The virological characteristics were compared across groups based on factors such as age, gender, and ALT levels, aiming to understand the clinical features of patients with high viral loads.

Results:

Patients with ultra-high viral loads exhibit significant heterogeneity, characterized by a high rate of abnormal ALT levels and a certain degree of significant fibrosis and hepatic steatosis. In these patients, elevated ALT is more closely associated with a decrease in HBsAg levels rather than an increase in steatosis. The rise in liver stiffness measurement (LSM) is considered to correlate with the reduction in hepatitis B viral load. Patients over 30 years of age with ultra-high viral loads demonstrate clear progression in fibrosis, supporting the age of 30 as a critical threshold for initiating antiviral therapy. Additionally, an HBV-DNA level $>10^8$ IU/ml is more indicative of immune-tolerant characteristics.

Conclusions:

Keyword(s) : Ultra-High HBV Viral Load, chronic hepatitis B, HBeAg-positive

2595 - A case of artificial liver support system for Wilson's disease related acute on chronic liver failure complicated with hyperthyroidism

Hua Liu¹, Jingjing Wang¹, Junjun Cai²

Central Hospital, Tianjin University, Gastroenterology And Hepatology, Tianjin-China¹ Central Hospital, Tianjin University, Central Hospital, Tianjin University, Tianjin-China²

Background :

Wilson's disease is one of the causes of acute-on-chronic liver failure, characterized by a dangerous condition, rapid progression, and extremely high mortality.

CASE SUMMARY

The patient is a 60-year-old male who presented with jaundice of the skin and sclera for 11 days. He had a history of hyperthyroidism and was previously treated with tapazole. After developing jaundice, he was switched to iodine therapy. He had a history of alcohol consumption but had quit. At the time of admission, the patient's liver function tests showed ALT 197U/L, AST 149U/L, ALP 151 U/L, GGT 41 U/L, TBIL 265.1umol/L, DBIL 235.7 umol/L, INR 1.69, HBsAb, HBeAb, HbcAb (+), HBV-DNA (-), immune tests and respiratory virus tests were all negative, IgG 8.31g/L, AFP 242ng/ml, FT3 2.11pmol/L, FT4 17.4pmol/L, TSH

E-POSTER ABSTRACTS

<0.005, thyroid peroxidase antibody 158.75IU/ml, and thyroglobulin antibody 56.27 IU/ml.. The abdominal MRI indicates edema and thickening of the gallbladder wall, as well as a small amount of fluid accumulation around the liver and spleen. Upon admission, the patient was considered to have hyperthyroidism combined with subacute liver failure and was treated with medical therapy. However, the patient's liver function deteriorated progressively. Further examinations revealed ceruloplasmin 15 mg/dl and urinary copper 257.6 µg/24 h. An ophthalmological consultation identified K-F rings. The patient was treated with DPMAS plus half-volume plasma exchange therapy for 5 times, combined with comprehensive medical treatment, and continued to receive iodine therapy for hyperthyroidism. Genetic testing revealed a pathogenic variation in the ATP7B gene, with the mutation site being c.2975C>T (p.Pro992Leu). The patient was diagnosed with Wilson's disease, combined with acute-on-chronic liver failure and hyperthyroidism. After artificial liver therapy combined with comprehensive medical treatment, the patient's liver function and coagulation improved, and thyroid function stabilized. The patient is currently taking penicillamine for treatment. Follow-up outpatient examinations showed completely normal liver function and coagulation, as well as normal thyroid function. His daughter also underwent genetic testing and was found to carry the same gene variation.

Conclusions:

Wilson's disease induced acute-on-chronic liver failure is a critical condition, and the combination of hyperthyroidism increases the difficulty of treatment. Liver transplantation is an effective rescue method. In the context of a shortage of liver sources, artificial liver therapy combined with comprehensive medical treatment still achieves very effective treatment results.

Keyword(s) :

2597 - Asthenia Anaemia Liver cirrhosis Brucellosis

Jingjing Wang¹, Jing Liang¹, Hua Liu¹

The Third Central Hospital Of Tianjin, Department Of Gastroenterology And Hepatology, Tianjin-China¹

Background : Brucellosis is a zoonotic disease typically presenting with fever, fatigue, and arthralgia. Atypical afebrile cases with multisystem involvement are easily misdiagnosed, especially when complicated with cirrhosis. This study reports such a case to provide clinical references.

Methods: We report a 43-year-old male with alcoholic cirrhosis presented with fatigue for over one month, accompanied by anemia, shoulder arthritis, lower extremity numbness, dizziness, and hyperpigmentation (no fever/abdominal pain). Laboratory findings: severe anemia (Hb 56g/L, unimproved post-transfusion), elevated immunoglobulins, negative hemolysis screening, polyclonal hypergammaglobulinemia, transudative ascites, and *Brucella* spp. isolated from ascitic fluid culture.

Results: Differential diagnoses (cirrhosis-related anemia, POEMS syndrome, hemolytic anemia) were ruled out. Diagnosis was confirmed by SAAG 2.95g/L, 3-day positive ascitic fluid culture, and serum agglutination test (1:200). Piperacillin-tazobactam (4.5g q8h) for 48h rendered ascitic fluid mNGS negative. After 2-month anti-infective therapy (ceftriaxone/moxifloxacin/doxycycline), Hb improved to 71g/L with ascites absorption; the patient continues moxifloxacin 0.4g QD + doxycycline 0.1g q12h.

Conclusion : Brucellosis' "anemia-ascites-shoulder pain" triad is non-specific. Cirrhotic ascites with SAAG >1.1g/L requires culture (transudate ≠ sterile). Early positive culture indicates high bacterial load. Piperacillin-tazobactam may be effective for abdominal brucellosis, mNGS negativity may relate to technique limitations, reduced bacterial load, or treatment efficacy. Cirrhotic patients with anemia need comprehensive etiology screening.

Keyword(s) : Liver cirrhosis, Brucellosis, Asthenia, Anaemia

2598 - Research on Artificial Liver Treatment for Non Hepatocellular Carcinoma Patients with Severe Immune Checkpoints Related Liver Injury

Hua Liu¹, Junjun Cai¹, Lei Liu¹, Ying Liu¹, Jing Wen¹
Central Hospital, Tianjin University, Gastroenterology And Hepatology, Tianjin-China¹

Background:

As immunotherapy is widely applied in various tumors, immune-related liver injury, as an important part of drug-induced liver injury, has attracted increasing attention. The majority of patients recover liver function after hormone treatment, but patients with poor response to hormone therapy pose a challenge for clinicians.

E-POSTER ABSTRACTS

Materials and Methods:

This study reviewed 18 patients with liver injury caused by immune checkpoint inhibitors who were admitted to Tianjin Third Central Hospital after October 2020. We have meticulously documented the patients' anti-tumor medication usage, clinical biochemical indicators, and artificial liver conditions, and will continue to follow up until December 31, 2025.

Results:

There were 17 males and 3 females with an average age of 62.20 ± 11.18 years. The tumors included 8 cases of lung cancer, 6 cases of gastric cancer, 1 case of esophageal cancer, 1 case of colon cancer, 1 case of soft tissue malignancy, and 1 case of bile duct cancer. Among them, there were 2 patients with chronic viral hepatitis B and 1 patient with liver metastasis. The immune checkpoint drugs used included Tislelizumab, Indilimumab, Carilimumab, Tremelimumab, and Soolilimumab. Upon admission, the patients' liver function tests showed ALT 487.95 ± 291.49 U/L, GGT 637.35 ± 440.93 U/L, TBIL 221.89 ± 98.84 μ mol/L, total bile acid 265.41 ± 150.95 μ mol/L, BUN 7.20 ± 4.44 mmol/L, Cr 73.79 ± 45.92 μ mol/L, NR 1.13 ± 0.44 , IgG 17.41 ± 6.39 g/L, ANA 1:100 in 5 cases, and ANA 1:320 in 1 case. The patients did not respond well to hormone and drug treatments and were all given artificial liver therapy. The modes of artificial liver therapy included plasma exchange, plasma adsorption, dual plasma molecular adsorption, and dual plasma molecular adsorption combined with plasma exchange. The number of treatments ranged from 1 to 20. Among them, 12 patients died, 8 patients survived, and 3 patients resumed immunotherapy.

Conclusions:

Immune checkpoint-related liver injury is a significant adverse reaction affecting the survival of cancer patients. On the one hand, patients may have underlying chronic liver disease that is not screened before cancer treatment. On the other hand, various combination therapies such as chemotherapy and targeted therapy may exacerbate liver injury. Therefore, hormone therapy is ineffective, and patients may even progress to liver failure, with a high mortality rate. Given that cancer patients often do not have the opportunity for liver transplantation, artificial liver therapy may become an important treatment method for rescuing immune-related liver injury.

2599 - Residual metabolic and steatotic risk in chronic viral hepatitis real world evidence from the

Italian PITER cohort

Loreta A. Kondili¹, Luigina Ferrigno¹, Maria Giovanna Quaranta¹, Salvatore Petta², Luca Miele³, Luca Valenti⁴, Alessio Aghemo⁵, Barbara Coco⁶, Francesco Paolo Russo⁷, Mario Masarone⁸, Umberto Vespasiani-gentilucci⁹

Istituto Superiore Di Sanità, Centre For Global Health, Italy-Italy¹ Università Di Palermo, Dipartimento Biomedico Di Medicina Interna E Specialistica, Palermo-Italy² Università Cattolica Del Sacro Cuore, Dipartimento Di Medicina E Chirurgia Traslazionale, Rome-Italy³ Università Degli Studi Di Milano, Dipartimento Di Fisiopatologia Medico-chirurgica E Dei Trapianti, Milan-Italy⁴ Università Humanitas, Dipartimento Scienze Biomediche, Milan-Italy⁵ Azienda Ospedaliero-universitaria Pisana, Unità Operativa Di Epatologia, Pisa-Italy⁶ Università Di Padova, Dipartimento Di Scienze Chirurgiche Oncologiche E Gastroenterologiche, Padua-Italy⁷ Università Di Salerno, Dipartimento Di Medicina, Chirurgia E Odontoiatria "scuola Medica Salernitana", Salerno-Italy⁸ Università Campus Bio-medico, Area Di Medicina Interna Unità Di Epatologia, Rome-Italy⁹

Background / Hypothesis:

In chronic viral hepatitis, liver disease progression is mainly driven by viral injury. However, steatosis and metabolic dysfunction features included in the MASLD construct (BMI ≥ 25 kg/m², diabetes, hypertension, dyslipidemia) may represent an additional residual risk in patients with eradicated HCV RNA, controlled HBV infection, and ongoing chronic HDV infection.

Materials and Methods:

Cross-sectional analysis of a nationwide Italian PITER cohort. We described the demographics, cirrhosis and HCC prevalence, and the distribution of steatosis and metabolic dysfunction features in the cohorts for HCV, HBV, and HDV. In HBV and HCV, we compared the distributions of ALT, GGT, and fibrosis stage between patients with and without steatosis and metabolic dysfunction.

Results:

We evaluated 6,804 HCV, 4,203 HBV, and 694 HDV patients. Median ages were 62, 59, and 56 years, and males accounted for 54.5%, 62.1%, and 61.0%, respectively. Cirrhosis prevalence was 50.5% (HCV), 26.5% (HBV) and 64.5% (HDV); HCC prevalence was 4.0%, 3.1% and 9.8%, respectively. Steatosis prevalence was 31.1% (HCV), 28.2% (HBV) and 23.9% (HDV). Overweight/obesity prevalence was 49.9% (HCV), 53.7% (HBV), and 46.4% (HDV); diabetes 14.3 (HCV)%, 10.1% (HBV), and 7.1% (HDV); hypertension 33.1% (HCV), 22.1% (HBV), and 19.2% (HDV); dyslipidemia

E-POSTER ABSTRACTS

5.3% HCV), 22.0% (HBV), and 13.4% (HDV), respectively. In HBV, compared with patients without steatosis plus metabolic dysfunction features, those with this phenotype were older (63 vs 58 years, $p < 0.001$), more frequently Italian-born (89.7% vs 76.4%, $p < 0.001$), and had higher ALT > 35 (17.9% vs 13.4%, $p = 0.021$), higher GGT > 35 (24.4% vs 13.8%, $p < 0.001$), and higher cirrhosis prevalence (24.5% vs 19.2%, $p < 0.001$).

In HCV, compared with patients without steatosis plus metabolic dysfunction features, those with this phenotype had a significantly different fibrosis stage distribution ($p < 0.001$), with lower F0–F1 (22.6% vs 28.0%) and higher F3 (15.7% vs 11.0%), and F4 (51.3% vs 49.2%).

In multivariable models, steatosis plus metabolic dysfunction features remained independently associated with advanced fibrosis in HBV (adjusted OR 1.36, 95% CI 1.00–1.85) and HCV (adjusted OR 1.28, 95% CI 1.08–1.51), but not in HDV (adjusted OR 0.87, 95% CI 0.52–1.47 for F3–F4/cirrhosis and/or HCC vs F0–F2 and no HCC).

Conclusions:

Steatosis and metabolic dysfunction features are common in viral hepatitis and identify a residual risk phenotype beyond viral injury. This identifies a large, currently under-recognised population that may be eligible for MASH therapies in real-world practice.

Keyword(s) : viral hepatitis, steatosis, metabolic dysfunction, fibrosis, cirrhosis, real world cohort, risk stratification

2603 - Prevalence and Diagnostic Variability in Cirrhotic Cardiomyopathy A Meta analysis

Gizem Dağci ¹, Mehmet Akif Yağlı ¹, Bilger Çavuş ², Filiz Akyüz ², Kadir Demir ¹, Selman Fatih Beşişik ¹, Sabahattin Kaymakoglu ¹

Istanbul University Istanbul Faculty Of Medicine, Department Of Gastroenterology, Istanbul-Türkiye ¹
Istanbul University Istanbul Faculty Of Medicine, Department Of Gastroenterology, Istanbul-Türkiye ²

Background / Hypothesis:

Cirrhotic cardiomyopathy (CCM) is an underrecognized but clinically significant complication in patients with advanced liver disease. Prevalence estimates in the literature vary widely, likely due to inconsistent diagnostic criteria and methodological heterogeneity. In this meta-analysis, we aimed to estimate the pooled prevalence of CCM and evaluate the influence of diagnostic criteria and reported risk factors through subgroup and meta-regression analyses.

Materials and Methods:

A systematic review was conducted to identify studies reporting the prevalence of CCM among adult cirrhotic patients. Seven studies ($n = 1,138$) met the inclusion criteria and were included in the meta-analysis, which was performed using the Jamovi platform with a random-effects model (REML).

Results:

The overall pooled prevalence of CCM was 39.4% (95% CI: 25.4–53.4%). Heterogeneity was low and statistically insignificant ($I^2 = 0\%$, $Q = 3.74$, $p = 0.71$).

Subgroup analysis according to diagnostic criteria revealed notable differences in prevalence: 48.6% in studies using Cirrhotic Cardiomyopathy Criteria 2019 (CCC 2019), 39.6% with the Montreal definition, and 37.2% with classical criteria. This suggests that variability in diagnostic definitions contributes substantially to the reported differences in prevalence. Linear regression using proBNP reporting and age as predictors yielded no statistically significant associations with prevalence ($R^2 = 11.7\%$, $p = 0.78$). QTc interval reporting could not be included in the regression model, as all studies in the dataset reported QTc, leading to insufficient variability for modeling.

Conclusions: In conclusion, the prevalence of CCM remains high at approximately 40%, though diagnostic criteria significantly influence this estimate. Despite low statistical heterogeneity, methodological variability—particularly in diagnostic definitions—limits comparability across studies. There is a clear need for standardized diagnostic criteria in future research to enable more consistent epidemiological characterization and to identify clinically relevant risk factors.

2610 - Comparative Efficacy of Combined Targeted and Immunotherapy Regimens in Unresectable Hepatocellular Carcinoma Impact on Survival and Conversion Surgery Outcomes

Yan Xu ¹, Kai Tan ¹, Xilin Du ¹

Tangdu Hospital, Fourth Military Medical University, Department Of General Surgery, Xi An-China ¹

Background / Hypothesis:

The combination of targeted therapy and immunotherapy has emerged as a pivotal strategy for unresectable hepatocellular carcinoma (uHCC), with the potential to enable conversion surgery. However, comparative outcomes among different regimens and

E-POSTER ABSTRACTS

predictors of long-term survival remain inadequately defined.

Materials and Methods:In this retrospective cohort study, 360 patients with uHCC receiving combined targeted and immunotherapy between January 2020 and September 2025 were included. Patients were stratified into four groups based on regimen: bevacizumab plus PD-1 inhibitor, lenvatinib plus PD-1 inhibitor, donafenib plus PD-1 inhibitor, and apatinib plus PD-1 inhibitor. Overall survival (OS) was analyzed using Kaplan–Meier method and Cox regression. Perioperative outcomes were compared between patients undergoing conversion surgery and those treated with direct resection.

Results:Median OS was 30 months in the bevacizumab group, 28 months in the lenvatinib group, 36 months in the donafenib group, and 30 months in the apatinib group, with no statistically significant difference across groups ($P = 0.373$). Objective response (OR) and subsequent conversion surgery were identified as the strongest prognostic factors. Responders showed significantly longer median OS than non responders (37 vs. 24 months, $P < 0.01$). Patients who underwent conversion surgery achieved a median OS of 51 months, superior to 29 months in those without resection ($P = 0.015$). The conversion therapy group exhibited distinct preoperative alterations, including lower lymphocyte counts, coagulopathy, and elevated transaminases, which were associated with longer operative times and greater intraoperative blood loss.

Conclusions:In patients with uHCC treated with combined targeted immunotherapy, the specific regimen had limited impact on overall survival. Achieving an objective response followed by successful conversion surgery constituted the primary determinant of prolonged survival. The distinct preoperative profile of conversion candidates underscores the need for meticulous perioperative management.

Keyword(s) : Hepatocellular carcinoma; Targeted therapy; Immunotherapy; Conversion therapy; Survival analysis; Hepatectomy.

2611 - Pre emptive Transjugular Intrahepatic Portosystemic Shunt Improves Survival in Advanced Cirrhosis Patients with Gastric Fundal Variceal Bleeding A Multicenter Cohort Study

Jie Xue¹, Guangchuan Wang¹

Shandong Provincial Hospital, Department Of Gastroenterology, Jinan-China¹

Background / Hypothesis:

Although preemptive TIPS (p-TIPS) is the standard of care for high-risk esophageal variceal bleeding, its survival benefit for gastric fundal varices remains uncertain. We aimed to compare the survival outcomes of p-TIPS versus standard care in patients with acute gastric fundal variceal bleeding.

Materials and Methods:

We performed a multicenter, retrospective cohort study of patients with cirrhosis treated for gastric fundal variceal bleeding between June 2019 and June 2024. Patients received either p-TIPS (within 5 days of bleeding) or endoscopic cyanoacrylate injection (ECI) plus NSBB. Propensity score matching (PSM) was used to balance baseline characteristics. The primary endpoint was all-cause mortality.

Results:

The propensity-matched cohort included 836 patients with a median follow-up of 29.2 months. Overall, p-TIPS significantly reduced rebleeding (19.95% vs. 48.53%, $p < 0.001$) and further decompensation (58.32% vs. 77.23%, $p < 0.001$) compared to ECI+NSBB, though overall mortality was similar (26.53% vs. 30.55%, $p = 0.105$). Notably, stratification by liver function revealed a significant survival benefit for p-TIPS in patients with Child-Pugh class B or C (mortality: 28.66% vs. 36.31%, $p = 0.028$), alongside reductions in rebleeding and decompensation. In contrast, for Child-Pugh class A patients, p-TIPS offered no survival advantage (21.89% vs. 15.89%, $p = 0.377$).

Conclusions:

While p-TIPS is superior to ECI+NSBB in preventing rebleeding for all patients with gastric fundal varices, its survival benefit is restricted to those with Child-Pugh class B or C cirrhosis. These findings support the use of p-TIPS as the preferred strategy for high-risk patients, whereas it may be unnecessary for patients with preserved liver function (Child-Pugh A).

Keyword(s) : liver cirrhosis; portal hypertension; gastric varices; TIPS; survival analysis

2613 - Development and validation of a time stratified risk model for acute variceal bleeding in hepatocellular carcinoma

Jiao Qin¹, Li Qiang², Liang Huang¹, Lin Wang¹, Hong Zhang¹

Public Health Clinical Center Of Chengdu, Hepatology,

E-POSTER ABSTRACTS

Chengdu-China ¹ The Affiliated Hospital Of Southwest Medical University, Hepatology, Luzhou-China ²

Background / Hypothesis: Acute variceal bleeding (AVB) in patients with hepatocellular carcinoma (HCC) often delays decision-making regarding tumor-directed therapies. To inform precision clinical decision-making for HCC management, this study aimed to develop and validate a prognostic model using risk factors for AVB occurrence, enabling time-dependent risk stratification of AVB in patients with HCC.

Materials and Methods: A two-center retrospective analysis was performed on patients diagnosed with HCC. A competing risk model was constructed in the training cohort and externally validated in the validation cohort. The primary endpoint was the occurrence of variceal bleeding. The secondary endpoint was all-cause mortality.

Results: Among 457 patients (training cohort: 372 patients; validation cohort: 85 patients), multivariate analysis identified the LDRf classification of esophagogastric varices (hazard ratio [HR], 4.910 [95% confidence interval (CI), 3.594–6.709]), portal vein tumor thrombus grade (HR, 1.628 [95% CI, 1.328–1.997]), and ascites grade (HR, 1.372 [95% CI, 1.139–1.653]) as independent predictors of AVB in HCC. The model stratified patients into low-, medium-, and high-risk groups. In the training cohort, the cumulative incidence of bleeding at 3, 6, 12, and 24 months was (1.5%, 18.0%, 57.6%), (5.1%, 24.0%, 64.7%), (7.3%, 36.0%, 75.3%), and (10.2%, 41.0%, 80.0%), respectively (all $P < 0.0001$). The model demonstrated robust performance in the validation cohort.

Conclusions: The time-dependent risk stratification model based on clinical parameters including the LDRf classification of esophagogastric varices, portal vein tumor thrombus grade, and ascites grade effectively stratifies patients with HCC into distinct risk groups for AVB. By integrating readily accessible clinical parameters, this practical tool holds promise for facilitating and optimizing personalized treatment strategies for patients with HCC.

Keyword(s) : hepatocellular carcinoma, variceal bleeding, risk model, Clinical decision-making

2615 - Liver graft rejection after liver transplantation in Kazakhstan a single center experience

Malika Khassenova¹, Lyazzat Nur¹, Marzhan Zhanasbayeva¹

National Research Oncology Center, Department Of Hepatology And Gastroenterology, Astana-Kazakhstan
¹

Background / Hypothesis: Liver graft rejection remains a common and clinically relevant complication after liver transplantation (LT). Despite advances in immunosuppressive therapy, rejection rates and outcomes vary across centers. This study aimed to identify predisposing factors and evaluate treatment response after liver transplantation.

Materials and Methods: Clinical data of 127 patients following LT at our center between January 2013 and December 2025 were retrospectively analyzed.

Results: Rejection was observed in 29 LT recipients (45 episodes) - 14 women and 15 men. 34 episodes were acute liver rejection (ACR) and 11 were chronic liver rejection (CR). Living donor liver transplantation was performed in 71.4% of cases, while 28.6% underwent deceased donor liver transplantation.

The mean age at transplantation was 42 years (range 23-63). HBV/HDV co-infection (44.8%) and primary biliary cholangitis (10.3%) were the most common cause of end stage liver disease.

In univariate analysis, subtherapeutic tacrolimus concentrations and non-compliance with immunosuppressive therapy (57.78%), biliary complications (42.22%) were significantly associated with graft rejection.

Late acute rejection (>91 days) predominated among ACR episodes (n = 25). Liver biopsy according to the Banff criteria was performed in 24 cases of ACR, with mild (50%, n = 12), moderate (37.5%, n = 9), and severe rejection (12.5%, n = 3) based on the rejection activity index (RAI). In 10 cases, ACR was diagnosed clinically.

Pulse corticosteroid therapy was administered in 24 cases of ACR, and was successful in 66.7% cases. Among non-responders, antithymocyte globulin therapy was initiated in 4 patients and was effective in 2 of them. 9 ACR cases treated with immunosuppressive escalation, a response was achieved in 78% of them.

Statistically significant changes were detected in liver function tests + ALT, AST, total bilirubin, ALP ($p < 0.05$).

E-POSTER ABSTRACTS

All 11 cases of CR were managed by adjustment of immunosuppressive therapy, without clinical response. 5 patients required LT.

Overall survival rates at 1, 3, and 5 years after rejection were 54.8% (95% confidence interval [CI]: 38.4–78.1%), 48.7% (95% CI: 31.9–74.3%), and 36.5% (95% CI: 20.4–65.4%), respectively.

Conclusions: In our study, late ACR was more frequently observed among episodes of acute liver graft rejection. The most common predisposing risk factors were biliary complications and non-compliance with immunosuppressive therapy. ACR generally showed a good response to pulse corticosteroid therapy. In contrast, CR was poorly responsive to medical treatment and frequently required liver retransplantation.

Keyword(s) : Acute rejection, Chronic rejection, Liver transplantation, Immunosuppression

2616 - The influence of hepatitis HBV HCV and HDV viruses on the development of sarcopenia in patients with liver cirrhosis

Ramilya Abdieva¹

Clinic Of The Virology Research Institute Of The Republican Specialized Scientific And Practical Medical Center For Epidemiology, Microbiology, Infe, Department Of Chronic Hepatitis And Liver Cirrhosis, Tashkent-Uzbekistan ¹

Background / Hypothesis:

The presence of long-term chronic liver disease contributes to the development and progression of muscle mass and strength disorders. The number of patients with sarcopenia increases with the progression of liver cirrhosis (LC). In our study, we investigated how HBV, HCV, and HDV viruses affected the development of sarcopenia in patients with LC.

Materials and Methods:

During the period from 2021 to 2024, we consistently included into the study patients with verified LC of HBV, HCV, and HDV aetiology. All patients were divided into grades of LC according to the Child-Pugh (Ch-P) scale in agreement with the criteria. Patients underwent assessment of body mass index (BMI); handgrip strength (less than 20 kg in women, less than 30 kg in men); muscle mass assessment using computed tomography (CT) of native images at the middle of the L3 transverse section of the spinal column (less than 55 cm²/m² for men and less than 39 cm²/m² for women).

Results:

Among 73 patients with liver cirrhosis grade A on the

Ch-P scale, there were 26 patients, with grade B – there were 34, and with grade C – there were 14. It was found that sarcopenia was present in 31% of cases with LC. According to the severity of LC, sarcopenia was found in 6 (8%) patients with Ch-P grade A and in 23% of cases with grades B and C. Regardless of the etiology, it was 1.2 times more common in patients who had both HBV and HDV (95% CI: 0.23-6.90; p=1). In the group of patients with sarcopenia, viral hepatitis was diagnosed on a median of 2009 ± 2.3 years, and in patients without sarcopenia, on a median of 2013 ± 2.5 years (p=0.26). Early onset of viral hepatitis, on average 4 years with a high viral load of HBV DNA 6.9 log₄ ± 6.9 log₄ IU/ml, led to the development of sarcopenia in 57% of cases.

Conclusions:

Perhaps the increase in the incidence of sarcopenia is associated with progressive destruction of hepatocytes during active replication of HBV viruses, impaired detoxification function of the liver, high levels of ammonia in the blood, and the presence of portal hypertension. Consequently, patients need to receive effective antiviral therapy against viral hepatitis with monitoring of HBV DNA levels in the blood.

Keyword(s) : liver cirrhosis, sarcopenia, viral hepatitis

2618 - Alistipes putredinis Alleviates Metabolic Associated Fatty Liver Disease via the Acetate GPR43 Axis by Suppressing Neutrophil ROS Generation

Feihu Bai Bai Feihu¹, Daya Zhang Zhang Daya ¹

The Second Affiliated Hospital Of Hainan Medical University, Department Of Gastroenterology, Haikou-China ¹

Background / Hypothesis:

Intestinal dysbiosis contributes to the pathogenesis of metabolic-associated fatty liver disease (MAFLD), though precise bacterial targets and mechanisms remain incompletely elucidated. This study investigated whether the depletion of *Alistipes putredinis* (AP) in adolescents obesity-associated MAFLD is causally linked to disease progression and aimed to delineate its downstream signaling pathway.

Materials and Methods:

Fecal samples from 29 obese adolescents with MAFLD and 17 healthy controls in Hainan Province were analyzed by metagenomic sequencing. A high-fat diet-induced MAFLD mouse model was established and

E-POSTER ABSTRACTS

randomized into control, MAFLD, and AP-gavaged groups (12 weeks). Untargeted metabolomics and targeted short-chain fatty acid profiling were performed on fecal, hepatic, and AP culture supernatant samples. Liver transcriptomics, Western blot, and co-immunoprecipitation were employed to identify and validate involved molecular pathways.

Results:

AP abundance was significantly lower in MAFLD patients compared with controls. AP supplementation ameliorated hepatic lipid accumulation in MAFLD mice. Metabolomic analysis identified acetate as the principal mediator of AP's protective effects. Acetate derived from AP activated the GPR43 receptor on hepatic neutrophils, inhibiting intracellular Ca^{2+} flux and NADPH oxidase 2 (NOX2) activity, thereby reducing reactive oxygen species (ROS) generation. Reduced ROS levels attenuated JNK phosphorylation, decreased LXR α binding to the SREBP-1c promoter, and suppressed proteolytic activation of SREBP-1c, leading to downregulation of key lipogenic enzymes ACC1 and FASN.

Conclusions:

Alistipes putredinis ameliorates MAFLD via acetate-mediated activation of the GPR43 receptor on hepatic neutrophils, which suppresses the Ca^{2+} -NOX2-ROS signaling cascade and inhibits ROS-dependent SREBP-1c activation and lipogenic gene expression. These findings reveal a previously unrecognized gut microbiota-neutrophil signaling axis as a potential therapeutic target in MAFLD.

2621 - Construction and Evaluation of a Nobiletin Hepatic Targeted Nanodelivery System for the Treatment of MASLD

妍 娄¹

Jiangsuprovince Hospital Of Chinesemedicine, Endocrinology, 南京市-China¹

Background:

The disease spectrum of MASLD encompasses a continuous pathological progression from simple hepatocellular steatosis, to MASH accompanied by hepatocyte injury and inflammation, and further to liver fibrosis, cirrhosis, and even hepatocellular carcinoma.

The four key pathological components, namely lipotoxicity, hypoxia, inflammation, and fibrosis, do not advance in a linear manner; instead, they constitute a tightly coupled, self-amplifying vicious network cycle. Interventions targeting any single node can be counteracted by other persistently active driving forces within the cycle, which explains why numerous therapeutic strategies directed at a single target have exhibited limited efficacy in clinical trials. Therefore, the development of novel therapeutic strategies capable of concurrently intervening at multiple nodes and exerting the potential to break this cycle has become an urgent need and a major focus of current research.

Materials and Methods:As a natural polymethoxylated flavonoid extracted from citrus peels, nobiletin has exhibited multifaceted ameliorative effects against MASLD/MASH in numerous preclinical studies. Its pharmacological mechanisms involve multiple processes associated with the aforementioned vicious cycle, including antioxidation, anti-inflammation, regulation of lipid metabolism, and potential anti-fibrotic activity. Nanozyme-based delivery platforms present unique and integrative advantages, which elevate them beyond conventional carriers to act as an integrated "theranostic-delivery" or "therapy-delivery" system. The core value of nanozymes lies in their intrinsic enzyme-mimetic catalytic activity. A mild in situ hydrofluoric acid generation etching method is commonly employed. Using Ti3AlC2 MAX phase as the precursor, a mixed solution of hydrochloric acid and lithium fluoride is utilized as the etchant. LiF reacts with HCl to generate HF in situ, and the Al atomic layers are selectively etched away under controlled conditions, yielding multilayered Ti3C2Tx MXene (where T denotes surface terminal groups, i.e., -OH, -O, and -F). Residual etchant and byproducts are removed via repeated centrifugation and washing. Subsequently, gentle ultrasonication or an intercalation-exfoliation process is performed under inert gas protection to further delaminate the multilayered MXene into few-layered or single-layered nanosheets, so as to achieve a larger specific surface area and more active edge sites. A stably dispersed colloidal solution of few-layered MXene is obtained by centrifugation, or the product is freeze-dried into powder for subsequent use.

Results Conclusions:Nanomaterials can break the pathological vicious cycle mediated by lipotoxicity, play a role in

2622 - Itaconic acid improves MASH through regulating ferroptosis by Nrf2 HO 1

Shaoya Li¹, Jiawei Cui¹, Zhandong Lin¹, Qianqian Zheng¹, Yikang Song¹, Yukai Chen¹, Yaoyao Mao¹, Yue Shi¹, Congyue Zhang¹, Xiangxin Chen¹, Yuemin Nan¹

Hebei Medical University, Department Of Traditional And Western Medical Hepatology, Shijiazhuang-China¹

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) is one of the most prevalent chronic liver diseases worldwide. Its pathogenesis is complex and not yet fully elucidated, and there are currently no widely accepted disease-specific therapeutic agents. In recent years, itaconate has attracted increasing attention because of its anti-inflammatory and antioxidant properties. Accumulating evidence indicates that ferroptosis is involved in the initiation and progression of MAFLD, and that inhibition of ferroptosis can alleviate disease severity. However, whether itaconate mitigates MAFLD through the regulation of ferroptosis remains unclear.

Materials and Methods:

An in vivo MASH model was established by feeding wild-type mice and myeloid-specific ACOD1 knockout mice a high-fat, high-sugar, high-cholesterol diet for 21 weeks, followed by intervention with 4-octyl itaconate (4-OI). In parallel, an in vitro MASH model was generated by incubating AML-12 cells with free fatty acids for 24 hours.

Results:

Compared with control mice, myeloid-specific ACOD1 knockout mice exhibited more pronounced hepatic steatosis, inflammation, and fibrosis, accompanied by enhanced oxidative stress, aggravated mitochondrial damage, and increased ferroptosis, along with marked downregulation of the Nrf2/HO-1 signaling pathway. In contrast, intraperitoneal administration of 4-OI significantly attenuated GAN diet-induced hepatic steatosis and inflammation, and alleviated mitochondrial damage and ferroptosis. In vitro, 4-OI similarly improved steatosis, inflammatory responses, lipid metabolic dysregulation, and ferroptosis in the NASH cell model, whereas silencing Nrf2 partially reversed the protective effects of 4-OI.

Conclusions: Collectively, these findings suggest that itaconate exerts a protective effect against GAN diet-induced hepatotoxicity by activating Nrf2-dependent antioxidant pathways and suppressing ferroptosis, providing new mechanistic insights into potential therapeutic targets for MAFLD.

Keyword(s) : MAFLD, Nrf2, ferroptosis, oxidative stress

2624 - Risk Factors for Liver Fibrosis Severity in Patients with Nonalcoholic Steatohepatitis A Study Based on Liver Pathology

Pengyu Pan¹, Chunyan Wang¹

Tianjin Medical University, Tianjin Second People Hospital, Tianjin-China¹

Background / Hypothesis:

To identify independent risk factors associated with the severity of liver fibrosis in patients with nonalcoholic steatohepatitis (NASH) based on liver pathology results.

Materials and Methods:

A retrospective analysis was conducted on 122 patients diagnosed with NASH via liver biopsy at Tianjin Second People's Hospital between December 2014 and December 2024. Clinical, laboratory, and pathological data were collected. Patients were categorized into F1, F2, and F3 stages based on fibrosis scores. Univariate analysis was used to compare variables across fibrosis and liver pathology stages. We used the Kappa statistic to evaluate the consistency between LSM findings and pathological liver fibrosis staging. Ordinal logistic regression with backward stepwise selection was applied to identify independent risk factors, with odds ratios (ORs) and 95% confidence intervals (CIs) calculated.

Results:

1.The mean age of participants was 41.6 ± 14.2 years, with 66 males (54.1%).According to fibrosis staging, there were 21 cases (17.2%) in F1 stage, 86(70.5%) in F2 stage, and 15(12.3%) in F3 stage. 2. Liver pathology in all groups showed that with the progression of liver fibrosis, the degree of hepatocellular steatosis and interlobular inflammation in all three groups tended to worsen, with statistically significant differences ($P < 0.05$). There was no statistically significant difference in the degree of ballooning degeneration among the three groups.3.Contingency Table Analysis showed that the overall concordance rate between

E-POSTER ABSTRACTS

LSM measurement results and pathological liver fibrosis staging was 48.4%, with an underestimation rate of 37.7%. Agreement analysis showed poor consistency between LSM and pathological fibrosis staging (Kappa=0.206). 4. ALT and AST levels increased significantly with the progression of hepatocellular steatosis, while only AST levels increased significantly with the progression of interlobular inflammation. These differences were statistically significant ($P < 0.05$). Among patients with different degrees of ballooning degeneration, AST levels showed marginal significance ($P=0.068$). 5. Ordinal logistic regression identified lobular inflammation (OR=5.058, $P<0.001$), hepatic steatosis (OR=2.768, $P=0.003$), diabetes (OR=3.815, $P=0.021$), and elevated LDL levels (OR=1.669, $P=0.025$) as independent risk factors associated with the severity of liver fibrosis in patients with NASH.

Conclusions:

Lobular inflammation, hepatic steatosis, diabetes, and elevated LDL levels are independent risk factors associated with the severity of liver fibrosis in patients with NASH.

Beni Suef, Endemic Medicine, Cairo-Egypt⁶

Background / Hypothesis:

Thrombocytopenia (TP) is the earliest and most common cytopenia in patients with liver cirrhosis (LC), with a reported prevalence of up to 77%. TP may interfere with routine clinical care by delaying or complicating diagnostic and therapeutic procedures. Elevated circulating endotoxins and pro-inflammatory cytokines in LC contribute to increased platelet consumption and the development of TP. Rifaximin is a non-absorbable, broad-spectrum antibiotic targeting aerobic and anaerobic Gram-positive and Gram-

negative gastrointestinal microorganisms, and its administration has been associated with reduced endotoxemia.

The study aimed to assess the effect of intestinal decontamination with rifaximin on thrombocytopenia in patients with hepatitis C-related liver cirrhosis

Materials and Methods:

This randomized controlled clinical trial included 165 cirrhotic patients with thrombocytopenia attending hepatology clinics at two tertiary hospitals in Egypt. Cirrhosis severity was assessed using the Child-Pugh classification. Inclusion criteria were: absence of active bacterial infection; no history of variceal bleeding within two weeks before enrollment; no antibiotic use (including rifaximin) or cytokine-modifying agents within eight weeks before enrollment; absence of neoplasia, including hepatocellular carcinoma; and no red blood cell or plasma transfusion within one month before enrollment. Thrombocytopenia was classified as mild ($>75,000/\text{mm}^3$), moderate ($50,000-75,000/\text{mm}^3$), or severe ($<50,000/\text{mm}^3$).

Patients were randomized into two groups: group A ($n=85$) received rifaximin 550 mg twice daily for four weeks, while group B ($n=80$) served as the control group and did not receive rifaximin. All patients underwent baseline clinical evaluation and laboratory investigations, including complete blood count, liver function tests, and renal function tests. Platelet counts were reassessed after four weeks.

Results:

Mean platelet count increased significantly in the rifaximin group compared with the control group (median increase of 14.5%, $p < 0.001$). A significant improvement in platelet count was observed in patients with Child-Pugh class B and C cirrhosis ($p < 0.001$), whereas no significant change was observed in patients with Child-Pugh class A cirrhosis ($p=0.506$). A greater increase in platelet count was observed in patients with moderate to severe thrombocytopenia (24.6%) than in those with mild thrombocytopenia (8.1%).

Conclusions:

Rifaximin therapy significantly improves thrombocytopenia in patients with advanced hepatitis

2629 - Clinical characteristics and risk factors for early liver function abnormalities in young adults with MAFLD

Songting Wu¹, Guangyao Zhao², Jingyuan Xu³, Xiaolan Lu¹

Shanghai Pudong Hospital, Gastroenterology, Shanghai-China¹ Hongmei Community Health Service Center, General Practice, Shanghai-China² Suzhou Municipal Hospital, Gastroenterology, Suzhou-China³

Background / Hypothesis: Metabolic dysfunction-associated fatty liver disease (MAFLD) is increasingly prevalent among young adults, yet early liver function abnormalities are often overlooked. We aimed to identify risk factors for early liver function abnormalities in young adults with MAFLD.

Materials and Methods: A total of 1008 young adults (18-45 years) with MAFLD detected during health examinations at Fudan University Pudong Medical Center were retrospectively analyzed. Participants were categorized into abnormal (n=506) and normal (n=502) liver function group. Variables significant in univariate analysis were further refined using least absolute shrinkage and selection operator (LASSO) regression and multivariate logistic regression.

Results: The prevalence of MAFLD among young adults was 19.9%, with 33.1% showing early liver function abnormalities—significantly higher than in middle-aged and older adults (33.1% vs 15.6%, $P < 0.05$). The degree of alanine aminotransferase elevation was closely associated with metabolic disturbances, with central obesity, hypercholesterolemia, and hyperuricemia significantly more prevalent in the moderate and severe elevation groups. Independent risk factors included waist circumference ($P < 0.001$, OR = 1.034), hemoglobin ($P < 0.001$, OR = 1.043), uric acid ($P < 0.001$, OR = 1.005), and low-density lipoprotein cholesterol ($P < 0.001$, OR = 2.04) as independent risk factors, while age ($P = 0.008$, OR = 0.967) and high-density lipoprotein cholesterol ($P = 0.001$, OR = 0.267) were protective.

Conclusions: Early liver function abnormalities are common in young adults with MAFLD. Identifying modifiable metabolic risk factors facilitates early stratification and timely intervention to delay or reverse disease progression.

2631 - High ammonia promotes EHHADH dependent pyrimidine degradation to induce inflammatory cell death in HCC

Jinhui Wei¹, Chuanzhao Zhang², Baohua Hou³, Shanzhou Huang²

Guangdong Provincial People's Hospital, Guangdong Cardiovascular Institute, Guangzhou-China¹ Southern Medical University, Department Of General Surgery, Guangdong Provincial People's Hospital, Guangzhou-China² Maoming People's Hospital, Department Of Hepatological Surgery, Maoming-China³

Background / Hypothesis

Metabolic reprogramming characterizes Hepatocellular Carcinoma (HCC), where urea cycle disruption leads to ammonia buildup in the liver. Ammonia influences tumor cells differently based on its concentration: low levels encourage tumor growth, while high levels are toxic and can cause cell death. Given that high systemic ammonia correlates with poor patient outcomes, this study seeks to identify targets involved in ammonia-induced HCC cell death to create new treatments.

Materials and Methods:

We developed a new transgenic HCC mouse model on a high-ammonia diet and analyzed the role of the high-ammonia-induced gene EHHADH in cell death through metabolomics, metabolic flux analysis, transcriptomics, proteomics, and modification-omics. Cell viability was measured by LDH and HMGB1 release, with inflammatory cell death visualized via electron microscopy. Dihydropyrimidine Dehydrogenase (DPYD) activity was assessed through protein purification and enzymatic assays. We also explored how EHHADH overexpression affects the HCC immune microenvironment using single-cell RNA sequencing. Lastly, we evaluated the therapeutic potential of combining an EHHADH agonist with an anti-PD-1 monoclonal antibody in vivo.

Results:

High ammonia treatment effectively inhibited HCC tumor growth by inducing inflammatory cell death marked by Cleaved-Caspase-3 and GSDME-N. This process involved the accumulation of polyunsaturated fatty acids (PUFAs), which activated PPARA to increase EHHADH expression. Elevated EHHADH boosted peroxisomal ROS production and disrupted the mitochondrial TCA cycle, leading to cytosolic Acetyl-CoA accumulation. This shift caused DPYD acetylation, enhancing its activity and accelerating pyrimidine catabolism, resulting in nucleotide depletion and

E-POSTER ABSTRACTS

replication stress, which ultimately triggered GSDME-dependent pyroptosis. Furthermore, targeting EHHADH-mediated inflammatory cell death substantially augmented the infiltration of phagocytes and CD8⁺ T cells into the tumor microenvironment (TME), thereby synergistically enhancing the efficacy of anti-PD-1 immunotherapy.

Conclusions:

This study elucidates a novel "Metabolic-Immune" axis in which elevated ammonia levels exploit the PPAR- α -EHHADH signaling pathway to promote pyrimidine catabolism and replication stress, consequently inducing inflammatory cell death. Targeting EHHADH emerges as a promising therapeutic strategy to inhibit tumor growth and enhance the sensitivity of hepatocellular carcinoma to immune checkpoint blockade therapy.

The First Affiliated Hospital Of Kunming Medical University, Yunnan Institute Of Digestive Disease, Kunming-China ¹

Background / Hypothesis: Metabolic dysfunction-associated fatty liver disease (MAFLD) has become a global health issue due to its high prevalence and widespread health consequences. The spleen-strengthening and lipid-regulating herbal formula (JPTZ), a traditional Chinese preparation, is used to treat hyperlipidemia, obesity, and even MAFLD, but its molecular mechanisms remain unclear.

Materials and Methods: Clinically, data on various indicators were collected, including body weight, waist circumference, plasma lipids, fasting glucose and insulin, HbA1c, liver and renal function tests, complete blood count, and FibroTouch test, both before and after a 3 - month administration of JPTZ in patients with MAFLD, in order to assess its efficacy and safety in the treatment of MAFLD. For basic research, establish a mouse model of MAFLD to evaluate the therapeutic efficacy of JPTZ and determine the key regulatory pathways through which JPTZ improves MAFLD via mRNA sequencing. Subsequently, HPLC-QTOF/MS and ADMET rules were utilized to identify the candidate bioactive constituents in JPTZ, and the corresponding

putative targets were predicted via the TCMIP platform. An interaction network was constructed to link MAFLD-related differentially expressed genes and JPTZ's putative targets, and to screen the key targets using CytoScape, which were verified through a series of in-vivo experiments.

Results: JPTZ significantly improves abnormal liver function and lipid metabolism disorders in MAFLD patients, as well as FibroTouch examination parameters. In animal studies, JPTZ alleviated hepatic steatosis, liver injury, and fibrosis in high-fat diet-induced MAFLD mice, while improving their glucose tolerance and insulin resistance. Chemical profiling identified 178 constituents in JPTZ, 43 of which met the optimal ADMET criteria. The transcriptomic results indicated that the PPAR signaling pathway was one of the key pathways through which JPTZ exerted its effects. The experiments further verified that JPTZ directly bound to PPAR α and PPAR γ , activated downstream signaling, regulated lipid metabolism, and alleviate inflammatory response.

Conclusions: JPTZ is a potential pan-PPAR agonist that improves lipid metabolism and alleviates inflammation by modulating the PPAR pathway, thereby treating MAFLD and offering a novel therapeutic strategy for this condition.

2633 - Chylous Ascites in Liver Cirrhosis Diverse Mechanisms Diagnostic Challenges and Multidisciplinary Management — A Case Series

Christine Velasquez ¹, Fatima Anne Apacible ², Floen Michael Enriquez ², Sharlene Nicole Chan ², Madaline Eternity Labio ³, Angelo Jonathan Cruz ³, John Derek Clutario ¹

Makati Medical Center, Gastroenterology, Makati-Philippines ¹ Makati Medical Center, Internal Medicine, Makati-Philippines ² Makati Medical Center, Hepatology, Makati-Philippines ³

Background:

Chylous ascites (CA), defined as triglyceride-rich milky peritoneal fluid (>200 mg/dL), is an uncommon but clinically significant complication of advanced liver disease, accounting for approximately 1 in 20,000 hospital admissions. In cirrhosis, CA may result from portal hypertension-related lymphatic rupture, malignancy-associated obstruction, or iatrogenic lymphatic injury. Because its presentation may mimic

E-POSTER ABSTRACTS

refractory or infected ascites, delayed recognition can lead to repeated procedures, malnutrition, and poor outcomes. We describe the clinical spectrum, mechanisms, and management challenges of CA in cirrhotic patients.

Methods:

We conducted a descriptive case series of three adults with established cirrhosis who developed CA. Clinical features, imaging, ascitic fluid analysis, etiologies, treatment strategies, and outcomes were reviewed. Diagnosis was confirmed by diagnostic paracentesis demonstrating elevated ascitic triglycerides.

Results:

All patients presented with progressive abdominal distension and turbid or milky ascites. Ascitic triglyceride levels ranged from 248 to 1,356 mg/dL. Etiologies included lymphatic obstruction from non-Hodgkin lymphoma with cirrhosis, portal hypertension with repeated paracentesis-related lymphatic trauma, and metabolic dysfunction-associated steatotic liver disease-related cirrhosis complicated by hepatohydrothorax. Management targeted the underlying cause and included chemotherapy, sodium restriction, diuretics, medium-chain triglyceride-based low-fat diet, albumin, octreotide, and serial therapeutic paracentesis. Resolution or reduction of chylous output was achieved in two patients, while one progressed with cirrhosis-related complications.

Conclusion:

Chylous ascites represents a rare but important manifestation of decompensated cirrhosis with heterogeneous mechanisms. Routine triglyceride analysis of atypical or turbid ascites facilitates early diagnosis. A multidisciplinary, etiology-directed approach combining nutritional, pharmacologic, and disease-specific therapy may reduce morbidity and unnecessary invasive interventions.

Keyword(s) : chylous ascites, cirrhosis, portal hypertension, MASLD, case series

2636 - Macrophage ACAT1 aggravates alcoholic hepatitis by inducing mitochondrial damage and NLRP3 activation

Xi Zhao ¹, Qiang Zhu ², Yingchun Wang ³, Ping Yao ¹, Shiyu Peng ¹

The First Hospital Of Xinjiang Medical University, Gastroenterology, Urumqi-China ¹ Provincial Hospital Of Shandong First Medical University, Infection, Jinan-China ² Provincial Hospital Of Shandong First Medical

University, Gastroenterology, Jinan-China ³

Background / Hypothesis:

ALD is caused by chronic excessive alcohol consumption, with current clinical treatments limited and ineffective. As a key esterification enzyme in macrophages, ACAT1 mediates cholesterol esterification involved in inflammatory regulation. This study investigated the expression, function and associated pathway enrichment of ACAT1 in ALD, and further verified that ACAT1 modulates alcohol- and LPS-induced macrophage inflammation by inducing mitochondrial damage to activate the NLRP3 inflammasome, so as to explore its potential as a therapeutic target for ALD.

Materials and Methods:

In vitro, macrophages were stimulated with alcohol plus LPS; Western blot and RT-qPCR detected the protein and mRNA levels of ACAT1 and NLRP3 inflammasome-related inflammatory molecules, and immunofluorescence co-localization verified the expression of F4/80 and ACAT1. Flow cytometry assessed ROS, mtROS and MMP, TEM observed mitochondrial morphology, and transcriptome sequencing analyzed ALD-associated signaling pathways. Additionally, ACAT1 inhibition by K-604 and knockdown by siRNA were performed to evaluate its regulatory effects on inflammatory molecules in macrophages. In vivo, an ALD mouse model was established and treated with K-604 inhibitor and clodronate liposomes; liver histopathology was examined by H&E, Oil Red O and ROS immunofluorescence staining, and liver function was evaluated via ALT, AST levels and liver-to-body weight ratio. RT-qPCR and Western blot quantified ACAT1 and inflammatory factor expression in liver tissues, while ELISA detected serum inflammatory factors and triglyceride levels in mice.

Results:

- (1) ACAT1 mRNA and protein were significantly upregulated in the ALD model; in E+L-stimulated macrophages, ACAT1 was synchronously elevated with the macrophage marker F4/80 and colocalized with it.
- (2) E+L significantly upregulated the transcriptional and protein levels of proinflammatory factors and NLRP3 inflammasome-related molecules in macrophages; ACAT1 inhibition/knockdown reversed

E-POSTER ABSTRACTS

this effect, whereas its overexpression further promoted their expression.

(3) E+L induced increased ROS and mtROS production, mitochondrial damage, and lipid droplet accumulation in macrophages, which were significantly ameliorated by K-604. Transcriptome sequencing identified the NOD-like receptor signaling pathway as a key ACAT1-regulated differential pathway in ALD.

(4) In vivo, hepatic ACAT1 expression was significantly elevated in ALD model mice. Macrophage depletion or K-604 administration significantly reduced hepatic ALT, AST, TG and ROS levels, diminished lipid deposition, and downregulated hepatic proinflammatory factors.

Conclusions:

ACAT1 is highly expressed in macrophages and acts as a key regulator of ALD inflammation. It induces mitochondrial damage to activate the NLRP3 inflammasome, promoting the expression and release of proinflammatory cytokines and ROS, and enhancing lipid deposition to exacerbate macrophage inflammation.

Keyword(s) : ALD, ACAT1, NLRP3, mitochondrial damage

2637 - Predictors of minimal clinically important improvement in cardiorespiratory fitness following unsupervised exercise training in metabolic dysfunction associated steatotic liver disease

Ping-lun Hsieh ¹, Li-ying Wang ², Chun-jen Liu ³
National Taiwan University Hospital, Physical Therapy Center, Taipei City-Taiwan ¹ National Taiwan University, School And Graduate Institute Of Physical Therapy, Taipei City-Taiwan ² National Taiwan University Hospital, Hepatitis Research Center, Taipei City-Taiwan ³

Background: Our previous randomized controlled trial showed that patients with metabolic dysfunction-associated steatotic liver disease (MASLD) following unsupervised high-intensity interval training (HIIT) and moderate-intensity continuous training (MCT) showed varied improvement in cardiorespiratory fitness and exercise performance. This study aimed to identify factors associated with the improvement in cardiorespiratory fitness which reached minimal clinically important difference (MCID) following HIIT or MCT in this patient population.

Materials and Methods: We analyzed data from a randomized controlled trial which recruited 95 patients with MASLD who were randomly assigned to an

unsupervised HIIT or MCT program for 24 weeks. Ninety-four participants with complete data at baseline and at week 24 were included in this study. Participants exhibiting a change in peak oxygen consumption ($\dot{V}O_{2peak}$) of ≥ 1 metabolic equivalent (MET) following exercise training were classified as responders and all others were classified as non-responders. Univariate binary logistic regression analyses were performed to screen for independent variables with a p value < 0.10 . These selected variables were further entered multivariate binary logistic regression model to identify predictors associated with clinically important improvement in $\dot{V}O_{2peak}$. The significance level was set at p < 0.05 .

Results: Thirty-eight patients exhibited clinically important improvement in their $\dot{V}O_{2peak}$ (2.1 ± 0.9 MET) following exercise training and were classified as the responders, with 25 patients (65.8%) from the HIIT group and 13 patients (34.2%) from the MCT group. After adjustment for age, sex, and baseline body mass index, patients undergoing HIIT, compared with MCT, had higher odds of reaching MCID in $\dot{V}O_{2peak}$ following exercise training (adjusted odds ratio [aOR] 6.30, 95% confidence interval [CI] 2.11–18.81, p = 0.001). Higher exercise adherence (aOR 1.04, 95% CI 1.02–1.06, p < 0.001) and baseline step counts < 10000 steps/day (aOR 4.87, 95% CI 1.07–22.26, p = 0.041) were also independently associated with greater odds of reaching MCID in $\dot{V}O_{2peak}$ following exercise training, while higher baseline cardiorespiratory fitness ($\dot{V}O_{2peak}$ expressed in MET unit) lowered the odds of clinically significant improvement in $\dot{V}O_{2peak}$ (aOR 0.65, 95% CI 0.45–0.93, p = 0.020).

Conclusions: These findings suggest that patients with MASLD who underwent HIIT, demonstrated higher adherence to exercise training, and had lower baseline physical activity levels are more likely to reach minimal clinically important improvement in cardiorespiratory fitness after 24 weeks of unsupervised exercise training, while higher baseline cardiorespiratory fitness reduces this likelihood.

Keyword(s) : Metabolic dysfunction-associated steatotic liver disease, high-intensity interval training, moderate-intensity continuous training, cardiorespiratory fitness, minimal clinically important improvement

2638 - Machine learning prediction of functional cure to pegylated interferon alpha therapy in two HBV populations advantaged populations and HBeAg negative patients

Jiajie Li ¹, Huilin Li ², Caorui Lin ³, Renquan Jiang ⁴,

E-POSTER ABSTRACTS

Longfei Wang ¹, Yujue He ⁴, Xin Yang ⁴, Kaitao Gong ¹,
Zhen Xun ⁴, Qi Zheng ¹

The First Affiliated Hospital Of Fujian Medical University, Department Of Hepatology, Hepatology Research Institute, Fuzhou, Fujian Province-China ¹ Fujian Medical University, School Of Medical Technology And Engineering, Fuzhou, Fujian Province-China ² The Second Hospital, Cheeloo College Of Medicine, Shandong University, Department Of Clinical Laboratory, Jinan, Shandong-China ³ The First Affiliated Hospital Of Fujian Medical University, Department Of Laboratory Medicine, Fujian Key Laboratory Of Laboratory Medicine, Fuzhou, Fujian Province-China ⁴

Background / Hypothesis: Achieving a functional cure (sustained HBsAg loss) in chronic hepatitis B (CHB) remains a challenge. We aimed to develop and validate baseline prediction models using routine clinical indicators to identify HBeAg-negative patients, particularly the guideline-defined "advantaged population", who are most likely to achieve functional cure with pegylated interferon-alpha (PEG-IFN α) therapy.

Materials and Methods: This retrospective study included 202 HBeAg-negative CHB patients (114 advantaged) for derivation/internal validation and 183 external patients (117 advantaged) for validation. From 48 baseline variables, key predictors were selected via LASSO regression. Two nomogram models were constructed using multivariable logistic regression: the SHAN model for all HBeAg-negative patients and the FLASH-N model specifically for the advantaged population.

Results: The SHAN model, based on four predictors (log(HBsAg+1), age, neutrophil percentage, sex), achieved areas under the curve (AUCs) of 0.908 (training) and 0.949 (testing). The FLASH-N model, incorporating two additional variables (alpha-fetoprotein, lactate dehydrogenase), showed an AUC of 0.920 (bootstrap-corrected 0.889). In external validation, the SHAN and FLASH-N models maintained robust discriminative ability with AUCs of 0.861 and 0.800, respectively. Both models demonstrated excellent calibration and provided superior clinical net benefit in decision curve analysis.

Conclusions: We developed two practical nomograms using readily available baseline variables. These models effectively predict the probability of functional cure with PEG-IFN α therapy, offering valuable tools for personalized clinical decision-making and refined risk stratification in HBeAg-negative and advantaged CHB patients.

Keyword(s) : Chronic hepatitis B; Functional cure; Prediction model; Pegylated interferon-alpha; Machine learning

2642 - Design development and pilot evaluation of a comprehensive liver disease registry in the Philippines

Abegail Jayne Amoranto ¹, Lance Gabriel Arcega ¹, Carlos Angelo Rayos ¹, Gienelle You Xin Tan ¹, Jhaki Mendoza ¹, Cayleen Capco ¹, Raymond Francis Sarmiento ¹, Janus Ong ²

University Of The Philippines Manila, National Telehealth Center, National Institutes Of Health, Manila-Philippines ¹ University Of The Philippines Manila, College Of Medicine, Manila-Philippines ²

Background / Hypothesis: Liver diseases impose a growing public health burden in the Philippines, yet the lack of a standardized national registry limits surveillance, research, and health planning. This study describes the design, development, and pilot evaluation of a comprehensive liver disease registry targeting six priority conditions – Hepatitis B, Hepatitis C, Metabolic Dysfunction-Associated Steatotic Liver Disease, Alcohol-related Liver Disease, Liver Cirrhosis, and Hepatocellular Carcinoma. We focused on feasibility, usability, data quality, and readiness for national scale-up.

Materials and Methods: We conducted a mixed-methods implementation study. Digital health readiness was evaluated using the E-Ready questionnaire. Registry design was informed by a consensus dataset established through a three-round modified Delphi process (reported separately). The architecture enabled manual entry, bulk uploads, and application programming interface (API)-based submissions. Pilot deployment occurred in one public tertiary hospital and one private specialty hospital, enrolling 181 patients. We assessed registry quality and functionality using the CIPROS checklist and usability with the System Usability Scale (SUS). Preliminary data quality assessment was performed on 112 required variables from 47 randomly selected patients.

E-POSTER ABSTRACTS

Qualitative feedback from end-users was thematically analyzed.

Results: Readiness assessment revealed strong individual competencies and positive organizational attitudes towards registry use, but highlighted perceived structural constraints, including limited time, resources, and trained personnel. The registry was deployed as a secure, FHIR-based web platform with built-in validation, audit trails, and modular user management functions. A total of 181 patients were enrolled, with 77.9% recruited from the public hospital. Mean SUS scores were 70.8 post-beta and 67.1 post-training/deployment, indicating marginal to acceptable usability. Data quality assessment demonstrated 100% structural completeness, 67.1% data completeness, and 77.4% data accuracy, with errors stemming from unstructured documentation, manual encoding, and variability in routine clinical recording practices. CIPROS evaluation demonstrated strengths in software architecture, standards alignment, security and privacy compliance, organizational governance, and training, while highlighting gaps in interfaces and interoperability, analytical functionality, and sustainability mechanisms.

Conclusions: The pilot demonstrates the feasibility of implementing a comprehensive, multi-disease liver registry in the Philippines. While core architecture, governance, and usability are acceptable for early deployment, improvements in interoperability, workflow integration, and analytical capabilities are essential for scale-up and institutionalization. Our findings also reveal critical trade-offs between data comprehensiveness, workflow burden, and data reliability, providing actionable insights to inform system refinement and expansion of disease registries in similar resource-constrained settings.

2645 - Traditional Medicine Yiqi Huoxue Relieves Nonalcoholic Steatohepatitis by Remodeling Intestinal Microbiota and Metabolites

Yaoyao Mao Mao¹, Yuemin Nan Nan¹

Third Hospital Of Hebei Medical University, Hebei Provincial Key Laboratory Of Liver Fibrosis In Chronic Liver Diseases, Hebei-China¹

Background/Hypothesis: Non-alcoholic steatohepatitis

(NASH) lacks effective therapy. Yiqi Huoxue Formula (YQHX) shows potential, but its mechanisms remain unclear. YQHX alleviates NASH by modulating the gut-liver axis and contains active components that directly inhibit hepatocyte necroptosis.

Materials and Methods: C57BL/6J mice were fed a high-fat diet for 120 days to establish NASH, then treated with YQHX for 14 days. Metabolic parameters, liver pathology, gut microbiota (16S sequencing), serum metabolomics, and hepatic transcriptomics were analyzed. Intestinal barrier integrity and key proteins were examined. YQHX-derived components were identified via UPLC-MS/MS and screened through molecular docking. Cimifugin's effects were validated in FFA-induced AML12 cells using flow cytometry, TEM, and functional assays.

Results: YQHX improved metabolic indices, liver steatosis, and inflammation. It restored gut microbiota composition, enhanced intestinal barrier function, and modulated serum metabolites. Transcriptomics revealed inhibition of necroptosis and inflammatory pathways. YQHX reduced hepatic p-MLKL and macrophage infiltration. Cimifugin (10 μ M) inhibited FFA-induced necroptosis, improved mitochondrial structure and function, and enhanced fatty acid β -oxidation.

Conclusion: YQHX alleviates NASH through gut-liver axis modulation, with Cimifugin directly targeting mitochondrial function and necroptosis. This study provides mechanistic insights supporting YQHX's therapeutic potential.

Keyword(s) : Yiqi Huoxue Formula (YQHX), Non-alcoholic steatohepatitis (NASH), Gut-liver axis, Necroptosis

2646 - Exploring the Predictive Value of the DiabetesLiver Score for Liver Fibrosis in Patients with Type 2 Diabetes Mellitus and MAFLD Based on the Dual Disease Nursing Management Model

Meiyuxi Li¹, Xuan Liang², Yan Wang¹, Lijia Zhang¹, Xing Liu¹

The Sixth People's Hospital Of Shenyang, Science And Education Department, Shenyang-China¹ The Fifth People's Hospital Of Shenyang, Science And Education Department, Shenyang-China²

Background / Hypothesis:

To explore the predictive value of the DiabetesLiver Score (DLS) for liver fibrosis in patients with type 2

E-POSTER ABSTRACTS

diabetes mellitus and metabolic dysfunction-associated steatotic liver disease (MAFLD) based on the dual disease nursing management model.

Materials and Methods:

A total of 120 T2DM patients with MAFLD were enrolled in the present study. All patients were given the interventions of the diabetes liver disease nursing management model and followed up for one year. Changes of weight, waist circumference, serological indicators (complete blood count, blood lipids, blood glucose, glycated hemoglobin, liver function), liver transient elastography (TE) examination, as well as indices such as the Fibrosis-4 Index (FIB-4), DLS, and the Non-alcoholic Fatty Liver Disease Fibrosis Score (NFS) were compared before and after the follow-up period. Furthermore, based on Receiver Operator Characteristic (ROC) curve analysis, the diagnostic performance of the three non-invasive models (FIB-4, DLS, and NFS) for liver fibrosis was compared.

Results:

Compared with the pre-follow-up period, the patients showed an increase in albumin after one year of follow-up, along with significant decreases in cholesterol, low-density lipoprotein, fasting blood glucose, DLS, NFS, as well as the CAP value and LSM measured by TE examination. The differences between the two groups were statistically significant ($P < 0.05$). DLS demonstrated good performance in predicting $\text{LSM} \geq 8 \text{ kPa}$, $\geq 10 \text{ kPa}$, and $\geq 12 \text{ kPa}$, with area under the curve (AUC) values of 0.824, 0.973, and 0.981, respectively. Its predictive performance was superior to that of FIB-4 and NFS, whose AUC values were 0.785, 0.922, 0.927 and 0.748, 0.799, 0.889, respectively.

Conclusions:

The Diabetes Liver Disease Nursing Management Model is an effective comprehensive intervention measure, and the DLS demonstrated good performance in identifying liver fibrosis in T2DM population.

Keyword(s) : Diabetes mellitus; Metabolic fatty liver disease; Dual disease nursing management model; DiabetesLiver score

2648 - Comparative Analysis of WHO 2024 EASL 2025 AASLD IDSA 2025 and APASL 2026 CHB Treatment Guidelines Implications for Treatment Eligibility and Antiviral Management Strategies

Public Health And Primary Care, Hong Kong / Hk-Hong Kong SAR, China¹ Institute Of Liver And Biliary Sciences, Institute Of Liver And Biliary Sciences, New Delhi-India² Capital Medical University, Beijing Friendship Hospital, Beijing-China³ Fifth Medical Center Of Chinese PLA General Hospital, Senior Department Of Hepatology, Beijing-China⁴ Task Force For Global Health, Coalition For Global Hepatitis Elimination, Ga-United States⁵ Health Care Policy And Aging Research (ifh), Rutgers Institute For Health, Nj-United States⁶ Imperial College London, Faculty Of Medicine, London-United Kingdom⁷ Chang Gung Memorial Hospital, Linkou Medical Center, Department Of Gastroenterology And Hepatology, Taoyuan-Taiwan⁸ Kaohsiung Medical University Hospital, Kaohsiung Medical University, Hepatobiliary Division, Department Of Internal Medicine, Kaohsiung-Taiwan⁹ The University Of Hong Kong, The University Of Hong Kong, Hong Kong-Hong Kong SAR, China¹⁰ Humanity And Health Medical Group, Humanity And Health Clinical Trial Center, Hong Kong-Hong Kong SAR, China¹¹

Background / Hypothesis:

Major international guidelines for chronic hepatitis B (CHB) differ substantially in treatment thresholds, fibrosis assessment, and nucleos(t)ide analogue (NUCs) discontinuation strategies. This review compared the WHO 2024, EASL 2025, AASLD/IDSA 2025, APASL 2026 guidelines to identify key divergences.

Materials and Methods:

A structured, domain-based comparison of the guidelines was conducted across three key domains: (1) indications for treatment by alanine aminotransferase (ALT), HBV DNA, and fibrosis thresholds; (2) recommended first-line antiviral regimens; and (3) strategies for NA discontinuation. Recommendations were systematically extracted and compared to highlight differences in clinical approach.

Results:

Who and when to treat: WHO 2024 expanded treatment eligibility using a pragmatic framework incorporating significant fibrosis ($\text{APRI} > 0.5$ or transient elastography $> 7.0 \text{ kPa}$), elevated ALT with HBV DNA $> 2,000 \text{ IU/mL}$, presence of co-infections or comorbidities, or persistently elevated ALT when virologic testing is unavailable. EASL 2025 broadened access via a phase-based algorithm integrating HBV DNA and non-invasive fibrosis assessment, including patients with normal ALT but elevated HCC risk.

E-POSTER ABSTRACTS

AASLD/IDSA 2025 maintained a conservative, risk-stratified approach with strict numeric thresholds (HBV DNA $\geq 20,000$ IU/mL for HBeAg-positive and $\geq 2,000$ IU/mL for HBeAg-negative disease). APASL 2026 adopted a simplified “treat-all” approach, removing most biomarker restrictions to encourage early initiation. All guidelines recommended treatment for patients with cirrhosis.

How to treat: First-line therapy across guidelines is high-genetic-barrier NUCs (entecavir, tenofovir disoproxil fumarate, or tenofovir alafenamide), with tenofovir preferred during pregnancy. WHO recommends tenofovir plus lamivudine (3TC) or tenofovir plus emtricitabine (FTC) as alternative regimens. APASL 2026 uniquely positions pegylated interferon- α as first-line or add-on option to promote HBsAg loss. EASL 2025 most extensively integrates quantitative biomarkers (HBcrAg, HBV RNA, qHBsAg) to guide finite therapy.

When to stop therapy: NUC discontinuation is generally restricted to patients with sustained HBsAg loss, although EASL 2025 and APASL 2026 provide more permissive stopping criteria in selected non-cirrhotic patients.

Conclusions:

Major HBV guidelines reflect different priorities: APASL 2026 adopts the most inclusive treatment approach, EASL 2025 balances broad eligibility with finite-therapy pathways, AASLD/IDSA 2025 emphasizes shared decision-making with predominantly indefinite therapy, and WHO 2024 prioritizes feasibility in resource-limited settings. These differed priorities have implications for implementation and HBV elimination strategies in the Asia-Pacific region.

Keyword(s) : chronic hepatitis B; Clinical Guidelines; biomarkers; pegylated interferon

2650 - The Evolving Role of Vitamin D in Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD) From Pathogenesis to Clinical Practice – An Updated Synthesis for 2026

Hongxia Chen ¹, Zhuoran Zhu ², Xia Wang ³, Zhongji Meng ⁴

Taihe Hospital, Hubei University Of Medicine, Institute Of Biomedical Research, Shiyan-China ¹ Hubei University Of Medicine, Department Of Anatomy, Shiyan-China ² School Of Public Health, Cheeloo College Of Medicine, Shandong University, Department Of Maternal And Child Health, Jinan-China ³ Taihe Hospital, Hubei University Of Medicine, Institute Of

Biomedical Research, Department Of Infectious Diseases, Shiyan-China ⁴

Background / Hypothesis: The escalating global burden of MASLD underscores the urgent need to elucidate modifiable determinants of disease onset and progression. Vitamin D—a secosteroid hormone with well-established roles in calcium homeostasis, immune modulation, insulin sensitivity, and hepatic metabolic regulation—has emerged as a biologically plausible candidate. Although numerous observational studies consistently associate vitamin D deficiency with higher MASLD prevalence, severity, and adverse histological outcomes, the nature of this association—causal versus epiphenomenal—remains unresolved. This review critically integrates contemporary evidence to advance understanding beyond mere correlation, focusing on mechanistic pathways linking vitamin D status to MASLD pathogenesis—including genetic susceptibility (e.g., VDR variants), gut-liver axis dysregulation, and downstream cellular and molecular targets.

Materials and Methods: We performed a rigorous, non-systematic narrative synthesis prioritizing high-quality, conceptually influential evidence. Key sources included: (1) prospective longitudinal cohort studies and robust Mendelian randomization (MR) investigations evaluating causal inference; (2) RCTs assessing the efficacy of vitamin D supplementation on imaging- or biopsy-confirmed hepatic steatosis, inflammation, and fibrosis; (3) mechanistic preclinical and translational studies examining VDR-mediated signaling in hepatocytes, hepatic stellate cells, Kupffer cells, and intestinal epithelial cells; (4) emerging research on vitamin D-microbiome-bile acid interactions; and (5) epigenomic analyses exploring vitamin D-dependent regulation of genes involved in lipid metabolism, oxidative stress, and fibrogenesis.

Results: Current evidence reveals a multifaceted and context-dependent relationship. While low circulating 25(OH)D concentrations remain strongly and independently associated with MASLD diagnosis, advanced fibrosis, and cardiometabolic comorbidities in observational cohorts, MR analyses do not support a direct causal role for vitamin D deficiency in MASLD development—instead implicating shared underlying drivers such as obesity, physical inactivity, and systemic inflammation. Similarly, RCTs evaluating vitamin D monotherapy have generally failed to demonstrate clinically meaningful reductions in liver fat content or fibrosis stage. Nevertheless, experimental data increasingly highlight vitamin D's regulatory influence on hepatic autophagy flux, mitochondrial bioenergetics, NLRP3 inflammasome activation, and

E-POSTER ABSTRACTS

endotoxin tolerance. Critically, vitamin D insufficiency appears to potentiate hepatocellular injury under conditions of "second hits", including gut-derived LPS translocation secondary to dysbiosis and increased intestinal permeability. Preliminary subgroup findings suggest that targeted repletion—particularly in patients with baseline 25(OH)D < 20 ng / mL and concomitant high-risk metabolic phenotypes—may yield modest benefits when integrated with comprehensive lifestyle modification.

Conclusions: Vitamin D is a disease modifier, not a primary driver, in MASLD. Universal supplementation is unsupported, but correcting VD deficiency remains a prudent clinical adjunct. Future work must define responsive subgroups and explore its role in combinatorial, precision-hepatology strategies.

2651 - A Systems Cross omics Framework Uncovers Microbiota Driven Molecular Targets for MAFLD Therapy

Weixuan Liang ¹, Ziyang Yang ¹, Zhuofeng Wen ¹, Jiahui Lai ¹, Jiyuan Zhou ¹

The Second Affiliated Hospital, Guangzhou Medical University, Department Of Gastroenterology, Guangzhou-China ¹

Background / Hypothesis: Metabolic dysfunction-associated fatty liver disease (MAFLD) is strongly influenced by the gut microbiota, yet microbiota-regulated host therapeutic targets remain incompletely defined. We aimed to develop a genetics-informed framework to identify and prioritize actionable targets for microbiota-driven MAFLD intervention.

Materials and Methods: Using GWAS data, we assessed the causal effects of gut microbial traits on MAFLD, mapped causal variants to host genes, and integrated cross-omics evidence across transcriptomic, proteomic, metabolomic, and splicing layers. Liver transcriptomic datasets were used for in silico validation. Druggability annotation, phenome-wide MR across 679 traits for safety profiling, composite evidence scoring for prioritization, and molecular docking for binding affinity estimation were subsequently performed to rank actionable targets.

Results: We identified 15 gut microbial traits causally associated with MAFLD, mapping 215 instrumental

SNPs to 191 candidate host genes. Cross-omics integration prioritized 55 high-confidence targets. A composite evidence-scoring system incorporating multi-omics support, liver expression, pathway enrichment, druggability, and phenome-wide safety stratified candidates into four tiers, highlighting nine Tier-1 genes with CMKLR1 ranked highest. Overall, 21 targets showed favorable safety profiles, and molecular docking supported strong binding between prioritized targets and metabolic agents, with CMKLR1 exhibiting the highest affinity for canagliflozin.

Conclusions: This integrative framework prioritizes host targets linking gut microbiota to MAFLD and identifies CMKLR1 as the leading therapeutic candidate supported by multi-omics and pharmacological evidence, providing a roadmap for microbiota-targeted drug discovery.

2652 - A retrospective study on nirmatrelvir ritonavir and azvudine in treating COVID 19 in patients with cirrhosis

Wenli Jiang ¹, Lei Luo ¹, Wenlong Yang ¹

The Second Affiliated Hospital Of Nanchang University, Department Of Infectious Diseases, Nanchang-China ¹

Background / Hypothesis: While numerous pivotal clinical studies have compared anti-COVID-19 therapies, no study has yet evaluated the efficacy of nirmatrelvir/ritonavir versus azvudine specifically in the cirrhotic population.

Materials and Methods: Data from 156 hospitalized cirrhosis patients with COVID-19 at The Second Affiliated Hospital of Nanchang University between November 1, 2022, and November 30, 2023, were collected. The analysis included 97 patients in the no-treatment group, 29 in the nirmatrelvir/ritonavir group, and 22 in the azvudine group. Clinical outcomes were compared among the three groups, including 30-day all-cause mortality, mechanical ventilation rate, and ICU admission rate.

Results: Among the included patients, regarding mortality, 13 deaths occurred in the no-treatment group (22.68%), 7 in the Paxlovid group (24.14%), and 7 in the azvudine group (31.82%) (P=0.666). From the perspective of mechanical ventilation, 23 cases required ventilation in the no-treatment group

E-POSTER ABSTRACTS

(23.71%), 4 in the Paxlovid group (13.79%), and 4 in the azvudine group (18.18%) ($P=0.485$). In terms of ICU admission, 22 cases were admitted in the no-treatment group (22.68%), 4 in the Paxlovid group (13.79%), and 5 in the azvudine group (22.73%) ($P=0.573$).

Conclusions: This study indicates that among cirrhosis patients with COVID-19, no significant differences were observed in 30-day mortality, mechanical ventilation, or ICU admission among the no-treatment, Paxlovid, and azvudine groups. These findings may be related to the reduced incidence of severe COVID-19 outcomes following widespread vaccination.

2653 - From Prediction to Decision A Dynamic Multi Modal Causal Machine Learning System for Optimized Clinical Management of Chronic Hepatitis B in a 150 000 Patient Longitudinal Cohort

Yuan-hai Zhou ¹, Qiao Tang ¹, Hu Li ¹, Peng Hu ¹
The Second Affiliated Hospital Of Chongqing Medical University, Department Of Infectious Diseases, Chongqing-China ¹

Background / Hypothesis:

Achieving functional cure, determining safe cessation of Nucleos(t)ide Analogues (NAs), and precise surveillance of Hepatocellular Carcinoma (HCC) remain the three major challenges in Chronic Hepatitis B (CHB) management. Traditional AI models focus on correlation-based prediction but fail to answer "what-if" interventional questions. We aimed to develop a dynamic artificial intelligence approach utilizing a massive multi-modal longitudinal cohort to estimate Individual Treatment Effects (ITE) and provide actionable clinical decision support.

Materials and Methods:

We constructed a longitudinal cohort of 150,000 CHB patients from a single tertiary center, reconstructing their complete clinical history. The dataset integrated multi-modal real-world data (RWD), including longitudinal laboratory tests, electronic health records, imaging (CT/MRI/US), and liver pathology. We employed deep representation learning combined with counterfactual inference algorithms to construct a holistic decision-support engine. This system quantifies

Individual Treatment Effects (ITE) across the full spectrum of disease progression, enabling precision strategies for the critical trilemma of functional cure attainment, safe nucleos(t)ide analogue cessation, and dynamic hepatocellular carcinoma surveillance.

Results:

We successfully established a massive, high-fidelity longitudinal cohort comprising 158,214 unique CHB patients. The time span ranges from December 2006 to December 2025, the cohort is predominantly male (60.20%), the average age is 48 years old (IQR: 36-58). This dataset is highly multidimensional, containing over 130,000 (83%) abdominal ultrasound records and 41,000 (26.5%) multimodal imaging data of abdominal CT and abdominal MRI. Through rigorous data cleaning, we achieved a high reconstruction rate; All patients possessed complete, granular longitudinal data specifically quality-controlled for causal inference algorithms. The AI engine has been successfully integrated into the hospital's clinical workflow. Preliminary deployment validates the system's computational feasibility to process multi-modal inputs in real-time and generate individual counterfactual treatment trajectories.

Conclusions: Our study showcases a pioneering dynamic Causal AI framework built on a massive multi-modal cohort. By moving beyond conventional prediction to dynamic counterfactual analysis, the system facilitates personalized clinical decision-making for functional cure, safe NA cessation and hepatocellular carcinoma surveillance. This initiative underscores the power of causal inference in transforming large-scale RWD into actionable, dynamic insights for chronic hepatitis B management.

2655 - Single Cell Trajectory and Communication Profiling Reveals a Metabolic Death Switch Driven by Macrophage Polarization in Hepatocellular Carcinoma Radioresistance

Shiji Wu ¹, Wenxi Wu ¹, Xingte Chen ¹, Junxin Wu ¹
Fujian Medical University, Clinical Oncology School Of Fujian Medical University, Fujian Cancer Hospital, Fuzhou-China ¹

Background: Radioresistance remains a formidable challenge in the treatment of hepatocellular carcinoma

E-POSTER ABSTRACTS

(HCC). While intra-tumor heterogeneity is a known driver of treatment failure, the dynamic evolutionary process and the extrinsic microenvironmental triggers that govern the transition from a radiosensitive to a resistant state remain poorly understood.

Methods: We performed single-cell RNA sequencing (scRNA-seq) on HCC clinical samples, categorized into complete response (CR) and non-complete response (non-CR) groups. We utilized Monocle3 for pseudotime trajectory inference and CellChat to characterize the cell-cell communication landscape. A functional scoring system was developed to quantify "Mitoxyperiosis"—a specific mode of oxidative-stress-induced cell death.

Results: Trajectory analysis revealed a clear evolutionary continuum from sensitive to resistant aneuploid epithelial cells. We identified a critical "Metabolic-Death Switch" at the late stage of evolution: as cells progressed toward the resistant pole (LowMitoxy), there was a dramatic down-regulation of the Mitoxyperiosis score, coupled with a sharp induction of FABP1 expression. Notably, FABP1 acted as a metabolic shield, neutralizing oxidative stress and preventing cell death.

Integrated microenvironmental analysis demonstrated that this switch was tightly regulated by macrophage polarization. M1 macrophages were significantly enriched in CR samples and exhibited intense pro-apoptotic signaling toward the HighMitoxy (sensitive) subpopulation. Conversely, M2 macrophages were predominantly clustered in non-CR samples and established a robust communication axis with the LowMitoxy (resistant) subpopulation. Specifically, M2-derived ligands (e.g., TGF- β 1 and SPP1) were identified as key extrinsic inducers that triggered FABP1-mediated metabolic reprogramming in tumor cells.

Conclusion: Our study delineates a novel mechanism of radioresistance where the M2 macrophage-dominant niche drives HCC cells to undergo a metabolic transition, characterized by FABP1 elevation and Mitoxyperiosis evasion. These findings identify the M2-TGF β 1-FABP1 axis as a potential therapeutic target to sensitize HCC to radiotherapy.

Keyword(s) : Mitoxyperiosis, Hepatocellular carcinoma, Single-cell RNA sequencing, Macrophage polarization

2656 - Relationship of liver fibrosis risk score (FIB 4) with echocardiographic findings in myocardial infarction with non obstructive coronary artery disease (MINOCA)

Mehmet Harapoz ¹, Sabrina Naz ², Matthew Zada ¹, Henning Gronbaek ³, Jacob George ⁴, Liza Thomas ⁵
Department Of Cardiology, Westmead Hospital, Sydney, Nsw, Australia And Westmead Clinical School, University Of Sydney, Nsw, Australia, Cardiology, Sydney-Australia ¹ Westmead Applied Research Centre, University Of Sydney, Sydney, Nsw, Australia, Westmead Applied Research Centre, Sydney-Australia ² Department Of Hepatology & Gastroenterology, Aarhus University Hospital, Aarhus, Denmark, Hepatology & Gastroenterology, Aarhus-Denmark ³ Department Of Gastroenterology, Westmead Hospital, Sydney, Nsw, Australia And Storr Liver Centre, Westmead Institute For Medical Research, Westmead Ho, Gastroenterology, Sydney-Australia ⁴ Department Of Cardiology, Westmead Hospital, Sydney, Nsw, Australia And Westmead Clinical School, University Of Sydney, Nsw, Australia And South West, Cardiology, Sydney-Australia ⁵

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) is associated with cardiac disease including myocardial infarction. Myocardial infarction with non-obstructive coronary artery disease (MINOCA) accounts for 6–8% of myocardial infarction presentations. The FIB-4 index is a non-invasive risk tool for assessing hepatic fibrosis and may predict major adverse cardiovascular events. We hypothesized that MINOCA patients with higher FIB-4 scores would demonstrate left ventricular (LV) systolic and diastolic dysfunction compared with those with lower FIB-4 scores.

Materials and Methods:

This retrospective study identified patients with MINOCA from October 2022 to October 2023 at Westmead Hospital, New South Wales, Australia. Exclusion criteria included obstructive coronary artery disease ($\geq 50\%$ stenosis), MINOCA mimicking disease processes, prosthetic or severe valvular disease, pre-existing liver disease, or unavailable liver function pathology within 3 months of presentation. Contemporaneous transthoracic echocardiograms were analysed offline for LV, right ventricular (RV) and left atrial (LA) structural and functional parameters, diastolic function indices, and speckle tracking derived global longitudinal strain (GLS). FIB-4 scores were calculated using age, liver tests and platelet count.

E-POSTER ABSTRACTS

Results:

Seventy patients comprised the study cohort, categorized into low, indeterminate and high-risk groups using the FIB-4 score. There were 34 patients in the low-risk FIB-4 group (<1.30), 31 in the indeterminate group ($1.30\text{--}2.67$) and 5 in the high-risk group (>2.67); the indeterminate and high-risk groups were combined for analysis. Overall, 34 patients were female (48.6%) and mean age was 57 ± 18 years. The low vs indeterminate and high FIB-4 groups differed in age (48 vs 66 years, $p<0.001$), with no other significant demographic differences. Echocardiographic parameters significantly different between groups were peak A wave velocity (64 vs 79 cm/s, $p=0.028$), lateral e' (9 vs 8, $p=0.028$), E/e' ratio (9.09 vs 11.41, $p=0.021$), LVEF (55.7% vs 53.7%, $p=0.008$) and LV GLS (-17.1% vs -14.7% , $p<0.001$). On age-adjusted univariate general linear modelling, peak E wave velocity and LV GLS were associated with FIB-4 score ($p<0.2$). When included in multivariate age-adjusted analysis model, including LV GLS and peak E wave velocity, only LV GLS was significantly associated with FIB-4 score ($p=0.010$).

Conclusions:

Among echocardiographic parameters, LV GLS was the only independent marker associated with FIB-4 group after adjusting for age. LV GLS is a sensitive marker of subclinical LV function and is associated with worse cardiovascular outcomes. Higher FIB-4 scores were associated with reduced GLS, indicating impaired myocardial strain could be associated with higher liver fibrosis stage.

Keyword(s) : FIB-4, Echocardiography, MINOCA

2657 - Clinical characteristics and influencing factors for recompensation in patients with first time decompensated hepatitis B cirrhosis with esophageal and gastric variceal rupture and bleeding in the Western Region of

Li Wenting Li¹

The Second Affiliated Hospital, Baotou Medical College, Baotou-China¹

Background / Hypothesis:

To explore the clinical characteristics and influencing factors of patients with first-time decompensated hepatitis B cirrhosis accompanied by esophageal and gastric fundus variceal rupture and bleeding who have achieved recompensation in the western region of Inner Mongolia

Materials and Methods:

A retrospective analysis was conducted on inpatients with hepatitis B cirrhosis in the western region of Inner Mongolia from January 2015 to January 2024. All patients were followed up with the occurrence of the first recompensation or ≥ 2 decompensations (continuous decompensation) as the end point. The outcomes of the patients were divided into the recompensation group and the continuous decompensation group. Analyze the independent influencing factors of re-compensation. Compare the differences in the cumulative occurrence of liver cancer among patients with different compensatory states. The comparison of measurement data between the two groups was conducted using the Mann-Whitney U test; The comparison of count data between the two groups was conducted using the χ^2 test. The influencing factors of recompensation were analyzed using the multivariate Cox proportional hazards regression model. The survival curve was plotted using the Kaplan-Meier method, and the survival curve was tested by log-rank.

Results:

among 69 patients with decompensated hepatitis B cirrhosis, ultimately, 32 cases achieved re-decompensation and 37 cases were persistent decompensation. Compared with patients with persistent decompensation, Age {compensated group 53.22 (9.42) vs decompensated group 60.49 (10.42)} (HR=0.94, 95%CI 0.90-0.99, $p=0.02$), CTP scores {compensated group 6(5,6.75) vs decompensated group 9 (8,11.5)} (HR=0.63, 95%CI 0.46-0.86, $p<0.05$), Meld scores {compensated group 6.1 (3.29,8.28) vs decompensated group 12.74 (7.16,17.45)} (HR=0.9, 95%CI 0.85-0.96, $P<0.05$) are independent influencing factors of re-compensation; The comparison of the recompensation group and its first decompensation clinical data: there was a significant statistical difference in CTP scores {compensated group 6.12 (1.07) vs first decompensated group 7.91 (1.59)} (OR= 1.79, 95%CI 1.01-3.16, $P=0.05$), ALB {compensated group 38.80 (4.51) vs first decompensated group 30.98 (4.98)} (OR=0.82, 95%CI 0.68-0.97, $P=0.02$), HGB {compensated group 123.28 (28.96) vs first decompensated group 89.69 (23.49)} (OR= 0.96, 95%CI 0.93-0.99) ($P=0.01$); the incidence of tumors in patients with recompensation was significantly lower than that in patients with continuous decompensation

E-POSTER ABSTRACTS

(HR=0.23, 95%CI 0.37-0.57, P=0.02)

Conclusions:

Compared with the baseline data of patients with first decompensation, there were significant statistical differences in CTP score, ALB and HGB in the re-decompensation group. Compared with the data of the continuous decompensation group, patients with younger age, lower CTP scores and Meld scores were more likely to achieve recompensation, and the cumulative incidence of tumors in recompensated patients was significantly lower than that in continuous

2658 - Real world impact of 48 week tenofovir amibufenamide therapy on lipid profiles in chronic hepatitis B

Jingjing Wang¹, Wenya Chen¹, Qi Wang¹, Hong Zhao¹, Ligai Liu¹, Wen Xie¹

Capital Medical University Affiliated Beijing Ditan Hospital, Liver Disease Center, Beijing-China¹

Background / Hypothesis:As a first-line treatment for chronic hepatitis B (CHB), the long-term impact of tenofovir amibufenamide (TMF) on lipid metabolism remains to be further clarified in real-world settings. This study aimed to evaluate the effect of 48-week TMF treatment on the lipid profile of CHB patients.

Materials and Methods:This was a single-center retrospective study conducted at Beijing Ditan Hospital, Capital Medical University. A total of 302 CHB patients who received TMF monotherapy for at least 48 weeks were consecutively included. Lipid parameters, including total cholesterol (TC), triglycerides (TG), high-density lipoprotein cholesterol (HDL-C), and low-density lipoprotein cholesterol (LDL-C), were collected and compared at baseline and after 48 weeks of treatment.

Results:Compared with the baseline level, no significant changes were observed in any lipid parameters after 48 weeks of treatment: TC was 4.52 (IQR: 4.07, 5.09) vs 4.37 (IQR: 3.91, 5.26) mmol/L, P = 0.310; TG was 1.06 (IQR:0.68, 1.48) vs 1.02 (IQR:0.72, 1.57) mmol/L, P = 0.120; HDL-C was 1.23 (IQR:1.04, 1.40) vs 1.18 (IQR:1.01, 1.44) mmol/L, P = 0.469; LDL-C was 2.74 (IQR: 2.32, 3.24) vs 2.69 (IQR:2.16, 3.30) mmol/L, P = 0.150.

Conclusions:This real-world study demonstrates that 48-week TMF treatment has no significant adverse effect on lipid metabolism in patients with CHB,

confirming its favorable lipid safety profile.

2659 - Agenesis of the Dorsal Pancreas Caused by HNF 1 β Gene Mutation Presenting with Abnormal Liver Function as the Initial Manifestation A Case Report

Shi-heng Liu¹, Yong-wei Wang¹, Ya-nan Li¹, Hai-fang Wang¹, Yu-guo Zhang¹

The First Hospital Of Hebei Medical University, Hepatology, Shijiazhuang-China¹

Background / Hypothesis:

Agenesis of the dorsal pancreas (ADP) is a rare congenital anomaly in which the dorsal pancreatic anlage fails to develop, resulting in partial or complete absence of the pancreatic body and tail. While most cases are sporadic, mutations in developmental genes such as hepatocyte nuclear factor 1 β (HNF-1 β) and GATA binding protein 4 (GATA4) have been implicated. Patients may be asymptomatic or present with diabetes, recurrent pancreatitis, steatorrhea, or non-specific abdominal complaints; hepatic dysfunction is rarely the entry sign. We describe an adolescent boy who initially presented with persistently elevated transaminases and was ultimately diagnosed with HNF-1 β -related ADP.

Materials and Methods:

We describe a 17-year-old male who presented with elevated transaminases and was found to have hyperglycemia. Imaging revealed absence of the pancreatic body and tail and multiple bilateral renal cysts. Liver biopsy suggested non-alcoholic fatty liver disease. Genetic testing identified a heterozygous pathogenic deletion of HNF-1 β exons 1–9, confirming HNF-1 β -related ADP.

Results:

After initiation of insulin and hepatoprotective therapy, liver enzymes and glycemic control improved.

Conclusions:

This case broadens the phenotypic spectrum of ADP and highlights the importance of considering this diagnosis in adolescents with unexplained abnormal liver function and diabetes, prompting timely imaging and genetic evaluation.

Keyword(s) : Agenesis of the dorsal pancreas; hepatocyte nuclear factor-1 β ; abnormal liver function; diabetes; gene deletion

2661 - Macrophage metabolic reprogramming mediated by PKM2 deacetylation in liver fibrosis

Jing Chen ¹, Xiang Liu ¹, Bo Yang ¹, Huili Yang ¹, Yufeng Xing ¹

Shenzhen Hospital Of Traditional Chinese Medicine/fourth Clinical Medical College Of Guangzhou University Of Traditional Chinese Medicine, Department Of Hepatology, Shenzhen-China ¹

Liver fibrosis is a common pathological process of a variety of chronic liver diseases, which is characterized by the activation of hepatic astrocytes (HSCs) and excessive deposition of extracellular matrix. In recent years, immunometabolism research has revealed that macrophages play a key role between inflammation and fibrosis, among which metabolic reprogramming is the core mechanism that determines their function. Pyruvate kinase M2 (PKM2) drives the anti-inflammatory effect of M1 macrophages by regulating glycolysis and inflammatory signals; while silent information regulatory factor 3 (SIRT3) regulates the configuration of PKM2 through deacetylation modification, reduces lactic acid production, and promotes the transformation of macrophages to anti-inflammatory phenotypes, thus reducing Fibrosis. Existing research confirms that the SIRT3-PKM2 axis not only affects macrophage metabolism, but also forms crosstalk with HSC through lactic acid and epigenetic modification, forming the core loop of inflammation and fibrosis. This paper reviews the mechanism of PKM2 and its deacetylation in liver fibrosis, emphasizes its value as a potential treatment target, and puts forward a multi-dimensional strategy that should be combined with metabolic regulation, immune intervention and epigenetic regulation in the future to achieve accurate treatment of liver fibrosis.

Keyword(s) : liver fibrosis; macrophage polarization; PKM2; SIRT3; metabolic reprogramming; glycolysis; treatment strategy

2662 - Exploring the Dose Response of Shugan Xiaozhi Formula Granules and MRI Radiomics Based MAFLD Prediction

Jing Chen ¹, Xiang Liu ¹, Bo Yang ¹, Huili Yang ¹, Yufeng Xing ¹

Shenzhen Hospital Of Traditional Chinese

Medicine/fourth Clinical Medical College Of Guangzhou University Of Traditional Chinese Medicine, Department Of Hepatology, Shenzhen-China ¹

Background / Hypothesis:

Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD) is the most common chronic liver disease worldwide and is closely related to metabolic syndrome. There is a lack of specific therapeutic drugs. Traditional Chinese medicine (TCM) has shown multi-target advantages in the treatment of MAFLD, but traditional decoctions have limitations. As a modern dosage form, the equivalence and dose-effect relationship of TCM formula granules need to be verified. At the same time, the diagnosis of MAFLD relies on invasive examinations, and radiomics can provide non-invasive predictive tools.

This study aims to evaluate the clinical equivalence, safety, and dose-effect relationship of the Shugan Xiaozhi Decoction and different doses of formula granules in patients with liver depression and spleen deficiency type MAFLD, and to construct a MAFLD prediction model based on MRI radiomics.

Materials and Methods:

The first part is a literature review and a clinical randomized controlled trial, including 120 patients with liver depression and spleen deficiency type MAFLD, randomly divided into a decoction group and full-dose, 2/3-dose, and 1/2-dose granule groups (30 cases each). The intervention lasted for 12 weeks, and changes in MRI-PDFF, CAP values, BMI, blood lipids, liver function, and TCM syndromes were observed. The second part is a retrospective study, including 172 patients (112 with MAFLD and 60 healthy controls). MRI radiomics features were extracted, and the Rad-score was constructed. Serum markers (ALT, AST, TC) were integrated to establish a combined prediction model.

Results:

In the clinical trial, the Shugan Xiaozhi Decoction significantly improved liver steatosis, metabolic indicators, and TCM syndromes ($P < 0.05$). The decoction group was equivalent to the full-dose group ($P > 0.05$), and a dose-dependent relationship was observed (higher dose was better than lower dose). The safety was good, with no serious adverse events. In the radiomics model, the Rad-score was a strong independent predictor ($OR = 1.98$, $P < 0.001$), and the combined model had an AUC of 0.918, an internal validation C-index of 0.896, and excellent calibration and clinical utility.

E-POSTER ABSTRACTS

Conclusions:

The full-dose Shugan Xiaozhi Decoction granules are equivalent to the decoction and have a dose-dependent relationship. The radiomics combined model provides an efficient tool for non-invasive diagnosis of MAFLD. Future multicenter validation is needed to optimize its application.

Keyword(s) : Metabolic Dysfunction-Associated Fatty Liver Disease; Shugan Xiaozhi Decoction; TCM formula granules; Dose-effect relationship; Radiomics; Prediction model Abstract

2665 - Evaluation of the Egyptian Club of Ascites Diagnostic Algorithm for Etiological Diagnosis of Ascites A Single Center Study"

Eman Fares¹, Abrar M. Lotfy², Ahmed A. Gomaa¹, Essam A. Hassan¹

Fayoum University, Endemic Medicine, Fayoum-Egypt¹
Ministry Of Health, Hepatogastroenterology, Fayoum-²

Background / Hypothesis:

Ascites is a common clinical problem with diverse etiologies. Accurate differentiation between portal hypertension-related and non-portal hypertension causes is essential for appropriate management and prognosis. The Egyptian Club of Ascites (ECA) proposed a diagnostic algorithm based primarily on serum-ascites albumin gradient (SAAG) and ascitic fluid total protein (AFTP). The study aimed to evaluate the performance of the Egyptian Club of Ascites (ECA) diagnostic algorithm in determining the etiology of ascites.

Materials and Methods:

A cross-sectional study included 100 patients with previously uninvestigated ascites at a single Egyptian tertiary center (April–October 2025). All patients underwent detailed clinical evaluation and diagnostic paracentesis. Ascitic fluid analysis included SAAG and AFTP measurements. Additional laboratory, radiological, and diagnostic procedures were performed as clinically indicated to establish the final etiology of ascites.

Results:

Patients had a mean age of 57.4 ± 10.5 years; 57% were males, and cirrhotic ascites predominated (87%). Ascitic fluid appearance was significantly associated with etiology ($p < 0.001$); transparent yellow ascites

predominated in cirrhotic cases, whereas cloudy, bloody, or milky ascites were more frequent in malignant, tuberculous, inflammatory, and traumatic causes.

High SAAG (≥ 1.1 g/dL) was observed in 87% of patients and identified portal hypertension-related ascites with a sensitivity of 96.7%, specificity of 100%, and AUC of 98.4% ($p < 0.001$). Low SAAG (< 1.1 g/dL) was detected in 13% of patients; four cases (30.7%) were related to portal hypertension, while all malignant ascites, tuberculous peritonitis, SLE serositis, and hemoperitoneum cases had low SAAG values ($p = 0.001$).

Low AFTP (< 2.5 g/dL) predominated in cirrhotic ascites, whereas high AFTP (≥ 2.5 g/dL) was mainly associated with cardiac, malignant, tuberculous, and inflammatory ascites. AFTP demonstrated high diagnostic accuracy for transudative ascites (sensitivity 94.6%, specificity 100%, AUC 97.3%; $p < 0.001$).

The combined ECA algorithm (SAAG + AFTP) demonstrated high diagnostic performance, with sensitivity and specificity of 96.6% and 100% for hepatic ascites, 75% and 100% for cardiac ascites, 100% and 96% for Nephrogenic ascites and protein-losing enteropathy, and 87.5% and 98.9% for tuberculous and malignant ascites (all $p < 0.001$).

Conclusions:

The Egyptian Club of Ascites' diagnostic approach provides a reliable and highly accurate framework for etiological diagnosis of ascites. The combined use of SAAG and AFTP provides excellent diagnostic discrimination between portal hypertension-related and non-portal causes and can be confidently applied in routine clinical practice.

2667 - HBV recurrence in patients with hepatocellular carcinoma and cholangiocarcinoma following liver transplantation

Xi He¹, Zhijie Li¹, Xiaofeng Niu¹, Hui Ren¹, Yudong Wang², George Lau², Zhenwen Liu¹

Senior Department Of Hepatology, The Fifth Medical Center Of Chinese People's Liberation Army General Hospital, Beijing, China., Liver Disease, Beijing-China¹
Humanity And Health Medical Group, Hong Kong Sar, China, Humanity And Health Clinical Trial Center, Beijing-China²

Background / Hypothesis:

To investigate risk factors for hepatitis B virus (HBV)

E-POSTER ABSTRACTS

recurrence following liver transplantation in patients with HBV-related hepatocellular carcinoma (HCC) or cholangiocarcinoma.

Materials and Methods:

This study included patients with cirrhosis due to chronic HBV infection who underwent liver transplantation for HCC or cholangiocarcinoma between February 2015 and February 2019 at a tertiary hospital. Participants were stratified based on post-transplant HBV recurrence status. Inter-group comparisons for categorical variables were performed using the chi-square test, while continuous variables were analyzed using Student's t-test or the Mann-Whitney U test, as appropriate. Univariate and multivariate Cox proportional hazards regression analyses were conducted to identify independent risk factors.

Results:

Among 112 enrolled patients, 109 had HCC and 3 had cholangiocarcinoma. Compared to patients without HBV recurrence, those with recurrence had significantly higher rates of detectable HBV DNA pre-transplantation (75.0% vs. 27.0%, $P=0.001$), microvascular invasion (100% vs. 67.8%, $P=0.020$), and more advanced TNM stages (Stage III+IV: 58.3% vs. 16.5%, $P=0.001$). They also exhibited larger maximum tumor diameter (6.3 cm vs. 2.5 cm, $P<0.001$) and were more likely to exceed the "Up-to-seven" criteria (83.3% vs. 22.0%, $P<0.001$). No significant differences were found in age ($P = 0.362$), sex ($P = 0.480$), or MELD score ($P = 0.678$). Post-transplantation, HBV recurrence occurred in 12 patients (10.71%) after a median interval of 15.0 months (IQR: 6.5-21.1). Of these, 11 cases (10.1% of HCC patients) followed HCC recurrence, and 1 case (33.3% of cholangiocarcinoma patients) followed cholangiocarcinoma recurrence. Overall, 33 patients experienced tumor recurrence, and 30 died. Among the 12 with HBV recurrence, 11 died due to tumor progression, while 1 remains alive with HCC under treatment. Multivariate analysis identified exceeding the "Up-to-seven" criteria (OR: 7.99, 95% CI: 1.19-53.49, $P=0.032$) and the presence of cholangiocarcinoma (OR: 116.7, 95% CI: 6.06-2250.5, $P=0.002$) as independent risk factors for HBV recurrence.

Conclusions: HBV recurrence is closely associated with tumor recurrence post-liver transplantation. Patients presenting with larger or multiple tumors or with

cholangiocarcinoma before transplantation, are at significantly higher risk for HBV recurrence. Mortality in this cohort was primarily driven by tumor progression rather than HBV recurrence itself.

Keyword(s) : HBV recurrence; HCC recurrence; liver transplantation; risk factors.

2668 - Efficacy and Safety of Elobixibat in Patients with Chronic Constipation A Meta Analysis of Randomized Controlled Trials

Daniele Alek Calda¹, Federico Iv Peralta¹, Enrik Aguila²
St. Luke's Medical Center - Global City, Insitute Of Digestive And Liver Disease, Taguig-Philippines¹ St. Luke's Medical Center - Global City, Institute Of Digestive And Liver Disease, Taguig-Philippines²

Background / Hypothesis:

Elobixibat is a first-in-class, minimally absorbed, locally acting inhibitor of the ileal bile acid transporter (IBAT), approved for the treatment of chronic constipation. By interrupting enterohepatic bile acid circulation in the terminal ileum, elobixibat increases colonic bile acid delivery, stimulating fluid secretion and high-amplitude propagated contractions to enhance colonic motility. It's overall clinical efficacy and safety profile remain inconsistent across individual trials. This meta-analysis aimed to synthesize available evidence on the therapeutic efficacy and safety of elobixibat in chronic constipation.

Materials and Methods:

A systematic search of PubMed, EMBASE, and Cochrane was conducted for randomized controlled trials (RCTs) published through January 2026. Adult patients diagnosed with functional constipation according to Rome IV criteria were included. Study quality and risk of bias were assessed in accordance with PRISMA guidelines. Data were pooled using RevMan version 5.4. Efficacy outcomes were expressed as risk ratios (RRs) for categorical variables and least-square mean differences for continuous variables, with statistical significance set at $p < 0.05$.

Results:

Three RCTs comprising 507 patients met inclusion criteria. Elobixibat significantly improved weekly spontaneous bowel movement frequency compared with placebo (RR = 1.45; 95% CI, 1.20-1.75; $p < 0.001$). Abdominal pain, the most commonly reported adverse effect, occurred less frequently in the elobixibat group than in the placebo group [RR = 0.26 (0.08-0.82), $P = .02$]. Most reported adverse events were mild in severity.

Conclusions: Elobixibat is effective in improving bowel

E-POSTER ABSTRACTS

movement frequency in patients with chronic constipation and demonstrates a favorable safety profile. These findings support its role as a therapeutic option for patients requiring prompt and sustained symptom relief. Larger, multicenter randomized trials are warranted to further define its long-term efficacy and adverse event profile.

Keyword(s) : elobixibat, ileal bile acid transporter inhibitor, IBAT, constipation

2669 - Multicohort metagenomic analysis of cholangiocarcinoma non invasive diagnosis and functional validation of key microbes

Zhigang Ren¹, Benchen Rao¹, Zujiang Yu¹

The First Affiliated Hospital Of Zhengzhou University, Department Of Infectious Diseases, Zhengzhou-China¹

Background / Hypothesis:

Cholangiocarcinoma (CCA) is a highly lethal malignancy with limited early diagnostic options. While emerging evidence implicates the gut microbiome in CCA tumorigenesis, its potential as a non-invasive diagnostic biomarker remains unexplored. This study aimed to characterize CCA-associated gut microbial alterations and evaluate their diagnostic utility across diverse Chinese populations.

Materials and Methods:

Metagenomic sequencing was performed on fecal samples collected from 643 individuals across three geographically distinct regions in China (East, Central, and Northwest). We analyzed microbial community composition and functional pathways to identify CCA-specific dysbiosis patterns. Diagnostic models were constructed using both species-level taxonomic markers and functional pathway-based features. Model performance was evaluated in the discovery cohort and validated in two independent cross-regional cohorts. Additionally, we assessed the model's ability to differentiate CCA from hepatocellular carcinoma (HCC) and examined disease specificity using 6,847 samples from 31 published studies spanning 11 disease conditions.

Results:

CCA patients exhibited distinct gut microbial dysbiosis characterized by significant enrichment of lipopolysaccharide-producing bacteria (*Klebsiella aerogenes*, *Citrobacter koseri*) and depletion of butyrate-synthesizing organisms (*Faecalibacterium*

prausnitzii, *Roseburia intestinalis*). Species-level diagnostic models demonstrated superior discriminatory capacity compared to pathway-based approaches, achieving area under the curve (AUC) values of 98.63% and 99.42% in the East China discovery cohort. Importantly, robust cross-regional validation yielded AUCs of 80.89% in Central China and 80.43% in Northwest China, confirming model generalizability. The model effectively distinguished CCA from HCC (AUC=95.58%), addressing a critical clinical differential diagnosis challenge. Meta-analysis of public datasets revealed moderate disease specificity for the CCA microbiome signature, with performance influenced by biomarker overlap across different pathological conditions. Mechanistically, depleted *Bifidobacterium pseudocatenulatum* suppressed CCA progression through inhibition of the PI3K-AKT-mTOR pathway.

Conclusions:

This study establishes gut microbiome metagenomics as a promising non-invasive diagnostic tool and identifies potential therapeutic targets for cholangiocarcinoma.

Keyword(s) : cholangiocarcinoma, gut microbiome, metagenome, diagnostic model, liver cancer

2674 - Model combining MELD ICG R15 and systemic immune inflammation index predicts 28 day clinical progression in hepatitis B virus related acute on chronic liver failure patients

Jian Li¹, Lei Luo¹, Wenlong Yang¹

The Second Affiliated Hospital Of Nanchang University, Infectious Diseases Department, Nanchang-China¹

Background / Hypothesis:

Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) carries high short-term mortality. Existing prognostic scores are often static and may not fully capture dynamic liver reserve and systemic inflammation.

Materials and Methods:

A retrospective study included 66 HBV-ACLF patients admitted between June 2023 and December 2024, categorized by 28-day outcome into improvement (n=49) and progression (n=17) groups. Clinical data, indocyanine green clearance test parameters, and systemic immune-inflammation index (SII) were collected. Logistic regression identified predictors for model construction. Model discrimination was

E-POSTER ABSTRACTS

evaluated using the receiver operating characteristic curve, with internal validation via bootstrap and assessment of calibration and clinical net benefit.

Results:

Multivariate analysis identified SII/1000 as an independent risk factor (OR=5.77, 95% CI: 1.64-20.37, P=0.006), with MELD-ICG R15 score showing marginal significance (P=0.082). The final model was: $\text{logit}(P) = -6.658 + 0.060 \times (\text{MELD-ICG R15}) + 1.753 \times (\text{SII}/1000)$. The area under the curve was 0.761 (95% CI: 0.627-0.873), with bootstrap-corrected area under the curve of 0.732. At the optimal cutoff of 0.209, sensitivity was 82.4% and specificity 65.3%. The calibration curve showed good agreement, and decision curve analysis indicated positive clinical net benefit.

Conclusions:

The combination of MELD-ICG R15 and SII effectively predicts 28-day clinical progression risk in HBV-ACLF patients, offering a potential tool for early risk stratification and personalized intervention.

2675 - The Mechanism of Necroptosis in Metabolic dysfunction associated Fatty Liver Disease and related targeted therapy

Xiang Liu ¹, Jing Chen ¹, Bo Yang ¹, Huili Yang ¹, Yufeng Xing ¹

Shenzhen Hospital Of Traditional Chinese Medicine/fourth Clinical Medical College Of Guangzhou University Of Traditional Chinese Medicine, Department Of Hepatology, Shenzhen-China ¹

Metabolic dysfunction-associated fatty liver disease is a common chronic liver disease worldwide, with a continuously rising incidence rate. The traditional "two-hit" theory has gradually been replaced by the "multiple hit" hypothesis, which emphasizes the synergistic effect of multiple pathogenic factors. Necroptosis, as an inflammatory form of death that combines the morphological characteristics of necrosis and the signaling mechanism of apoptosis, its core lies in the RIPK1-RIPK3-MLKL signaling axis. It not only directly leads to the death of hepatocytes, releasing damage-related molecular patterns to trigger inflammatory responses and promote the fibrosis process, but is also closely related to the metabolic reprogramming of the liver. This review aims to

summarize the activation mechanism of necroptosis in metabolic dysfunction-associated fatty liver disease, its effects on liver inflammation, fibrosis and metabolism, and explore its therapeutic strategies and application prospects.

Keyword(s) : Necroptosis, MAFLD, mechanism, treatment

2676 - the Mechanism of Ruangan Formula in Regulating Macrophage Glycolysis for the Prevention and Treatment of Liver Fibrosis via SIRT1 Mediated PKM2 Deacetylation

Bo Yang ¹, Jing Chen ¹, Xiang Liu ¹, Huili Yang ¹, Chief Physician Xing ¹

Shenzhen Hospital Of Traditional Chinese Medicine/fourth Clinical Medical College Of Guangzhou University Of Traditional Chinese Medicine, Department Of Hepatology, Shenzhen-China ¹

Background / Hypothesis:

Liver fibrosis is a critical stage in the progression of chronic liver diseases, and effective drugs for its reversal are currently lacking. Inflammatory polarization of macrophages (M1 phenotype) is a key driver of fibrosis, closely associated with cellular metabolic reprogramming, particularly the activation of glycolysis. Ruangan Formula is an effective traditional Chinese medicinal compound for clinically preventing and treating liver fibrosis, but its mechanism of action remains incompletely understood. This study aims to investigate whether Ruangan Formula exerts its anti-fibrotic effects by regulating macrophage glycolysis and the SIRT1/PKM2 signaling axis.

Materials and Methods:

A CCl₄-induced mouse liver fibrosis model and an LPS-stimulated primary bone marrow-derived macrophage (BMDM) polarization model were established. The effects of Ruangan Formula on liver histopathology, collagen deposition, inflammatory cytokine expression, and glycolytic indicators were evaluated. Network pharmacology was employed to predict core targets, and molecular docking was used to verify the binding affinity of Ruangan Formula's active components with SIRT1. Myeloid-specific PKM2 knockout mice were generated using the Cre-loxP system. Combined with the SIRT1 inhibitor EX527, the necessity of the SIRT1/PKM2 pathway in the action of Ruangan Formula was validated both in vivo and in vitro. Immunoprecipitation, mass spectrometry, and site-directed mutagenesis were used to identify PKM2 acetylation sites.

E-POSTER ABSTRACTS

Results:

Clinical and animal experiments confirmed that Ruangan Formula significantly improved pathological indicators of liver fibrosis, inhibited M1 macrophage polarization, and reduced the production of lactate, a key glycolytic product. Network pharmacology screening suggested SIRT1 as a core target of Ruangan Formula, and molecular docking showed good binding potential between its active components and SIRT1. Experiments demonstrated that Ruangan Formula upregulated SIRT1 expression, decreased PKM2 acetylation levels, inhibited its nuclear translocation, and suppressed the transcription of downstream glycolytic genes. The anti-fibrotic and metabolic regulatory effects of Ruangan Formula were significantly attenuated following PKM2 knockout or SIRT1 inhibition.

Conclusions:

Ruangan Formula likely upregulates SIRT1, promotes PKM2 deacetylation, inhibits its nuclear translocation and glycolysis reprogramming, thereby modulating macrophage polarization towards the M1 phenotype and ultimately exerting anti-liver fibrosis effects. This research provides a modern molecular mechanism for the traditional Chinese medicine principle of "Strengthening Healthy Qi and Removing Blood Stasis" and offers new scientific evidence for the clinical application of Ruangan Formula.

Keyword(s) : Liver fibrosis; Ruangan Formula; Macrophage polarization; Glycolysis; SIRT1; PKM2; Deacetylation

2677 - Barriers and Facilitators to Chronic Hepatitis B Management in Primary Care A Systematic Review from Patient and Physician Perspectives

Jing Chen ¹, Wei Yuan ¹, Thanh Thuy Pham ², Saeed Hamid ³, Phillipa Easterbrook ⁴, Wen-juei Jeng ⁵, Ming-lung Yu ⁶, Bonnie Wang ⁷, Ching-lung Lai ⁸, George Lau ⁹

University Hospital, Kaohsiung Medical University, Hepatobiliary Division, Department Of Internal Medicine, Kaohsiung-Taiwan ⁶ Hksar Government, Department Of Health, Health Protection, Public Health Services Branch, Special Preventive Programme, Special Preventive Programme Head Office, Hong Kong-Hong Kong SAR, China ⁷ The University Of Hong Kong, The University Of Hong Kong, Hong Kong-Hong Kong SAR, China ⁸ Humanity And Health Medical Group, Humanity And Health Clinical Trial Center, Hong Kong-Hong Kong SAR, China ⁹

Background / Hypothesis:

Decentralisation of chronic hepatitis B (CHB) management to primary care is increasingly promoted to improve diagnosis, linkage to care, and long-term follow-up. However, successful implementation depends on the preferences, experiences, and perceived barriers of both patients and physicians. This systematic review synthesised patient- and physician-level perspectives on CHB management in primary care settings.

Materials and Methods:

A systematic literature search using subject headings and keywords was conducted in PubMed, Embase, Web of Science, and PsycINFO, yielding 7,087 records. After duplicate removal (n = 6,555), 532 records were screened by title and abstract, and 437 were excluded. Ninety-five articles underwent full-text review, of which 50 met inclusion criteria (22 patient-focused and 28 physician-focused). Data were analysed using thematic synthesis to identify patient- and provider-level barriers and proposed solutions.

Results:

At the patient level, five major barriers to CHB management in primary care were identified: (1) healthcare system barriers (e.g. fragmented care, poor continuity, long waiting times, and perceived low quality of primary care); (2) cultural and social barriers (e.g. language discordance, conflicting health beliefs, family dynamics); (3) stigma and psychosocial barriers (e.g. fear of discrimination and shame); (4) knowledge barriers (e.g. low awareness and misconceptions about CHB); and (5) economic barriers (transportation, time constraints). Proposed solutions included decentralization of care to community settings, culturally and linguistically tailored health education, strengthened reminder systems, and financial support mechanisms.

E-POSTER ABSTRACTS

At the physician level, barriers included systemic constraints (limited diagnostics, funding, and unclear guidelines), limited knowledge and confidence in CHB management, communication challenges with migrant and high-risk groups and stigma towards affected populations. Proposed solutions included targeted continuing medical education, simplified and standardized guidelines, implementation of clinical tools and recall systems, culturally adapted communication strategies, and shared-care models between primary and specialist services.

Conclusions:

This systematic review demonstrated that multilevel barriers hinder effective CHB management in primary care. Addressing system, cultural, educational, economic-level challenges through integrated, culturally sensitive, and shared-care models is critical to scaling up primary care-led CHB management and achieving goals towards viral hepatitis elimination.

Keyword(s) : Chronic Hepatitis B; Primary health care; Decentralization; Shared-care model

2680 - Evaluation of NLR as a novel Predicting biomarker for Disease Severity and Clinical Outcomes in Acute Hepatitis A and E

Md. Shakhawat Hossain¹, Khondoker Monirul Alam², Makhsudul Alam¹

Rangpur Medical College Hospital, Gastroenterology, Rangpur-Bangladesh¹ Rangpur Medical College Hospital, Medicine, Gazipur-Bangladesh²

Background / Hypothesis:

Acute hepatitis A (HAV) and E (HEV) infections can progress to severe liver injury or acute liver failure (ALF). Early biomarkers for risk stratification are essential. This study was aimed to evaluate the utility of the neutrophil-to-lymphocyte ratio (NLR) in predicting disease severity and outcomes in acute HAV and HEV.

Materials and Methods:

A cross-sectional study of 200 acute hepatitis patients (100 HAV, 100 HEV) was conducted over 12 months from February 2024 to February 2025 at Department of gastroenterology, Hepatology, Medicine of Rangpur medical college Hospital and five private chamber in Rangpur city. NLR, clinical parameters (bilirubin, ALT, INR, albumin), and outcomes (liver failure, hospitalization duration, mortality) were analyzed.

Severity was classified as mild (no complications), moderate (coagulopathy/or prolonged symptoms), or severe (ALF/death). Statistical analyses included ROC curves, multivariate regression, and correlation testing.

Results:

Elevated NLR (>5.0) strongly correlated with disease severity ($p < 0.001$) in acute hepatitis. HEV patients had higher median NLR (6.2 vs. 4.8; $p = 0.003$) and ALF rates (18% vs. 8%). NLR >5.0 predicted ALF with 84% sensitivity and 76% specificity (AUC: 0.87). Patients with NLR >5.0 had longer hospital stays (14 vs. 7 days; $p < 0.001$) and higher mortality (10% vs. 1.5%; $p = 0.002$). NLR positively correlated with bilirubin ($r = 0.72$) and INR ($r = 0.65$), and negatively with albumin ($r = -0.58$).

Conclusions: NLR is a cost-effective biomarker for predicting severity and poor outcomes in acute HAV and HEV. An NLR >5.0 signals high risk for ALF, prolonged hospitalization, or death, enabling early intervention.

2682 - Isolated Pancreatic tuberculosis masquerading as Malignancy in a patient with drug induced liver injury A case report

Lili Zhao¹, Li Zhou¹, Jia Li¹

Tianjin Second People's Hospital, Department Of Gastroenterology And Hepatology, Tianjin-China¹

A 25-year-old Asian male was admitted to our department with a 3-day yellow urine after took Norfloxacin for diarrhea and vomiting. Laboratory examinations showed elevated liver enzymes and serum bilirubin. Drug-induced liver injury should be considered because the patient had used a liver injury drug. Autoimmune-antibodies showed indicate positive ANA and elevated IgG levels, so Autoimmune Hepatitis should be excluded clinically. However, he was misdiagnosed with pancreatic carcinoma because abdominal enhanced CT, MRI and PET-CT showed a space-occupying lesion in the pancreatic head, but his alpha-fetoprotein, carbohydrate antigen 19-9, and ferroprotein levels were normal. Bilirubin was significantly decreased after anti-infective treatment, so the pancreatic lesion considered may be an infectious lesion. A subsequent T-Spot test result was positive and erythrocyte sedimentation rate increased.

E-POSTER ABSTRACTS

patient then underwent endoscopic pancreatic fine needle aspiration biopsy and cytology and metagenomic detection of pathogenic microorganism. The histological of the pancreatic mass showed granulomatosis, and mycobacterium tuberculosis was detected by NGS, so the mass diagnosed as a isolated pancreatic tuberculosis. The patient had elevated liver enzymes, so ultrasound-guided liver biopsy was performed. The histologic characteristics include mild inflammation, fibrous and small bile duct proliferation of interlobular portal areas, and normal structure of hepatic lobule, so the pathologic diagnosis might be drug-induced liver injury. The patient's liver function of was improved after liver protection therapy, but active anti-tuberculosis therapy was needed due to the pancreatic tuberculosis. The patient was complicated with severe liver injury, and the anti-tuberculosis treatment started with streptomycin combined with levofloxacin with very low hepatotoxicity. The patient continued to have normal liver function and and the drugs were gradually adjusted to the first-line anti-tuberculosis treatment regimen: Streptomycin, Ethambutol, Isoniazid and Rifampicin. The patient accordingly received anti tuberculosis agents for 12 months, resulting in a significant decrease in the size of the pancreatic mass and recovered well.

2683 - Prior Tyrosine Kinase Inhibitor Therapy Is Associated with an Increased Risk of Hepatitis B Virus Reactivation in HBV Related Hepatocellular Carcinoma Patients with Undetectable HBV DNA Receiving PD 1 Inhibitor-Based Combination Therapy

Yang Li¹, Chuyue Xiong², Xuanxuan Duan¹, Fanping Meng³

Peking University 302 Clinical Medical School, Infectious Diseases, Beijing-China¹ Medical School Of Chinese People's Liberation Army, Infectious Diseases, Beijing-China² Medical School Of Chinese People's Liberation Army ;peking University 302 Clinical Medical School, Infectious Diseases, Beijing-China³

Background / Hypothesis:Although prophylactic antiviral therapy is recommended for hepatocellular carcinoma (HCC) patients receiving programmed cell death protein-1 (PD-1) inhibitors combined with tyrosine kinase inhibitors (TKIs), hepatitis B virus reactivation (HBVr) still occurs, even in patients with low baseline viral load. Baseline high HBV DNA levels are a well-established risk factor for HBVr;however, the

incidence and risk factors of HBVr in HCC patients with undetectable HBV DNA prior to treatment remain unclear. This study aimed to evaluate the incidence and identify risk factors for HBVr in this specific population receiving PD-1 inhibitor plus TKI therapy.

Materials and Methods:This retrospective study included 163 patients with HBV-related HCC who received PD-1 inhibitors combined with TKIs at our center between March 2020 and June 2024. Among them, 45 patients with undetectable serum HBV DNA before treatment (defined as <20 IU/mL) were enrolled for analysis. Patients were classified into an HBVr group (n = 14) and a non-HBVr group (n = 31) based on whether HBV DNA became detectable during treatment. Univariate and multivariate Cox proportional hazards models were applied to identify independent predictors of HBV reactivation.

Results:During a median follow-up of 13.8 months (range: 1.2–59.2 months), HBV reactivation occurred in 31.1% (14/45) of patients. In baseline characteristics, larger maximum tumor diameter (HR = 1.21, P = 0.003) and absence of ablation therapy (HR = 0.23, P = 0.024) were significantly associated with an increased risk of HBVr. Multivariate Cox regression analysis identified prior TKI therapy (HR = 5.83, 95% CI: 1.81–18.79, P = 0.003) and higher serum gamma-glutamyl transferase (GGT) levels (HR = 1.01, 95% CI: 1.01–1.01, P = 0.004) as independent risk factors for HBV reactivation.

Conclusions:HBV reactivation can still occur in patients with HBV-related HCC despite prophylactic nucleos(t)ide analogue therapy. HCC patients with undetectable baseline HBV DNA remain at risk of HBVr when treated with PD-1 inhibitor plus TKI combination therapy. Prior exposure to TKI therapy and elevated GGT levels are independent predictors of HBVr. Therefore, close monitoring of HBV DNA during treatment is essential, and treatment sequencing should be carefully considered to minimize the risk of HBV reactivation.

2684 - Hydrogen sulfide donor S Propargyl cysteine remodels the HCC microenvironment and enhances immunotherapy efficacy an integrated metabolomic and molecular analysis

Yuxin Liang¹, Qinyan Yang¹

Sichuan Cancer Hospital & Institute, Liver Transplantation Center And Hbp Surgery, Chengdu-China¹

Background / Hypothesis:

Hepatocellular carcinoma exhibits aberrant angiogenesis and immune suppression that restrict durable benefit from PD 1 blockade. We hypothesized that S propargyl cysteine (SPRC), an endogenous H₂S donor, engages cystathionine gamma lyase (CSE) to suppress NF κB and STAT3 signaling, reduce VEGF activity and tumor cell PD L1 expression, and enhance antitumor T cell function.

Materials and Methods:

SPRC binding to CSE was measured by surface plasmon resonance. In HUVECs, NF κB p65 and STAT3 phosphorylation and VEGFA expression were assessed by immunoblotting, and angiogenic capacity was quantified by Matrigel tube formation with CSE knockdown and rescue. In HepG2 and T cell co culture, tumor cell PD L1 and T cell phenotypes were analyzed by flow cytometry, and cytotoxic activity was evaluated by granzyme B secretion, with STAT3 inhibition as a mechanistic comparator. Promoter associated H3K27ac enrichment at RELA and STAT3 was measured by ChIP qPCR. In an HCC mouse model, anti PD 1 alone or combined with SPRC was evaluated by tumor volume, intratumoral CD8 positive T cells and Tregs by flow cytometry, and vascular density by CD31 immunohistochemistry. Untargeted LC MS metabolomics and oxidative stress indices including MDA and SOD were used to characterize metabolic coordination and redox status.

Results:

SPRC bound recombinant CSE with nanomolar affinity and reduced NF κB p65 and STAT3 phosphorylation in endothelial cells, accompanied by decreased VEGFA and impaired tube formation. These antiangiogenic effects were attenuated by CSE silencing and partially restored by CSE re expression, supporting CSE dependence. In co culture, SPRC reduced PD L1 on HepG2 cells, increased CD8 alpha, decreased FoxP3, and increased granzyme B secretion, consistent with

improved cytotoxic effector function. SPRC increased H3K27ac enrichment at RELA and STAT3 promoters. In vivo, SPRC plus anti PD 1 achieved greater tumor growth inhibition than anti PD 1 alone, increased intratumoral CD8 positive T cells, decreased Tregs, and reduced CD31 indexed vascular density. Metabolomic profiling indicated coordinated pathway level rewiring and was accompanied by reduced MDA and increased SOD activity, consistent with alleviated oxidative stress.

Conclusions:

SPRC engages a CSE linked program that suppresses NF κB and STAT3 to couple antiangiogenic activity with reduced PD L1 mediated immune inhibition and enhanced cytotoxic immunity. SPRC augments PD 1 blockade in HCC with coordinated immune, vascular, metabolic, and redox remodeling, supporting its development as an adjunct strategy to overcome the vascular immune barrier.

2685 - Early diagnostic and analysis of the high risk factors of covert hepatic encephalopathy

Pin Han¹, Lili Zhao², Jia Li²

Tianjin Second People's Hospital, Department Of Gastroenterology And Hepatology, Tianjin-China¹
Tianjin Second People's Hospital, Tianjin Second People's Hospital, Tianjin-China²

Background: The present study was designed to analyze the risk factors for Covert Hepatic Encephalopathy (CHE) in cirrhotic patients, to evaluate the diagnostic efficacy of different neuropsychological tests in cirrhotic patients with CHE, and to establish an easy-to-administer screening and diagnostic method with reliable results, so as to provide a new clinical idea for the early diagnosis of CHE.

Methods: Patients who were hospitalized in the Department of Hepatology of Tianjin Second People's Hospital and Tianjin First Central Hospital with clinical and/or pathological diagnosis of cirrhosis from November 2024 to March 2025, as well as subjects who had healthy physical examinations were included as study subjects. The gender, age, and years of education of cirrhotic patients and healthy subjects were recorded, and the laboratory examination data of cirrhotic patients were collected to complete the Psychological Score of HE (PHES), Encephal APP, Animal Naming Test (ANT), and the Chinese version of Montreal Cognitive Assessment-Based (MoCA-BC)

E-POSTER ABSTRACTS

scale. SPSS 26.0 was applied to process the data, and independent risk factors for the occurrence of CHE in cirrhotic patients were analyzed by binary logistic regression.

Results: Eighty patients with cirrhosis were finally included in this study. The combination of MoCA-BC with other neuropsychological tests yielded that the diagnostic efficacy of the MoCA-BC-NCT-A combination, the MoCA-BC-SDT combination, and the MoCA-BC-LTT combination was superior to the other combinations in the cirrhotic population in the low-years-of-education group for the diagnosis of CHE, with a statistically significant difference ($P < 0.01$), and that the MoCA-BC-Quick Stroop combination was superior to the other combinations in the cirrhotic population in the middle- and high-years-of-education group ($P < 0.01$). MoCA-BC-Quick Stroop combination had better diagnostic efficacy for CHE than other combinations, with statistical differences ($P < 0.01$). Conclusion: The MoCA-BC test has good diagnostic efficacy in diagnosing CHE with a cutoff score of 20 in the low-education group and 26 in the middle-high education group. MoCA-BC-NCT-A combination, MoCA-BC-SDT combination and MoCA-BC-LTT combination can be selected for CHE diagnosis in the cirrhosis population of the low education group; in the cirrhosis population of the middle and high education group, MoCA-BC-Quick Stroop combination can be selected for CHE diagnosis, which has a good diagnostic efficacy.

2686 - Multisystem Crosstalk in MAFLD An Integrative Perspective from Organ Dialogue to Hepatic Pathology

Ziwei Yuan¹, Yaqian Mao¹, Yuanbin Zhong¹

The First Affiliated Hospital Of Nanchang University, Infectious Diseases Department, Nanchang-China¹

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MASLD/MAFLD) has evolved from the traditional "second-hit" pathological model, where the liver serves as the initial site of disease onset, into a systemic disorder involving dynamic interactions among multiple organs. The core mechanism lies in dysregulated crosstalk among multiple organ axes, with the gut-liver axis serving as the disease initiation point. Gut barrier disruption and dysbiosis lead to lipopolysaccharide translocation and bile acid

metabolism disorders, subsequently activating hepatic inflammatory responses via the portal vein. Building upon this, the adipose tissue-liver axis exacerbates hepatic lipotoxicity through free fatty acid overflow and adipokine imbalance, while insufficient activation of brown adipose tissue weakens protective lipid clearance mechanisms. Additionally, the brain-liver axis modulates hepatic metabolism and inflammation via neuroendocrine signaling (e.g. brain-derived neurotrophic factor and vagus nerve pathways), while the kidney-liver axis shares insulin resistance and fibrosis pathways, forming bidirectional pathological associations. At the intrahepatic level, intercellular communication networks further amplify systemic signals: hepatic lipid accumulation triggers Kupffer cell polarization toward a proinflammatory phenotype, accelerating stellate cell activation and fibrosis via the senescence-associated secretory phenotype; sinusoidal endothelial capillary formation induces microenvironment hypoxia, synergistically promoting disease progression. These multiscale interactions collectively drive a vicious cycle of chronic inflammation, mitochondrial dysfunction, and metabolic reprogramming.

Based on these mechanisms, therapeutic strategies shift toward multi-target integrated interventions. For instance, FXR agonists and PPAR agonists can simultaneously repair the gut-liver axis and lipid metabolism, while GLP-1 receptor agonists concurrently improve pancreatic function, central appetite regulation, and hepatic inflammation. Cellular senescence-targeting drugs (e.g. senolytics) and fibrosis pathway inhibitors address advanced pathological stages. Future directions emphasize personalized treatment through multi-omics data and patient stratification, overcoming the limitations of single-pathway therapies. This crosstalk perspective not only explains disease heterogeneity but also provides a theoretical basis for combination therapies, marking the entry of MASLD/MAFLD management into the era of systems medicine.

2687 - The Mediating Roles of HOMA β and TG HDL C in the Associations of General and Central

E-POSTER ABSTRACTS

Adiposity with metabolic dysfunction associated fatty liver disease A Cross Sectional Study

Guangqi Zhu ¹, Yingqiu Ma ², Jingfei Wu ³, Liang Chen ³, Xin Shen ³, Luwen Zhang ³, Haidong Zhu ³, Shibo Li ²
Nanjing Drum Tower Hospital, Department Of Infectious Diseases, Nanjing-China ¹ Zhoushan Hospital, Department Of Infectious Disease, Zhoushan-China ² Zhanmao Street Community Health Service Center, Department Of General Medicine, Zhoushan-China ³

Background / Hypothesis:

Obesity is a major risk factor for metabolic dysfunction-associated fatty liver disease (MAFLD), but its underlying mechanisms have not been fully elucidated. This study aims to quantify and compare the mediating roles of pancreatic islet β -cell function (HOMA- β) and atherogenic lipid profile (TG/HDL-C) in the association between general and central obesity and MAFLD.

Materials and Methods:

This study was a cross-sectional analysis, involving a total of 200 examinees. MAFLD was diagnosed according to the 2023 EASL criteria. General obesity was defined as BMI ≥ 24 kg/m², and central obesity was defined according to the China waist circumference standard. Multivariate logistic regression was used to analyze associations, and restricted cubic spline was applied to test nonlinear relationships. The proportion of mediating effects between HOMA- β and TG/HDL-C was quantified using a Bootstrap-based mediation model, and subgroup analysis was conducted to explore heterogeneity.

Results:

After adjusting for confounding factors, both BMI and waist circumference were significantly positively correlated with the risk of MAFLD (both $P < 0.01$). Mediation analysis showed that HOMA- β mediated 18.23% of the total effect of the BMI-MAFLD association and 12.35% of the waist circumference-MAFLD association (both $P = 0.026$). TG/HDL-C mediated 9.69% and 9.15% of the above associations, respectively (both $P = 0.04$). Subgroup analysis revealed that the association between BMI and MAFLD was stronger in individuals without hypertension (interaction $P = 0.031$), while the association between waist circumference and MAFLD was stronger in individuals without a history of diabetes and without a family history of diabetes (interaction $P = 0.007$ and 0.043 , respectively).

Conclusions:

In the association between obesity and MAFLD, both HOMA- β and TG/HDL-C play significant partial mediating roles, and the mediating effect of the islet β -cell function pathway accounts for a relatively higher proportion. The research results suggest that interventions targeting islet function and lipid metabolism may be of great value in the early pathogenesis of obesity-related MAFLD.

2688 - Immediate Improvement in HCV RNA Testing Following Active In Hospital Management An Interrupted Time Series Analysis

Jian Li ¹, Lei Luo ¹, Wenlong Yang ¹

The Second Affiliated Hospital Of Nanchang University, Infectious Diseases Department, Nanchang-China ¹

Background / Hypothesis:

The attrition between hepatitis C virus (HCV) antibody screening and confirmatory RNA testing remains a critical barrier to treatment initiation. We evaluated the immediate and sustained impact of a multi-component, active case management strategy implemented within a large hospital on this key step in the care cascade.

Materials and Methods:

A single-center, retrospective observational study was conducted. An interrupted time series analysis (ITS) was used to model the HCV RNA testing rate among anti-HCV-positive individuals before and after the sequential implementation of integrated interventions, including an informatics alert system, patient recall, and dynamic clinical reminders, from 2017 to 2024.

Results:

Linear regression modeling of the ITS data showed: 1) a non-significant pre-intervention annual trend increase of +2.47% ($P=0.056$); 2) a significant immediate level increase of +27.86% ($P=0.028$) upon intervention; and 3) a non-significant change in the post-intervention slope (-1.15% per year, $P=0.627$). This indicates a substantial, abrupt improvement in the RNA testing rate that was subsequently maintained at a higher plateau.

Conclusions:

A proactive, in-hospital management strategy resulted in a significant and immediate "step-up" in HCV RNA

E-POSTER ABSTRACTS

confirmation testing, effectively strengthening a fragile link in the micro-elimination cascade. The intervention's primary effect was an initial implementation shock that durably elevated performance.

2692 - Predictors of recompensation in autoimmune hepatitis related decompensated cirrhosis following immunosuppressive therapy in India

Sayan Malakar¹, Sumit Rungta¹, Vishwas Kapoor², Rajat Gupta³, S Rakesh Kumar⁴
King George Medical University, Gastroenterology, Lucknow-India¹ Sgpgims, Biostatistics, Lucknow-India² Mackay Base Hospital, Internal Medicine, Queensland-Australia³ Institute Of Medical Science And Sum Hospital, Gastroenterology, Bhubaneswar-India⁴

Background / Hypothesis: Data on the predictors of recompensation following immunosuppressive therapy (IST) in autoimmune hepatitis-related decompensated cirrhosis (AIH-DC) are scarce

Materials and Methods: In this retrospective study, data of all patients with AIH-DC who underwent treatment from 2015 to 2024 were retrieved from a prospectively maintained electronic database. Frequency and predictors of recompensation (according to Baveno VII) following IST were assessed in patients with AIH-DC and were compared with those of patients who received standard medical therapy (SMT). Other outcomes include overall survival (OS), flare-free survival, and infection rate in both cohorts.

Results: Of 77 patients, 53 received IST (12 high-dose steroids and 41 low-dose steroids). The other 23 patients received SMT. Median age at presentation was 45 [interquartile range (IQR) 34-51] years, and the majority were females (78%). Median follow-up period was 39 [IQR: 35.5-48] months. Baseline parameters were comparable between the IST and SMT groups. Of 54 patients, 18 (34%) achieved recompensation in the IST group ($p=0.001$). Predictors of recompensation include patients with less than grade 3 ascites [Odds ratio (OR): 95% CI: 34 (3.7-304); $p=0.002$] hepatic encephalopathy < grade 3 [OR 1.66 (95% CI: 1.05-2.78);

$p=0.035$], Child-Turcot Pugh (CTP) score <9 [OR 6.78 (95% CI: 1.49-30.15); $p=0.013$], model for end stage liver disease-sodium score <25 [OR 3.9 (95% CI 1.14-39.04); $p=0.001$], and serum immunoglobulin-G levels <2300 g/dL [OR 3.38 (95% CI 1.0-11.2); $p=0.046$]. On Kaplan Meier analysis IST group had a better OS as compared to the SMT group. No significant differences were noted in liver-related outcomes or infection rate between the high-dose and low-dose steroid groups.

Conclusions: 34% patients achieved recompensation following IST in patients with IST. Lower CTP, MELD-Na score, serum IgG, lesser grade of HE and ascites predicted recompensation following IST in AIH-DC.

2694 - Comparison of Diagnostic Performance of Non Invasive Steatosis and Fibrosis Scores and Ultrasound versus FibroScan in Metabolic Associated Fatty Liver Disease

Eman Fares¹, Nourhan S Ahmed², Nermeen A Foad³, Essam A. Hassan¹
Fayoum University, Endemic Medicine, Fayoum-Egypt¹ Fayoum University, Endemic Medicine, Fayoum-Egypt² Fayoum University, Rheumatology & rehabilitation, Fayoum-Egypt³

Background / Hypothesis:

Metabolically associated fatty liver disease (MAFLD) is an increasing global health burden. Early identification of hepatic steatosis and fibrosis is critical for diagnosis, risk stratification, and appropriate management of MAFLD. Although transient elastography (FibroScan) is widely used, simpler metabolic scores and conventional ultrasound (US) may offer more accessible alternatives, particularly in resource-limited settings.

The study aimed to compare the diagnostic performance of non-invasive serum-based metabolic scores and ultrasound with FibroScan for the evaluation of hepatic steatosis and fibrosis in patients with MAFLD.

Materials and Methods:

This cross-sectional study included 200 adult patients attending the hepatology clinic of a tertiary-care Egyptian hospital for FibroScan evaluation. All participants underwent detailed clinical assessment

E-POSTER ABSTRACTS

and anthropometric measurements, including body mass index, waist and hip circumferences, and waist-hip ratio. Laboratory investigations comprised complete blood count, liver and renal function tests, lipid profile, viral hepatitis markers, fasting blood glucose, 2-hour postprandial glucose, and HbA1c. Abdominal ultrasound and FibroScan were performed for all patients. Hepatic steatosis was defined using the controlled attenuation parameter (CAP), while liver fibrosis was assessed by liver stiffness measurement (LSM). The diagnostic performance of steatosis indices (HSI, FLI, TyG index, TyG-BMI, TyG-WC, TyG-WHR, TG/HDL ratio, and VAI) and fibrosis scores (FAST, Agile 3+, Agile 4, FIB-4, NAFLD fibrosis score, APRI, and BARD) was evaluated using receiver operating characteristic (ROC) curve analysis.

Results:

Ninety-eight patients (49%) were diagnosed with MAFLD based on CAP values. All evaluated non-invasive indices showed significant diagnostic ability for detecting hepatic steatosis ($p < 0.001$). Ultrasound demonstrated the highest diagnostic accuracy (AUC 0.892), followed by TyG-BMI (0.874), TyG-WC (0.863), FLI (0.846), and HSI (0.808), whereas the TyG index alone showed modest performance (AUC 0.715). Liver fibrosis was detected in 46 patients (23%) by LSM. Agile 3+ and Agile 4 scores showed the best overall performance for fibrosis detection (AUC 0.828 and 0.810, respectively; $p < 0.001$). Agile 3+ exhibited high sensitivity (85.3%) and negative predictive value (94.1%), while Agile 4 achieved the highest specificity (93.3%) and diagnostic accuracy (85.7%). Other scores like FIB-4, NFS, and BARD have moderate diagnostic performance, and APRI was not statistically significant.

Conclusions:

Ultrasound and selected metabolic indices, particularly TyG-BMI, TyG-WC, and FLI, demonstrate excellent diagnostic performance for hepatic steatosis compared with FibroScan. Agile fibrosis scores outperform traditional fibrosis indices, providing reliable, non-invasive tools for MAFLD assessment and supporting their use in routine clinical practice, especially in resource-constrained.

Background / Hypothesis:

Gastrointestinal (GI) diseases constitute a major public health burden in Egypt. However, nationally

E-POSTER ABSTRACTS

representative data describing their prevalence, geographic distribution, and associated risk factors remain limited. This study aimed to map the epidemiology of digestive diseases across Egyptian governorates and identify key demographic and lifestyle-related risk factors.

Materials and Methods:

A multicenter cross-sectional study was conducted between March 2023 to December 2024 and involved 2,027 patients presenting with gastrointestinal symptoms or diagnosed GI or liver diseases at hospitals and private clinics across multiple Egyptian governorates. Data collection included demographic characteristics, clinical presentations, comorbidities, lifestyle factors, and place of residence. Diagnoses were established according to ICD-11 criteria. Diseases were analyzed by anatomical category, geographic distribution, gender, and associated risk factors. Statistical analysis included chi-square tests, independent t-tests, and multivariate logistic regression to identify independent predictors.

Results:

Esophageal disorders were the most prevalent GI conditions (36.1%), followed by gastroduodenal (33.8%) and hepatic disorders (33.6%). Gastroesophageal reflux disease (GERD) accounted for 57.3% of esophageal disorders, while chronic gastritis represented 78% of gastroduodenal diseases. Viral hepatitis constituted 17.7% of hepatic cases, with hepatitis C virus (HCV) accounting for 80.5%. Functional gastrointestinal disorders were significantly more common among females ($p < 0.05$), whereas liver diseases predominated in males ($p < 0.001$). Diabetes mellitus showed a strong association with hepatic and malignant GI diseases, smoking was significantly linked to functional GI disorders, and urban residence emerged as an independent risk factor. Geographic variation was evident, with esophageal disorders most prevalent in Monufia (32.4%) and viral hepatitis highest in Asyut (18.8%).

Conclusions:

This study provides the first national-level epidemiological map of gastrointestinal diseases in Egypt, demonstrating marked regional, gender-based, and etiologic variability. GERD, chronic gastritis, and HCV-related liver disease remain dominant contributors to GI morbidity. These findings

underscore the need for region-specific prevention strategies, targeted screening programs, and tailored public health interventions to address Egypt's evolving digestive disease burden.

2697 - Demographic Profile and Clinical Indications of Patients Undergoing Liver Elastography in a Tertiary Government Hospital A Pilot Study

Alonzo, Uzziel Romar S. Alonzo ¹, Preza-carmona Preza-carmona, Sarah ¹, Te Marilyn ¹
Eamc, Gastroenterology, Malabon City-Philippines ¹

Background / Hypothesis: Chronic liver disease (CLD) is a major global health problem, with progressive fibrosis leading to cirrhosis and its complications. Accurate assessment of fibrosis stage is crucial because the degree of liver fibrosis determines prognosis and guides management in chronic liver disease. Our hospital – a tertiary government referral center – recently acquired shear-wave liver elastography capability (since 2024) to enhance care for patients with liver disease. However, local data on the profile of patients undergoing this test and the clinical contexts prompting its use are limited. This pilot study will retrospectively review the initial cases of liver SWE performed at our center. It will characterize the demographic profile of these patients and document the clinical indications for elastography. Ultimately, the findings will shed light on the patterns of elastography utilization in a government hospital setting, and whether they align with global trends. Such data can inform future larger studies and guide optimal use of elastography in our local practice.

Materials and Methods: The target population is all patients who underwent a liver shear-wave elastography scan at the hospital from 2024 to September 2025. The author employ total enumeration sampling. Based on radiology logs, approximately 60 patients have undergone liver elastography since the service's introduction in 2024, which will constitute our sample size.

•Inclusion Criteria:

- Patients of any age or gender who underwent a clinically indicated liver elastography exam at the hospital from 2024 to September 2025.
- Those with available medical records or referral forms detailing the reason for elastography and relevant clinical data.

•Exclusion Criteria:

E-POSTER ABSTRACTS

-Any elastography exam that was technically unsuccessful or invalid.

-Patients who had liver elastography done outside the study period will not be included in this pilot analysis.

Results: In terms of clinical indications, the majority of patients (65%) were referred for elastography due to cirrhosis or chronic liver disease, underscoring the role of liver elastography as a noninvasive tool for fibrosis assessment in patients with established or suspected advanced liver disease. The substantial proportion of patients with chronic viral hepatitis (11.7%), particularly hepatitis B, highlights the continued public health burden of viral hepatitis in the Philippines and reinforces the importance of elastography in disease staging and monitoring.

Conclusions: This pilot study describes the results of shear-wave liver elastography in a tertiary government hospital, demonstrating its use predominantly among middle-aged patients with suspected or established chronic liver disease.

Keyword(s) : elastography, chronic liver disease, hepatitis

2698 - Model combining MELD ICG R15 and systemic immune inflammation index predicts 28 day clinical progression in hepatitis B virus related acute on chronic liver failure patients

Jian Li ¹, Lei Luo ¹, Wenlong Yang ¹

The Second Affiliated Hospital Of Nanchang University, Infectious Diseases Department, Nanchang-China ¹

Background / Hypothesis:

Hepatitis B virus-related acute-on-chronic liver failure (HBV-ACLF) carries high short-term mortality. Existing prognostic scores are often static and may not fully capture dynamic liver reserve and systemic inflammation.

Materials and Methods:

A retrospective study included 66 HBV-ACLF patients admitted between June 2023 and December 2024, categorized by 28-day outcome into improvement (n=49) and progression (n=17) groups. Clinical data, indocyanine green clearance test parameters, and systemic immune-inflammation index (SII) were collected. Logistic regression identified predictors for model construction. Model discrimination was evaluated using the receiver operating characteristic curve, with internal validation via bootstrap and assessment of calibration and clinical net benefit.

Results:

Multivariate analysis identified SII/1000 as an independent risk factor (OR=5.77, 95% CI: 1.64-20.37, P=0.006), with MELD-ICG R15 score showing marginal significance (P=0.082). The final model was: $\text{logit}(P) = -6.658 + 0.060 \times (\text{MELD-ICG R15}) + 1.753 \times (\text{SII}/1000)$. The area under the curve was 0.761 (95% CI: 0.627-0.873), with bootstrap-corrected area under the curve of 0.732. At the optimal cutoff of 0.209, sensitivity was 82.4% and specificity 65.3%. The calibration curve showed good agreement, and decision curve analysis indicated positive clinical net benefit.

Conclusions:

The combination of MELD-ICG R15 and SII effectively predicts 28-day clinical progression risk in HBV-ACLF patients, offering a potential tool for early risk stratification and personalized intervention.

Keyword(s) : hepatitis B virus, acute-on-chronic liver failure, indocyanine green clearance test, systemic immune-inflammation index, prognosis, prediction model

2701 - MSC mediated Modulation of the IL 4 CD39 Axis in Treg cells Restores Immune Tolerance and Improves Treatment Outcomes in Steroid Resistant Autoimmune Hepatitis

Wanwan Shi ¹, Long Xu ¹

Peking University First Hospital, Department Of Infectious Diseases, Beijing-China ¹

Background / Hypothesis:

Autoimmune hepatitis (AIH) is an immune-mediated liver disease that poses significant challenges in treatment, particularly for patients who are steroid-resistant. Recent studies have highlighted that reduced CD39 expression on Treg cells, leading to impaired immunosuppressive function, is one of the key pathogenic mechanisms in AIH. Mesenchymal stem cells (MSCs), as a potential therapy, have demonstrated promising results in treating immune-related diseases. This study aims to explore the role of MSCs in restoring Treg cell function by modulating the IL-4/CD39 axis, providing a novel therapeutic strategy for steroid-resistant AIH patients.

Materials and Methods:

We assessed the expression of IL-4 in peripheral blood mononuclear cells (PBMCs) from steroid-resistant AIH patients using flow cytometry, and investigated the

E-POSTER ABSTRACTS

correlation between IL-4 expression and CD39 in Treg cells. Additionally, immunofluorescence staining was performed to examine the distribution of CD39 and IL-4 in liver tissue from these patients. To investigate the causal relationship between IL-4 and AIH susceptibility, we conducted a two-sample Mendelian randomization (MR) analysis. Furthermore, we evaluated the therapeutic effects of MSCs in a ConA-induced AIH mouse model by measuring liver injury biomarkers, immunoglobulin levels, and Treg cell subtypes and function, with a focus on the regulation of the IL-4/CD39 axis.

Results:

In PBMCs from steroid-resistant AIH patients, we observed significantly elevated IL-4 levels ($P < 0.01$), which correlated negatively with CD39 expression on Treg cells ($R = -0.42$, $P = 0.02$). MR analysis confirmed a significant causal relationship between IL-4 and AIH susceptibility. The analysis using the Inverse Variance Weighted method showed statistical significance (OR = 1.459027, 95% CI: 1.006 -2.115, $P = 0.046$) suggesting that IL-4 may increase the risk of AIH. These findings demonstrate a critical link between IL-4, CD39 deficiency, and impaired immune suppression in Treg cells. In the MSC-treated AIH mouse model, MSC treatment significantly reduced ALT, AST, and IgG levels ($P < 0.0001$), indicating effective immunoregulation. MSC treatment also significantly increased the proportion of Treg cells, restored CD39 expression on Treg cells, and decreased IL-4 expression, suggesting that MSCs restore Treg cell function by modulating the IL-4/CD39 axis.

Conclusions:

Our findings demonstrate that MSCs can modulate the IL-4/CD39 axis in Treg cells to restore immune tolerance and offer a potential new therapeutic solution for steroid-resistant AIH patients. This approach represents a novel strategy for treating autoimmune liver diseases.

Keyword(s) : MSC, IL-4, Treg, CD39, steroid-resistant, autoimmune hepatitis, immunoregulation, stem cell therapy

2702 - Modified Leipzig (Leipzig U) score is equally helpful for the early diagnosis of Wilson disease in children presenting with liver disease

Sanjeevani Kaul¹, Rajeev Khanna¹, Vikrant Sood¹, Bikrant Bihari Lal¹, Seema Alam¹
Ilbs, Pediatric Hepatology, New Delhi-India¹

Background and Aim: Leipzig score ≥ 4 confirms the diagnosis of Wilson disease (WD). However, 24-hour urine copper estimation and genetic results delay its application and timely initiation of chelation. Low uric acid (UA) is seen in WD due to proximal tubular dysfunction. We studied the diagnostic utility of serum UA as a simple biomarker for WD with its incorporation into a modified version of Leipzig score.

Methods: This retrospective data of 221 children with chronic liver disease was divided into 2 cohorts (derivation, $n=120$, WD = 58 and validation, $n=101$, WD = 58). UA levels were studied and centiles were derived from the derivation cohort. Based on centiles of UA, a score of 0, 1 and 2 were derived which were added into the Leipzig score without genetic diagnosis and without 24-hour urinary copper results. Area under receiver operating characteristic curves (AUROC) were studied.

Results: Mean UA levels were 2.60 ± 1.27 which were significantly lower in WD than autoimmune liver disease (ALD) (1.90 ± 0.89 vs 3.26 ± 1.22 , $p < 0.001$). Cut-off values at 50th (≤ 2.5 mg/dL) and 40th centiles (≤ 2.2 mg/dL) had a positive likelihood ratio of WD of 3.86 and 4.29. A score of 0, 1 and 2 were given for UA levels ≥ 2.5 , 2.2-2.5 and ≤ 2.2 mg/dL. Removing 24-hour urine copper and genetic diagnosis from the Leipzig score and adding UA score conferred a sensitivity and specificity of 91.4% and 100% (AUROC 0.986, $p < 0.001$) in the derivation cohort, and 94.8% and 97.7% (AUROC 0.965, $p < 0.001$) in the validation cohort, which is comparable to Leipzig score without genetic diagnosis in the whole cohort (sensitivity 91.4%, specificity 100%, AUROC 0.998, $p < 0.001$).

Conclusion: Using serum uric acid levels helps in early diagnosis of WD in the absence of genetic testing. Modified Leipzig (Leipzig-U) score needs validation in an external cohort.

2703 - Sequential plasma adsorption and therapeutic plasma exchange for extreme hyperbilirubinemia in Budd-Chiari syndrome with acute on chronic liver failure

Petr Piza¹

Ikem, Karip (transplant Icu), Prague-Czechia¹

Background / Hypothesis:

Extreme hyperbilirubinemia in advanced liver disease can contribute to multiorgan dysfunction and may

E-POSTER ABSTRACTS

complicate haemostatic assessment because of “rebalanced” haemostasis, in which the international normalized ratio (INR) does not reliably reflect bleeding risk. We hypothesized that sequential artificial liver support combining plasma adsorption and therapeutic plasma exchange can rapidly debulk bilirubin in Budd–Chiari–related acute-on-chronic liver failure, and that viscoelastic testing can provide clinically more relevant haemostatic information than INR alone. Primary endpoints were to evaluate the safety and efficacy of the therapy and bilirubin kinetics (total and direct). Secondary endpoints included renal markers (creatinine, cystatin C), inflammation (CRP, IL-6), conventional coagulation parameters (INR, fibrinogen, factor V), and viscoelastic haemostasis (thromboelastography with functional fibrinogen assessment).

Materials and Methods:

We report the case of a 47-year-old woman with Budd–Chiari syndrome complicated by acute-on-chronic liver failure and profound jaundice. Five procedures were performed over five consecutive days: two sessions of double plasma molecular adsorption and three sessions of therapeutic plasma exchange. Laboratory sampling was standardized to four time points per day: morning baseline, immediately pre-procedure, immediately post-procedure, and 6–12 h post-procedure (with next-morning values representing 24 h follow-up).

Results:

Initial bilirubin concentration was extreme (total bilirubin 1003 $\mu\text{mol/L}$; direct bilirubin 677 $\mu\text{mol/L}$). Each procedure achieved a marked immediate reduction in total bilirubin (pre→post): 1003.0→740.4 (–26.2%), 813.5→500.7 (–38.5%), 729.1→472.0 (–35.3%), 601.7→407.2 (–32.3%), and 538.0→366.6 $\mu\text{mol/L}$ (–31.9%). A rebound pattern was observed 6–12 h post-procedure (range +2.3% to +24.6%). Across the 5-day sequence, total bilirubin decreased from 1003.0 to 366.6 $\mu\text{mol/L}$.

Conventional coagulation parameters changed discordantly depending on treatment modality: adsorption sessions were followed by INR worsening (2.08→4.13; 1.68→2.84), whereas plasma exchange improved INR (1.99→1.39; 3.15→1.40; 1.52→1.42) and increased factor V activity (30→61%; 35→59%; 46→73%) and fibrinogen levels (e.g., 1.6→1.9 g/L). Viscoelastic testing demonstrated only moderate

impairment of clot strength, with functional fibrinogen indices improving after plasma exchange, highlighting a discordance between INR and whole-blood haemostasis. All procedures were completed without major bleeding complications.

Conclusions:

In Budd–Chiari syndrome complicated by acute-on-chronic liver failure and extreme hyperbilirubinemia, sequential plasma adsorption and therapeutic plasma exchange achieved rapid bilirubin debulking with a reproducible post-treatment rebound. Modality-dependent INR fluctuations were not aligned with viscoelastic haemostatic profiles, supporting viscoelastic-guided interpretation within the framework of rebalanced haemostasis in advanced liver disease. This strategy may serve as a practical bridge while definitive therapy is pursued.

Keyword(s) :

2704 - Differences between non alcoholic liver disease and alcoholic liver disease related HCC

Jiwoong Jang ¹

Eulji Medical Center, Internal Medicine, Daejeon-South Korea ¹

Background / Hypothesis:

Non-alcoholic liver disease and alcoholic liver disease begin as simple steatosis that may progress to steatohepatitis and ensuing liver-related complications such as cirrhosis and hepatocellular carcinoma (HCC). We investigated differences in clinical characteristics between non-alcoholic liver disease (NALD) and alcoholic liver disease (ALD)-related HCC.

Materials and Methods:

NALD and ALD patients were identified from our department’s prospective HCC database. A total of 54 and 45 patients met predefined inclusion and exclusion criteria for the NALD-HCC and ALD-HCC groups, respectively. Clinical, biochemical and tumor characteristics were studied.

Results:

NALD-HCC patients were older compared to ALD-HCC patients (71±9 vs. 65±9 years, $P<0.001$) and less male predominant (64% vs. 97%, $P<0.001$). Prevalence of diabetes mellitus (77% vs. 35%, $P<0.001$) and hypertension (79% vs. 57%, $P<0.001$) were significantly higher in the NASH-HCC group. There were no differences in alpha-fetoprotein level, lesions found at

E-POSTER ABSTRACTS

diagnosis (unifocal/multifocal) or prevalence of portal vein invasion. In both group, almost half of the patients were in TNM stage 4 at the time of diagnosis and more than 50% of patients were not suitable for any therapy. Median survival in the NALD-HCC and ALD-HCC groups were 13 and 7 months respectively ($P=0.114$).

Conclusions:

Despite significant differences in demography of the NALD-HCC and ALD-HCC groups, liver and tumor characteristics were comparable. Most patients were diagnosed late and were not amenable to curative or locoregional therapies. Better characterization of patients with NALD and ALD at risk of HCC is necessary to optimize screening, surveillance, and management strategies.

Keyword(s) : Hepatocellular carcinoma, Alcoholic liver disease

2705 - Early Expansion of CCR7⁺ PD-1⁺ NK Cells and HBsAg Decline Predict Interferon Induced Immune Reconversion in Chronic Hepatitis B

Sisi Chen ¹, Yuting Li ¹, Ping Yu ², Yan Yan ³

Jiangnan University, Wuxi Medical College, Wuxi-China

¹ The Fifth People's Hospital Of Wuxi, Infectious Diseases Department, Wuxi-China ² The Fifth People's Hospital Of Wuxi, Clinical Medical Research Center, Wuxi-China ³

Background / Hypothesis:

Objective: Pegylated interferon-alpha (Peg-IFN- α) remains a cornerstone therapeutic agent for achieving functional cure in chronic hepatitis B (CHB), yet its overall efficacy remains suboptimal. This study aimed to identify early immune response predictors during Peg-IFN- α therapy for CHB and longitudinally characterize the dynamics of peripheral blood immune cell subsets to inform precision clinical management. Methods: This retrospective study comprised two components: 1) Serological prediction analysis: Ninety-six CHB patients receiving nucleos(t)ide analogues (NAs) plus Peg-IFN- α were stratified into responders ($n=24$) and non-responders ($n=72$) based on HBsAg seroconversion at 24 weeks. Baseline and 12-week serological markers were analyzed, with independent predictors of 24-week response identified via univariate/multivariate logistic regression and receiver operating characteristic (ROC) curve analysis. 2) Immunological response profiling: A subcohort including the interferon responder group (IRG), interferon non-responder group (INRG), and nucleos(t)ide analogue non-responder group (NANRG) was assessed longitudinally (0, 12, 24, 36, 48 weeks)

using multicolor flow cytometry. Key immune cell subset frequencies were evaluated, with response-specific immunokinetic markers identified through amplitude (Δ value), fold-change analysis, and generalized estimating equation (GEE)-based trajectory modeling.

Results: 1) Serological predictors: The logarithmic reduction in HBsAg at 12 weeks (Δ IgHBsAg) emerged as the strongest independent predictor of 24-week HBsAg response (adjusted OR = 3.90, $P < 0.001$). A dynamic model incorporating Δ IgHBsAg and alanine aminotransferase reduction (Δ ALT) demonstrated excellent predictive performance (AUC = 0.87). 2) Immunological dynamics: Compared to non-responders, IRG exhibited robust multilineage immune cell activation at 12 weeks, marked by significant expansion of CCR7⁺ PD-1⁺ NK cells, M1 macrophages, and CCR7⁺ PD-1⁺ CD8⁺ T cells ($P < 0.05$). Longitudinal trajectory modeling revealed distinct evolution patterns of CCR7⁺ PD-1⁺ NKbri cells among IRG, INRG, and NANRG (interaction $P < 0.001$), identifying this subset as the most discriminative immunokinetic biomarker. 3) Mechanistic insights: Successful immune reconstitution was characterized by early innate immune activation and exhausted CD8⁺ T cell reinvigoration, serologically reflected by rapid Δ IgHBsAg decline. Conclusion: The 12-week Δ IgHBsAg level represents a robust serological biomarker for predicting short-term therapeutic response to Peg-IFN- α , functioning as a composite indicator of successful multi-lineage immune activation in deep tissue compartments. The critical determinant of interferon efficacy lies in an early immune reconstitution program characterized by the specific kinetic profile of NK cells, particularly the CCR7⁺ PD-1⁺ NKbri subset. These findings establish both theoretical and clinical foundations for developing precision treatment strategies for chronic hepatitis B based on early dynamic immunological monitoring.

2707 - Microbial metabolism dysfunction induced by transarterial chemoembolization aggravates postprocedural liver injury in HCC

Liteng Lin¹, Rui Li¹, Jianxin Liu¹, Feilong Ye¹, Siqin He¹, Jingjun Huang¹, Kangshun Zhu¹

The Second Affiliated Hospital Of Guangzhou Medical University, Department Of Minimally Invasive Interventional Radiology And Interventional Cancer Center, Guangzhou-China¹

Background / Hypothesis:

Transarterial chemoembolization (TACE) is widely used to treat unresectable hepatocellular carcinoma (HCC). Liver injury induced by TACE (TACE-LI) is the most common complication and limits long-term outcomes. Beyond the conventional understanding of direct TACE-induced damage to normal liver tissue, the underlying mechanisms of TACE-LI remain unclear. We aimed to elucidate the relationship between gut microbiota disturbances and TACE-LI.

Materials and Methods:

Microbial multi-omics analysis, genetically engineered bacteria and transcriptomics were used to study microbiota disturbances and host responses in TACE-LI.

Results:

Rats with antibiotic-depleted gut microbiota, as well as rats receiving fecal transplants from donor rats or patients who had undergone TACE, exhibited more severe TACE-LI. *Limosilactobacillus reuteri* (*L. reuteri*) abundance was significantly reduced in TACE-treated rats and patients with HCC. Reduced *L. reuteri* abundance after TACE led to decreased levels of tryptophan metabolite indole-3-lactic acid (ILA), while administration of live *L. reuteri* or ILA provided effective protection against TACE-LI. Mechanistically, *L. reuteri* relied on the key enzyme phenyllactate dehydrogenase to generate ILA. ILA inhibits the ATPase activity of heat shock protein 90, thereby deactivating the NOD-like receptor protein 3-inflammasome in macrophages and suppressing hepatic pro-inflammatory responses. Reduced levels of *L. reuteri* and ILA were correlated with aggravated LI and poorer overall survival in TACE-treated patients with HCC.

Conclusions: This is the first study to identify gut microbiota disturbance, i.e. efficiency of *L. reuteri* metabolite ILA, as a significant cause of TACE-LI. Administration of *L. reuteri* or ILA may serve as a promising therapeutic strategy to mitigate TACE-related adverse effects and improve prognosis in HCC.

2708 - Risk Factors and Development of a Predictive Model for Chronic Kidney Disease in Patients with Metabolic Dysfunction-Associated Steatotic Liver Disease

Jiaojiao Zhu¹, Siqian Lu¹, Jinxia Liu¹

Affiliated Hospital Of Nantong University, Department Of Gastroenterology, Nantong-China¹

Background: To identify risk factors for chronic kidney disease (CKD) among patients with metabolic dysfunction-associated steatotic liver disease (MASLD) and to develop a risk prediction model for MASLD with CKD comorbidity to support targeted prevention and early screening.

Materials and Methods: We retrospectively enrolled 8,975 MASLD patients with MASLD diagnosed by color Doppler ultrasonography at the Affiliated Hospital of Nantong University between 2021 and 2023.

Participants were categorized into CKD and non-CKD groups according to standard diagnostic criteria. Baseline biochemical parameters, including markers of glucose, lipid metabolism, inflammation, and organ function, were compared between two groups.

Independent predictors were identified using multivariable logistic regression and incorporated into a nomogram. Model performance was temporally validated in an independent MASLD cohort from 2024 using receiver operating characteristic (ROC) analysis, calibration plots, and decision curve analysis (DCA). **Results:** Compared with the non-CKD group, the CKD group exhibited significantly higher levels of systolic blood pressure, creatinine, triglycerides, and uric acid to high-density lipoprotein cholesterol ratio, but lower hemoglobin compared with the non-CKD group ($P < 0.05$). Age, systolic blood pressure, hemoglobin, triglycerides, and uric acid to high-density lipoprotein cholesterol ratio were identified as independent predictors of MASLD with CKD. The nomogram demonstrated good discrimination ability, showed consistent calibration in temporal validation, and demonstrated favorable net benefit across clinically relevant threshold probabilities in DCA.

Conclusions: A nomogram based on routinely available indicators provides an effective approach to estimating CKD risk in patients with MASLD, which may facilitate early screening and individualized interventions for high-risk individuals.

2709 - Machine Learning Based Prediction of Incomplete UDCA Response in Primary Biliary Cholangitis Model Development and Assessment

Xinyue Wu ¹, Shumin Ma ¹, Xiaoyan Liu ¹, Cheng Li ¹, Shuangshuang Xie ¹, Jianbing Li ¹, Xuehui Bu ¹, Wenjun Du ¹

Public Health Clinical Center Affiliated To Shandong University, Division Of Liver Disease Center, Jinan-China ¹

Background / Hypothesis:

In patients with Primary Biliary Cholangitis (PBC), incomplete response to ursodeoxycholic acid (UDCA) is strongly associated with adverse clinical outcomes. This study aimed to develop a machine learning-based predictive model to enhance the accuracy of the early assessment of incomplete UDCA response.

Materials and Methods:

A retrospective study was conducted on patients with PBC who were hospitalized at the Public Health Clinical Center Affiliated to Shandong University from August 2011 to August 2024. Clinical data, including demographic information, symptoms and signs, medical history, comorbidities, laboratory tests, and imaging studies were collected. Baseline variables were screened using univariate analysis, least absolute shrinkage and selection operator (Lasso) regression, and the Boruta algorithm to identify predictors. Prediction models were developed using six machine learning algorithms, and their performance was evaluated. Model interpretability was achieved using SHAP.

Results:

Patients were randomly allocated to training (n=220) and validation (n=94) sets at a 7:3 ratio. The intersection of the three feature selection methods identified seven predictors: ALP, Stages, ALBI, GGT, Complement C3, D-dimer, and Direct Bilirubin. Among the models evaluated, Random Forest demonstrated superior performance with an area under the receiver operating characteristic curve (AUC) of 0.822, while Decision Curve Analysis (DCA) indicated favorable clinical utility.

Conclusions:

We developed an interpretable Random Forest model incorporating seven baseline clinical variables to predict UDCA response in patients with PBC. This model provides clinicians with a reliable tool for early, individualized treatment decision-making at the initial stage of therapy, offering significant practical value

and potential for broader application.

2710 - Construction of nomogram based on inflammatory markers to predict recurrence and survival of single small hepatocellular carcinoma after radiofrequency ablation

Ping Li ¹, Weike Chu ¹, Mengdi Wang ¹

Tianjin Medical University, Clinical School Of The Second People, Tianjin-China ¹

Background / Hypothesis:

Radiofrequency ablation (RFA) is a primary treatment for early-stage single small hepatocellular carcinoma (HCC), yet post-operative recurrence and mortality remain high. Inflammation plays a key role in HCC progression, and inflammatory markers may reflect tumor biology and prognosis. This study aimed to identify risk factors for recurrence and poor survival after RFA and to develop prognostic nomogram models based on inflammatory markers to guide clinical decisions.

Materials and Methods:

A retrospective analysis was conducted on 270 patients with early-stage single small HCC who underwent initial RFA between November 2011 and December 2020. Data included general, etiological, laboratory, and imaging information collected within one week pre-RFA. Patients were randomly split into training and verifying sets. Optimal cut-off values for inflammatory markers (NLR, RLR, PLR, LMR, PNI) were determined using X-tile based on 5-year recurrence-free survival (RFS) and overall survival (OS). Univariate and multivariate Cox regression analyses identified independent risk factors. Nomograms for RFS and OS were constructed and internally validated using Harrell's C-index, AUC-ROC, calibration, and decision curve analysis.

Results:

Multivariate analysis identified ascites, tumor diameter >2cm, AFP >400 ng/ml, and LMR <3.2 as independent predictors of RFS. For OS, male gender, AFP >400 ng/ml, early recurrence, and RLR ≥19 were independent predictors. Nomograms incorporating these factors showed good discrimination and calibration. The RFS model had C-indices of 0.706

E-POSTER ABSTRACTS

(training) and 0.705 (verifying); the OS model had C-indices of 0.851 and 0.841, respectively. AUCs for 1-, 3-, and 5-year predictions were consistently robust. Risk stratification based on the nomograms significantly distinguished between low- and high-risk groups in both sets ($P < 0.0001$).

Conclusions:

Inflammatory markers are significantly associated with liver function and patient demographics in HCC. NLR, LMR, and RLR are independent prognostic factors for recurrence and survival after RFA. The established nomograms, based on readily available clinical and inflammatory markers, provide accurate and practical tools for predicting individual recurrence probability and survival, aiding in risk stratification and clinical management.

Keyword(s) : hepatocellular carcinoma, radiofrequency ablation, nomogram, inflammatory markers, prognosis, recurrence, survival, neutrophil-to-lymphocyte ratio, lymphocyte-to-monocyte ratio, prognostic nutrition index

2712 - Development and Validation of a Nomogram Incorporating Thyrotropin and Metabolic Parameters for Predicting Metabolic Dysfunction Associated Steatotic Liver Disease Risk A Cross sectional study

Siqian Lu¹, Jiaojiao Zhu¹, Jinxia Liu¹

Hospital Of Nantong University, Department Of Gastroenterology, Nantong-China¹

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is a growing global health concern. Thyroid dysfunction influences metabolic homeostasis, but its role in predicting MASLD risk, especially in Eastern populations and within the euthyroid range, remains unclear. This study aimed to investigate the association between low thyroid function and MASLD and to develop a validated nomogram integrating thyroid-stimulating hormone (TSH) for individualized risk prediction.

Materials and Methods:

This retrospective study enrolled 3,734 subjects as a training cohort and 865 external subjects for validation. MASLD was defined as the presence of hepatic steatosis on ultrasound and at least one cardiometabolic risk factor. Thyroid function was categorized as strict-normal (TSH 0.4–2.5 mIU/L), low-

normal (TSH 2.5–4.2 mIU/L), or subclinical hypothyroidism (TSH ≥ 4.2 mIU/L). Independent predictors identified by multivariable logistic regression were incorporated into a nomogram. The model was assessed by its discrimination (area under the curve, AUC), calibration (calibration plot, Hosmer–Lemeshow test), and clinical utility (decision curve analysis).

Results:

Low thyroid function (TSH ≥ 2.5 mIU/L) was independently associated with higher MASLD risk (adjusted OR 1.73, 95% CI 1.47–2.04), showing a dose-response relationship. The final nomogram incorporated BMI, ALT, BUA, HDL, and TSH. It demonstrated excellent discrimination, with AUCs of 0.846 (training) and 0.848 (validation), superior to the TyG index. The model was well-calibrated and provided positive net benefit on decision curve analysis.

Conclusions:

Low thyroid function is an independent risk factor for MASLD. We developed a validated nomogram integrating TSH with metabolic parameters, offering a practical tool for individualized MASLD risk assessment and potential early intervention.

Keyword(s) : MASLD; TSH; Nomogram; Cross sectional

2713 - TRAF2 Deficiency Aggravates Mitochondrial Dysfunction Through PI3K AKT Pathway Inhibition in Acetaminophen Induced Liver Injury

Yelei Cen¹, Shouhan Yao¹, Guohua Lou¹, Yanning Liu¹, Min Zheng¹

The First Affiliated Hospital, Zhejiang University School Of Medicine, The State Key Laboratory For Diagnosis And Treatment Of Infectious Diseases, Hang Zhou-China¹

Background / Hypothesis:

Acetaminophen (APAP) overdose is a major factor in drug-induced acute liver failure. Mitochondrial dysfunction plays a central role in the pathogenesis of APAP-induced liver injury (AILI). Tumor necrosis factor receptor-associated factor 2 (TRAF2), an adaptor protein involved in the NF- κ B signaling pathway. Increasing evidence suggests it plays a role in regulating mitochondrial function. However, the role of TRAF2 in AILI is poorly understood.

Materials and Methods:

The AILI mouse model was established by intraperitoneal injection of 300 mg/kg APAP. The blood and liver tissues were collected for assessment

E-POSTER ABSTRACTS

of liver necrosis and mitochondrial function. To further verify the mechanism, hepatocyte-specific TRAF2 knockout (TRAF2-HKO) mice were generated.

Results:

APAP overdose significantly increased the mRNA and protein level of TRAF2 in the liver tissues of wild-type mice. To investigate the role of TRAF2 in AILI, TRAF2-HKO mice were treated with APAP. TRAF2 deficiency resulted in aggravated liver necrosis, increased serum ALT and AST levels, and exacerbated liver oxidative stress. RNA-Seq showed that the PI3K-AKT pathway was significantly downregulated in the TRAF2-HKO mice with AILI, which was verified by detecting the phosphorylation of AKT downstream proteins. Increased mitochondrial permeability was found in the livers of TRAF2-HKO mice. In vitro experiments demonstrated that TRAF2 knockdown increased GSK3 β activity by inhibiting AKT, thereby increasing mitochondrial permeability and reactive oxygen species. Gene set enrichment analysis revealed a significant downregulation of the oxidative phosphorylation (OXPHOS) subunits and mtDNA maintenance pathway in TRAF2-HKO mice, suggesting that TRAF2 may be related to mitochondrial biogenesis in AILI. TRAF2 deficiency reduced the OXPHOS subunits expression and mtDNA content in AILI mice. Mechanistically, TRAF2 knockdown could reduce NRF1 expression and mitochondrial biogenesis by inhibiting AKT activity.

Conclusions:

These results indicate that TRAF2 deficiency inhibits the PI3K-AKT pathway, thereby suppressing downstream GSK3 β phosphorylation and NRF1 expression, exacerbating mitochondrial dysfunction in AILI. This finding suggests that TRAF2 may be a potential novel therapeutic target for AILI.

Keyword(s) : acetaminophen, drug-induced liver injury, mitochondria, TRAF2

2715 - Va Cur@Lips Inhibits the Metastasis of Hepatocellular Carcinoma by Targeting the Peri Tumoral Fibrotic Microenvironment

Qi Yang¹, Jingjing Chen¹

Peking University Shenzhen Hospital, Ultrasound, Shenzhen-China¹

Background / Hypothesis: The incidence of local tumor progression (LTP) remains high after microwave ablation (MWA) for hepatocellular carcinoma (HCC). This study aimed to investigate the potential mechanism by which vitamin A-modified curcumin

nanoliposomes (Va-Cur@Lips) suppress the pro-tumor microenvironment by targeting peri-tumoral activated hepatic stellate cells (aHSCs), thereby reducing LTP after MWA of HCC.

Materials and Methods: Single-cell RNA sequencing was performed on tumor tissues and adjacent non-tumorous liver tissues from 3 HCC patients to analyze phenotypic transformation and distribution patterns of HSCs in peri-tumoral tissues. Va-Cur@Lips were prepared by thin-film hydration using lecithin and cholesterol as membrane materials, and the regulatory effects of Va-Cur@Lips on HSCs activation and migration was evaluated. A mouse orthotopic HCC model with incomplete MWA was established, and the in vivo distribution and targeting efficiency of Va-Cur@Lips in the aHSCs around the tumor were observed. The anti-tumor efficacy of Va-Cur@Lips combined with MWA was evaluated by histological assessment. Peri-tumoral tissues around the ablation zone were collected for Masson staining and immunohistochemistry to assess HSCs activation and clarify the in vivo regulatory effect of Va-Cur@Lips on peri-tumoral HSCs activation.

Results: Single-cell sequencing revealed significant remodeling of the HSCs compartment during HCC progression, with specific expansion of matrix-producing aHSC subsets in the tumor microenvironment. It was also confirmed the transition of HSCs from a quiescent phenotype to a tumor-associated activated phenotype. Va-Cur@Lips exhibited favorable physicochemical properties: particle size 174.27 ± 1.00 nm, PDI < 0.3 . The zeta potential and encapsulation efficiency (EE%) were found to be -18.99 ± 0.32 mV and $99.96 \pm 0.01\%$, respectively. Immunofluorescence staining showed the largest and strongest green-blue merged fluorescence in the Va-Cur@Lips group. Vitamin A modification further enhanced the uptake of curcumin liposomes by LX-2 cells. CCK-8 and wound-healing assays demonstrated that Va-Cur@Lips exerted the most significant inhibitory effects on LX-2 cells proliferation and migration. All curcumin formulations inhibited tumor growth, among which Va-Cur@Lips combined with MWA resulted in the slowest tumor growth and optimal anti-tumor efficacy. Masson staining indicated that residual cancer after incomplete ablation could activate the tumor fibrotic microenvironment. The Va-Cur@Lips+MWA group showed the smallest percentage of collagen fiber area, and fibrosis had almost completely reversed. Immunohistochemical showed a significantly reduced percentage of α -SMA-positive cells in the Va-Cur@Lips+MWA group.

E-POSTER ABSTRACTS

Conclusion : Va-Cur@Lips can effectively reverse the peri-tumoral fibrotic microenvironment of HCC by targeting and inhibiting HSCs activation, thereby better assisting MWA and suppressing the occurrence and progression of residual HCC after incomplete ablation.

2716 - Preoperative prediction power of radiomics and non radiomics fusion model based on US CEUS for microvascular invasion of hepatocellular carcinoma A multicenter study

Qi Yang¹, Yuanyuan Sun², Jun Cheng²

Peking University Shenzhen Hospital, Ultrasound, Shenzhen-China¹ Shenzhen University And Medical Ultrasound Image Computing (music) Lab, School Of Biomedical Engineering, Shenzhen-China²

Background / Hypothesis: To establish microvascular invasion (MVI) prediction radiomics and non-radiomics fusion model based on the preoperative gray-scale ultrasound (US), Color Doppler Flow Imaging (CDFI), and contrast-enhanced ultrasound (CEUS) imaging of patients with hepatocellular carcinoma (HCC).

Materials and Methods: A total of 489 HCC patients who underwent preoperative US-CEUS examinations from 8 hospitals between July 2020 and June 2025 were enrolled. According to the MVI status, all the patients were classified: MVI-negative (M0) and MVI-positive (M1/M2). The HCCs were randomly divided into training (n=337) and internal validations (IV, n=84) cohorts with a 4:1 ratio for developing and evaluating multimodal ultrasound deep learning models. Diagnostic performance of the model was verified using external validation (EV, n=68) cohort. Based on the different US modalities, five modules were established: ModelUS, ModelCDFI, ModelCEUS, ModelUS-CEUS, and ModelUS-CEUS+non-radiomics, and compare the diagnostic accuracy of these different models in preoperative predicting MVI.

Results: The AUC of ModelUS, ModelCDFI, ModelCEUS, ModelUS-CEUS,

and ModelUS-CEUS+non-radiomics for HCC-MVI was 0.594, 0.629, 0.841, 0.853, and 0.871 in the EV cohort, respectively. The diagnostic sensitivity of ModelUS-CEUS+non-radiomics were superior to

ModelUS-CEUS (80.8% vs 69.6%, $p < 0.01$), while the specificity of ModelUS-CEUS+non-radiomics was comparable to that of ModelUS-CEUS (76.3% vs 80.0%, $p > 0.05$). The diagnostic sensitivity and specificity of ModelUS-CEUS+non-radiomics were superior to <5-year (80.8% vs 66.7%, and 76.3% vs 50.0%, both $p < 0.01$, respectively) and >5-year skilled radiologists (80.8% vs 66.7%, and 85.5% vs 34.9%, both $p < 0.01$, respectively), respectively.

Conclusions: ModelUS-CEUS+non-radiomics with high sensitivity and specificity in preoperative HCC-MVI prediction shows its potential advantages, and its diagnostic performance is significantly superior to that of the ModelUS-CEUS and senior radiologists

2717 - Clinical Profile Comparison Between HBeAg Positive and HBeAg Negative Hepatocellular Carcinoma Patients Highlighting Advanced BCLC Staging and Low Antiviral Treatment Uptake in an Indonesian Cohort Analysis

Saut Horas H Nababan¹, Zahra Hanifah²

Dr Cipto Mangunkusumo Hospital Faculty Of Medicine Universitas Indonesia, Hepatobiliary Division Department Of Internal Medicine, Jakarta-Indonesia¹ Dr Cipto Mangunkusumo Hospital, Hepatobiliary Division Department Of Internal Medicine, Jakarta-Indonesia²

Background / Hypothesis:

HBeAg status is an independent risk factor for hepatocellular carcinoma (HCC) in chronic Hepatitis B. Despite the availability of antiviral treatment, many patients progress to malignancy without prior intervention. This study aims to analyze the clinical profiles differences and treatment history between HBeAg-positive and HBeAg-negative HCC patients within an Indonesian cohort

Materials and Methods:

A cohort of 100 HCC patients was analyzed, divided into HBeAg-positive (n=50) and HBeAg-negative (n=50) groups. Data collected included demographic profiles (age and sex), liver function tests (SGOT, SGPT, Albumin, and Bilirubin), coagulation markers (PT/INR), and platelet count. Clinical and virological assessments

E-POSTER ABSTRACTS

were also performed, including BCLC staging, Alpha-fetoprotein (AFP) levels, presence of cirrhosis, HBV DNA, and history of antiviral treatment. Statistical analysis was conducted to compare variables between the two groups

Results:

A significant majority of the total cohort (70%) were not receiving antiviral treatment at the time of diagnosis. Specifically, 66% of HBeAg-negative and 74% of HBeAg-positive patients were untreated ($p=0.51$). HBeAg-negative patients were significantly more likely to present with advanced disease, with 90% diagnosed at an intermediate-advanced BCLC stage compared to 68% in the HBeAg-positive group ($p=0.01$). While HBeAg-positive patients showed significantly higher median AFP levels (4.53×10^2 ng/dL) than HBeAg-negative patients (1.48×10^2 ng/dL) ($p=0.03$), other variables such as age, liver enzymes, and HBV DNA levels did not show statistically significant differences

Conclusions:

In this Indonesian cohort, HBeAg-negative HCC patients are more likely to present at an intermediate-advanced BCLC stage despite having lower AFP levels compared to HBeAg-positive patients. The finding that 70% of the patients were not on antiviral treatment highlights a significant gap in chronic Hepatitis B management in Indonesia. These results emphasize the importance of early viral treatment and rigorous surveillance

Keyword(s) : hepatitis B, hepatocellular carcinoma, Indonesia

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is a systemic condition linked not only to liver complications, such as cirrhosis and hepatocellular carcinoma, but also to cardiovascular, metabolic, and endocrine disorders. Current non-invasive tests provide indirect, threshold-based, and static risk stratification, limiting continuous and

E-POSTER ABSTRACTS

personalized prognosis. Existing models typically focus on single outcomes and rely on cross-sectional data, failing to capture longitudinal lifestyle effects. We hypothesized that integrating digital pathology from liver biopsy whole-slide images (WSIs), peri-biopsy laboratory data, and longitudinal lifestyle time-series information into an interpretable multimodal deep learning framework would enable dynamic, individualized prediction of multisystem MASLD-related outcomes and provide mechanistic insights for targeted prevention.

Materials and Methods:

This retrospective multicentre study included biopsy-confirmed MASLD patients (2005–2010) from nine Chinese centres. After exclusions, 814 patients were analyzed (546 training; 268 external validation), with a median follow-up of 203 months. Paired H&E and Sirius Red (SR) WSIs were processed using the Prov-GigaPath foundation model. Slide-level features were fused via cross-attention. Laboratory variables were normalized and embedded using a shallow Transformer. Annual lifestyle data were modeled using a Transformer-LSTM time-series module. The final trimodal framework (Prov-GigaPath-DCL) predicted 13 multisystem endpoints. Model performance was evaluated using AUROC, AUPRC, and time-dependent AUROC. Interpretability was achieved via saliency heatmaps, tile-level self-supervised clustering (24 histomorphological phenotype clusters, HPCs), and cell segmentation/classification using Hover-Net.

Results:

Dual-stain pathology (H&E+SR) improved prediction across 13 outcomes compared with H&E alone (Δ AUROC 0.013–0.144). Adding laboratory data further enhanced discrimination (Δ AUROC 0.103–0.167 for selected endpoints).

The trimodal model incorporating lifestyle dynamics achieved the best performance, with time-dependent AUROCs ranging from 0.784 to 0.853, and AUROC >0.8 for several outcomes including coronary artery disease, chronic kidney disease, arrhythmias, heart failure, insulin-treated T2DM, and hypothyroidism. Dynamic risk trajectories were sensitive to behavioral changes, including changes in exercise and smoking status. Interpretability analyses showed outcome-specific saliency regions. HPC clustering identified fibrosis-dominant clusters associated with cirrhosis and hepatocellular carcinoma, and inflammation-dominant clusters linked to cardiovascular events. Cell-level analysis confirmed higher fibroblast proportions in

fibrosis-associated clusters and inflammatory cells in vascular-event clusters.

Conclusions:

The study presents the first interpretable trimodal deep learning framework for dynamic, multi-outcome prediction in MASLD. By integrating digital pathology, laboratory data, and longitudinal lifestyle factors, the model enables individualized, time-updated risk stratification and mechanistic insight. This approach aligns with guideline-based biopsy practice and supports personalized secondary prevention in high-risk MASLD patients.

2719 - Periportal Arginine Deficiency Drives Macrophage Senescence to Blunt Aged Liver Regeneration

Haoran Hu¹, Yuan Liang¹, Hao Wang¹, Yuecheng Wang¹, Jian Xu¹, Yue Yu¹, Feng Cheng¹, Haoming Zhou¹

The First Affiliated Hospital With Nanjing Medical University, Hepatobiliary Surgery, Nanjing-China¹

Background / Hypothesis:

Liver regeneration is a vital reparative process following injury. While it is well-established that aging significantly compromises liver regeneration, yet the specific metabolic-immune crosstalk driving this impairment remains elusive. Macrophages are crucial non-parenchymal cells within the liver that play a pivotal role in regulating regeneration. This study aims to investigate the metabolic alterations in the aged liver during regeneration and determine how these changes impede the regenerative process via macrophages.

Materials and Methods:

We established a model of regeneration after 70% partial hepatectomy (PHx) using aged (100-week-old) and young (8-week-old) mice. Single-cell transcriptomics were employed to analyze alterations in hepatocytes and macrophages during regeneration. Spatial transcriptomics and spatial metabolomics were utilized to further characterize zonal variations in arginine metabolism within the aged liver. In vivo and in vitro experiments were conducted to assess the impact of arginine deficiency on macrophages senescence and liver regeneration.

Results:

E-POSTER ABSTRACTS

Our analysis revealed significant abnormalities in hepatic arginine metabolism in aged mice during the regenerative phase. Spatial multi-omics data confirmed that key enzymes in the arginine metabolism, specifically CPS1 and ASS1, were significantly downregulated in hepatocytes within the periportal (PV) zone of aged mice. Consequently, the abundance of multiple metabolites involved in arginine metabolism—such as citrulline and argininosuccinate—was markedly reduced in the PV zone of the aged group compared to young controls. This metabolic deficiency significantly induced the migration and senescence of CD274+ monocyte-derived macrophages, creating a microenvironment unfavorable for regeneration. Supplementation with arginine or its precursors reversed these alterations and improved liver regeneration in aged mice.

Conclusions:

Aberrant arginine metabolism in the PV zone of the regenerating aged liver induces the migration and senescence of CD274+ macrophages, leading to impaired liver regeneration. Strategies involving the exogenous supplementation of arginine and its precursors can alleviate macrophage senescence and restore regeneration in the aged liver.

Keyword(s) : Aging, Arginine metabolism, Liver zonation, Liver regeneration

2720 - PRE EXISTING ANEMIA INVERSELY RELATED TO RIBAVIRIN INDUCED ANEMIA IN CIRRHOTIC PATIENTS WITH VIRAL HEPATITIS C INFECTION

Siwanon Nawalerspanya¹, Natchanon Pongsatha¹, Pongnarin Nawalerspanya²

Phaholponpayuhasena Hospital, Internal Medicine, Kanchanaburi-Thailand¹ Tharongchang Hospital, Internal Medicine, Suratthani-Thailand²

Background: Sofosbuvir/velpatasvir (SOF/VEL) plus ribavirin (RBV) is the current treatment regimen for cirrhotic patients with hepatitis C infection (HCV) in Thailand. Several studies have shown that ribavirin can induce anemia, leading to admissions, blood transfusions, and dose reductions. Our study was therefore designed to systematically determine the prevalence and clinical predictors of ribavirin-induced anemia (RIA) and evaluate its impact on treatment outcomes in this cirrhotic population.

Methods: This retrospective study was conducted at a tertiary care hospital in Thailand. All patients over 18 years with HCV cirrhosis treated with SOF/VEL plus RBV between January 2021 and October 2025 were included. Patients with concomitant hemologic

diseases, renal failure, malignancy, presence of other causes of anemia were excluded. We collected clinical, laboratory, and outcomes data, with a focus on RIA prevalence, the need for treatment modification, and sustained virological response at 12 weeks (SVR12). Results: A total of 76 patients were included for analysis. Of these, 61.8% were male, with a median age of 58. 85.5% had a Child-Pugh score of A and a median Model for End-Stage Liver Disease (MELD) score of 9. The prevalence of RIA, defined as new-onset anemia after treatment initiation, was high at 61.8%. Hemoglobin (Hb) level in the RIA group was significantly lower than the non-RIA group at the 12th week of treatment ($p=0.039$). However, on the 12th week post-treatment, Hb levels were comparable ($p=0.827$). In the RIA group, almost one half (46.8%) developed at least a moderate degree of anemia, 12.8% had severe to life-threatening anemia, over one fifth (21.3%) needed blood transfusions, and 4.3% needed RBV dose reductions. Of note, RBV was halted in 2.1% of the RIA group. Surprisingly, multivariable logistic regression analysis demonstrated that patients who had pre-existing anemia by World Health Organization (WHO) definition were independently protected against developing progressive anemia during RBV treatment (OR 0.19, 95%CI 0.06-0.65; $p=0.008$). Nevertheless, the rates of SVR12 post-treatment were comparable between the 2 groups ($p=0.555$).

Conclusions: In cirrhotic HCV patients, RIA is common, with a prevalence of over 60%, and necessitates intervention, including blood transfusion, dose reduction, or even withdrawal of RBV treatment. However, this effect vanished at post-treatment 12 weeks. Importantly, the presence of pre-treatment anemia was inversely associated with progressive anemia during therapy. The comparable SVR12 rates suggested that RIA, when managed, didn't compromise virologic response. This finding supports the continued use of RBV in this high-risk population, but larger studies are warranted.

Keyword(s) : Anemia, Cirrhosis, Hepatitis C, Ribavirin

2721 - Prevalence Characteristics and Prognostic Value of Pituitary Target Gland Axis Dysfunction in Decompensated Cirrhosis A Prospective Cohort Study

Lu Bai¹, Jing Wang¹

The Second Affiliated Hospital Of Baotou Medical College, Inner Mongolia University Of Science And Technology, Gastroenterology Department, Bao Tou-China¹

E-POSTER ABSTRACTS

Background / Hypothesis: Decompensated cirrhosis is frequently complicated by various endocrine disturbances. While existing studies have largely focused on functional alterations of single peripheral glands, the systemic dysfunction of the pituitary-target gland axes, particularly as a distinct syndrome in decompensated patients, remains insufficiently characterized. The prevalence, risk factors, and prognostic value of this multi-axial dysfunction in decompensated cirrhosis have not yet been systematically elucidated. We hypothesize that multi-axial pituitary-target gland axis dysfunction is prevalent in patients with decompensated cirrhosis and is closely associated with liver disease severity, malnutrition, and systemic inflammation. We further postulate that this systemic neuroendocrine dysfunction is independently associated with an increased incidence of hepatic encephalopathy, infection, and mortality within one year.

Materials and Methods: This prospective cohort study enrolled 188 patients with decompensated cirrhosis. Pituitary-target gland axis hormones (including IGF-1, thyroid, adrenal, and gonadal axes), pituitary MRI, and nutritional status were assessed. Dysfunction was defined as hormone levels in ≥ 1 axis below the reference range, acknowledging functional alterations like low IGF-1. Patients were followed for 12 months for mortality, hepatic encephalopathy (HE), and infection.

Results: A total of 188 patients were included. The overall prevalence of pituitary-target gland axis dysfunction was 29.8% (56/188), with gonadal axis dysfunction (22.3%) and low IGF-1 levels (19.7%) being the most frequent abnormalities. Multivariate Logistic regression identified Child-Pugh class C, MELD-Na score > 20 , malnutrition (NRS-2002 ≥ 3), and elevated CRP (> 10 mg/L) as independent risk factors (all $P < 0.01$). Abnormal pituitary MRI findings were detected in 24.5% of patients and were positively correlated with the number of affected axes. During the 12-month follow-up, the dysfunction group exhibited significantly higher rates of all-cause mortality, hepatic encephalopathy, and bacterial infection compared to the normal function group ($P < 0.01$). After adjusting for potential confounders, pituitary-target gland axis dysfunction remained an independent predictor of 1-year all-cause mortality (HR = 2.43).

Conclusions: Decompensated cirrhosis is frequently associated with pituitary-target gland axis dysfunction,

primarily involving gonadal and GH-IGF-1 axes. This represents a systemic "Hepato-Neuroendocrine Failure Syndrome" linked to liver severity and inflammation rather than isolated pituitary pathology. It serves as a robust, independent prognostic marker surpassing traditional scoring systems alone.

Keyword(s) : Liver cirrhosis; Pituitary-target gland axis; Endocrine dysfunction; IGF-1; Prognosis

2722 - The predictive value of serum ferritin for Biochemical Non resolution (BNR) in DILI

Ping Li Li ¹, Zhe Chen Chen ¹, Yaxing Wen Wen ¹
Tianjin Medical University, Tianjin Second People,
Tianjin-China ¹

Background / Hypothesis:

Drug-induced liver injury (DILI) is a leading cause of acute and chronic liver disorders worldwide. In China, the widespread use of herbal medicines, dietary supplements, and anti-tuberculosis drugs contributes to a high DILI burden—23.80 per 100,000 annually, exceeding rates in Iceland (19.1), France (13.9), and the USA (2.7 per 100,000). Most patients recover after drug withdrawal, yet a growing subset develops chronic DILI with persistent inflammation, bile duct injury, or cirrhosis. Biochemical non-resolution (BNR)—persistent liver biochemistry abnormalities for ≥ 6 months—remains poorly understood. We evaluated serum ferritin (FER) as a predictor of BNR and its relationship with biochemical recovery time.

Materials and Methods:

We retrospectively analyzed 226 DILI patients diagnosed by clinical and pathological criteria at Tianjin Second People's Hospital (2012–2022). Patients were stratified by 6-month outcomes: biochemical resolution (BR) versus BNR. Normally distributed data were compared using t-tests or ANOVA; non-normal data used Mann-Whitney U or Kruskal-Wallis tests. Categorical variables were analyzed by chi-square test. Univariate and multivariate Cox regression assessed FER's impact on biochemical resolution time. X-tile determined optimal FER cutoffs for BNR prediction. Biochemical non-resolution rates across FER strata were plotted using GraphPad Prism 8.

Results:

FER levels distinguished BNR from BR patients ($p < 0.032$) and correlated with AST, ALT, GGT, and TBil (all $p < 0.05$). On univariate Cox regression, FER

E-POSTER ABSTRACTS

predicted biochemical resolution time (HR: 0.999, 95% CI: 0.999–1.000, $p=0.011$). This held across four multivariate models with progressive covariate adjustment ($p=0.036$, 0.016, 0.04, and 0.001). X-tile identified optimal thresholds for low-, medium-, and high-FER groups. Inter-group differences were significant for BNR rate ($p=0.048$), recovery days ($p=0.000$), hospitalization days ($p=0.002$), age, ALT, AST, TBil, and DBil (all $p\leq 0.001$). A clear gradient emerged: low-FER patients recovered fastest, followed by medium- and high-FER groups.

Conclusions:

Serum ferritin independently associates with biochemical non-resolution in DILI. Higher FER levels predict delayed biochemical recovery. FER may serve as a practical prognostic marker for identifying DILI patients at risk of chronic progression.

2723 - The Impact of Metabolic Dysfunction Associated Steatotic Liver Disease on Liver Stiffness in Chronic Hepatitis B Patients A Cohort Study

Aifang Liu ¹, Lei Luo ¹, Wenlong Yang ¹

The Second Affiliated Hospital Of Nanchang University, Department Of Infectious Diseases, Nanchang-China ¹

Background / Hypothesis:With the rising prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD), the proportion of chronic hepatitis B (CHB) patients with MASLD is increasing annually. MASLD may accelerate the progression of liver fibrosis in CHB patients, potentially through mechanisms involving metabolic abnormalities (such as insulin resistance and fat deposition) and chronic inflammation. Therefore, this study aims to investigate the effect of MASLD on liver stiffness measurement (LSM) changes in CHB patients.

Materials and Methods:We conducted a single-center retrospective cohort study of CHB patients with at least two LSM with FibroScan at the Second Affiliated Hospital of Nanchang University. We studied the absolute change in LSM and the change in LSM stage from the first LSM to the most recent LSM among CHB patients with MASLD compared to patients without MASLD.

Results:A total of 2498 patients were included (437

with CHB + MASLD and 2061 with pure CHB). The median follow-up was 1.9 years. Compared to patients without MASLD, those with MASLD had significantly higher LSM values at both the first and last measurements (5.9 vs. 5.6 kPa and 5.9 vs. 5.4 kPa, $p < 0.001$, respectively), a lower likelihood of achieving a decrease in LSM stage (42.2% vs. 55.3%, $P < 0.001$), and a higher likelihood of experiencing an increase in LSM stage (21.8% vs. 17.4%, $P = 0.049$). After propensity score matching, the results remained consistent. Among the 625 patients (25.0%) receiving antiviral therapy (AVT), AVT was associated with a decline in LSM ($p < 0.001$). However, patients with MASLD showed similar LSM stage reductions (55.0% vs. 56.0%, $P = 1.000$) and progression rates (15.4% vs. 15.9%, $P = 1.000$) after AVT.

Conclusions:In untreated CHB patients, the presence of MASLD is independently associated with higher LSM values, and MASLD patients are more likely to experience an increase in LSM over time. After the initiation of AVT, LSM decline is less pronounced in CHB patients with MASLD. Future studies could explore the relationship between different metabolic risk factors and liver stiffness changes, particularly with the support of multicenter studies and long-term follow-up data, to better define optimal individualized treatment strategies.

2724 - Silybin Capsules Protected Hepatocytes by Regulating Mitochondrial Homeostasis in the Organoid Model of Metabolic Dysfunction Associated Steatotic Liver Disease

Yongle Liu ¹, Jihui Jia ¹, Jing Lin ¹, Xiaohui Zhang ¹, Yu Chen ¹

Beijing Youan Hospital, Capital Medical University, Fourth Department Of Liver Diseases, Beijing-China ¹

Background / Hypothesis: Mitochondrial homeostasis imbalance is a critical molecular mechanism underlying the progression of metabolic dysfunction-associated steatotic liver disease (MASLD). Silybin capsules, a well-known hepatoprotective agent, have been extensively studied for its mechanisms in ameliorating lipid metabolism disorders and exerting antioxidant effects. However, its impact on mitochondrial function remains unexplored. The present study was aimed to investigate the regulation of silybin capsules on mitochondrial homeostasis in MASLD.

E-POSTER ABSTRACTS

Materials and Methods: An organoid model known as tissue-engineered fatty liver (TEF) was utilized. Triglycerides (TG), reactive oxygen species (ROS), aspartate aminotransferase (AST) were measured using commercial kits. Relative gene detected via qPCR. Mitochondrial membrane potential (MMP) was detected by JC-1 fluorescence-labeled microprobe.

Results: Compared to TEF liver, silybin capsules treatment resulted in 35% reduction of intracellular TG, and a 54% decrease in supernatant AST levels. MMP in TEF liver was 30% lower than normal controls, silybin capsules can significantly restored MMP to near-normal levels, accompanied by a reduction in ROS. Furthermore, Silybin capsules upregulated the mRNA expression of peroxisome proliferator-activated receptor γ coactivator 1- α (PGC1 α) and mitochondrial transcription factor (mitochondrial biogenesis), mitofusin 1/2 (mitochondrial fusion) and PINK1/Parkin (mitophagy), while down-regulated dynamin-related protein 1 (mitochondrial fission).

Conclusions: Silybin capsules regulated mitochondrial homeostasis in organoid model of MASLD to reduce liver damage.

Keyword(s) : MASLD, Silybin Capsules, mitochondrial homeostasis, organoid model

2725 - Suppression of gene expression of cholesterol in liver by royal jelly

Chi Wang¹, Zhenyu Jiang², Jing Wang², Yuanyuan Nian¹, Xianmei Meng²

Second Affiliated Hospital Of Baotou Medical College, Clinical Central Laboratory, Baotou City-China¹ Second Affiliated Hospital Of Baotou Medical College, Inner Mongolia Institute Of Digestive Diseases, Baotou City-China²

Background :

Excess cholesterol produced in the liver poses significant health risks and is a major contributing factor to various diseases, particularly fatty liver disease. Although royal jelly (RJ) has been shown to be effective in mitigating atherosclerosis in both human and animal models, the precise molecular mechanism by which RJ suppresses cholesterol-related gene expression remains unclear. This study hypothesizes that RJ downregulates the expression of squalene epoxidase (SE), a key enzyme in the cholesterol biosynthesis pathway, thereby reducing hepatic cholesterol production.

Materials and Methods :

HepG2 cells were treated with royal jelly, and changes in the gene expression of squalene epoxidase (SE) were evaluated. Gene expression levels were measured using real-time PCR and normalized to glyceraldehyde-3-phosphate dehydrogenase (GAPDH) as an internal control. To investigate the source of RJ's bioactivity, RJ samples from different geographical origins were compared. Furthermore, RJ was fractionated by ultrafiltration into molecular weight components, and the < 10 kDa fraction was examined for its suppressive effects, with additional separation of water-soluble and insoluble components.

Results :

Royal jelly treatment significantly decreased SE gene expression in HepG2 cells. The suppressive effect varied depending on the country of origin of the RJ. Fractionation analysis revealed that the < 10 kDa molecular weight fraction retained similar inhibitory activity on SE expression, with the water-soluble portion of this fraction showing the most pronounced effect.

Conclusions :

Our findings suggest that royal jelly suppresses hepatic cholesterol synthesis by downregulating squalene epoxidase gene expression. The bioactive components responsible for this effect are likely small, water-soluble molecules with a molecular weight of less than 10 kDa. These results provide new insights into the cholesterol-lowering mechanisms of royal jelly and highlight its potential as a functional food for managing cholesterol-related disorders.

2726 - Endothelial peroxisome proliferator activated receptor α prevents acetaminophen hepatotoxicity via maintenance of endothelial junctional integrity

Lu Peng¹, Long Xu¹, Qi Zhang², Xinxin Zhu³, Aijuan Qu², Yan Wang¹

Peking University First Hospital, Department Of Infectious Diseases, Beijing-China¹ Capital Medical University, Department Of Physiology And Pathophysiology, Beijing-China² Affiliated Beijing Chaoyang Hospital Of Capital Medical University, Department Of Laboratory, Beijing-China³

Background / Hypothesis: Microvascular injury represents an early event in acetaminophen (APAP)-

E-POSTER ABSTRACTS

induced acute liver injury (ALI), yet its underlying molecular mechanisms remain incompletely understood. Peroxisome proliferator-activated receptor α (PPAR α), a ligand-activated transcription factor highly expressed in the liver, plays significant roles in various liver diseases. However, the specific function of PPAR α in liver sinusoidal endothelial cells (LSECs) during ALI is unknown.

Materials and Methods: ALI was induced in endothelial cell-specific Ppara-knockout (Ppara Δ EC) and control mice by APAP (400 mg/kg). Liver injury was assessed histologically and biochemically. Sinusoidal barrier integrity was evaluated by scanning electron microscopy, Western blotting, and vascular permeability assays. Primary liver sinusoidal endothelial cells were subjected to RNA sequencing, and PPAR α binding to the CDH5 promoter was examined by chromatin immunoprecipitation.

Results: APAP challenge markedly reduced PPAR α expression in liver sinusoidal endothelial cells. Endothelial Ppara deficiency exacerbated liver necrosis, serum transaminase elevation, and sinusoidal hyperpermeability. Scanning electron microscopy revealed widened inter-endothelial gaps in Ppara Δ EC mice, indicating severe junctional disruption. RNA sequencing of primary endothelial cells showed that Ppara loss amplified APAP-induced transcriptional repression of adherens junction components, particularly CDH5 (encoding VE-cadherin). Quantitative PCR and Western blot confirmed pronounced downregulation of VE-cadherin in Ppara Δ EC livers. Mechanistically, chromatin immunoprecipitation identified a functional peroxisome proliferator response element in the CDH5 promoter, to which PPAR α directly bound. Reporter assays further demonstrated that PPAR α activation transactivated CDH5 promoter activity in a ligand-responsive manner. **Conclusions:** Endothelial-specific Ppara deficiency exacerbates APAP-induced microvascular injury by disrupting endothelial junctions, in part through the impaired transcriptional activation of CDH5.

2727 - HBV enforces interferon refractoriness by hijacking LUBAC mediated IRF9 linear ubiquitination

Peng Chen¹, Zheyu Dong¹, Libo Tang¹, Yongyin Li¹
Southern Medical University, Nanfang Hospital,
Department Of Infectious Diseases, Guangzhou-China¹

Background / Hypothesis:

Pegylated interferon- α (Peg-IFN α) therapy for chronic hepatitis B achieves hepatitis B surface antigen (HBsAg) loss in only a minority of patients, and the hepatocyte-intrinsic mechanisms limiting its antiviral efficacy remain incompletely understood. This study aimed to define how linear ubiquitin chain assembly complex (LUBAC) regulates interferon signaling and antiviral efficacy.

Materials and Methods:

We integrated analyses of liver biopsies from Peg-IFN α -treated patients with mechanistic studies in HBV-replicating hepatocytes and HBV mouse models. Hepatocyte-intrinsic interferon signaling and LUBAC function were interrogated using genetic perturbations, ubiquitination and protein interaction assays, together with structure-guided pharmacological targeting of the HOIL-1 C460 site.

Results:

Elevated accumulation of linear (M1-linked) ubiquitination was observed in the livers of Peg-IFN α non-complete responders compared with complete responders. Hepatic specifically inhibition of M1-linked ubiquitination, through HOIP knockdown or OUTLIN overexpression, synergistically enhanced IFN α antiviral efficacy and HBsAg loss in HBV mouse models. IFN- α transcriptionally upregulated the LUBAC subunits HOIP and HOIL-1 via STAT1- and IRF9/STAT2-dependent mechanisms, respectively, resulting in increased M1-linked ubiquitination. Mechanistically, HOIP interacted with IRF9, and selectively catalyzed its M1-linked ubiquitination at lysine 90, thereby impairing ISGF3 complex assembly and attenuating interferon-stimulated gene expression, establishing a negative feedback loop. The HBV regulatory protein HBx amplified this pathway by engaging the autoinhibitory cysteine 460 (C460) of HOIL-1, relieving autoinhibition and hyperactivating LUBAC to suppress interferon signaling. Translationally, structure-guided virtual screening and functional validation identified a small molecule, ITC, targeting the HOIL-1 C460 switch, which restored interferon signaling and synergized with IFN- α to markedly suppress serum HBsAg and intrahepatic HBcAg in vivo.

Conclusions:

These findings identify LUBAC-mediated linear ubiquitination of IRF9 as a hepatocyte-intrinsic checkpoint that constrains interferon signaling and limits Peg-IFN α antiviral efficacy. Targeting the HOIL-1-IRF9 axis represents a strategy to overcome

E-POSTER ABSTRACTS

interferon refractoriness in chronic hepatitis B.

2728 - Secretory ECM1a restores HBV specific CD8⁺ T Cell response via integrin β 1 blockade to promote HBsAg loss in chronic HBV infection

Peng Chen¹, Zheyu Dong¹, Libo Tang¹, Yongyin Li¹
Southern Medical University, Nanfang Hospital,
Department Of Infectious Diseases, Guangzhou-China¹

Background / Hypothesis:

Antigen-specific CD8⁺ T cells are crucial effectors for hepatitis B virus (HBV) clearance but become functionally impaired in chronic infection. Extracellular matrix protein 1 (ECM1), a component of the extracellular matrix essential for hepatic environmental homeostasis, is involved in regulating the immune response. This study aims to investigate the effect of ECM1 on HBV clearance and its underlying mechanism in anti-HBV immune responses.

Materials and Methods:

Blood and liver samples were obtained from 147 chronic HBV-infected individuals and 76 healthy controls. Multi-omics approaches including single-cell RNA sequencing (scRNA-seq), co-immunoprecipitation (Co-IP), mass spectrometry, and in vitro stimulation assays were employed to explore the effect of ECM1 on anti-HBV CD8⁺ T cell response. HBV mouse model with Hepatic stellate cell (HSC)-specific ECM1 knockout were established for in vivo validation.

Results:

Screening identified six upregulated extracellular matrix components (MMP2/7, ECM1, VCAN, COL5A1/15A1) in HBV-infected livers from GEO database. Crucially, serum ECM1 was the only component correlating with disease status in our cohort, showing significantly higher levels in patients achieving HBsAg clearance versus those with persistent infection. The assays of clinical liver specimens and HBV mouse models revealed that the elevated ECM1 originates from hepatic stellate cells (HSCs).

Functionally, the secretory isoform ECM1a, but not the non-secretory isoform ECM1b, enhanced HBsAg-specific cytotoxic T cell (CTL) responses, leading to HBsAg clearance. Moreover, HSC-specific ECM1 knockdown delayed HBV clearance in mice.

Mechanistically, the P300-H314 domain unique to ECM1a (deficient in ECM1b) competitively bound integrin β 1, thereby neutralizing the suppression of

CD8⁺ T cell function of integrin β 1 and restoring anti-HBV immunity. Meanwhile, scRNA-seq revealed that the reduction of integrin β 1 on peripheral and intrahepatic CD8⁺ T cells from chronic HBV-infected patients correlated with functional cure and favorable response to pegylated interferon- α therapy. Consistent with this finding, pharmacological inhibition of integrin β 1 signaling with ATN-161 accelerated viral clearance in HBV mouse models.

Conclusions:

The secretory isoform ECM1a facilitates HBV clearance by antagonizing integrin β 1-mediated CTL exhaustion, promoting cytotoxic cytokine production and HBsAg loss. Our findings unveil a novel extracellular matrix-immunity crosstalk mechanism and identify ECM1 as a therapeutic target for chronic HBV infection.

2730 - Association of monocyte to high density lipoprotein cholesterol ratio with liver histopathology in chronic hepatitis b

Yildiz Buse Koreli¹, Yasemin Gökden², Umut Yilmaz Koreli³

Istanbul Prof. Dr. Cemil Taşcıoğlu City Hospital,
Department Of Internal Medicine, Istanbul-Türkiye¹
Istanbul Prof. Dr. Cemil Taşcıoğlu City Hospital,
Department Of Gastroenterology, Istanbul-Türkiye²
Istinye State Hospital, Department Of Internal
Medicine, Istanbul-Türkiye³

Background / Hypothesis: Accurate assessment of liver fibrosis and histological activity is essential for clinical decision-making in chronic hepatitis B. Although liver biopsy remains the gold standard, its invasive nature has increased interest in non-invasive biomarkers. The monocyte-to-high-density lipoprotein cholesterol ratio (MHR) has been proposed as a simple marker of systemic inflammation; however, its relationship with liver histopathology in chronic hepatitis B remains unclear. This study aimed to evaluate the association between MHR and liver histopathological findings in patients with chronic hepatitis B.

Materials and Methods: This retrospective cross-sectional study included 148 patients with chronic hepatitis B who underwent liver biopsy between 2020 and 2025. Liver biopsy specimens were evaluated for fibrosis stage, histological activity index, and hepatic steatosis. Non-invasive fibrosis assessment was

E-POSTER ABSTRACTS

performed using the FIB-4 score. MHR was calculated from routine laboratory parameters. Associations between MHR, histopathological findings, FIB-4 score, and clinical-laboratory parameters were analyzed using correlation analyses, group comparisons, and receiver operating characteristic (ROC) analyses.

Results: No statistically significant association was observed between MHR and fibrosis stage, histological activity index, or hepatic steatosis. Although MHR values tended to be higher in patients with advanced fibrosis, this difference did not reach statistical significance. ROC analyses demonstrated limited performance of MHR in discriminating significant histological activity and advanced fibrosis. In contrast, MHR showed positive correlations with leukocyte and neutrophil counts, AST, ALT, GGT, triglyceride, and creatinine levels, and a negative correlation with total cholesterol. Higher MHR values were observed in patients with elevated HBV DNA levels.

Conclusions: MHR does not reliably reflect liver histopathology or fibrosis burden in patients with chronic hepatitis B. However, the findings suggest that MHR may primarily represent systemic inflammatory and metabolic status rather than liver-specific histological injury.

Keyword(s) : chronic hepatitis B, monocyte-to-HDL cholesterol ratio, liver biopsy, fibrosis, inflammation

2732 - Comparative evaluation of paper and digitized cognitive tests for diagnosis of hepatic encephalopathy in patients with liver cirrhosis

Alexander Nersesov¹, Arailym Maikenova¹, Dinara Suleimen¹, Aigul Raissova¹, Mariya Snadina¹, Gaukhar Baiduissenova¹, Madina Begedayeva¹, Aliya Kaissar¹, S.d.asfendiyarov Kazakh National Medical University, Gastroenterology, Almaty-Kazakhstan¹

Background / Hypothesis:

Minimal hepatic encephalopathy (MHE) is frequently underdiagnosed despite its impact on quality of life and risk of progression. Paper-based psychometric testing remains the reference standard, whereas digitized tools may offer practical advantages. We aimed to compare the diagnostic performance of paper-based and digitized cognitive tests in liver cirrhosis.

Materials and Methods:

This single-center study was conducted at the Institute of Gastroenterology, Hepatology and Metabolism, Interna Clinic. A total of 200 individuals were analyzed, including 100 patients with liver cirrhosis and 100 healthy controls. Hepatic encephalopathy was defined as any grade above absence according to clinical grading. Primary analysis included cirrhosis patients only (n=100; 82 with encephalopathy, 18 without). Secondary analysis focused on MHE (62 minimal/grade I vs 18 without encephalopathy; overt cases excluded). Paper-based testing included number connection tests A and B, digit symbol test, serial dotting test, and line tracing test. Digitized testing included the EncephalApp Stroop test, digitized number connection test A, and digitized digit symbol test. Multivariable logistic regression adjusted for age, sex, and education was applied. Model performance was evaluated using five-fold cross-validation with out-of-fold predictions. Diagnostic accuracy was assessed using area under the receiver operating characteristic curve, sensitivity, and specificity at optimal Youden thresholds.

Results:

Among individual paper-based tests, number connection test A demonstrated the highest diagnostic accuracy (area under curve 0.87), followed by number connection test B (0.86). Serial dotting and line tracing tests showed moderate accuracy (0.79–0.81), while the digit symbol test showed lower performance (0.76). Digitized tests showed lower discrimination. The EncephalApp Stroop test achieved area under curve 0.79 with relatively high sensitivity but reduced specificity. Digitized number connection test A and digitized digit symbol test demonstrated area under curve values of approximately 0.74 and 0.69, respectively. The combined paper-based battery demonstrated superior diagnostic performance (area under curve 0.90; sensitivity 84%; specificity 89%). The combined digitized battery showed lower accuracy (area under curve 0.79) and reduced sensitivity (~65%) despite comparable specificity.

Conclusions:

Paper-based psychometric testing provides superior diagnostic accuracy for MHE. Digitized cognitive tests demonstrate acceptable performance and may serve as screening tools; however, confirmatory assessment with validated psychometric batteries remains necessary.

E-POSTER ABSTRACTS

2734 - A Multidimensional Prognostic Signature Integrating a 4 Gene Panel Immune Contexture and Radiomic Features Predicts Progression Free Survival in Hepatocellular Carcinoma

Wei Xiang¹, Mufan Xiang², Xue Liu³, Jintao Huang⁴, Xiaoli Zhu¹

The First Affiliated Hospital Of Soochow University, Interventional Radiology, Suzhou-China¹ University Hospital Würzburg, Radiation Therapy, Würzburg-Germany² The Third Affiliated Hospital Of Naval Medical University, Interventional Radiology, Shanghai-China³ Zhongda Hospital Affiliated To Southeast University, Interventional Radiology And Vascular Surgery, Nanjing-China⁴

Background / Hypothesis: Hepatocellular carcinoma (HCC) is characterized by high heterogeneity and frequent early progression, limiting the effectiveness of current prognostic tools. To address this, we developed a progression-free survival (PFS)-oriented, multidimensional model integrating genomic, immune, drug sensitivity, and radiomic features for improved risk stratification and biological insight.

Materials and Methods: RNA-seq and matched radiomic data of HCC were obtained from The Cancer Genome Atlas (TCGA)-Genomic Data Commons (GDC) and The Cancer Imaging Archive (TCIA) database. The co-expression modules were analyzed by Weighted Gene Co-expression Network Analysis (WGCNA), and the differentially expressed genes (DEGs) were identified by "DESeq2" R package. Next, a RiskScore was established by univariate Cox and LASSO-Cox regression. The prognostic differences were assessed by Kaplan-Meier (KM) survival analysis, and Receiver Operating Characteristic (ROC) curve was used to evaluate the predictive accuracy. Additional analyses included CIBERSORT-based immune infiltration profiling, Gene Set Enrichment Analysis (GSEA) for pathway enrichment, oncoPredict-based drug sensitivity estimation, and integration of radiomic features into a clinical nomogram.

Results: We identified a robust PFS-associated gene signature (IYD, ACADL, B3GNTL1, C1S) that effectively stratified HCC patients into high- and low-risk groups with significantly distinct progression-free survival. The high-risk phenotype was characterized by enrichment of cell cycle and proliferative pathways, a dysfunctional immune landscape (such as the elevated Tregs), and reduced sensitivity to multiple targeted agents (e.g., Ribociclib_1632, Dihydrorotone_1827). Furthermore, three radiomic features linked to tumor heterogeneity and boundary irregularity were integrated into a nomogram that demonstrated strong predictive

performance, excellent calibration, and superior clinical net benefit.

Conclusions: We developed a PFS-oriented, multidimensional prognostic model for HCC integrating transcriptomic, immune, drug sensitivity, and radiomic feature analysis. It effectively stratifies risk and reflects underlying biological mechanisms of aggressive disease, such as immunosuppression and potential therapeutic resistance, highlighting its utility for guiding future translational research.

Keyword(s) : Hepatocellular carcinoma; Progression-free survival; Radiomics; Tumor microenvironment; Drug sensitivity

2735 - Significance of fibrinogen D dimer albumin and NLR in the progression of Acute on Chronic pre liver failure

Jun Lu¹

The Ninth Hospital Of Nanchang, The First Department Of Hepatology, Nanchang-China¹

Background / Hypothesis:

Acute-on-Chronic Liver failure is clinically characterized by coagulation disorders, jaundice, ascites, and hepatic encephalopathy, representing acute liver dysfunction that develops from chronic liver disease. Patients with Acute-on-Chronic liver failure often present with critical conditions, high mortality rates, and significant challenges in medical management. To investigate the clinical significance of fibrinogen, D-dimer, albumin, and NLR in the progression of Acute-on-Chronic pre-liver failure.

Materials and Methods:

A retrospective analysis was conducted on 239 patients with Acute-on-Chronic pre-liver failure (pre-failure group) and 36 patients with hepatic failure (hepatic failure group) and 28 patients with chronic hepatitis (chronic hepatitis group) admitted to the Ninth Hospital of Nanchang from January 2022 to June 2025. The clinical data, including coagulation parameters, were reviewed. The pre-hepatic failure group was further divided into a progressive subgroup and a non-progressive subgroup based on disease progression. Binary logistic regression analysis was used to screen independent risk factors and establish a predictive model.

Results:

Compared with the baseline clinical data of the three groups, only the indicators of TBiL, ALB, L%, INR, PT, FIB, as well as the incidence of hepatic encephalopathy and short-term prognosis showed statistically significant differences ($P < 0.05$), while other clinical

E-POSTER ABSTRACTS

data showed no statistically significant differences ($P>0.05$). Compared with the non-progressive subgroup, the progressive subgroup exhibited statistically significant differences only in the indicators of ALB, serum sodium, FIB, D-dimer, and incidence of hepatic encephalopathy, and short-term prognosis ($P<0.05$), while other data showed no statistically significant differences ($P>0.05$). Based on P-values and collinearity diagnostic analysis results, the relevant variables were included in the logistic multiple regression analysis, yielding the equation $\text{LogitP} = 1.022 - 0.523 \times \text{FIB (g/L)} + 3.587 \times \text{D-dimer (mg/L)} - 0.111 \times \text{ALB (g/L)} + 0.194 \times \text{NLR}$. Patients with pre-hepatic failure were divided into two groups based on the optimal cutoff value of LogitP : ≥ -0.915 and < -0.915 . Disease progression analysis revealed that the cumulative progression risk in the $\text{LogitP} \geq -0.915$ group was significantly higher than that in the $\text{LogitP} < -0.915$ group, with a statistically significant difference ($\chi^2 = 22.038$, $P = 0.000$).

Conclusions:

Fibrinogen, D-dimer, albumin, and NLR can predict disease progression in pre-hepatic failure and have certain clinical significance.

Keyword(s) : chronic hepatitis, pre-hepatic failure, D-dimer, Fibrinogen

Background / Hypothesis: Optimizing antiviral strategies and achieving hepatitis B surface antigen (HBsAg) loss remain major challenges in the management of chronic hepatitis B (CHB). This study aimed to evaluate the effects of 48-week peginterferon alfa-2b (Peg-IFN α -2b) therapy, with or without nucleos(t)ide analogues (NAs), in patients with CHB enrolled in the VISION study.

Materials and Methods: In May 2024, we launched the multicenter, prospective VISION study to assess the long-term effects of Peg-IFN α -2b with or without NAs in CHB patients. This 48-week analysis involved two treatment groups: Peg-IFN α -2b monotherapy and Peg-IFN α -2b in combination with NAs, with a primary focus on assessing effectiveness and safety. Baseline characteristics between the two groups were balanced using propensity score matching (PSM).

Results: A total of 1138 patients completed the 48-week follow-up. After PSM, 798 patients were included in the analysis, comprising 399 patients in the monotherapy group and 399 patients in the combination group. At baseline, there were no significant differences between the monotherapy and

E-POSTER ABSTRACTS

combination groups in the proportion of males (64.7% [258/399] vs. 64.2% [256/399], $p=0.882$), mean age (43.5 $\pm$ 9.6 vs. 43.4 $\pm$ 9.4 years, $p=0.958$), HBeAg positivity rate (19.8% [79/399] vs. 21.3% [85/399], $p=0.599$), HBsAg levels (2.2 $\pm$ 1.3 vs. 2.3 $\pm$ 1.2 log IU/mL, $p=0.226$), HBV DNA levels (1.9 $\pm$ 1.5 vs. 1.9 $\pm$ 1.6 log IU/mL, $p=0.636$), and ALT levels (34.1 $\pm$ 45.9 vs. 33.8 $\pm$ 31.0 U/L, $p=0.920$). At 48 weeks, HBsAg loss rates (30.1% [120/399] vs. 29.3% [117/399], $p=0.816$) and ALT levels (49.0 $\pm$ 87.3 vs. 46.0 $\pm$ 40.8 U/L, $p=0.587$) were comparable between the two groups, while HBV DNA levels were slightly higher in the monotherapy group (1.6 $\pm$ 1.4 vs. 1.2 $\pm$ 0.8 log IU/mL, $p=0.029$). Notably, subgroup analysis showed that among patients with baseline HBsAg levels of <100, 100–<500, 500–<1500, and $\geq$ 1500 IU/mL, HBsAg loss rates were 55.9% (81/145), 27.9% (24/86), 12.3% (8/65), and 6.8% (7/103) in the monotherapy group, and 56.3% (76/135), 27.8% (27/97), 10.0% (7/70), and 7.2% (7/97) in the combination group (all $p>0.05$). Both treatment groups were generally well tolerated, with no serious adverse events observed.

Conclusions: At 48 weeks, among patients with low baseline HBsAg and HBV DNA levels, Peg-IFN α -2b monotherapy and Peg-IFN α -2b plus NAs combination therapy demonstrated comparable HBsAg loss rates and ALT levels, with no evident short-term advantage of combination therapy. The long-term benefits of these regimens are currently under investigation.

Background / Hypothesis: Immunotherapy (IO-chemo) has become the first-line standard care for patients with advanced intrahepatic cholangiocarcinoma (iCCA), but the incremental benefit of adding IO varies greatly among individuals, making it urgent to develop systems for identifying high-benefit populations based on individualized treatment effect (ITE) estimation.

Materials and Methods: This multi-cohort study included patients with iCCA who underwent either IO-chemo or chemo. The discovery cohort (2018–2022) included patients from three centers, while an independent cohort (2017–2023) from seven other centers served for external validation. Target trial emulation was employed to obtain unbiased average treatment effect estimation. We developed a causal machine-learning (ML) model (CMICC) to estimate heterogeneous treatment effects for IO-chemo. Based on predicted ITE, patients were stratified into high-benefit, no-to-moderate-benefit, and negative-benefit groups for each treatment. Counterfactual analyses compared overall survival between model-guided treatment selection and treatment actually received. The Qini and TOC curves were used to evaluate model performance. Model interpretability was assessed using SHAP.

Results: A total of 1485 patients, 696 in the IO-chemo group and 789 in the chemo group, were included in the discovery cohort; 562 patients, 246 in the IO-chemo group and 316 in the chemo group, were included in the external validation cohort. Using a recursive feature addition approach, we selected 17 of

E-POSTER ABSTRACTS

55 multidimensional variables to build the CMICC model in the discovery cohort. In the high-benefit group, compared with chemo, the hazard ratio (HR) for IO-chemo was 0.39 (95% CI, 0.30, 0.52), $P < 0.001$, with mortality rates reduced by 24.1%, 31.2%, and 28.5% at 12, 24, and 36 months, respectively. In the no-to-moderate-benefit groups, IO-chemo did not significantly differ from chemotherapy (HR, 0.91; 95% CI, 0.70, 1.18; $P = 0.488$). In the negative-benefit groups, IO-chemo was associated with worse outcomes than chemo (HR, 1.91; 95% CI, 1.47, 2.48; $P < 0.001$), with 12-, 24-, and 36-month mortality increased by 29.9%, 11.0%, and 5.1%, respectively. Counterfactual analysis indicated that CMICC-guided treatment decisions could improve survival compared with actually received treatment (RecomIC-RecIC vs RecomIC-RecC: HR: 0.53 [95%CI, 0.43, 0.65], $P < 0.001$; RecomC-RecC vs RecomC-RecIC: HR: 0.62 [95%CI, 0.50, 0.77], $P < 0.001$). These results were independently confirmed in an external validation cohort.

Conclusions: This study demonstrated that the causal ML-based CMICC model estimated ITE in iCCA patients receiving IO-chemo, performing effective benefit stratification, and may improve survival through individualized, CMICC-guided treatment decisions.

2740 - Hepatocyte TrkB acts as a gatekeeper against MASH related liver fibrosis by suppressing the TGF β CCL2 axis and macrophage infiltration

Yueying Chen¹, Jiayi Wei¹, Shuxuan Li¹, Kefan Yin¹, Heming Wang², Yicheng Zhao³, Shuqiang Weng¹, Xizhong Shen¹, Guangqi Song², Changfeng Zhu¹, Qunyan Yao¹, Ling Dong¹

Fudan University, Department Of Gastroenterology And Hepatology, Shanghai-China¹ Puheng Biomedicine, Joint Laboratory Of Biomaterials And Translational Medicine, Suzhou-China² Guangzhou University Of Chinese Medicine, Chinese Medicine Guangdong Laboratory, Guangdong-China³

Background / Hypothesis:

Liver fibrosis is a critical pathological stage in chronic liver disease, driven by hepatic stellate cell (HSC) activation and immune cell recruitment. While our previous work showed that overexpressing tyrosine kinase receptor B (TrkB) in HSCs inhibits their activation and alleviates fibrosis, the functional role of TrkB in

hepatocytes—the main parenchymal cells responsible for liver homeostasis—remains poorly understood. Here, we investigate the mechanistic interplay between hepatocyte-specific TrkB signaling and liver fibrosis progression.

Materials and Methods:

We investigated the role of hepatocyte-specific TrkB signaling through integrated in vivo animal models and in vitro two- and three-dimensional culture systems.

Results:

Elevated TrkB expression in hepatocytes reduces pro-fibrotic and inflammatory cytokines, attenuates HSC activation via paracrine signaling, and impairs monocyte-derived macrophage (MoMF) recruitment. Mechanistically, TrkB modulates the TGF β /SMAD3 pathway by inhibiting p-SMAD3 nuclear translocation, thus suppressing the transcription of FOS. As a core component of the AP-1 transcription factor complex, FOS directly regulates CCL2, a pivotal chemokine for macrophage recruitment.

Conclusions:

These results establish TrkB as a key regulatory node in the TGF β /SMAD3/FOS/CCL2 signaling cascade, orchestrating macrophage-mediated fibrotic responses in the liver.

Keyword(s) : Liver fibrosis, TrkB, MoMFs recruitment, 3D model

2741 - Magnetic Resonance Cholangiopancreatography Based Radiologic Evaluation of Biliary Complications in Living Liver Donors A Single Center Imaging Study

Sezer Nil Yilmazer Zorlu¹, Diğdem Kuru Öz², Ayşe Erden²

Mamak State Hospital, Department Of Radiology, Ankara-Türkiye¹ School Of Medicine, Ankara University, Department Of Radiology, Ankara-Türkiye²

Background / Hypothesis: To characterize the imaging spectrum of biliary complications in living liver donors using magnetic resonance cholangiopancreatography (MRCP) and to examine the association between postoperative biliary complications and biliary anatomy.

Materials and Methods: In this retrospective single-center study conducted at a tertiary referral center,

E-POSTER ABSTRACTS

adult living liver donors who underwent transplantation between January 2017 and January 2025 were reviewed. Donors were followed clinically and with imaging according to institutional protocols, and MRCP was performed when biliary complications were suspected. Preoperative MRCP examinations were analyzed to classify biliary anatomy. Imaging characteristics of biliary complications were investigated, and biliary anatomy was compared between donors with and without complications. Numerical variables were analyzed using the independent samples t-test or Mann–Whitney U test according to data distribution, whereas categorical variables were compared using the chi-square test or Fisher's exact test. A p value <0.05 was considered statistically significant. Donors who underwent interventional procedures were reported descriptively.

Results: A total of 181 living liver donors were included, comprising 77 females (42.5%) and 104 males (57.5%) with a mean age of 32.99 ± 8.82 years; right-lobe grafts were performed in 124 donors (68.5%) and left-lobe grafts in 57 donors (31.5%). Radiologic biliary complications were detected in 16 donors (8.8%). Early bile leakage and biloma represented the most common imaging phenotype (68.8%), while biliary strictures were observed less frequently, emerging within the first postoperative month in three donors and at 5.5 and 8 months in two donors. Although variant biliary anatomy was numerically more prevalent among donors with complications, it was not significantly associated with complication development ($p=0.282$). Hepatocyte-specific contrast-enhanced magnetic resonance imaging enabled functional confirmation of active bile leakage in selected cases. Additionally, three donors showed biochemical cholestasis despite normal MRCP findings, underscoring the value of imaging in preventing unnecessary invasive interventions.

Conclusions: Biliary anatomy variants were not associated with biliary complications, and MRCP provides a comprehensive, noninvasive tool for detecting biliary complications in living liver donors, characterized by bile leak/biloma predominance and a smaller burden of biliary strictures.

Keyword(s) : Living donor liver transplantation, Magnetic resonance cholangiopancreatography (MRCP), Biliary complicationS, Bile leak, Biloma, Biliary stricture

2743 - Immune Signatures Across Chronic Hepatitis B Phases Serum IFN γ and CD8⁺ T Cell Counts in Untreated Patients at Dr. Mohammad Hoesin Hospital Palembang Indonesia

Ninda Septia Yuspar¹, Suyata Suyata², Legiran Legiran³

Mohammad Hoesin Hospital/ Sriwijaya University, Internal Medicine, Palembang-Indonesia¹ Mohammad Hoesin Hospital/ Sriwijaya University, Internal Medicine, Palembang-Indonesia² Sriwijaya University, Patologi Anatomy, Palembang-Indonesia³

Background / Hypothesis:

Chronic hepatitis B virus (HBV) infection evolves through four immunologically defined phases, reflecting dynamic host-virus interactions. Innate and adaptive immune responses, particularly interferon-gamma (IFN- γ) and CD8⁺ T cells, are central to viral control and may help differentiate disease phases in untreated patients. This study investigated the association of serum IFN- γ levels and CD8⁺ T-cell counts across the phases of chronic HBV infection.

Materials and Methods:

We conducted an analytical observational study with a comparative design at Dr. Mohammad Hoesin Hospital, Palembang, Indonesia, from August to November 2024. Eligible participants were chronic HBV patients who had never received antiviral therapy and fulfilled predefined inclusion and exclusion criteria. Serum IFN- γ levels were quantified using enzyme-linked immunosorbent assay (ELISA), and peripheral blood CD8⁺ T-cell counts were measured by flow cytometry. Phase classification followed standard chronic HBV phase criteria documented in medical records and laboratory profiles. Statistical analyses were performed using SPSS version 29. Interphase comparisons were assessed using one-way ANOVA, with $p < 0.05$ considered statistically significant.

Results:

Thirty-eight untreated chronic HBV patients were included. Mean serum IFN- γ levels differed significantly across phases ($p < 0.05$), peaking in the reactivation phase (0.98 ± 0.35 pg/mL) and reaching the lowest values in the inactive carrier phase (0.40 ± 0.30 pg/mL). CD8⁺ T-cell counts also varied significantly between phases ($p < 0.05$), with the highest mean count observed in the inactive carrier phase (710.22 ± 196.08 cells/ μ L) and the lowest in the immune-active phase (415.50 ± 304.02 cells/ μ L). Together, these findings indicate distinct phase-related immune patterns

E-POSTER ABSTRACTS

involving both cytokine signaling and cytotoxic T-cell compartments.

Conclusions:

Serum IFN- γ levels and CD8⁺ T-cell counts show significant phase-associated differences in untreated chronic HBV infection, supporting their potential utility as immunological indicators of disease phase in clinical settings.

Keyword(s) : CD8⁺ T lymphocytes, chronic hepatitis B, disease phase classification, flow cytometry, interferon-gamma,

2744 - Paracaval Triangle A Novel Anatomic Landmark for Central Hepatectomy

Qin-qin Liu¹, Xing-ru Wang¹

Southwest Hospital, Hepatobiliary Surgery, Chongqing-China¹

Background / Hypothesis: Central hepatectomies (resection of Segments 4, 5, and 8) are technically challenging due to the lack of clear standardized anatomic landmarks for defining the transection plane. This study aimed to describe a newly identified anatomic structure, the "paracaval triangle," and validate its value as a reliable landmark to standardize central hepatectomies.

Materials and Methods: The anatomical characteristics of the transected plane after central hepatectomy were systematically analyzed. The paracaval triangle was defined by three constituent points, and the spatial relationship with adjacent structures was clarified. A robotic-assisted central hepatectomy case is presented to demonstrate the application of this landmark.

Results: The transected plane after central hepatectomy consists of three planes: the left plane, the basal plane (paracaval triangle), and the right plane. The left plane is superficially demarcated by the falciform ligament and the intraparenchymal umbilical fissure vein when present. Using the paracaval triangle as a landmark, a robotic-assisted central hepatectomy was successfully performed with an operative time of 185 min, blood loss of 80 mL, and no postoperative complications. The patient was discharged on postoperative day 6, and no recurrence was observed during follow-up.

Conclusions: The paracaval triangle is a stable and reliable anatomic landmark for central hepatectomy. Identification of the paracaval triangle facilitates accurate localization of the transection plane, standardizes the surgical workflow, and improves the safety and efficacy of central hepatectomies, especially in robotic-assisted minimally invasive surgery.

Keyword(s) : Paracaval triangle; Central hepatectomy; Anatomical landmark; Robotic surgery; Hepatobiliary surgery

2745 - Laparoscopic Anatomical liver resection using ICG positive staining combined infrared laser guided

Qin-qin Liu¹, Xing-ru Wang¹

Southwest Hospital, Hepatobiliary Surgery, Chongqing-China¹

Background / Hypothesis: Precise liver puncture and staining under ultrasound guidance during laparoscopic liver surgery remains a technical challenge. Currently, the success rate of puncture is less than 60%, and the location of the puncture point is usually difficult to accurately determine, as is the depth of puncture. There is a lack of effective methods for precise puncture.

Materials and Methods: We describe laparoscopic anatomical resection of the ICG-positive Portal Territory in a patient with primary hepatocellular carcinoma using laparoscopic infrared laser-guided targeted portal vein puncture.

Results: The operation time was 130 min, blood loss was 50 mL, and there were no complications. The patient was discharged 7 days after the operation. There were no complications during the 1-month follow-up.

E-POSTER ABSTRACTS

Conclusions: Infrared laser-guided technology can achieve precise ICG-positive puncture and accurately control the puncture position and depth. Combined with ICG-positive staining, this technology can precisely locate and significantly increase the success rate of puncture.

Keyword(s) : Infrared laser guidance; Laparoscopic ultrasound; Anatomical liver resection; ICG positive staining

2746 - Sofosbuvir Velpatasvir Voxilaprevir in Chronic Hepatitis C A Systematic Review and Meta Analysis

Marrium Sultan Dar Dar¹, Nayab Shahid Shahid², Muhammad Aizaz Ur Rehman Rehman², Haziq Ovais Ovais², Zuhaa Rehman Rehman³

Indus Hospital And Health Network, Office Of Research Innovation And Commercialization, Karachi-Pakistan¹
Agha Khan University Hospital, Radiation Oncology, Karachi-Pakistan² Jinnah Sindh Medical University, Medicine, Karachi-Pakistan³

Background / Hypothesis: Treatment failure occurs in a subset of chronic hepatitis C (HCV) patients, particularly those previously exposed to NS5A inhibitors, as resistance-associated substitutions (RASs) often persist and limit retreatment options. Voxilaprevir, a pangenotypic NS3–NS4A protease inhibitor, when combined with sofosbuvir/velpatasvir, provides a potent triple regimen (SOF/VEL/VOX). To better define the efficacy and safety of this regimen, we conducted a systematic review and meta-analysis of available studies.

Materials and Methods: A comprehensive literature search was conducted across PubMed, Google Scholar, DOAJ, and the Cochrane Library to identify studies evaluating the efficacy and safety of SOF/VEL/VOX in chronic HCV infection. The primary outcome was the proportion of patients achieving sustained virologic response (SVR), while secondary outcomes included reported adverse events. A random-effects model was employed to calculate the Risk Ratio (RR) with 95% Confidence Intervals (CI). Meta-analysis was performed using Review Manager version 5.4.1.

Results: A total of 19 RCTs and observational studies comprising 3339 patients were included. The pooled SVR rate was 95%. SVR rates were 94% in patients with comorbidities and 95% in those without comorbidities. Among cirrhotic patients, SVR was 93%, including 92% in those with comorbidities, compared with 97% in

non-cirrhotic patients. SVR rates were significantly lower in cirrhotics compared with non-cirrhotics (RR = 0.96; 95% CI = 0.93–0.99; p = 0.004). SVR rates were 96% for genotype 1 and 2, 92% for genotype 3, 93% for genotype 4, 95% for genotype 5, and 100% for genotype 6. Pairwise comparisons across all genotypes demonstrated that genotype 3 was associated with significantly lower SVR rates compared with other genotypes (RR = 0.95, 95% CI 0.94–0.97, p < 0.001), whereas genotype 6 achieved considerably higher SVR rates (RR = 1.05; 95% CI = 1.03–1.07; p < 0.001). Overall, adverse events occurred in 67% of patients across all studies, most commonly headache (26%), fatigue (22%), and diarrhea (18%), while abdominal pain was reported in 4%. Laboratory-related adverse events were uncommon, with hemoglobin <10 g/dl in 3%, thrombocytopenia <50,000/mm³ in 1%, and hyperglycemia >250 mg/dl in 1%.

Conclusions: Despite its high efficacy as a retreatment option for chronic HCV, SOF/VEL/VOX is still expensive in LMICs. To increase accessibility and cost-effectiveness in these contexts, tactics like generic production, price negotiations, and participation in public health initiatives are crucial.

Keyword(s) : Hepatitis C Virus, Sofosbuvir/Velpatasvir/Voxilaprevir, Sustained Virological Response, Liver

2747 - Hepatic Artery Pseudoaneurysm Presenting Overt Obscure Gastrointestinal Bleeding

Chelsea Colleen Paris¹, Marquez Maria Angelica², Burgonio Beatrice², Maralit Ruter¹

Philippine General Hospital, Department Of Medicine - Division Of Gastroenterology, Manila-Philippines¹
Philippine General Hospital, Department Of Medicine, Manila-Philippines²

Hepatic artery pseudoaneurysm (HAP) is a rare, frequently overlooked but life-threatening cause of gastrointestinal (GI) bleeding. It is associated with hepatobiliary interventions, abdominal trauma, inflammation, or infection. Because of its rarity and variable presentation, diagnosis is often delayed, especially when initial endoscopic findings are inconclusive. We present a case of a right hepatic artery pseudoaneurysm manifesting as recurrent overt GI bleeding in a patient with prior penetrating abdominal trauma.

A 55-year-old male with a history of penetrating abdominal injury five months prior which managed

E-POSTER ABSTRACTS

with exploratory laparotomy revealing no significant intra-abdominal pathology, presented with a two-month history of intermittent blood-streaked stools. On the day of admission, he experienced hematochezia accompanied by vomiting, epigastric pain, and generalized weakness. On evaluation, he was found to be anemic and was admitted for further workup. Initial esophagogastroduodenoscopy (EGD) demonstrated healed gastric ulcers, while colonoscopy revealed large mixed hemorrhoids. He was discharged stable after supportive management with no immediate recurrence of bleeding.

The patient subsequently returned with persistent epigastric pain and recurrent hematochezia. Repeat colonoscopy with push ileoscopy demonstrated terminal ileal ulcers and hookworm infestation, for which antihelminthic therapy was initiated. Despite treatment, intermittent hematochezia persisted which admitted and progressively increased in volume. A repeat EGD was performed to reassess for a brisk upper GI source. Although no active ulcers or mass lesions were identified, blood clots were noted in the duodenum. Careful examination revealed blood-tinged bile emanating from the papilla.

Contrast-enhanced computed tomography angiography of the abdomen confirmed the presence of a saccular aneurysm of anterior segmental branch of the right hepatic artery. The patient underwent celiacomesenteric angiography, which confirmed the pseudoaneurysm, followed by successful coil embolization. Immediate cessation of bleeding was achieved, and no further episodes of hematochezia were observed during hospitalization and follow-up. This case underscores the importance of maintaining a high index of suspicion for vascular etiologies in patients with recurrent GI bleeding, especially in the setting of prior abdominal trauma. Endovascular embolization remains safe and effective therapy for control of bleeding for these cases.

Keyword(s) : Hepatic Artery Pseudoaneurysm, GI bleeding

2749 - Beyond the Stomach Rapunzel Syndrome Presenting with Sepsis and Multi organ Failure

Nida Rasool¹

Siut, Hospital Karachi, Gastroenterology, Karachi, Sindh-Pakistan¹

Background / Hypothesis:

Bezoars are accumulations of undigested material in the gastrointestinal tract. They are classified according to their composition: phytobezoars (undigested fruits

and vegetables), trichobezoars (hair mixed with food particles), lactobezoars (milk curds), and pharmacobezoars (medications).

Trichobezoars form because human hair is resistant to digestion and, due to its smooth surface, is not effectively propelled by peristalsis. Progressive accumulation in the stomach leads to formation of a large mass that may extend beyond the pylorus.

This condition is commonly associated with Trichotillomania, a compulsive psychiatric disorder characterized by repetitive hair pulling, often followed by trichophagia (ingestion of hair). It is frequently associated with anxiety, depression, and poor self-image.

We report a case of gastric trichobezoar with life-threatening complications to highlight the importance of early recognition and multidisciplinary management.

Materials and Methods:

This is a single-patient case report of a 12-year-old female presenting to the emergency department in a critical condition.

Clinical evaluation included:

Detailed history from attendants

Physical examination

Laboratory investigations

Contrast-enhanced CT scan of the abdomen

Ascitic fluid analysis and culture

Upper gastrointestinal endoscopy

Results:

A 12-year-old girl presented in a lethargic and gasping state with a one-year history of hair ingestion and recent worsening abdominal pain, vomiting, and distention.

On examination:

Pale and cachectic appearance

E-POSTER ABSTRACTS

Bald patches over the scalp

Distended abdomen with a firm, non-tender epigastric mass

Laboratory findings revealed:

Severe hypoglycemia

Metabolic acidosis

Microcytic anemia

Leukocytosis

Hypokalemia

Severe hypoalbuminemia

CT imaging demonstrated a large heterogeneous gastric mass extending into the duodenum, consistent with trichobezoar, along with ascites and mediastinal shift. Ascitic fluid culture grew *Escherichia coli*.

Upper GI endoscopy confirmed a large hair mass occupying the stomach and duodenum. Due to severe metabolic derangements and sepsis, surgical intervention was initially deferred pending stabilization.

Conclusions:

Trichobezoars are rare but potentially life-threatening if not diagnosed and treated promptly. High clinical suspicion is warranted in young female patients presenting with abdominal pain, palpable mass, and history of hair ingestion.

Early imaging and endoscopic evaluation are essential for diagnosis. Large trichobezoars require surgical removal, while psychiatric evaluation and long-term psychological support are crucial to prevent recurrence.

A multidisciplinary approach involving physicians, surgeons, and mental health professionals is fundamental for optimal outcomes.

Keyword(s) :

2750 - Role of "PAST F model" in predicting advanced liver fibrosis in Autoimmune Hepatitis

Nida Rasool¹

Siut, Hospital Karachi, Gastroenterology, Karachi, Sindh-Pakistan¹

Background / Hypothesis:

The progression of autoimmune hepatitis (AIH) can lead to liver fibrosis and ultimately cirrhosis, significantly impacting patient outcomes. Early identification of patients at risk for advanced fibrosis is crucial for optimizing management strategies and improving prognosis. Although liver biopsy remains the gold standard for diagnosing and staging liver fibrosis, it is invasive and associated with potential complications. Therefore, there is a growing need for non-invasive methods to predict advanced fibrosis in AIH patients.

Materials and Methods:

Objective:

To evaluate the diagnostic accuracy of the PAST-F model in predicting advanced liver fibrosis in patients with autoimmune hepatitis and to establish an optimal cutoff score for clinical application.

Methods:

This retrospective study included patients of either gender with features of AIH on the basis of liver biopsy from January 2016 to December 2023. Patients with concomitant liver diseases were excluded. Liver fibrosis was evaluated using the Metavir scoring system on liver parenchymal biopsy. The outcome was observed in terms of advanced fibrosis on liver biopsy. Univariate followed by multivariate logistic regression analysis was performed to identify independent predictors of advanced fibrosis in patients with AIH.

On multivariate analysis, the following independent predictors were identified and incorporated into the PAST-F model: platelet count $<135 \times 10^9/L$ (OR 1.025; 95% CI 1.015–1.035; 1 point), albumin ≤ 3 g/dl (OR 33.6; 95% CI 10.714–105.7; 6 points), seronegativity (OR 4.9; 95% CI 1.593–41.1; 3 points), total bilirubin (OR 5.134; 95% CI 3.3–8.1; 3 points), and female gender (OR 25.9; 95% CI 6.6–100.2; 4 points).

The diagnostic performance of the model was assessed using AUROC.

Results:

The PAST-F model demonstrated high diagnostic accuracy in predicting advanced liver fibrosis in patients with autoimmune hepatitis with AUROC 0.85 ($p < 0.001$). The sensitivity was 80.14%, specificity 87.67%, positive predictive value (PPV) 80.71%, negative predictive value (NPV) 87.27%, and overall

E-POSTER ABSTRACTS

diagnostic accuracy 84.72%.

Conclusions:

The PAST-F model shows high diagnostic accuracy and may serve as a reliable non-invasive tool for predicting advanced liver fibrosis in patients with autoimmune hepatitis.

Keyword(s) :

2751 - Fucoidan Alleviates MASH by Inhibiting JNK Phosphorylation Mediated Hepatocyte Apoptosis

Jingyi Si¹, Yifan Gao¹, Changfeng Zhu¹, Xizhong Shen¹, Qunyan Yao²

Zhongshan Hospital Affiliated To Fudan University, Department Of Gastroenterology And Hepatology, Shanghai-China¹ Zhongshan Hospital Affiliated To Fudan University, Zhongshan Hospital Affiliated To Fudan University, Shanghai-China²

Background / Hypothesis:

Metabolic dysfunction-associated steatohepatitis (MASH) is a severe subtype liver disease, characterized by hepatic steatosis accompanied by inflammation, hepatocyte injury and apoptosis, with a high risk of progression to liver fibrosis. Fucoidan is a natural sulfated polysaccharide abundant in brown algae, and numerous studies have reported its protective effect on metabolic dysfunction-associated fatty liver disease (MAFLD), mainly focusing on improving hepatic steatosis and regulating metabolic disorders. However, studies on the effect and mechanism of fucoidan on MASH are still scarce. This study focuses on the protective effect of fucoidan on MASH and its related molecular mechanisms, filling the gap in existing research.

Materials and Methods:

First, the key c-Jun N-terminal kinase (JNK) pathway involved in the pathogenesis of MASH was screened out by transcriptome sequencing enrichment analysis. Subsequently, mechanism exploration was carried out around this molecule to observe the effect of fucoidan intervention on the pathological state, inflammatory level, steatosis degree, liver fibrosis level and liver function of liver tissue in CDAHFD MASH model mice, and to clarify the correlation between fucoidan and JNK phosphorylation, hepatocyte apoptosis as well as liver fibrosis.

Results:

The results showed that fucoidan intervention could

significantly alleviate the pathological damage of liver tissue in MASH model mice, effectively reduce the level of liver inflammation, steatosis and liver fibrosis, and improve the liver function of mice. From the perspective of molecular mechanism, fucoidan could effectively inhibit the abnormal phosphorylation of JNK, a key signaling molecule involved in regulating hepatocyte apoptosis, inflammatory response and liver fibrosis progression, whose abnormal increase in phosphorylation level is closely related to hepatocyte apoptosis and liver fibrosis progression. The inhibitory effect of fucoidan on JNK phosphorylation further reduced the activation of downstream apoptotic signaling pathways, and ultimately decreased the hepatocyte apoptosis rate, thereby alleviating liver inflammation and liver fibrosis.

Conclusions:

Fucoidan has a significant protective effect on MASH, and its mechanism is related to regulating the JNK phosphorylation pathway, inhibiting hepatocyte apoptosis and reducing liver fibrosis. It provides a new potential strategy for the prevention and treatment of MASH, and enriches the application theory of fucoidan in metabolic-related liver diseases.

Keyword(s) : Metabolic dysfunction-associated steatohepatitis; fucoidan; apoptosis; c-Jun N-terminal kinase

2752 - Protein phosphatase regulatory subunit enhances scaffold protein expression through an RNA binding protein and promotes invasion and immune remodeling in intrahepatic cholangiocarcinoma

Zhuomiaoyu Chen¹, Fumei Cao¹, Zhao Li¹

Peking University People's Hospital, Department Of Hepatobiliary Surgery, Beijing-China¹

Background / Hypothesis:

Intrahepatic cholangiocarcinoma is an aggressive malignancy characterized by early invasion and metastasis. We identified high expression of protein phosphatase 1 regulatory subunit 1B in the more invasive large duct subtype of intrahepatic cholangiocarcinoma and hypothesized that it enhances scaffold protein expression through an RNA binding protein, thereby promoting tumor invasion and immune remodeling.

Materials and Methods:

Tumor and matched adjacent tissues from 45 patients with intrahepatic cholangiocarcinoma were subjected to single-cell transcriptomic sequencing. Malignant

E-POSTER ABSTRACTS

cells were stratified according to regulatory subunit expression levels. Differential gene expression and pathway enrichment analyses were performed. Functional validation was conducted in gene overexpression and gene silencing intrahepatic cholangiocarcinoma cell lines. Protein interactions were examined using immunoprecipitation and mass spectrometry. RNA–protein interactions were assessed by computational prediction and enhanced crosslinking immunoprecipitation assays. Immune infiltration and ligand–receptor interactions were analyzed using single-cell transcriptomic data and validated in an independent tissue microarray cohort by multiplex immunofluorescence staining. Results:

High regulatory subunit expression was associated with enrichment of genes involved in cell–substrate junction and cadherin binding pathways. AHNAK was identified as a key downstream effector with significant differential expression. Transcriptomic profiling confirmed that regulatory subunit overexpression increased AHNAK expression, which was further validated in tissue microarrays by immunohistochemistry.

Protein interaction analysis demonstrated binding between the regulatory subunit and the RNA binding protein HNRNP, which was confirmed by mass spectrometry of immunoprecipitated complexes. Enhanced crosslinking immunoprecipitation assays confirmed interaction between HNRNP and AHNAK messenger RNA, supporting a regulatory connection between these molecules.

Consistent with these findings, AHNAK-high malignant cells were enriched in pathways associated with extracellular matrix adhesion, epithelial–mesenchymal transition, hypoxia, glycolysis, and anoikis. Pseudotime analysis suggested progressive accumulation of AHNAK-high epithelial cells toward terminal evolutionary states, indicating a role in tumor progression.

In addition to invasive phenotypes, AHNAK expression negatively correlated with dendritic cell and PLG2-positive cytotoxic T cell infiltration. Ligand–receptor analysis identified COL6A1–CD44 as a shared interaction axis potentially mediating these effects.

Tissue microarray validation using multiplex immunofluorescence demonstrated increased alternatively activated macrophages and exhausted cytotoxic T cells in AHNAK-high tumors.

Conclusions:

These findings support a regulatory subunit–RNA binding protein–AHNAK axis that promotes invasion and contributes to the formation of an

immunosuppressive microenvironment in intrahepatic cholangiocarcinoma and may represent a potential therapeutic target.

Keyword(s) : Intrahepatic cholangiocarcinoma, Tumor invasion, Tumor microenvironment, AHNAK, HNRNP

2754 - THE CONTRIBUTION OF MRCP IN DETERMINING THE NEED FOR ENDOSCOPIC INTERVENTION IN ANASTOMOTIC BILE DUCT STRICTURES IN LIVER TRANSPLANT RECIPIENTS

Sezer Nil Yilmazer Zorlu ¹, Diğdem Kuru Öz ², Ruhi Erdem Ergüden ³, Muhammed Fatih Karakaya ⁴, Mesut Gümüşsoy ⁵, Hale Gökcan ⁵, Ayşe Erden ², Ramazan Idilman ⁵

Mamak State Hospital, Department Of Radiology, Ankara-Türkiye ¹ School Of Medicine, Ankara University, Department Of Radiology, Ankara-Türkiye ² Atatürk State Hospital, Department Of Radiology, Zonguldak-Türkiye ³ Medica International Ankara Hospital, Department Of Gastroenterology, Ankara-Türkiye ⁴ School Of Medicine, Ankara University, Department Of Gastroenterology, Ankara-Türkiye ⁵

Background / Hypothesis: Magnetic resonance cholangiopancreatography (MRCP) is a valuable noninvasive imaging tool for evaluating biliary complications in liver transplant recipients. Specific MRCP-derived biliary imaging characteristics may differ between patients requiring endoscopic intervention and those managed conservatively. This study aimed to identify MRCP features associated with endoscopic intervention in liver transplant recipients with anastomotic biliary strictures.

Materials and Methods: This retrospective study included adult liver transplant recipients with MRCP findings consistent with anastomotic biliary stricture who were evaluated for suspected biliary complications. Patients were categorized into an endoscopic intervention group and a conservatively managed group with at least 12 months of follow-up. MRCP-derived biliary imaging parameters included stricture length, intrahepatic biliary dilatation grade, bile duct calibers proximal and distal to the stricture, and donor–recipient bile duct caliber dominance patterns. Logistic regression analyses were performed to identify imaging features associated with intervention.

Results: A total of 38 liver transplant recipients with MRCP findings suggestive of biliary anastomotic stricture were included: 17 patients underwent

E-POSTER ABSTRACTS

endoscopic intervention (referred to as the "intervention group"), while 21 patients (55.3%) were managed conservatively (referred to as the "non-intervention group"). The intervention group demonstrated significantly longer anastomotic strictures (6.4 ± 4.4 vs. 2.8 ± 3.5 mm, $p = 0.002$), more advanced intrahepatic biliary dilatation ($p < 0.001$), larger donor bile duct caliber proximal to the stricture (7.2 ± 3.4 vs. 4.7 ± 0.9 mm, $p < 0.001$), and a higher prevalence of a donor-dominant bile duct caliber pattern ($p = 0.040$). Donor bile duct caliber showed excellent discriminatory performance for predicting intervention (AUC = 0.838). In multivariable analysis, donor bile duct caliber remained independently associated with endoscopic intervention (OR = 3.09, $p = 0.013$).

Conclusions: MRCP-derived features, particularly increased donor bile duct caliber, were associated with endoscopic intervention in anastomotic biliary strictures after liver transplantation. These findings highlight MRCP as a valuable noninvasive imaging tool for identifying functionally significant strictures and guiding advanced endoscopists in clinical decision-making.

2755 - The Ptn Sdc2 axis regulates meningeal fibrosis and lymphatic function in hepatic encephalopathy

Yinhua Liang¹, Mengting Li¹, Guqing Luo¹, Chihao Zhang¹

Shanghai Ninth People's Hospital, School Of Medicine, Shanghai Jiao Tong University, General Surgery, Shanghai-China¹

Background / Hypothesis:

Meningeal lymphatic vessels are essential for CNS homeostasis, clearing metabolic waste and regulating neuroimmune interactions. Recent studies show that in hepatic encephalopathy (HE), meningeal lymphatic drainage increases compensatorily, alleviating neuroinflammation and improving motor function, yet the underlying mechanisms remain poorly understood. Here, we profiled the meningeal transcriptome to investigate how changes in the meningeal microenvironment influence meningeal lymphatic function in HE.

Materials and Methods:

We employed bioinformatics analysis of single-cell RNA sequencing and quantitative proteomics to characterize meningeal microenvironmental changes in a rat model of HE induced by 4-week bile duct ligation (BDL). Functional lymphatic drainage was assessed by tracking fluorescent tracer from the cisterna magna to deep cervical lymph nodes. Meningeal fibrosis and lymphatic changes were evaluated by whole-mount immunofluorescence. For mechanistic validation, we performed intracisternal administration of recombinant Ptn protein or AAV-Sdc2 to modulate the pathway in vivo.

Results:

Single-cell transcriptomic profiling revealed marked reduction of meningeal fibroblasts in BDL rats compared to Sham controls, accompanied by decreased expression of collagen-related genes, which was corroborated by quantitative proteomics. This fibrotic decline was attributed to downregulation of the Ptn-Sdc2 signaling axis in the meningeal microenvironment. Functionally, lymphatic drainage from the cisterna magna to deep cervical lymph nodes was significantly enhanced in BDL rats, alongside reduced collagen deposition and increased lymphatic area. Mechanistically, intracisternal administration of recombinant Ptn protein or AAV-Sdc2 restored meningeal fibrosis, suppressed lymphatic drainage, and further exacerbated the behavioral deficits, confirming that loss of Ptn-Sdc2 signaling alleviates fibrotic constraint, facilitates lymphatic function.

Conclusions:

In this study, we report for the first time that HE induces meningeal microenvironment changes characterized by reduced fibrosis, which facilitates lymphatic drainage. This fibrotic decline was driven by downregulation of the Ptn-Sdc2 axis, identified as a novel regulator mechanism of meningeal fibrosis. These findings provide a potential therapeutic target in HE by disrupting the Ptn-Sdc2 interaction.

Keyword(s) : Hepatic encephalopathy, Meningeal lymphatic vessels, Meningeal microenvironment, Meningeal lymphatic function, fibrosis, lymphatic drainage.

2757 - Diagnostic Accuracy of Leukocyte Esterase Dipstick Test in Early Detection of Spontaneous

E-POSTER ABSTRACTS

Bacterial Peritonitis in Cirrhotic Patients

Anam Shakeel ¹, Tanveer Hussain ¹

Rawalpindi Medical University, Gastroenterology,
Rawalpindi-Pakistan ¹

Background / Hypothesis:

Objective: To assess the investigative precision of the leukocyte esterase dipstick test in detecting Spontaneous Bacterial Peritonitis (SBP) among cirrhotic patients.

Materials and Methods:

During the study period. 132 cirrhotic patients were enrolled reported with grade 2 or 3 ascites. Investigative abdominocentesis was completed under stringently sanitised circumstances. A smaller sample of ascitic fluid (10mL) screened for the analysis whereas, a larger sample (30mL) was kept for the dipstick test to determine the granulocyte esterase activity. Using a color-calibrated scale, Leukocyte levels were computed. ++ and +++ dipstick results were marked as positive. Critical investigative metrics were measured discretely for positive dipstick grades.

Results:

The results of the study showed that with LERS++, the confirmation rate for SBP was 85.7% in contrast to the patients with LERS+++ which was increased to 87.5%. LERS++ threshold was calculated as follows: overall diagnostic accuracy, 79.5%, specificity, 96.7%, sensitivity, 42.9%, PPV, 85.7%, NPV, 78.4%. LERS+++ threshold was as follows: overall diagnostic accuracy 81.8%, sensitivity 50%, specificity, 80.6%, PPV 87.5%, and NPV 80.6%.

Conclusions: In order to detect SBP in cirrhotic patients, the LERS (leukocyte esterase dipstick) test appears to possess speedy, cost-economical, and sensible diagnostic benefits having affordable diagnostic precision.

2758 - Mutation Profiles of three selected driver genes from Circulating cfDNA as Non Invasive Prognostic Biomarkers in HBV Induced

Hepatocellular Carcinoma

Afzalun Nessa Nessa ¹, Sharmin Sultana Sultana ¹,
Sabinur Akter Akter ¹, Farzana Laila Laila ¹
Bangladesh Medical University, Virology, Dhaka-
Bangladesh ¹

Background / Hypothesis:

Chronic hepatitis B virus (HBV) infection is one of the major etiological agents of hepatocellular carcinoma (HCC), a leading cause of cancer-related mortality worldwide. Somatic mutations in TERT, TP53 and CTNNB1 genes are frequently tied-up with hepatocarcinogenesis as they drive tumor initiation, aggressiveness and define tumor phenotype and treatment response respectively. Circulating cell free DNA (cfDNA) is a promising non-invasive alternative of conventional biopsy material for detection of genetic alterations. This study is aimed to detect the hot spot mutations of the above mentioned genes from cfDNA during different stages of HCC and to predict the disease severity using bioinformatics tools.

Materials and Methods:

30 HCC patients of early, intermediate and late stages of HCC and 20 healthy controls were evaluated for TERT, TP53 and CTNNB1 gene hotspot mutations from liquid biopsy (cfDNA extracted from peripheral venous blood using QIAamp Circulating Nucleic Acid Extraction Kit) by Sanger-based cycle sequencing assay. Mutation detection frequencies were determined by MEGA 11 software comparing with specific reference sequences whereas pathogenicity prediction was determined by Predict-SNP and PhD-SNP bioinformatics tools.

Results:

: 40.0% (12/30) of HCC patients had hotspot mutations in selected three genes with 30% (3/10) in early, 44.4% (4/9) in intermediate and 45.5% (5/11) in late stages of HCC which was not statistically significant. No hotspot mutation was detected among healthy controls. TERT promoter mutations were observed 3.3% (1/30) at position c.124 C>T (p. P228L) and 6.7% (2/30) at c.146 C>T (p.L 250L). A highest mutation frequency was found 13.3% (4/30) at position c.746 G>A (p.G249S) of TP53 and then 6.7% (2/30) at c.735 C>T (p.A 245V) and 3.3% (1/30) at c.747 G>T (p.G249V) of same gene. The CTNNB1 showed mutations at position c.110 C>A (p.S37Y) and c.133 T>A (p.S45Thr), 3.3% (1/30) in each. Mutation at codon c124 and c146 of TERT; codon c735,

E-POSTER ABSTRACTS

c746 and c747 of TP53 and codon c133 of CTNNB1 gene predict 83% deleterious effect using Predict SNP and PhD SNP bioinformatics tool.

Conclusions::

No significant differences of mutations among early, intermediate and late stages indicate most of the mutations are occurred in early stage of HCC. Mutations detection from liquid biopsy may be helpful for early prediction and monitoring the progression of HCC.

Keyword(s) : HBV, HCC, liquid biopsy, driver mutation, cfDNA, TERT, TP53, CTNNB1

2761 - CORRELATION OF NON INVASIVE FIBROSIS TEST RESULTS WITH THE NUMBER OF METABOLIC RISK FACTORS IN PATIENTS WITH METABOLIC DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE

Danielle Lucero¹, Stephen Wong¹, Frederick Dy¹, Rommel Romano¹, Alvin Brian Velasco¹, Carmelita Dalupang¹, Estrelita Ruiz¹, Ann Margaret Navarroza¹, Maria Fleurdeliz Goco-siatan¹
University Of Santo Tomas Hospital, Medicine - Section Of Gastroenterology, Santa Rosa City-Philippines¹

Background / Hypothesis:

The multiplicity of metabolic risk factors is a prognostic indicator in metabolic dysfunction-associated steatotic liver disease (MASLD). We aimed to evaluate the association between the number of metabolic risk factors and liver fibrosis severity as assessed by the Fibrosis-4 score (FIB-4), NAFLD Fibrosis Score (NFS), and transient elastography among patients with MASLD.

Materials and Methods:

A retrospective review of outpatient records of MASLD patients was conducted. Patients were stratified into those with one metabolic risk factor (Group1) and those with two or more risk factors (Group2). Fibrosis severity was categorized using established cutoffs for FIB-4, NFS, and FibroScan.

Results:

A total of 1,193 MASLD patients were included and 227 were classified as Group1 and 966 as Group2. Group 2 patients were older (52.9 ± 14.9 vs 46.4 ± 15.7 years) and had a higher prevalence of obesity (76.6% vs 64.8%), with a slightly higher mean BMI (27.8 ± 4.2 vs 27.0 ± 4.6 kg/m²). Sex distribution was similar, with male predominance in both groups (~57–58%). Liver enzymes were comparable between groups (ALT ~63 U/L, AST ~45 U/L). Platelet count was modestly lower

in Group 2, while serum albumin levels were similar, indicating generally preserved synthetic function. Advanced fibrosis ($\geq F3$) was significantly higher in Group 2 than Group 1 (9.4% vs 2.6%; $p < 0.001$) by FIB-4 and NFS (7.1% vs 1.0%; $p < 0.001$), while low-risk scores were less frequent using FIB-4 (62.1% vs 78.2%) and NFS (55.0% vs 90.1%). Similar findings were observed using NFS, with more high-risk fibrosis in Group 2 (7.1% vs 1.0%) and fewer low-risk scores (55.0% vs 90.1%; $p < 0.001$). Frequency of advanced fibrosis on FibroScan did not differ significantly (Group2=29.7% vs. Group1=22.1%; $p = 0.215$).

Conclusions:

A higher metabolic burden is significantly associated with increased noninvasive fibrosis risk in MASLD, supporting targeted fibrosis screening to improve early detection and management of patients at risk for advanced liver disease.

Keyword(s) : metabolic dysfunction-associated steatotic liver disease; non-invasive fibrosis test; NFS; FIB-4; FibroScan

2763 - Comparison of Body Composition Parameters Between Cirrhotic and Non Cirrhotic MASLD patients

Kevin Shah¹, Rohit Shetty¹, Sitaram Sabne¹, Mahesh Choudhary¹, Ameetkumar Mandot¹, Chetan Kalal¹, Samriddhi Poyekar¹
Gleneagles Hospital, Hepatology, Mumbai-India¹

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease is the most prevalent chronic liver disorder globally and represents the hepatic manifestation of systemic metabolic dysfunction. It is closely associated with obesity, insulin resistance, type 2 diabetes mellitus, dyslipidemia, and cardiovascular disease, contributing significantly to long-term morbidity and mortality. Emerging evidence suggests that fat distribution, predominantly increased visceral adiposity, plays a more critical role in disease progression than overall obesity measured by body mass index (BMI).

Materials and Methods:

In the present study, 151 patients with Metabolic Dysfunction-Associated Steatotic Liver Disease were included, with a mean age of 47.99 ± 11.49 years (range: 23–76 years). The gender distribution was nearly equal, with 49.67%

E-POSTER ABSTRACTS

females and 50.33% males, demonstrating that MASLD affected middle-aged adults of both sexes almost uniformly in this cohort.

Results:

In the present study, patients with cirrhosis and MASLD showed clear differences in body composition compared to non-cirrhotic patients. Cirrhotic patients had a significantly lower subcutaneous fat area ($278.03 \pm 94.46 \text{ cm}^2$ vs. $369.37 \pm 130.86 \text{ cm}^2$; $p < 0.0001$) and a significantly higher visceral-to-subcutaneous fat ratio (0.61 ± 0.071 vs. 0.52 ± 0.073 ; $p < 0.0001$). However, there was no significant difference in absolute visceral fat area between the two groups (184.09 ± 47.62 vs. 196.79 ± 67.01 ; $p = 0.18$). This suggests that, disease progression is mainly associated with loss of subcutaneous fat rather than an increase in visceral fat.

Conclusions:

The Study revealed that in patients of MASLD, cirrhotic patients had a significantly lower subcutaneous fat area and a significantly higher visceral-to-subcutaneous fat ratio.

2766 - Association of radiotherapy with atezolizumab plus bevacizumab with survival in advanced hepatocellular carcinoma

Hyunjae Shin¹

Seoul National University Hospital, Internal Medicine, Seoul-South Korea¹

Background and Aims: Immunotherapy is the standard first-line therapy for advanced hepatocellular carcinoma (HCC). Radiotherapy (RT) is well established for achieving local control and may also induce systemic immune effects, thereby augmenting the efficacy of immunotherapy. We evaluated the association of RT with outcomes in patients receiving Atezolizumab plus Bevacizumab (Ate+Bev).

Methods: Patients who received RT during Ate+Bev therapy ($n=88$) in 2021–2023 were compared with patients treated with Ate+Bev alone ($n=396$). Overall survival (OS) and progression-free survival (PFS) were analyzed with multivariable Cox proportional hazards models.

Results: Median follow-up was 18.3 months and the median interval from Ate+Bev initiation to RT was 32 days. Baseline tumor characteristics and liver function were comparable between the two groups. Compared with Ate+Bev alone, Ate+Bev+RT was associated with longer OS (aHR=0.71, 95% CI=0.53–0.97, $P=0.030$) and PFS (aHR=0.57, 95% CI=0.45–0.74, $P<0.001$). Effects were consistent across subgroups for PFS (all interaction $P>0.05$). In RT recipients, OS (aHR=1.38, 95% CI=0.65–2.93, $P=0.40$) and PFS (aHR=0.92, 95% CI=0.55–1.52, $P=0.73$) did not differ based on the timing of RT. In patients with extrahepatic RT targets, OS (aHR=7.91, 95% CI=2.90–21.6, $P<0.001$) and PFS (aHR=3.63, 95% CI=1.85–7.12, $P<0.001$) were inferior to those with intrahepatic RT targets. RT-related adverse events occurred in 3.4% of patients, and the overall incidence of adverse events was comparable between the two groups ($P=0.211$).

Conclusions: Combining RT with Ate+Bev was associated with longer OS and PFS, particularly in patients with intrahepatic RT targets. These findings support the potential role of RT as an effective adjunct to immunotherapy and warrant prospective validation.

2767 - Diagnostic value of homocysteine combined with IgG in differentiating drug induced liver injury and autoimmune hepatitis

Xue Jiao¹, Jing Liu², Ping Li³

Tianjin University Of Traditional Chinese Medicine, College Of Integrated Traditional Chinese And Western Medicine, Tian Jin-China¹ Tianjin Medical University, Department Of Hepatology, Tian Jin-China² Tianjin Second People's Hospital, Department Of Hepatology, Tian Jin-China³

Background / Hypothesis:

Background and Aim: Autoimmune hepatitis (AIH) and drug-induced liver injury (DILI) often present with overlapping clinical features, yet their management strategies differ significantly, posing diagnostic challenges. Currently, there is a lack of non-invasive biomarkers with high specificity for differentiating between the two conditions. This study aimed to investigate the diagnostic value of serum homocysteine (Hcy) in distinguishing AIH from DILI and to evaluate its diagnostic performance when combined with the conventional biomarker immunoglobulin G (IgG).

Materials and Methods:

E-POSTER ABSTRACTS

A retrospective case-control design was adopted, including 324 patients confirmed by liver biopsy (AIH: 143 cases, DILI: 181 cases). Diagnostic performance was assessed using receiver operating characteristic (ROC) curve analysis and multivariate logistic regression models.

Results:

Results showed that serum Hcy levels were significantly higher in the AIH group compared to the DILI group ($P < 0.001$). The area under the ROC curve (AUROC) for Hcy in diagnosing AIH was 0.881 (95% CI: 0.834–0.927). At the optimal cutoff value of 10.05 $\mu\text{mol/L}$, sensitivity was 88.1% and specificity was 92.3%. The AUROC for IgG was 0.732 (95% CI: 0.677–0.788). When Hcy and IgG were combined, the AUROC increased to 0.903 (95% CI: 0.864–0.942). Multivariate logistic regression analysis confirmed Hcy as an independent predictor for distinguishing AIH from DILI (OR=1.694, 95% CI: 1.404–2.043, $P < 0.001$).

Conclusions: Serum Hcy demonstrates superior diagnostic performance in differentiating AIH from DILI compared to the traditional biomarker IgG, and their combination significantly improves diagnostic accuracy. These findings suggest that Hcy may serve as a potential non-invasive tool for clinical differentiation, with important implications for clinical practice. Further validation through prospective, multicenter studies is needed to confirm its applicability across diverse populations and clinical settings.

Keyword(s) : AIH, DILI, Homocysteine, IgG, differential diagnosis

2768 - Diagnostic Value of the SS FIB VT Model Integrating Spleen Stiffness Fibrinogen and Retinal Vessel Tortuosity for High risk Esophageal Varices in Liver Cirrhosis

He Menyao ¹, Kuang Yuyan ², Li Qian ², Li Yuyu ², Ma Chao ², Wang Zuanguo ², Jiengsinuer Saiylashi ³, Ning Zhonghui ³, Wang Xiaozhong ⁴, Guo Feng ⁴
Xinjiang Medical University, Department Of Hepatology, Affiliated Hospital Of Traditional Chinese Medicine, Urumqi-China ¹ Xinjiang Medical University, Department Of Hepatology, Affiliated Hospital Of Traditional Chinese Medicine, Xinjiang Medical University, Urumqi-China ² Xinjiang Uygur Autonomous Region Hospital Of Traditional Chinese Medicine, Xinjiang Uygur Autonomous Region Hospital Of Traditional Chinese Medicine,, Urumqi-China ³ Xinjiang

Uygur Autonomous Region Hospital Of Traditional Chinese Medicine, Xinjiang Uygur Autonomous Region Hospital Of Traditional Chinese Medicine, Urumqi-China ⁴

Background / Hypothesis:

Gastroscopy is currently the gold standard for screening high-risk esophageal varices (HEV) in patients with liver cirrhosis, but its invasive nature limits widespread application. This study aimed to develop and validate a non-invasive diagnostic model (SS-FIB-VT) integrating spleen stiffness, the serum fibrosis marker (FIB), and retinal vascular morphology features to assess its diagnostic value in discriminating HEV.

Materials and Methods:

High-risk Esophageal Varices; Non-invasive Diagnosis; SS-FIB-VT Model; Spleen Stiffness; Retinal Vessel Tortuosity ;

Methods: This study was a diagnostic investigation. A total of 56 consecutive hospitalized patients with liver cirrhosis from December 2024 to September 2025 were enrolled, all of whom underwent gastroscopy. According to the gastroscopic findings, patients were divided into the HEV group (moderate/severe varices, $n=28$) and the non-HEV group (no/mild varices, $n=28$). Clinical serological indicators, liver and spleen stiffness values measured by transient elastography, and the average tortuosity parameters of retinal vessels in specific regions quantified by the EvisionAI fundus photography intelligent analysis system were collected and analyzed. Significant predictors were screened via univariate logistic regression analysis, and a combined diagnostic model was constructed using multivariate logistic regression. The model's performance was evaluated by indicators including the area under the receiver operating characteristic curve (AUC), sensitivity, and specificity.

Results:

Univariate logistic regression analysis identified six predictors significantly associated with HEV (all $P < 0.05$): platelet count, liver stiffness value, FIB, spleen stiffness value, average tortuosity of vessels in the inferonasal region within a 6.9 mm annular area, and average vessel tortuosity within the 9-13.5 mm annular area. Among the single-indicator diagnostic models, platelet count (AUC=0.787) and the FIB-4 index (AUC=0.795) demonstrated relatively high diagnostic value. Diagnostic efficacy was significantly improved

E-POSTER ABSTRACTS

through multi-parameter joint modeling. Among all tested combinations, the model integrating spleen stiffness value, FIB, and the average tortuosity of vessels in the inferonasal region within the 6.9 mm annular area was identified as the optimal diagnostic combination, named the SS-FIB-VT model. The AUC for this model was 0.886 (95% CI: 0.800-0.973). At the optimal predictive threshold of 0.46, the model maintained both high sensitivity (89.3%) and specificity (78.6%).

Conclusions:

The SS-FIB-VT model constructed in this study, by combining three types of non-invasive parameters- spleen stiffness, FIB, and retinal vessel tortuosity- demonstrates good diagnostic value (AUC 0.886) for identifying the presence of high-risk esophageal varices in patients with liver cirrhosis. This model provides an accurate and convenient new non-invasive screening strategy for clinical practice, facilitating the optimization of HEV risk stratification and management processes.

Keyword(s) : High-risk Esophageal Varices; Non-invasive Diagnosis; SS-FIB-VT Model; Spleen Stiffness; Retinal Vessel Tortuosity ;

2769 - "Diabetic Ketoacidosis After Laparoscopic Cystectomy for Hydrosalpinx A Case Illustrating Postoperative Metabolic Vulnerability"

Mery Friyanti Pandiangan¹, El- Varel Baby Berlianza¹, Ivan Banjuradja²

Universitas Indonesia Hospital, Emergency Department, Depok-Indonesia¹ Universitas Indonesia Hospital, Internal Medicine Department, Depok-Indonesia²

Background / Hypothesis:

Diabetic ketoacidosis (DKA) is a life-threatening metabolic emergency commonly associated with uncontrolled diabetes and acute illness. Its occurrence in the postoperative period following minimally invasive gynecologic surgery is rare and often unexpected. Surgical stress may precipitate metabolic decompensation, even after procedures considered low risk.

Materials and Methods:

We report a case of a 36-year-old woman with unknown diabetic history who underwent laparoscopic cystectomy for hydrosalpinx with an initially uneventful intraoperative and postoperative course. On postoperative day 7, the patient was discharged from

hospital. On postoperative day 7, the patient was readmitted to the hospital with the complaints of abdominal pain, nausea, vomiting, and unexplained metabolic acidosis. Laboratory evaluation demonstrated marked hyperglycemia (334 mg/dL), elevated anion gap metabolic acidosis, and positive ketone bodies (1.3), confirming the diagnosis of diabetic ketoacidosis. The patient was managed promptly with intravenous insulin infusion, aggressive fluid resuscitation, and electrolyte correction, resulting in progressive clinical and biochemical improvement.

Results:

This case highlights the potential role of perioperative surgical stress, counter-regulatory hormone release, and relative insulin deficiency in triggering DKA following minimally invasive gynecologic surgery. Despite smaller incisions and faster recovery profiles, laparoscopic procedures can still induce significant metabolic stress in susceptible individuals.

Conclusions:

Diabetic ketoacidosis, although rare, should be considered in the differential diagnosis of unexplained postoperative metabolic derangements following minimally invasive gynecologic procedures particularly in patients without known diabetes. Vigilant perioperative glucose monitoring and rapid intervention are key to favorable outcomes.

Keyword(s) : Diabetic Ketoacidosis, Laparoscopic Cystectomy for Hydrosalpinx, Postoperative

2770 - The Value of Serum Immature Granulocyte Levels in Predicting Disease Activation in Patients with Ulcerative Colitis

Esra Taşgetiren¹, Kadir Gisi¹, Bülent Kantarçeken¹
Sutcu Imam University, Gastroenterology,
Kahramanmaraş-Türkiye¹

Background / Hypothesis:Ulcerative colitis (UC) is a chronic inflammatory bowel disease affecting the colon and rectum, characterized by periods of remission and activation. Current markers used to monitor disease activity (CRP, ESR, etc.) have some limitations. This study aimed to investigate the diagnostic value of a novel inflammatory marker, the Delta Neutrophil Index (DNI), also known as Immune Granulocyte (IG) level, in determining disease activation in UC patients and differentiating active patients from those in remission.

E-POSTER ABSTRACTS

Materials and Methods:The study included patients diagnosed with UC and followed up in the gastroenterology clinic. Participants were divided into "active UC" and "remission" groups based on their clinical and endoscopic findings. Demographic characteristics, daily bowel movements, and laboratory parameters (IG, CRP, ESR, WBC, Hemoglobin) were examined retrospectively/prospectively. ROC curves and correlation tests were used to analyze the data.

Results:The study revealed that serum IG levels in patients with active ulcerative colitis (UC) were significantly different from those in remission. Statistically significant correlations were found between daily bowel movement frequency and laboratory parameters reflecting inflammation levels. ROC analysis results suggest that serum IG level has high diagnostic performance in predicting UC activation and can be used as a reliable marker to differentiate active disease from remission.

Conclusions:Serum IG level may be an inexpensive, readily accessible, and effective biomarker for assessing disease activity in UC patients. The use of this marker in clinical practice could contribute to the personalization of disease management and more effective planning of treatment strategies.

2771 - Infliximab as Salvage Therapy in Multidrug Resistant Autoimmune Hepatitis A Seven Year Clinical Course

Sami Fidan ¹, Arif Mansur Cosar ¹

Ktu, Gastroenterology, Trabzon-Türkiye ¹

Background / Hypothesis:Autoimmune hepatitis (AIH) is a chronic immune-mediated liver disease that typically responds to corticosteroids and azathioprine. However, approximately 10–20% of patients develop treatment-refractory disease. Management of such cases remains challenging, and data regarding biologic therapies are limited. We report a case of refractory AIH successfully controlled with infliximab after failure of multiple immunosuppressive regimens.

Case Presentation:

A 15-year-old female patient presented in 2019 with fatigue and mild scleral icterus. Laboratory evaluation revealed ALT 697 U/L, AST 438 U/L, total bilirubin 1.46 mg/dL, and elevated IgG 34.6 g/L (7-16). Antinuclear antibody (ANA) was positive. Magnetic resonance

imaging revealed no pathology other than mild hepatomegaly (165 mm). Liver biopsy demonstrated severe lymphoplasmacytic infiltration, interface hepatitis, and portal-portal bridging fibrosis, consistent with autoimmune hepatitis. The patient was diagnosed with autoimmune hepatitis, started on prednisolone 64 mg, and azathioprine 100 mg treatment was added after 2 weeks. Although an initial biochemical response was achieved, relapse occurred during steroid tapering. Over subsequent years, persistent transaminase elevation was observed despite azathioprine optimization. Anti-smooth muscle antibody (ASMA) seroconversion developed during follow-up. Mycophenolate mofetil and later tacrolimus were sequentially introduced without achieving complete biochemical remission. A repeat liver biopsy in January 2024 confirmed ongoing active interface hepatitis. Given refractory disease and sustained biochemical activity, off-label infliximab therapy was initiated in March 2025 after informed consent. Treatment was well tolerated. By January 2026, significant biochemical improvement was observed: ALT 57 U/L, AST 43 U/L, total bilirubin 0.67 mg/dL, and IgG 16.9 g/L. No major adverse events occurred during follow-up. Changes in ALT and IgG levels with treatment from the time of diagnosis are shown in Figure 1.

Conclusions:

This case highlights infliximab as a potential salvage therapeutic option in carefully selected patients with refractory autoimmune hepatitis. Biologic therapy may be considered after failure of conventional and second-line immunosuppressive agents, with close monitoring for safety and disease activity. Further prospective studies are required to define the role of anti-TNF therapy in AIH.

Keyword(s) : Autoimmune Hepatitis. AntiTNF, Infliximab, Salvage Therapy

2772 - Development of a new nutritional screening score in hospitalized patients with cirrhosis.

Antony Kahwagi ¹, Perla Wehbe ¹, Tarek Costa ¹, Anthony Aaraj ¹, Michele Tabbal ¹, Eid Mahfouz ¹, Joseph Amara ¹, Khalil Honein ¹, Rita Slim ¹, Cesar Yaghi ¹

Hôtel-dieu De France, Gastroenterology And Hepatology, Beyrouth-Lebanon ¹

Background / Hypothesis:

Malnutrition strongly predicts cirrhosis complications, including infections and hepatic encephalopathy. Nutritional risk screening in cirrhotic patients enables

E-POSTER ABSTRACTS

early detection of eating disorders and prompt management. Several tools are used (CNAQ, MNA-SF, RFH-NPT), but none alone adequately captures the nutritional specificities of cirrhosis. Therefore, this study aims to develop a cirrhosis-specific nutritional score combining components of the CNAQ, MNA-SF, and RFH-NPT.

Materials and Methods:

The sample consisted of 40 patients with cirrhosis, hospitalized for less than 24 hours at the time of evaluation. Patients with hepatocellular carcinoma (HCC) or with uncontrolled comorbidities (diabetes, arterial hypertension, or dyslipidemia) were excluded from the study. The following questionnaires were then administered to a sample of 40 hospitalized cirrhotic patients: the CNAQ, whose items include those of the Simplified Nutritional Appetite Questionnaire (SNAQ), the MNA-SF, and the RFH-NPT.

Results:

The mean age of the studied population was 65 years. There were respectively 6 patients, 15 patients, and 19 patients classified as Child–Pugh A, B, and C. The mean SNAQ score was 10.35 ± 3.61 , while the mean CNAQ score reached 20.28 ± 6.28 . Regarding the other nutritional measures, the total MNA-SF score was 7.40 ± 3.18 , and the RFH-NPT had a mean of 2.65 ± 1.46 .

The total SNAQ score showed a very strong correlation with the CNAQ score ($r = 0.968$, $p < 0.001$), a positive correlation with the MNA-SF ($r = 0.727$, $p < 0.001$), and a moderate negative correlation with the RFH-NPT ($r = -0.699$, $p < 0.001$).

Using the MNA-SF as the clinical reference, the CNAQ and its derivative, the SNAQ, both showed excellent discriminative ability, with an area under the curve (AUC) greater than 0.9.

However, a new combined score, composed of 7 items from the CNAQ and 5 items from the MNA-SF, presented an AUC of 0.994 (SE = 0.009, $p < 0.001$), higher than that of the SNAQ (AUC = 0.965, SE = 0.028, $p < 0.001$) and the CNAQ (AUC = 0.983, SE = 0.019, $p < 0.001$).

Conclusions:

The SNAQ demonstrates excellent psychometric properties with a strong correlation with the CNAQ and high discriminative ability. However, the superior performance of the combined score (AUC = 0.994) suggests that the CNAQ and the MNA-SF assess complementary dimensions of nutritional risk. Integrating these behavioral and anthropometric

components could optimize early screening for malnutrition while preserving clinical feasibility.

2775 - Circadian Rhythm Disruption Induces Abnormal Serine Metabolism and Immune Suppression to Promote Hepatocellular Carcinoma Progression

Liming Zheng¹, Hao Liu¹, Xuemei Zhang¹, Hai Feng², Yueqiu Gao¹, Zhuo Yu¹

Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Department Of Hepatopathy, Shanghai-China¹ Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Institute Of Infectious Disease, Shanghai-China²

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is a rapidly progressing and fatal malignancy. Circadian rhythm disruption (CRD) has been shown to promote HCC by altering liver metabolism and the immune microenvironment. This study investigates the role of CRD in activating the serine metabolism pathway, leading to serine accumulation and accelerating HCC progression in mice. Single-cell RNA sequencing revealed that CRD increases neutrophil populations, especially hypoxia-induced neutrophils, with elevated expression of CCL2 in the HIF-1 α signaling pathway, indicating immune suppression in the tumor microenvironment.

Materials and Methods:

Hepa 1-6 liver cancer cells were orthotopically injected into C57BL/6N mice to establish an HCC model. Sleep deprivation was induced for 21 days. Mouse HCC tissues were analyzed by untargeted metabolomics. In vitro, CCK-8 and EdU assays were used to assess metabolite effects, and qPCR and molecular docking were employed to study the impact of circadian rhythm factors on serine synthesis enzymes. Single-cell RNA sequencing was performed to evaluate the immune microenvironment.

Results:

Sleep deprivation significantly increased tumor volume, tumor-to-body weight ratio, and mortality in HCC mice ($P < 0.01$), with no significant change in body weight. Immunohistochemistry revealed increased Ki67 and

E-POSTER ABSTRACTS

PCNA expression ($P < 0.05$), indicating enhanced proliferation. Untargeted metabolomics showed upregulation of DL-serine ($P < 0.05$), indicating altered serine metabolism. In vitro, DL-serine treatment ($0\mu\text{M}$, $25\mu\text{M}$, $100\mu\text{M}$) significantly increased cell proliferation ($P < 0.05$), with the $100\mu\text{M}$ group showing the strongest effect. Silencing Clock and Bmal1 with siRNA significantly increased Psat1 expression ($P < 0.01$). Molecular docking confirmed that Clock and Bmal1 bind to the Psat1 promoter, regulating its expression. Single-cell RNA sequencing identified 36,626 cells from HCC tissues, with neutrophils being the most abundant population (13,613 cells). The hypoxia-induced neutrophil subgroup exhibited the most significant differences, and CCL2 expression was upregulated in the HIF-1 α pathway, suggesting immune suppression.

Conclusions:

Circadian rhythm disruption promotes HCC progression by inducing serine accumulation and enriching immune suppressive neutrophils.

Keyword(s) : Hepatocellular carcinoma, Circadian rhythm disruption, serine metabolism, immune suppressive neutrophils

2776 - Serum Vitamin A D and B12 Levels and Their Association with Disease Severity and Treatment Response in Chronic Hepatitis C

Abdulrahim Eren ¹, Mehmet Demir ², Ammar Alramadan ²

Yayladağ State Hospital, Internal Medicine, Hatay-Türkiye ¹ Hatay Mustafa Kemal University, Gastroenterology, Hatay-Türkiye ²

Background / Hypothesis:

Vitamin A and vitamin B12 are predominantly stored in the liver, whereas vitamin D undergoes hepatic 25-hydroxylation as part of its activation pathway. These liver-related vitamins participate in immune regulation, oxidative balance, and stellate cell biology, all of which are central to hepatic inflammation and fibrogenesis. Alterations in their serum levels have been reported in chronic liver diseases; however, their association with antiviral treatment response in chronic hepatitis C (CHC) remains unclear. We aimed to investigate the relationship between serum vitamin A (retinol), vitamin D, and vitamin B12 levels and disease severity, viral parameters, and sustained virologic response (SVR) in patients with CHC.

Materials and Methods:

This case-control study included 106 patients with CHC (79 treatment-naïve and 27 previous non-responders to pegylated interferon plus ribavirin) and 50 age- and sex-matched healthy controls. Serum vitamin A levels were measured using high-performance liquid chromatography, while vitamin D and B12 levels were assessed by immunoassay. HCV-RNA was quantified by real-time PCR and genotyping was performed. Associations between vitamin levels, clinical parameters, and SVR were analyzed.

Results:

The mean age of CHC patients was 56.3 ± 12.1 years, and 58.5% were female. Mean serum vitamin B12 levels were 352.3 ± 143.1 pg/mL in CHC patients and 379.0 ± 201.9 pg/mL in controls ($p > 0.05$). Mean vitamin D levels were 18.1 ± 7.2 ng/mL vs. 19.0 ± 8.8 ng/mL ($p = 0.518$), and mean vitamin A levels were 605.5 ± 242.0 ng/mL vs. 469.7 ± 219.4 ng/mL ($p = 0.328$), respectively. When stratified by vitamin A levels, patients with levels ≥ 400 ng/mL showed higher SVR rates compared to those with lower levels (mean 620.6 ± 239.8 vs. 567.5 ± 247.8 ng/mL), although this difference did not reach statistical significance ($p = 0.31$). No significant association was observed between vitamin D or B12 levels and treatment response.

Conclusions:

Higher serum vitamin A levels were associated with improved SVR rates in CHC patients, although statistical significance was not achieved. Vitamin D and B12 levels were not significantly associated with disease severity or treatment outcomes. Larger prospective studies are needed to clarify the potential predictive role of vitamin A in antiviral therapy response.

2777 - Profile of HSD17B13 rs72613567 TA allele Variant in Indonesian Patients With Metabolic Dysfunction-Associated Fatty Liver Disease and Type 2 Diabetes Mellitus and Its Association With Liver Steatosis Severity

Andry Kurniawan ¹, Juferdy Kurniawan ², Hasan Maulahela ³, Dicky Levenus Tahapary ⁴, Saut Horas Nababan ², Eka Ginanjar ⁵, Findy Prasetyawaty ⁶, Achmad Fauzi ³

Cipto Mangunkusumo National General Hospital, Internal Medicine, Jakarta-Indonesia ¹ Cipto Mangunkusumo National General Hospital, Hepatobiliary Division Of Internal Medicine, Jakarta-

E-POSTER ABSTRACTS

Indonesia ² Cipto Mangunkusumo National General Hospital, Gastroenterology, Pancreatobiliary, Digestive Endoscopy Division Of Internal Medicine, Jakarta-Indonesia ³ Cipto Mangunkusumo National General Hospital, Endocrinology, Metabolic, Diabetes Division Of Internal Medicine, Jakarta-Indonesia ⁴ Cipto Mangunkusumo National General Hospital, Cardiology And Vascular Medicine Of Internal Medicine, Jakarta-Indonesia ⁵ Cipto Mangunkusumo National General Hospital, Hematology And Medical Oncology Division Of Internal Medicine, Jakarta-Indonesia ⁶

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) is the most common cause of chronic liver disease and is frequently observed in individuals with type 2 diabetes mellitus (T2DM). Patients with concomitant MAFLD and T2DM are at greater risk of disease progression toward liver steatosis. In addition to metabolic risk factors, genetic determinants are believed to contribute to disease severity. The HSD17B13 rs72613567 TA allele has been reported to exert a potential protective effect against hepatic inflammation, steatosis and fibrosis. However, evidence regarding the association of this genetic variant with steatosis severity among Indonesian patients with MAFLD and T2DM has never been explored previously. This research tried to determine the distribution and frequency of the HSD17B13 rs72613567 TA allele and to evaluate its association with liver steatosis severity in Indonesian patients with MAFLD and T2DM.

Materials and Methods:

This analytical observational study employed a cross-sectional design and included 268 patients with MAFLD and T2DM. Data was achieved from the Indonesia Multicenter Genomic Study Biobank of patients with diabetes mellitus conducted between November 2025 and January 2026 who met the eligibility criteria. Demographic, anthropometric, and metabolic characteristics were systematically collected. Genotyping of the HSD17B13 rs72613567 TA allele was performed using molecular techniques. Liver steatosis severity was assessed using validated non-invasive liver elastography. Statistical analyses were conducted to determine the association between the HSD17B13 rs72613567 TA allele and the degree of liver steatosis.

Results:

Most subjects were younger than 60 years, female, and obese. The majority had severe steatosis (S3), about 52,2% of population. The genotype distribution consisted of dominant homozygotes (T/T),

heterozygotes (T/A/T), and recessive homozygotes (T/A/T/A), with an overall variant frequency of 47%. No statistically significant differences were found in clinical characteristics between carriers and non-carriers of the TA allele (all $p > 0.05$), except for triglyceride levels ($p = 0.006$) and SGPT ($p = 0.002$). Bivariate analysis showed no significant association between the HSD17B13 rs72613567 TA allele and liver steatosis ($p = 0.623$, PR = 1,146, 95% CI = 0,665-1,974).

Conclusions:

In Indonesian patients with MAFLD and T2DM, the HSD17B13 rs72613567 TA allele had a frequency of 47% and was not significantly associated with liver steatosis severity.

Keyword(s) : MAFLD; type 2 diabetes mellitus; HSD17B13 rs72613567 TA allele; liver steatosis

2778 - A Novel Non Invasive Index for Predicting Non Alcoholic Fatty Liver Disease in Patients with Chronic Hepatitis B The Hatay Index

Yusuf Can Ardaşir ¹, Mehmet Demir ², Ammar Alramadan ², Kübra Berat Yavuz Ergin ¹, Ali Haydar Duman ¹

Hatay Mustafa Kemal University, Internal Medicine, Hatay-Türkiye ¹ Hatay Mustafa Kemal University, Gastroenterology, Hatay-Türkiye ²

Background / Hypothesis:

Non-alcoholic fatty liver disease (NAFLD) is increasingly recognized in patients with chronic hepatitis B (CHB) and may influence disease assessment and long-term outcomes. Accurate identification of hepatic steatosis in this population is challenging, as most non-invasive steatosis indices were developed in the general population and may be affected by viral- and treatment-related factors. Liver biopsy provides a reliable reference for detecting steatosis but is not feasible for routine clinical use. This study aimed to develop a novel non-invasive index for predicting NAFLD using a biopsy-confirmed CHB cohort, with the ultimate goal of applying this index to CHB patients with suspected NAFLD and, subsequently, to broader NAFLD populations.

Materials and Methods:

In this retrospective, single-center study, 163 adult patients with CHB who underwent liver biopsy between 2018 and 2024 were included. Hepatic steatosis exceeding 5% on histopathology was defined as NAFLD and used as the reference standard. Demographic, anthropometric, biochemical, metabolic,

E-POSTER ABSTRACTS

virological, and histopathological data were analyzed. Variables associated with NAFLD were first evaluated using univariate analyses, and significant parameters were incorporated into a multivariate regression model to derive the Hatay Index. The diagnostic performance of the index was assessed using receiver operating characteristic (ROC) curve analysis.

Results:

The mean age of the patients was 42.8 ± 12.3 years, and 58.3% were male. NAFLD was identified in 35.6% of the cohort. Patients with NAFLD had significantly higher TyG index, fasting glucose, HbA1c, triglyceride, and uric acid levels, and lower HDL cholesterol levels compared with those without NAFLD (all $p < 0.05$). No significant differences were observed in HBV-DNA levels, HBeAg status, histological activity index, or fibrosis stage. Multivariate regression analysis identified TyG index, uric acid, ALT, and LDL cholesterol as independent predictors of NAFLD, forming the Hatay Index. The area under the ROC curve was 0.760. At a cut-off value of 19.13, the index demonstrated a specificity of 91.4%, sensitivity of 50%, and an overall diagnostic accuracy of 76.7%.

Conclusions:

Using liver biopsy-confirmed CHB patients as a reference population, we developed the Hatay Index, a simple and non-invasive tool for predicting NAFLD. This index may facilitate the identification of hepatic steatosis in CHB patients without the need for invasive procedures and provides a foundation for future validation and application in broader NAFLD populations.

Keyword(s) : Chronic hepatitis B; Non-alcoholic fatty liver disease; Liver biopsy; Non-invasive index; Hatay Index

2780 - Antiviral therapy in treatment naive patients with hepatitis B related cirrhosis and low level or undetectable viremia long term outcomes

Gulziba Kurax¹, Lihua Sun¹, Yuting Mao¹, Nurbiya Abdukayyum¹

The First Affiliated Hospital Of Xinjiang Medical University, Department Of Infectious Disease, Liver Disease Center, Urumqi-China¹

Background / Hypothesis:

Current guidelines recommend antiviral therapy for all patients with hepatitis B virus (HBV)-related cirrhosis regardless of viral load. However, the clinical benefit in treatment-naïve patients with low-level (<2000 IU/mL)

or undetectable (<20 IU/mL) viremia remains uncertain. This study evaluated the long-term impact of antiviral therapy in this undertreated population.

Materials and Methods:

This retrospective study enrolled 208 treatment-naïve patients with HBV-related cirrhosis and low-level viremia or undetectable HBV DNA (antiviral therapy group, $n=150$; control group, $n=58$), followed for 1 to 5 years. Generalized estimating equations (GEE) with group-by-time interaction terms were used to analyze longitudinal changes in virological response, liver function, and clinical decompensation, and to assess between-group differences. Overall survival was evaluated by Kaplan–Meier analysis and Cox proportional hazards models.

Results:

GEE analysis revealed that the annual decline in HBeAg positivity was significantly greater in the treatment group than in controls (aOR=0.25, 95% CI: 0.10–0.62, $P=0.003$). Geometric mean annual decreases in ALT and TBIL were 7.4% and 8.8% greater, respectively, in the treatment group than in controls (ALT: $\beta = -0.032$, 95% CI: -0.062 to -0.001 , $P = 0.043$; TBIL: $\beta = -0.037$, 95% CI: -0.065 to -0.008 , $P = 0.011$). The annual risk of progression to decompensation was 29% lower in the treatment group (aOR=0.71, 95% CI: 0.56–0.92, $P=0.009$), as were annual incidences of ascites (aOR=0.72, 95% CI: 0.54–0.97, $P=0.029$) and of spontaneous bacterial peritonitis (aOR=0.70, 95% CI: 0.52–0.95, $P=0.020$). Multivariable Cox analysis identified antiviral therapy as an independent protective factor for overall survival (HR=0.215, 95% CI: 0.070–0.657, $P=0.007$); 5-year survival was higher in the treatment group than in controls (92.25% vs. 68.84%, $P<0.001$).

Conclusions:

In treatment-naïve patients with HBV-related cirrhosis and low-level or undetectable viremia, long-term antiviral therapy significantly improves virologic status, liver function, and survival, and reduces decompensation events. These findings support antiviral intervention for HBV-related cirrhosis regardless of baseline viral load.

Keyword(s) : hepatitis B virus, cirrhosis, low-level viremia, antiviral therapy, overall survival

2782 - Liver Cirrhosis Promotes Hepatocellular Carcinoma Progression by Regulating Myeloid Differentiation in Spleen

Junkai Ma¹, Qi Zhang¹, Tingbo Liang¹

The First Affiliated Hospital Of Zhejiang University School Of Medicine, Hepatobiliary And Pancreatic

E-POSTER ABSTRACTS

Surgery, Hangzhou-China ¹

Background / Hypothesis: Among the diverse risk factors for hepatocellular carcinoma (HCC), liver cirrhosis is widely recognized as the most critical premalignant condition. Cirrhosis is characterized by persistent hepatic inflammation, sustained immune activation, and elevated systemic levels of pro-inflammatory cytokines, which may disrupt hematopoietic homeostasis and alter the functional state of hematopoietic stem and progenitor cells (HSPCs). In particular, chronic inflammatory cues may bias HSPCs toward myeloid differentiation, thereby reshaping the hematopoietic landscape and promoting the expansion of tumor-supportive myeloid populations. However, how liver cirrhosis systemically reprograms hematopoietic lineages and drives skewed myeloid differentiation to facilitate HCC progression remains poorly understood. The key regulatory mechanisms linking cirrhosis-induced inflammatory stress to hematopoietic remodeling and tumor-promoting myelopoiesis require further elucidation. A clearer understanding of this systemic crosstalk may provide new insights into the pathogenesis of HCC and identify potential therapeutic targets.

Materials and Methods: We first collected clinical data from patients with HCC to assess the association between liver cirrhosis and prognosis. Liver cirrhosis was induced in C57BL/6 mice by carbon tetrachloride (CCl₄) injection, followed by establishment of an HCC model to evaluate tumor progression. Single-cell RNA sequencing was performed on splenic HSPCs to analyze changes in cell abundance and immune features. The role of heme in regulating cirrhosis-driven HSPC differentiation was further examined. Splenic transplantation and UBC-GFP lineage tracing were used to investigate the migration of splenic myeloid cells to the liver. Single-cell transcriptomics was also applied to characterize splenic myeloid cell profiles in cirrhosis-associated HCC.

Results: Clinical analysis revealed that patients with HCC accompanied by liver cirrhosis exhibited significantly poorer prognosis compared with non-cirrhotic HCC patients. In murine models, cirrhosis markedly accelerated HCC progression. Mechanistically, cirrhotic mice displayed elevated levels of free heme in circulation and spleen, which was associated with

increased DNA damage in splenic HSPCs. This genomic stress promoted myeloid-biased differentiation, resulting in the expansion of immunosuppressive myeloid populations. Lineage tracing and splenic transplantation experiments further demonstrated that these cirrhosis-associated myeloid cells migrated from the spleen to the liver, where they accumulated within the tumor microenvironment and facilitated HCC progression.

Conclusions: Our findings demonstrate that liver cirrhosis worsens HCC prognosis by systemically remodeling splenic hematopoiesis. Elevated free heme induces DNA damage in splenic HSPCs, driving myeloid-skewed differentiation and the expansion of immunosuppressive myeloid cells. The migration of these spleen-derived myeloid cells to the liver establishes a tumor-promoting microenvironment, thereby accelerating HCC.

2783 - Methyldopa induced acute liver failure successfully managed with drug withdrawal and supportive care A case report

Janaka Subasinghe ¹, Sanjeeva Aryasingha ²
National Hospital, Sri Lanka, Gastro Enterology And Hepatology, Kurunegala-Sri Lanka ¹ National Hospital, Colombo, Gastroenterology And Hepatology, Colombo-Sri Lanka ²

Background : Methyldopa is a centrally acting antihypertensive drug that is now infrequently used in general practice but remains an important option in pregnancy due to its favorable maternal and fetal safety profile. Although mild aminotransferase elevations are relatively common, severe drug-induced liver injury (DILI) and acute liver failure (ALF) are rare. Methyldopa may cause drug-induced autoimmune-like hepatitis (DI-ALH), which clinically and serologically resembles autoimmune hepatitis.

Materials and Methods:

A 40-year-old Sri Lankan woman presented with fatigue, nausea, progressive jaundice, and somnolence. She had commenced methyldopa 500 mg three times daily ten weeks earlier for newly diagnosed hypertension prior to in vitro fertilization. She denied

E-POSTER ABSTRACTS

alcohol use, herbal medications, previous liver diseases, or family history. Examination revealed low Glasgow Coma Scale (GCS) of 14 with flapping tremors consistent with grade 2 hepatic encephalopathy (HE). She was deeply icteric with mild right hypochondrial tenderness. Laboratory evaluation demonstrated a hepatocellular pattern of liver injury with AST 1100 U/L, ALT 1201 U/L, alkaline phosphatase of 160 u/dL, total bilirubin 18.1 mg/dL, and INR 1.8. Hepatitis A, B, E, C, cytomegalovirus, Epstein-Bar, and varicella virus screening were negative; other infectious and metabolic causes were excluded. Anti-nuclear antibody was strongly positive (titre 1:1250) with elevated IgG (1847 mg/dL). However, other immune markers such as anti mitochondrial antibody, anti smooth muscle antibody and anti neutrophilic cytoplasmic antibodies were negative. Imaging showed features of acute hepatitis, and excluded biliary obstruction, as well as intra or extra hepatic bile duct dilatation. Liver biopsy revealed moderate portal inflammation with neutrophils and eosinophils, mild fibrosis and interface hepatitis. The presence of grade II hepatic encephalopathy together with an elevated INR was consistent with early acute liver failure.

Results: Methylodopa was discontinued immediately, and a standard regimen of intravenous N-acetylcysteine was administered for 72 hours. The Roussel Uclaf Causality Assessment (RUCAM) score of the patient was 9, indicating a highly probable DILI. The patient gradually improved both clinically and biochemically over the following 2 weeks. Corticosteroid therapy or plasma exchange were not attempted. The patient was reviewed at 2 weeks and 2 months after discharge. Liver enzymes, INR, and ANA had normalized within two months.

Conclusions: Methylodopa can rarely cause severe hepatocellular injury mimicking autoimmune hepatitis which progress to acute liver failure. Early recognition and prompt withdrawal of the offending drug are critical and may prevent the need for immunosuppression, plasma exchange or liver transplantation. Early NAC may contribute to improvement of ALF due to DILI which needs more trials.

Keyword(s) : Acute liver failure, drugs induced liver injury, methylodopa, jaundice, hepatic encephalopathy

2786 - Restoring sleep in cirrhosis A prospective three arm double blind randomized clinical trial of lemborexant efficacy and hepatic safety

Pitt Akbar¹, Sarah Melissa¹, Rino Gani²

Dr. Cipto Mangunkusumo General Hospital, Internal Medicine, Jakarta-Indonesia¹ Dr. Cipto Mangunkusumo General Hospital, Internal Medicine, Jakarta-²

Background / Hypothesis:

Liver cirrhosis is a chronic condition characterized by extensive liver tissue damage that often leads to sleep disturbances, affecting 60–80% of patients. These disturbances significantly impair quality of life and worsen disease prognosis by exacerbating cognitive dysfunction and hepatic encephalopathy. While Lemborexant—a dual orexin receptor antagonist—is effective for insomnia in the general population, data regarding its use in patients with impaired liver function is limited. This study aims to evaluate the safety and efficacy of Lemborexant in improving sleep quality among cirrhosis patients, hypothesized to be an effective treatment with a manageable safety profile.

Materials and Methods:

This study was a prospective, three-arm, double-blind, randomized clinical trial conducted at a national referral hospital. A total of 82 patients with liver cirrhosis and sleep disturbances (Pittsburgh Sleep Quality Index/PSQI > 5) were randomized into three groups: Placebo (n=28), lemborexant 5 mg (n=28), and lemborexant 10 mg (n=26). Parameters assessed included change in sleep quality scores and hepatic safety markers (aspartate aminotransferase, alanine aminotransferase, and bilirubin) over a 2-week treatment period.

Results:

At baseline, mean sleep quality scores indicated poor sleep across all groups (Placebo: 10.0; 5 mg: 12.71; 10 mg: 14.23). After 2 weeks of treatment, both lemborexant groups showed significant clinical improvement; the 5 mg group score decreased to 5.71 ($p < 0.001$) and the 10 mg group to 5.96 ($p < 0.001$). In contrast, the placebo group showed no significant change (9.0 at week 2, $p = 0.112$). Regarding safety, there were no statistically significant differences between groups in liver enzymes, albumin, or total bilirubin levels, suggesting a balanced and safe clinical profile for both doses in this population.

E-POSTER ABSTRACTS

Conclusions:

Lemborexant is effective in significantly improving sleep quality in patients with liver cirrhosis, as evidenced by the substantial reduction in PSQI scores compared to placebo. Furthermore, the treatment demonstrated a favorable safety profile with no adverse impact on liver function parameters during the study period. These findings suggest that Lemborexant, particularly at a 5 mg or 10 mg dose, is a viable and safe therapeutic option for managing sleep disturbances in patients with chronic liver disease.

Keyword(s) : Lemborexant, Liver cirrhosis, Sleep disturbances

2787 - Variceal bleeding due to stride immunotherapy induced or cirrhosis driven

Vamsi Krishna Ankam¹, Anand Kulkarni²

Aig Hospitals, Medical Gastroenterology, Hyderabad-India¹ Aig Hospitals, Hepatology, Hyderabad-India²

Background / Hypothesis:

Portal hypertension (PHTN) affects up to half of patients with hepatocellular carcinoma (HCC) and significantly worsens outcomes due to variceal bleeding. Recently approved systemic therapies for unresectable HCC—atezolizumab-bevacizumab (atezo-bev) and STRIDE (single tremelimumab + durvalumab)—have improved survival. Variceal bleeding is a known risk with atezo-bev (IMbrave150 trial), but was not observed with STRIDE in the HIMALAYA trial, likely because patients with portal vein tumor thrombosis (PVTT) were excluded. Based on this, AASLD guidelines recommend STRIDE in patients with high-risk varices or prior bleeding. We report the first fatal case of variceal bleeding following STRIDE, questioning its safety in real-world practice.

Materials and Methods:

Single-case observational report of a cirrhotic HCC patient with PVTT treated with SBRT followed by STRIDE. Clinical, laboratory, imaging, and endoscopic findings were prospectively documented. Management of bleeding followed standard endoscopic and rescue protocols.

Results:

A 53-year-old diabetic male with MASLD-related cirrhosis with Prior variceal bleed (treated with ligation + glue for GOV2); no recurrence, last endoscopy 5 days before presentation showed eradicated varices. On

carvedilol 12.5 mg/day with good HR control (55-60 bpm).

Baseline status: Child-Pugh A (6), MELD 12 Labs: Bilirubin 2.1 mg/dL, Albumin 3.6 g/dL, INR 1.33, Imaging: 15.3 × 13.5 cm HCC with main PVTT (BCLC Stage C)

Treatment: 5 sessions of SBRT, followed 6 weeks later by STRIDE (per AASLD guidance due to prior bleed).

Clinical course:

Day 8 post-STRIDE patient presented with melena on upper GI endoscopy revealed high-risk esophageal + fundal varices noted and managed with EUS-guided coil + glue for fundal varices and banding for esophageal varices. later patient Developed new-onset ascites; managed with diuretics and continued carvedilol. Two weeks later patient presented with massive hematemesis + melena; endoscopy showed post-banding ulcer bleed. Emergency DANIS stent placed, but patient died from hemorrhagic shock and renal failure.

Conclusions:

This is the first reported fatal variceal bleed after STRIDE in cirrhotic HCC with portal hypertension. While the IMbrave150 trial reported few episodes of variceal bleeding with atezolizumab bevacizumab, the landmark HIMALAYA trial on STRIDE did not report any bleeding events likely due to exclusion patients with portal vein tumoral thrombosis. Multiple factors—portal hypertension, prior interventions, portal vein thrombosis, and immunotherapy—likely contributed to refractory variceal bleed in our patient. STRIDE, though guideline-endorsed for patients with high-risk varices, may not be universally safe.

Careful patient selection, endoscopic surveillance, and individualized prophylaxis are essential. Large real world studies are needed to define bleeding risk in this population.

2788 - Double plasma molecular adsorption system (DPMAS) for liver failure early institutional experience at a tertiary hospital in the Philippines

Paul Ian Banchiran¹, Michael Chu¹, Sarah Preza¹, Lovell Gatchalian¹, Felix Domingo¹

East Avenue Medical Center, Section Of Gastroenterology, Department Of Internal Medicine, Quezon City-Philippines¹

Background / Hypothesis:

Acute liver failure and acute-on-chronic liver failure are associated with high mortality rates when liver

E-POSTER ABSTRACTS

transplantation is not feasible. Extracorporeal plasma adsorption therapies may improve early biochemical parameters, but clinical impact in mixed-etiology, real-world settings remains uncertain. We aimed to describe case-mix, baseline severity, early biochemical response, and short-term clinical outcomes after double plasma adsorption therapy (DPMAS) at a tertiary hospital in the Philippines.

Materials and Methods:

We conducted a single-center, retrospective descriptive cohort including adults (18 years or older) with acute liver failure or acute-on-chronic liver failure who underwent at least one complete index session of double plasma adsorption therapy. Baseline demographics, comorbidities, etiology, and prognostic scores (Model for End-Stage Liver Disease score with sodium correction, Child-Pugh score, hepatic encephalopathy grade) were summarized. Paired pre-post index-session laboratory outcomes included total bilirubin, international normalized ratio, creatinine, sodium, albumin, platelets, and hemoglobin. Clinical outcomes included intensive care unit length of stay, number of sessions during admission, and disposition. Analyses were descriptive (medians with interquartile ranges; proportions with 95% confidence intervals).

Results:

Thirteen patients were included (median age 36 years, 76.9% female) with heterogeneous etiologies. Baseline severity was high (median Model for End-Stage Liver Disease score with sodium correction 34 [27–38]; Child-Pugh 12 [12–13]; hepatic encephalopathy grade 3 [2–3]); 69.2% had encephalopathy grade three or higher, 69.2% required vasopressors, and 53.8% required invasive ventilation. Median total bilirubin decreased from 17.38 to 12.12 mg/dL (median percent change –16.9%); Median international normalized ratio improved from 2.47 to 1.32 (median change –0.88; paired data available for 11 patients). Median intensive care unit length of stay was 17 days (12–19), average sessions per admission was 2 (2–3), and in-hospital mortality was 61.5%.

Conclusions:

Plasma adsorption therapy was feasible and associated with early improvements in total bilirubin and international normalized ratio in a severely ill cohort, but mortality remained high. Larger prospective studies with standardized scoring and safety documentation are needed to establish whether early biochemical changes and timing of therapy correlate with clinical

outcomes.

Keyword(s) : acute liver failure, acute-on-chronic liver failure, extracorporeal support, plasma adsorption, bilirubin

2790 - Prevalence and clinical correlates of metabolic burden and fibrosis severity among non cirrhotic HBsAg positive patients

Ammar Alramadan¹, Mehmet Demir¹, Kübra Berat Yavuz Ergin²

Hatay Mustafa Kemal University, Gastroenterology, Hatay-Türkiye¹ Hatay Mustafa Kemal University, Internal Medicine, Hatay-Türkiye²

Background / Hypothesis:

Metabolic dysfunction has emerged as an important modifier of liver disease progression across chronic liver diseases. In patients with chronic hepatitis B, the impact of cumulative metabolic risk on liver fibrosis severity, particularly in non-cirrhotic individuals, remains incompletely characterized. This study aimed to determine the prevalence of metabolic burden and to evaluate its clinical correlates in non-cirrhotic HBsAg-positive patients.

Materials and Methods:

This retrospective cross-sectional study included adult non-cirrhotic HBsAg-positive patients followed in gastroenterology outpatient clinics between January 2024 and December 2025. Metabolic burden was defined as the cumulative presence of obesity, type 2 diabetes mellitus, hypertension, and dyslipidemia, and was analyzed as both a continuous score and a categorical variable (low vs. high burden). Liver fibrosis severity was assessed using the Fibrosis-4 (FIB-4) score. Associations between metabolic burden and clinical, biochemical, and liver-related parameters were evaluated using appropriate univariable and multivariable statistical analyses.

Results:

A total of 110 patients were included (mean age 51.9 ± 12.1 years; 63.6% male). High metabolic burden was observed in 22.7% of patients and was associated with higher FIB-4 scores in univariable analyses. In multivariable linear regression analysis, age ($B = 0.029$, standardized $\beta = 0.464$, $p < 0.001$) and type 2 diabetes mellitus ($B = 0.424$, standardized $\beta = 0.221$, $p = 0.020$) were independently associated with increased fibrosis severity, whereas hypertension showed an inverse association with fibrosis severity ($B = -0.406$, standardized $\beta = -0.226$, $p = 0.035$).

E-POSTER ABSTRACTS

Conclusions:

Metabolic burden is common among non-cirrhotic HBsAg-positive patients and is associated with greater fibrosis severity. These findings highlight the importance of systematic metabolic risk assessment in the early management of chronic hepatitis B.

Keyword(s) : Metabolic burden; Chronic hepatitis B; HBsAg positivity; Liver fibrosis; FIB-4; Diabetes mellitus; Hepatic steatosis

2791 - Research on Resveratrol loaded Tetrahedral Framework Nucleic Acids and Their Therapeutic Mechanisms for Metabolic Dysfunction Associated Fatty Liver Disease

Yifan Gao¹, Jingyi Si¹, Changfeng Zhu¹

Fudan University, Gastroenterology And Hepatology, Shanghai-China¹

Background / Hypothesis:

To address the inherent limitations of resveratrol (RSV), such as poor aqueous solubility and low bioavailability, a novel nanodrug delivery platform (tFNAs-RSV) was engineered using tetrahedral framework nucleic acids (tFNAs). This study aims to investigate the therapeutic potential of this system against Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD) and to elucidate the underlying molecular mechanisms through which it modulates the NF- κ B signaling pathway.

Materials and Methods:

Tetrahedral framework nucleic acid (tFNA) nanoscaffolds were precisely engineered via DNA molecular self-assembly, achieving high-efficiency loading of resveratrol (RSV). The morphology, particle size, and structural stability of tFNAs-RSV were systematically characterized using polyacrylamide gel electrophoresis (PAGE), dynamic light scattering (DLS), and transmission electron microscopy (TEM). A high-fat diet (HFD)-induced mouse model of MAFLD was established, and the animals were randomly assigned to different groups to receive intervention with equivalent doses of either free RSV or tFNAs-RSV via oral gavage. Therapeutic efficacy was evaluated by assessing hepatic lipid deposition, serum biochemical parameters, and histopathological analysis.

Results:

Physicochemical characterization confirmed that tFNAs-RSV exhibited high structural uniformity and superior aqueous dispersibility, which significantly

enhanced the stability of RSV under physiological conditions. In vivo pharmacodynamic evaluation revealed that, benefiting from the exceptional carrier properties of tFNAs, tFNAs-RSV significantly reduced the degree of hepatic steatosis and serum transaminase levels compared to free RSV. Histological analysis demonstrated that tFNAs-RSV intervention effectively suppressed the pathological infiltration of macrophages and neutrophils within the liver. Molecular mechanistic studies confirmed that tFNAs-RSV downregulated the phosphorylation levels of the nuclear transcription factor p65, thereby inhibiting the transcriptional expression of endothelial adhesion molecules and subsequently blocking the chemotaxis and recruitment of inflammatory cells toward hepatic lesions.

Conclusions:

In this study, a smart nanodrug delivery platform with excellent biocompatibility was successfully constructed, effectively overcoming the physicochemical limitations of RSV. This platform achieved precise modulation of the hepatic inflammatory microenvironment and provides a novel nanomedicine strategy for the clinical intervention of MAFLD.

Keyword(s) : Tetrahedral framework nucleic acids (tFNAs), Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD), NF- κ B signaling pathway

2792 - Risk of Hepatitis B Reactivation Among HBsAg Negative Anti HBc-Positive Breast Cancer Patients Undergoing Chemotherapy

Goknur Yapar Toros¹, [Sabahat Çeken](#)¹, Ayşe Ocak Duran², Öztürk Ateş²

Etlik City Hospital, Infectious Diseases And Clinical Microbiology, Ankara-Türkiye¹ Dr Abdurrahman Yurtaslan Onkoloji Research And Education Hospital, Medical Oncology, Ankara-Türkiye²

Background / Hypothesis:

Hepatitis B virus (HBV) reactivation is a recognized complication of immunosuppressive and cytotoxic therapies. Although traditionally associated with chronic HBV infection, clinically significant reactivation may also occur in patients with resolved infection (HBsAg-negative, anti-HBc-positive). Breast cancer represents a clinically relevant context, as systemic chemotherapy remains a cornerstone of treatment in both early-stage and metastatic disease. However, real-world data regarding HBV reactivation risk in breast

E-POSTER ABSTRACTS

cancer patients with resolved infection are limited. This study evaluated the incidence, clinical characteristics, and determinants of HBV reactivation in HBsAg-negative, anti-HBc-positive breast cancer patients receiving systemic therapy without antiviral prophylaxis.

Materials and Methods:

In this retrospective multicenter cohort study, adult patients (≥ 18 years) with confirmed breast cancer treated at two tertiary hospitals in Ankara, Türkiye, were screened. Eligible patients were HBsAg-negative and anti-HBc-positive at baseline, received at least one cycle of systemic chemotherapy or targeted therapy, and had a minimum follow-up of six months after treatment initiation. HBV reactivation was defined according to international guideline criteria. The primary outcome was the incidence of HBV reactivation during or after systemic therapy. Secondary outcomes included time to reactivation, virological kinetics, and clinical severity.

Results:

A total of 139 anti-HBc-positive patients were included (mean age 60.1 ± 10.7 years). At baseline, 89.2% were anti-HBs positive, with a mean anti-HBs titer of 278.0 ± 378.4 IU/L. The mean follow-up duration was 11.1 ± 6.7 months. Most patients had early-stage (43.2%) or locally advanced disease (30.9%).

HBV reactivation occurred in one patient (0.7%). This 61-year-old woman, with anti-HBs < 10 IU/L and undetectable baseline HBV DNA, received anthracycline-based chemotherapy (doxorubicin-cyclophosphamide). Approximately four months after treatment initiation, she developed acute hepatitis with marked transaminase elevation (ALT 1533 U/L, AST 1247 U/L), hyperbilirubinemia, HBsAg seroreversion, and high-level viremia (HBV DNA 6.9×10^7 copies/mL). Entecavir therapy was promptly initiated, resulting in rapid virological decline and complete viral suppression by six months. Follow-up at ten months demonstrated HBsAg clearance without development of protective anti-HBs antibodies.

Conclusions:

HBV reactivation was rare in this multicenter cohort of HBsAg-negative, anti-HBc-positive breast cancer

patients managed without antiviral prophylaxis. The single event occurred in a patient lacking anti-HBs immunity who received anthracycline-based chemotherapy, supporting emerging evidence that both serologic status and regimen intensity influence reactivation risk. These findings favor a risk-adapted strategy incorporating baseline serologic profiling and targeted monitoring rather than universal prophylaxis in routine breast cancer chemotherapy settings.

Keyword(s) :

2794 - Extending Resectability in Fibrolamellar Hepatocellular Carcinoma Through Associating Liver Partition and Portal Vein Ligation for Staged Hepatectomy (ALPPS) A Case Report

Leo Francis Gerardo¹, Juliet Gopez-cervantes¹

St. Luke's Medical Center, Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Fibrolamellar hepatocellular carcinoma (FL-HCC) is a rare histologic subtype of hepatocellular carcinoma, accounting for approximately 1% of primary liver malignancies. It predominantly affects adolescents and young adults without underlying chronic liver disease or cirrhosis and is characterized by distinct clinical, histopathologic, and molecular features. Despite preserved baseline hepatic function, FL-HCC often presents at an advanced stage with large tumor burden, frequently limiting upfront surgical resectability because of an inadequate future liver remnant (FLR). Complete surgical resection remains the most important determinant of long-term survival, underscoring the need for strategies that expand resectability in select patients. Associating liver partition and portal vein ligation for staged hepatectomy (ALPPS) is an advanced two-stage surgical technique that induces rapid hypertrophy of the FLR, allowing resection of otherwise unresectable hepatic tumors; however, its use is limited by concerns regarding increased perioperative morbidity, and evidence in FL-HCC remains scarce.

Materials and Methods:

A 25-year-old man presented with a 19-month history of recurrent epigastric pain and was found to have a large, heterogeneous hepatic mass involving segments IVb, V, and VIII on contrast-enhanced computed tomography. Percutaneous biopsy confirmed fibrolamellar hepatocellular carcinoma. Multidisciplinary evaluation determined that the extent

E-POSTER ABSTRACTS

of disease precluded safe single-stage hepatectomy due to an inadequate FLR. The patient underwent multimodal therapy, including transarterial chemoembolization, selective internal radiation therapy, and systemic treatment with lenvatinib, with the intent of disease control and potential downstaging. Despite these interventions, interval imaging demonstrated progressive tumor enlargement. Salvage surgical management with ALPPS was therefore pursued.

Results:

Stage 1 ALPPS involved portal vein ligation with in situ parenchymal transection and was complicated by ischemia-reperfusion injury and acute kidney injury, both of which were managed conservatively. Follow-up imaging demonstrated marked hypertrophy of the remnant liver, permitting successful completion of stage 2 hepatectomy without additional major complications.

Conclusions:

This case demonstrates that ALPPS may serve as an effective salvage strategy to achieve curative resection in carefully selected patients with advanced fibrolamellar hepatocellular carcinoma and insufficient future liver remnant. Given the associated perioperative risks, ALPPS should be considered only after thorough multidisciplinary evaluation and performed in experienced centers, with careful patient selection remaining critical to optimizing outcomes.

Keyword(s) : Fibrolamellar hepatocellular carcinoma, Associating liver partition and portal vein ligation for staged hepatectomy, ALPPS, Future liver remnant, Liver resection, Salvage surgery

2795 - Achieving Recompensation in Hepatitis B Cirrhosis via Targeted Albumin Infusion A Multicenter Randomized Controlled Trial Protocol

Background / Hypothesis: China bears a high burden of hepatitis B, and effective management of hepatitis B-related cirrhosis remains a major clinical challenge. Although "cirrhosis recompensation" has recently been recognized as a distinct disease stage and carries substantial theoretical and societal value, practical treatment guidelines are lacking. To further evaluate the efficacy of different human albumin treatment regimens in achieving recompensation at week 72, we established a prospective cohort and are currently conducting this randomized controlled trial.

Materials and Methods: This is a 72-weeks, randomized (1:1), multicenter clinical trial based on human albumin treatment. Patients with decompensated HBV-related cirrhosis were recruited from 17 centers across China and centrally randomized to an intensive or standard treatment group. Based on the validation of Baveno VII criteria for recompensation in entecavir-treated patients with hepatitis B-related decompensated cirrhosis, an albumin target of 34 g/L was set for the intensive group. Albumin was infused at baseline, with levels rechecked after 3–5 days and discontinued once ≥ 34 g/L was achieved. Albumin levels were reassessed at weeks 8, 16, and 24, and additional infusions were given if targets were not met. In the standard group, the albumin target was 30 g/L, with other interventions identical to the intensive group.

E-POSTER ABSTRACTS

Results: The primary objective of the trial is to evaluate the proportion of subjects with decompensated hepatitis B cirrhosis who achieve recompensation at week 72 under two different human albumin treatment regimens. Secondary objectives include assessing the effects of the two treatment regimens on liver and renal function, Child-Pugh score, and MELD score, as well as the incidence of cirrhosis-related decompensation events and liver disease-related mortality and adverse events between the two treatment groups.

Conclusions: The results of this trial are expected to identify an optimized albumin administration regimen for patients with decompensated hepatitis B cirrhosis.

Keyword(s) : Hepatitis B cirrhosis, Recompensation, Human albumin, Randomized controlled trial protocol

2797 - Incidental Multifocal Hepatic Masses in an Asymptomatic Patient A Neuroendocrine Tumor in Disguise

Leo Francis Gerardo¹, Joseph Bocobo¹

St. Luke's Medical Center, Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Incidental hepatic lesions are increasingly detected with the widespread use of abdominal imaging for screening and unrelated indications. Although the majority of these lesions are benign, the presence of multiple hepatic masses often raises concern for malignancy and necessitates comprehensive diagnostic evaluation. Differentiating among primary hepatic tumors, metastatic disease, infectious processes, and benign conditions can be particularly challenging when imaging findings are atypical and patients are asymptomatic. Well-differentiated neuroendocrine tumors (NETs) are frequently indolent and nonfunctional, often resulting in delayed or incidental diagnosis. These tumors may demonstrate variable and nonspecific imaging characteristics, occasionally mimicking infectious, inflammatory, or metastatic hepatic lesions. Furthermore, their low proliferative activity may limit the sensitivity of fluorodeoxyglucose positron emission tomography (FDG PET), increasing the risk of diagnostic uncertainty when imaging is relied upon in isolation.

Materials and Methods:

A 64-year-old man was incidentally found to have multiple hepatic masses during a routine executive health evaluation. He was asymptomatic, with no constitutional or gastrointestinal complaints. His medical history was notable only for hypertension and dyslipidemia. Physical examination was unremarkable, with no stigmata of chronic liver disease. Four-phase contrast-enhanced computed tomography of the liver demonstrated multiple ill-defined hepatic lesions with central hypodensity and peripheral venous enhancement, without arterial hyperenhancement or delayed washout. Magnetic resonance imaging with hepatobiliary contrast revealed T2 hyperintense and T1 iso- to hypointense lesions with thick peripheral enhancement, persistent central necrosis, and associated restricted diffusion, raising concern for infectious, inflammatory, or neoplastic etiologies. FDG PET-CT demonstrated no hypermetabolic hepatic or extrahepatic lesions.

Results:

Given persistent diagnostic uncertainty and potential implications for management, an image-guided liver biopsy was performed. Histopathologic examination revealed atypical epithelial cells with neuroendocrine morphology. Immunohistochemical staining was positive for cytokeratin, CK20, MOC-31, INSM1, chromogranin, synaptophysin, and CD56, with a Ki-67 proliferation index of approximately 2.25%, consistent with a well-differentiated neuroendocrine tumor, World Health Organization Grade 1.

Conclusions:

Well-differentiated neuroendocrine tumors may present as incidental, asymptomatic hepatic lesions with misleading imaging features and absent FDG uptake. Restricted diffusion and peripheral enhancement are nonspecific findings and should not be assumed to represent infection or aggressive malignancy. When imaging findings are inconclusive, histopathologic confirmation remains essential for accurate diagnosis and appropriate management. This case underscores the importance of maintaining neuroendocrine tumors in the differential diagnosis of incidental hepatic lesions and highlights the limitations of imaging alone in their evaluation.

Keyword(s) : Neuroendocrine tumor, Incidental liver

2798 - Small Bowel Obstruction Secondary to Post Operative Adhesions and Gastrointestinal Vasculitis in Systemic Lupus Erythematosus A Rare and Challenging Case

Leo Francis Gerardo¹, Flor Maramag¹

St. Luke's Medical Center, Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Small bowel obstruction (SBO) is a common cause of acute abdominal pain and emergency hospitalization, most frequently resulting from post-operative adhesions. In the absence of strangulation or ischemia, adhesive SBO is typically managed conservatively. However, coexisting gastrointestinal pathology may complicate the clinical presentation, delay definitive diagnosis, and alter management. Systemic lupus erythematosus (SLE) is a multisystem autoimmune disease in which gastrointestinal involvement is common but often nonspecific. Rarely, lupus-related gastrointestinal vasculitis affects the small intestine, leading to bowel wall ischemia, ulceration, stricture formation, and intestinal obstruction. These manifestations may closely mimic mechanical SBO on clinical and radiologic evaluation, posing a diagnostic challenge in gastroenterology practice.

Materials and Methods:

A 46-year-old woman with no known comorbidities presented with an 18-day history of intermittent epigastric pain and vomiting, initially responsive to treatment for *Helicobacter pylori*-associated gastric ulcer. Symptoms recurred and progressed to severe, crampy abdominal pain with bilious vomiting, unintentional weight loss, and intermittent fever. She also reported inflammatory arthralgia and had a remote history of cesarean section. On examination, she was tachycardic with hypoactive bowel sounds and localized abdominal tenderness without peritoneal signs. Laboratory evaluation revealed anemia, electrolyte abnormalities, and elevated inflammatory markers. Contrast-enhanced computed tomography demonstrated multiple dilated small bowel loops with a transition point at the distal jejunum-proximal ileum, associated mesenteric fat stranding, and moderate ascites, consistent with SBO, with post-operative adhesions considered the most likely etiology. Despite an initial trial of conservative management, symptoms persisted, prompting exploratory laparotomy. Intraoperative findings revealed a strictured proximal

ileal segment densely adherent to the anterior abdominal wall with proximal bowel dilatation, necessitating segmental resection with primary anastomosis.

Results:

Histopathologic examination showed chronic ileitis with mucosal necrosis and ulceration, serosal adhesions, and small- to medium-vessel vasculitis with fibrinoid necrosis. Subsequent immunologic evaluation demonstrated hypocomplementemia, positive antinuclear antibodies, elevated anti-double-stranded DNA titers, and lupus anticoagulant, fulfilling the 2019 EULAR classification criteria for SLE. A diagnosis of adhesive SBO complicated by SLE-associated gastrointestinal vasculitis was established, and the patient improved following immunosuppressive therapy.

Conclusions:

This case highlights the rare coexistence of adhesive small bowel obstruction and lupus-related gastrointestinal vasculitis. In patients with SBO who exhibit persistent symptoms, systemic inflammatory features, or unexpected histopathologic findings, gastroenterologists should consider underlying autoimmune disease. Early recognition of SLE-associated gastrointestinal vasculitis and prompt immunosuppressive therapy are essential to improving outcomes and preventing serious gastrointestinal complications.

Keyword(s) : Small bowel obstruction, Post-operative adhesions, Systemic lupus erythematosus, Gastrointestinal vasculitis, Lupus enteritis

2800 - An observational study to evaluate the incidence clinical profile risk factors of biliary complications in adult post-liver transplant recipients.

Sitaram Sabane¹, Mahesh Kumar Choudhary¹, Kevin Shah¹, Rohit Shetty¹, Ameet Mandot¹, Chetan Kalal¹, Samridhi Poyekar¹
Gleneagles Hosp, Hepatology, Mumbai-India¹

Background / Hypothesis:

Biliary complications remain the most frequent technical cause of morbidity after liver transplantation, particularly in settings where living donor liver transplantation (LDLT) predominates and multiple

E-POSTER ABSTRACTS

small duct anastomoses are common. These complications, including anastomotic strictures, bile leaks, and non-anastomotic strictures, lead to recurrent cholangitis, prolonged hospital stay, repeated interventions, and may jeopardize graft survival, making their systematic evaluation crucial.

Materials and Methods:

This was a prospective observational study of adult post-liver transplant patients (age ≥ 18 years) who underwent transplantation and subsequently developed biliary complications. Detailed donor, recipient, perioperative, and follow-up data were collected, including demographics, etiology of liver disease, comorbidities, graft-to-recipient weight ratio (GRWR), cold and warm ischemia times, biliary anatomy, type and number of ductal anastomoses, type and timing of biliary complications. Statistical analysis was performed using SPSS, with appropriate parametric and non-parametric tests and a significance level of $p < 0.05$.

Results:

A total of 100 post-transplant recipients with biliary complications were analysed; most grafts were from LDLT donors (97%) with a mean donor age of 38.35 ± 8.17 years and predominantly ABO-compatible grafts (95%). Among recipients, 81% were male, middle-aged (majority 51–60 years), and largely overweight/obese (85%), with decompensated chronic liver disease as the main indication for transplant (84%) and alcohol-associated liver disease (40%) and MASLD (39%) as leading etiologies. The mean GRWR was 0.996 ± 0.156 , with acceptable cold (74.3 ± 5.86 min) and warm (22.36 ± 2.87 min) ischemia times, and most patients had two or more ductal anastomoses reflecting complex LDLT anatomy. Overall incidence of biliary complications was 29.4% in LDLT versus 12.0% in DDLT recipients. Anastomotic strictures were the predominant complication (86%), followed by bile leaks (11%) and non-anastomotic strictures (3%). Clinically, 88% of patients were symptomatic, most commonly with fever (39%) and pruritus (28%), and symptoms were predominantly late in onset (81%), correlating with the typical course of anastomotic strictures.

Conclusions:

Biliary complications after liver transplantation were common in this LDLT-predominant cohort, with a higher incidence in LDLT compared with DDLT and anastomotic strictures forming the major burden. High frequency of complications was seen in recipients with complex biliary anatomy and multiple duct anastomoses.

Keyword(s) : Biliary complications, liver transplantation, anastomotic strictures

2801 - A Rare Cause of Massive Painless Hematochezia Acute Hemorrhagic Rectal Ulcer Syndrome in a Critically Ill Patient

Leo Francis Gerardo¹, Flor Maramag¹

St. Luke's Medical Center, Gastroenterology, Quezon City-Philippines¹

Background / Hypothesis:

Lower gastrointestinal bleeding (LGIB) is a common cause of hospitalization among elderly patients and is associated with significant morbidity and mortality, particularly in those with advanced age and multiple comorbidities. Frequently encountered etiologies include diverticular disease, ischemic colitis, colorectal neoplasia, and anorectal disorders. However, uncommon causes of LGIB may be overlooked in critically ill patients, resulting in delayed diagnosis and recurrent hemorrhage. Acute hemorrhagic rectal ulcer syndrome (AHRUS) is an underrecognized condition characterized by sudden-onset, painless, and often massive hematochezia arising from rectal ulcerations unrelated to malignancy, inflammatory bowel disease, or infectious colitis. AHRUS predominantly affects elderly, immobilized, or systemically ill patients and is commonly associated with sepsis, diabetes mellitus, cerebrovascular disease, chronic kidney disease, and antithrombotic use. Endoscopically, it is typified by distal rectal ulcers with exposed vessels or active arterial bleeding and is notable for a high risk of rebleeding despite initial hemostatic therapy. Optimal management remains challenging, particularly when endoscopic therapy fails.

Materials and Methods:

A 76-year-old woman with multiple comorbidities, including invasive breast carcinoma status post modified radical mastectomy, peripheral arterial disease, chronic cerebrovascular disease, and type 2 diabetes mellitus, was admitted after cardiopulmonary arrest secondary to septic shock and hyperosmolar hyperglycemic state. During hospitalization, she

E-POSTER ABSTRACTS

developed coffee-ground output via nasogastric tube, prompting initial evaluation for upper gastrointestinal bleeding. Despite conservative management, she subsequently developed recurrent episodes of painless hematochezia accompanied by progressive anemia and intermittent hemodynamic instability. Contrast-enhanced abdominal computed tomography demonstrated rectal wall thickening suggestive of inflammatory changes.

Results:

Flexible sigmoidoscopy revealed two distal rectal ulcers approximately 4 cm from the anal verge, including a large semi-circumferential ulcer with active pulsatile bleeding. Endoscopic hemostatic interventions, including hemoclippping, epinephrine injection, and thermocoagulation, were attempted but failed to achieve sustained hemostasis. Given persistent hemorrhage and clinical instability, angiographic evaluation was performed. Superselective catheterization identified abnormal hyperemia involving branches of the superior rectal artery, and particle embolization was successfully performed. Following embolization, bleeding ceased, hemoglobin levels stabilized with transfusion support, and no recurrence of hematochezia was observed.

Conclusions:

AHRUS is an uncommon but clinically significant cause of massive LGIB in elderly and critically ill patients. Diagnosis is challenging due to nonspecific presentation and the presence of competing etiologies of gastrointestinal bleeding. While endoscopic hemostasis remains first-line therapy, angiographic embolization is an effective rescue modality in refractory cases. Early recognition and a multidisciplinary approach, with attention to both local hemostasis and optimization of underlying systemic conditions, are essential to improving outcomes.

Keyword(s) : Acute hemorrhagic rectal ulcer syndrome, Lower gastrointestinal bleeding, Hematochezia, Rectal ulcer, Angiographic embolization

2802 - Melatonin Ameliorates LPS Induced Acute Liver Injury via Upregulating Sirtuin 4(SIRT4) Expression and Inhibiting Macrophage Extracellular Trap(MET) Formation

Yuelin Sun ¹, Feng Zhang ², Rong Li ³, Jun Zheng ¹
The Third Affiliated Hospital Of Sun Yat-sen University,
Department Of Hepatic Surgery And Liver

Transplantation Center, Guangzhou-China ¹ The Third Affiliated Hospital Of Sun Yat-sen University, Biological Treatment Center, Guangzhou-China ² The Third Affiliated Hospital Of Sun Yat-sen University, Guangdong Provincial Key Laboratory Of Liver Disease Research, Guangzhou-China ³

Background / Hypothesis:

Sepsis is a life-threatening systemic inflammatory response syndrome, which often leads to multiple organ dysfunction including sepsis associated acute liver injury(SALI). This study aimed to investigate whether melatonin confers protection against SALI by regulating macrophage extracellular trap(MET) formation, and to further delineate the molecular mechanisms underlying this protective effect.

Materials and Methods:

In this study, we established a lipopolysaccharide(LPS)-induced murine model of sepsis-associated acute liver injury(SALI) for in vivo experiments, and employed a murine macrophage cell line for in vitro assays. We first investigated the functional role of macrophages in the pathogenesis of SALI, as well as the hepatoprotective efficacy of melatonin against SALI in the established model. Subsequently, we systematically delineated the molecular mechanisms underlying melatonin-mediated regulation of macrophage extracellular trap(MET) formation using RNA sequencing, mitochondrial functional assessments, and adeno-associated virus serotype 2(AAV2)-mediated targeted gene manipulation.

Results:

In this study, we demonstrated that melatonin has a significant hepatoprotective effect against LPS-induced acute liver injury, which was achieved by suppressing the inflammatory activation of intrahepatic macrophages and the formation of macrophage extracellular traps(METs). Mechanistically, melatonin promoted the nuclear translocation of the transcription factor Forkhead box M1(FoxM1), which in turn transcriptionally upregulated sirtuin 4(SIRT4) expression. We further identified that SIRT4 directly interacted with mitofusin 2(Mfn2) and modulated its acetylation status, thus facilitating mitochondrial fusion, restoring mitochondrial homeostasis and normal function, and ultimately inhibiting MET formation. Furthermore, knockdown of SIRT4 markedly abrogated the hepatoprotective effect of melatonin, as well as its inhibitory action on MET generation, in both in vivo and in vitro models.

E-POSTER ABSTRACTS

Conclusions:

This study pharmacologically confirmed that melatonin inhibited the formation of METs and ameliorated LPS-induced acute liver injury by activating the FoxM1/SIRT4 signaling pathway, regulating Mfn2 acetylation, and enhancing mitochondrial fusion and function. These findings provide a theoretical foundation for the development of melatonin as a potential therapeutic agent for sepsis-associated acute liver injury(SALI).

2803 - Medical Knowledge and Therapeutic Practices Regarding Hepatitis B and C A Study Among Lebanese Physicians

Ghadi Dagher¹, Perla Wehbe², Antony Kahwagi², Rita Murr¹, Tala Najdi³, Rita Slim², Joseph Amara², Eid Mahfouz², Khalil Honein², Cesar Yaghi²
Hotel Dieu De France University Hospital - Saint Joseph University Of Beirut, Internal Medecin, Beirut-Lebanon¹
Hotel Dieu De France University Hospital - Saint Joseph University Of Beirut, Gastroenterology, Beirut-Lebanon²
Hotel Dieu De France University Hospital - Saint Joseph University Of Beirut, Oncology, Beirut-Lebanon³

Background / Hypothesis: Viral hepatitis B (HBV) and C (HCV) remain major public health concerns worldwide and in the region. In Lebanon, the ongoing socio-economic crisis and disparities in access to care may hinder screening, diagnostic confirmation, access to treatment, and prevention strategies, particularly in the perinatal setting. In this context, assessing physicians' knowledge, attitudes, and practices (KAP) regarding HBV and HCV prevention and management is essential to identify gaps and guide targeted interventions.

Materials and Methods: This cross-sectional observational study was conducted in Lebanon among practicing physicians involved in viral hepatitis care (gastroenterology/hepatology, internal medicine, infectious diseases, pediatrics, and obstetrics–gynecology). Participation was voluntary; medical students and non-practicing physicians were excluded. Data were collected using an anonymous self-administered questionnaire based on recent literature and international guidelines. Results were summarized

using descriptive statistics (percentages and means/medians). Comparisons across specialties used chi-square or Fisher's exact tests

Results: In total, 115 physicians participated, mainly gastroenterologists (38.3%), pediatricians (26.1%), and obstetrics–gynecology physicians (18.3%), with most practicing in Beirut (32.2%) and Mount Lebanon (35.7%) and having ≥ 10 years of experience. Among 64 respondents who completed the HCV section, perceived prevalence was most often 0–0.1%, with most reporting diagnosing 0–3 cases/year. Treatment was frequently considered from early fibrosis stages (F0–F1), yet the annual number of treated patients remained low. Reported DAA use was polarized (42.2% estimated treating 0–10% of patients vs 35.9% estimating 80–100%), and DAA utilization differed significantly by specialty ($p=0.015$), with high-use responses predominantly from gastroenterology. Sofosbuvir/velpatasvir was the most cited widely used regimen (35.9%), and very high use was reported only by gastroenterologists ($p=0.011$). SVR after HCV therapy was generally high (SVR $>60\%$ reported by 65.6%), although 28.1% reported SVR $\leq 20\%$. For HBV (64 respondents), perceived prevalence was around 1–1.5%; entecavir was most commonly reported as widely used (40.6%), followed by tenofovir/TDF (15.6%). In the perinatal setting, birth-dose HBV vaccination was perceived as relatively high, whereas early HBIG administration was mostly reported as low; most gynecologists did not repeat pregnancy screening if premarital testing had been performed.

Conclusions: This study highlights a gap between theoretical knowledge of viral hepatitis management strategies and their real-world implementation in Lebanon, in a context shaped by economic, logistical, and organizational constraints. The findings support pragmatic measures, including simplifying and standardizing the HBV, HCV care cascade (screening–confirmation–treatment–follow-up), strengthening institutional perinatal protocols (screening during pregnancy, access to HBV DNA testing, HBIG availability and delivery pathways, checklists), and improving follow-up documentation (including SVR).

Keyword(s) : Hepatitis B; Hepatitis C; Lebanon; Physicians; Knowledge-attitudes-practices (KAP); Perinatal prophylaxis.

E-POSTER ABSTRACTS

2804 - Sequential liver transplantation after combined therapy for hepatocellular carcinoma rejection risk and management

Zhouying Zheng¹, Jian Li¹

The Fifth Affiliated Hospital Of Sun Yat-sen University, Hepatobiliary Surgery, Zhuhai-China¹

Background / Hypothesis: The safety of immune checkpoint inhibitors (ICIs) plus targeted therapy as bridging or downstaging before liver transplantation (LT) for hepatocellular carcinoma (HCC) remains debated, particularly regarding post-LT rejection risk.

Materials and Methods: We retrospectively analyzed nine HCC patients who achieved significant pathological response (pathological complete response (pCR) or partial response (PR)) after combined therapy and underwent LT (2021–2025). Clinical data, dynamic alpha-fetoprotein (AFP), washout period, immunosuppression, and outcomes were assessed.

Results: Median age was 54 years (range 43–67), and 88.9% were male. Median washout period was 31 days (range 11–237). All rejection episodes (3/9, 33.3%) occurred in the short washout (≤ 30 days) group (3/5, 60%) vs. none in the long washout group (0/4). Profound AFP decline (median reduction 93% in pCR group vs. 46.8% in PR group) was associated with pCR. All patients received tacrolimus sustained-release capsules (FK506) plus mycophenolate sodium enteric-coated tablets (EC-MPS) as baseline immunosuppression, with mammalian target of rapamycin inhibitor (mTORi) added after 30 days post-LT if wound healed. Among five short-washout patients, three developed rejection requiring high-dose steroids; two rejection-free patients successfully added mTORi without prolonged steroids. Survival analysis showed a trend toward worse overall survival (OS) in the rejection group (log-rank $P=0.157$), though recurrence-free survival (RFS) was similar ($P=0.637$).

Conclusions: Short washout (≤ 30 days) is a key risk factor for post-LT rejection. AFP deep response may predict pathological benefit. In this cohort, successful mTORi addition without prolonged steroids was observed in rejection-free short-washout patients, suggesting mTORi-based maintenance may benefit this high-risk group. Larger studies are warranted.

2805 - Evaluation of Factors Affecting Bone Mineral Density in Chronic Hepatitis B Patients Receiving Oral Antiviral Therapy "HEBDEM Study"

Mustafa Kemal Çelen¹, Çigdem Mermutluoglu¹, Rengin Esen Karakus², Vasfiye Demir Pervane³, Yakup Demir⁴

Dicle University Faculty Of Medicine, Department Of Infectious Diseases And Clinical Microbiology, Diyarbakir-Türkiye¹ Gazi Yasargil Training And Research Hospital, Department Of Infectious Diseases And Clinical Microbiology, Diyarbakir-Türkiye² Dicle University Faculty Of Medicine, Department Of Family Medicine, Diyarbakir-Türkiye³ Private Memorial Hospita, Department Of Infectious Diseases And Clinical Microbiology, Diyarbakir-Türkiye⁴

Background / Hypothesis: Declining bone mineral density (BMD) is a clinically important long-term issue in chronic hepatitis B (CHB), with potential implications for fracture risk and physical functioning. In routine practice, factors shaping BMD over time are not fully defined, particularly the contribution of antiviral regimens alongside hepatic parenchymal changes detected on ultrasound. Using the HEPDEM retrospective cohort, we examined baseline and 5-year longitudinal correlates of lumbar BMD indices, focusing on tenofovir disoproxil fumarate (TDF), tenofovir alafenamide (TAF), and entecavir (ETV).

Materials and Methods: We included adult CHB patients with baseline (Visit 0) and up to 5 years of follow-up. Lumbar T- and Z-scores were the primary outcomes. Baseline associations were analysed with multivariable linear regression using robust standard errors. Repeated measures over time were assessed with population-averaged models accounting for within-patient correlation (GEE), adjusting for follow-up time, baseline age and sex, body mass index (BMI), liver enzymes, comorbidity burden (≥ 2 comorbidities), ultrasound steatohepatosis, coarse hepatic echotexture, baseline osteopenia, and time-varying antiviral regimen (ETV as reference).

Results: At baseline, mean age was 46.2 ± 12.1 years; 60% were male; mean BMI was 25.7 ± 2.2 kg/m². Mean lumbar T-score and Z-score were -1.23 ± 0.62 and -1.25 ± 0.60 , respectively. In baseline models, increasing age was associated with lower T- and Z-scores, whereas male sex was positively associated with T-score. Over 5 years, both indices declined, with baseline age and follow-up time showing the most consistent independent associations (annual change: T-

E-POSTER ABSTRACTS

score $\beta = -0.099$; Z-score $\beta = -0.094$; both $p < 0.001$). Relative to ETV, TDF exposure was linked to lower T-score ($\beta = -0.187$; $p = 0.011$) and Z-score ($\beta = -0.178$; $p = 0.020$). Ultrasound-defined steatohepatitis contributed little after adjustment, while coarse hepatic echotexture showed a stronger and more consistent association with lower BMD indices. Patients with ≥ 2 comorbidities also had lower scores. Baseline osteopenia was associated with lower T- and Z-scores after multivariable adjustment. Conclusions regarding TAF were limited by smaller numbers and/or heterogeneous follow-up.

Conclusions: In this real-world CHB cohort, lumbar BMD indices declined over five years, largely reflecting aging and time. TDF exposure, coarse hepatic echotexture, higher comorbidity burden, and baseline osteopenia identified patients with a less favourable BMD profile. These findings support more focused bone health monitoring, particularly for patients receiving TDF and for those with parenchymal changes on ultrasound and multiple comorbidities.

Keyword(s) : Chronic hepatitis B; Bone mineral density; Tenofovir disoproxil fumarate

2806 - Prevalence and Impact of Cirrhotic Cardiomyopathy on adverse outcomes following Liver Transplantation A systematic review and a Meta analysis

Ramish Sumbal ¹, Raja Taha Yaseen Khan ¹, Muhammad Qaiser Panezai ¹, Danish Kumar ¹, Tooba Umer ¹, Muhammad Usama Kiyani ¹, Ghazi Abrar ¹, Abbas Ali Tasneem ¹, Nasir Hasan Luck ¹
Sindh Institute Of Urology And Transplantation,
Gastroenterology And Hepatology, Karachi-Pakistan ¹

Background / Hypothesis:

Approximately one-third of liver transplant patients have underlying Cirrhotic cardiomyopathy (CCM), which may contribute to post-transplant complications such as mortality and heart failure. However, the results are subject to various contradictions. Therefore, we aim to conduct a systematic review and a meta-analysis to determine the prevalence of CCM in Liver Transplant patients

Materials and Methods:

Electronic databases such as PubMed, Google Scholar and Cochrane were searched. Articles were selected based on predefined criteria. New Castle Ottawa score

was used to estimate the quality of included studies. Comprehensive Meta-analysis and Review Manager were used to pool prevalence and Hazard ratio (OR) with a 95% confidence interval.

Results:

A total of 6 studies evaluating 1370 patients were included. The pooled prevalence of CCM in liver transplants is 40% (95% CI 22.2% – 60.8%). Additionally, we found that Pre-transplant CCM was significantly associated with post-transplant Major Adverse Cardiovascular Events MACE (OR 1.75 [95%CI 1.23, 2.43]; $p = 0.002$), Heart failure (OR 2.58 [95%CI 1.37, 4.84]; $p = 0.003$), Arrhythmias (OR 2.47 [95%CI 1.63, 3.75]; $p < 0.0001$), and Atrial fibrillation (OR 3.20 [95%CI 1.89, 5.42]; $p < 0.0001$). In contrast, there was no significant relationship between CCM and post-transplant mortality.

Conclusions:

Approximately 40% of individuals who underwent liver transplants had an underlying CCM. Pre-transplant CCM was significantly associated with post-transplant MACE, Heart failure, Arrhythmias, and Atrial fibrillation. However, CCM was not related to post-transplant mortality.

Keyword(s) : Liver transplant; Cirrhotic Cardiomyopathy; Meta-analysis; Prevalence; Outcomes

2807 - Awareness of Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD) in Healthcare Workers A KAP Study

Syedda Ayesha ¹, Masood Mohammad Kareem ¹, Arfa Fatima ¹, Abdul Hadi Shahid ¹, Faisal Waseem Ismail ¹
Aga Khan University Hospital, Medicine, Karachi-Pakistan ¹

Background / Hypothesis: Metabolic dysfunction-associated steatotic liver disease (MASLD), affecting about one-third of the global population, is the most common liver disorder and a key contributor to liver morbidity, cardiovascular disease, and mortality. Despite its rising prevalence, awareness of MASLD among healthcare professionals remains limited across medical specialties. This knowledge gap contributes to missed diagnoses and suboptimal patient management. Hence, the objective of the study is to assess the existing knowledge regarding MASLD across healthcare specialties in Pakistan.

E-POSTER ABSTRACTS

Materials and Methods:

A multi-centre, hospital-based cross-sectional survey was conducted from January to May 2025 among general practitioners, internists, cardiologists, gastroenterologists, and endocrinologists working as consultants or residents across Pakistan. Students, nurses, paramedics, and dieticians were excluded. A total of 237 participants were recruited through non-probability consecutive sampling after obtaining informed consent. Data were collected using a structured questionnaire assessing demographics, area of expertise, awareness of MASLD prevalence and risk factors, and current screening, diagnostic, and management practices. Data were analyzed using SPSS version 19. Descriptive statistics were computed, and chi-square tests were used for significance testing post-stratification. The study was approved by the institutional ethical review committee, and all data were kept confidential to uphold ethical standards

Results:

A total of 237 physicians participated, including gastroenterologists (n=85), internists (n=77), endocrinologists (n=25), cardiologists (n=24), and family physicians (n=26). Most were consultants (67.9%) and based in Sindh (64.6%). Only 33.8% felt very comfortable diagnosing MASLD, with gastroenterologists contributing 67.1% of those confident ($p<0.001$). Awareness of global MASLD prevalence was highest among gastroenterologists (71.8%) and lowest among endocrinologists (48.0%) ($p<0.001$). Obesity (94.9%), diabetes (81.0%), and dyslipidemia (79.3%) were the most recognized risk factors, though dyslipidemia awareness varied significantly across specialties ($p=0.005$). BMI ($p=0.001$) and waist circumference ($p=0.006$) were more accurately identified as diagnostic criteria by endocrinologists and gastroenterologists. Diagnostic modality preference differed, with ultrasound (39.2%) and FibroScan (38.0%) most common. Only 18.1% felt very confident managing MASLD, with cardiologists reporting the lowest confidence (0%, $p<0.001$). While 56.5% used guidelines most of the time, 13.9% were unaware of any. Barriers to screening included lack of awareness (84.8%) and limited understanding of disease reversibility (50.2%).

Conclusions:

Marked variation in MASLD-related knowledge and clinical confidence exists across specialties with

gastroenterologists showing the highest awareness. Targeted, specialty-specific educational interventions are needed to enhance early detection and standardized management of MASLD in Pakistan.

Keyword(s) : MASLD, AWARENESS, DIAGNOSIS

2808 - HYPOALBUMINEMIA AS A PREDICTOR OF COMPLICATIONS IN PATIENTS WITH LIVER ABSCESS A SYSTEMIC REVIEW AND META ANALYSIS

Ramish Sumbal ¹, Raja Taha Yaseen Khan ¹, Muhammad Qaiser Panezai ¹, Danish Kumar ¹, Tooba Umer ¹, Khushboo Kumari ¹, Muhammad Usama Kiyani ¹, Ghazi Abrar ¹, Abbas Ali Tasneem ¹, Nasir Hasan Luck ¹

Sindh Insitute Of Urology And Transplantation, Gastroenterology And Hepatology, Karachi-Pakistan ¹

Background / Hypothesis:

Pyogenic liver abscess (PLA) remains a serious infectious condition associated with high morbidity and mortality. Serum albumin, a marker of nutritional and inflammatory status, has been proposed as a prognostic indicator in infectious diseases. This systematic review and meta-analysis evaluated the impact of hypoalbuminemia on adverse clinical outcomes in PLA.

Materials and Methods:

A comprehensive literature search of PubMed, Google Scholar, and Cochrane databases was conducted from inception to May 1, 2025, following PRISMA guidelines. Studies were included if they compared PLA patients with low versus normal serum albumin levels and reported adverse outcomes. Data extraction and quality assessment using the Newcastle–Ottawa Scale were performed independently by two reviewers. Pooled odds ratios (ORs) were calculated using fixed- or random-effects models based on heterogeneity.

Results:

Five retrospective studies involving 1,779 patients met inclusion criteria, of whom 860 had hypoalbuminemia. Pooled analysis demonstrated that low serum albumin was significantly associated with increased adverse outcomes in PLA (OR 2.64; 95% CI 1.27–5.48; $p = 0.009$), with moderate heterogeneity.

Hypoalbuminemia was also associated with acute kidney injury, prolonged hospitalization, and, in some studies, mortality and metastatic complications. Although albumin cut-off values varied (<2.5 – 3.5 g/dL), the direction of association was consistent. All included

E-POSTER ABSTRACTS

studies were of high methodological quality.

Conclusions:

Hypoalbuminemia is a significant predictor of poor outcomes in patients with PLA, reflecting systemic inflammation and disease severity. Routine assessment of serum albumin may improve early risk stratification and guide clinical decision-making. Prospective studies are required to determine whether albumin correction improves outcomes.

Keyword(s) : Hypoalbuminemia, Liver abscess, Systematic review

2811 - COMPARATIVE POTENTIAL OF DIFFERENT EDIBLE OILS TO IMPROVE THE STATUS OF NONALCOHOLIC STEATOHEPATITIS

Samia Zainab¹, Shahid Rasool²

The University Of Faisalabad, Nutrition And Dietetics, Faisalabad-Pakistan¹ Madina Teaching Hospital, Gastroenterology, Faisalabad-Pakistan²

Background / Hypothesis:

In world's population around 25% recently supposed to have NAFLD. Nonalcoholic steatohepatitis NASH is the advanced stage of fatty liver disease and it is the phase of chronic liver damage and can grow to cirrhosis may lead to hepatocellular carcinoma (HCC). International guidelines describe the health alimentary regimen, based on the lifestyle changes. The main component of the Mediterranean diet MD is their fat choices mainly the olive oil. Mustard oil ensure balanced ratio of monounsaturated, polyunsaturated and small amount of saturated fatty. The oils demonstrated antioxidant and the anti-inflammatory possessions

Materials and Methods:

The current study was carried out to evaluate the effect of edible oils on the different complicated condition of NASH, among the age group of 25-60 years. Then the included subjects were further divided into three groups such as G0, G1 and G2 respectively for the period of 12 weeks. Control group G0 receiving no treatment consumed conventional oil (20g), G1 consumed olive oil (20g) and G2 consumed mustard oil (20g)

Results:

It was observed that there was significant decrease in USG, BMI, CRP, and HbA1c in both treatment groups

along with the significant difference between values of ALT of G1 group consumed olive oil (Mean value= 69.66, SD= 10.5) (Mean value= 49.73, SD= 17.64) at week1 and week 12 respectively, and G2 group that was consumed mustard oil (Mean value= 73.73, SD= 16.16) (Mean value= 54.20, SD= 11.10) at week 1 and week 12 respectively. And There was also significant difference between ALP of G1 group (Mean value = 165.33, SD= 17.82) (Mean value= 127.40, SD= 19.37) at week 1 and week 12 respectively, and G2 group (Mean value= 158.26, SD=18.30) (Mean value = 134.26, SD=14.82) at week1 and week 12 respectively.

Conclusions:It has been evaluated from the current research that showed significant reduction in the treatment groups (G1and G2) compared to control group consuming conventional oil. This was directed to the concluded that the edible oils have beneficial potential against the above mentioned parameters in the condition of NASH.

E-POSTER ABSTRACTS

Background / Hypothesis:

Alcohol-associated hepatitis (AH) has a high short-term mortality in patients with a severe episode (sAH), defined by MELD score > 20. Corticosteroids (CS), the only available medication in patients with sAH, currently is a sub-optimal treatment, as 40-50% of patients are ineligible and a response (CS-R) rate of 50-60% in those who are eligible to receive CS. Further, response can only be determined after administration of CS for at least 7 days (Lille Score <0.45), with a risk of bacterial and fungal infections especially in non-responders to CS (CS-NR). Signal regulatory protein alpha (SIRPa) is an immune cell receptor that regulates efferocytosis and inflammatory responses. Cleavage of SIRPa from ADAM10 depends upon macrophage polarization, with its cleavage and release into the plasma in pro-inflammatory or M1 macrophage. The role of SIRPa has not been studied in patients with AH.

Materials and Methods:

A prospective cohort of sAH patients (2019-2024) enrolled in the Alchep Network study and treated with CS were studied. Plasma samples before administration of CS were analyzed by ELISA for several cytokines and SIRPA levels (ng/mL). Patients were followed for up to 180 days from the time of CS treatment.

Results:

Of 134 sAH patients treated with CS, 88 (mean age 46.4 yrs., 39% females, 86% NH White, mean MELD 23.7, mean CTP score 10.4, mean albumin 2.56, mean WBC 9.7) with available Lille score at d-7 were analyzed. CS-R (n=52) vs. NR (n=36) were younger with lower MELD (22.6 vs. 25.4), BUN (11.9 vs. 18.8), and WBC (8.6 vs. 11.3). Baseline mean plasma SIRPa levels were higher in CS-NR vs. CS-R (216.6 vs. 176.2, Fig. 1A). A total of 18 (20.5%), 29 (33%), and 32 (36.4%) died by 28, 90, and 180-d respectively. Stratifying the data at a median SIRPa level of 187, probability of survival at d-180 was higher in 44 patients with SIRPa levels <187 vs. ≥187 ng/mL (Fig. 1B). In a cox regression model controlled for MELD score, WBC, SIRPa, and Lille score, strongest predictor of death at d-180 was Lille score at d-7, with HR (95% CI) of 16.6 (2.8-99.7), p=0.002.

Conclusions:

Plasma SIRPa is a potential biomarker to predict CS-R, and can personalize CS use in patients with sAH. Future pre-clinical studies are suggested to examine how loss of SIRPa expression or its cleavage contributes to AH pathogenesis. Prospective studies are suggested to

validate SIRPa as a biomarker in use of CS for sAH patients.

2813 - Differential therapeutic effectiveness of atezolizumab plus bevacizumab in unresectable HCC by CHB viral activity

Hyunjae Shin¹, Yunmi Ko¹

Seoul National University Hospital, Internal Medicine, Seoul-South Korea¹

Background/Aims: Atezolizumab plus bevacizumab (Atezo/Bev) is recommended as the first-line therapy for unresectable hepatocellular carcinoma (uHCC). Previous studies suggested differential immunotherapy responses between viral and non-viral HCC; however, the mechanisms remained unclear. We investigated the impact of hepatitis B virus (HBV) DNA detectability, an indicator of viral replication activity that may influence the intrahepatic immune microenvironment, on Atezo/Bev outcomes.

Methods: This retrospective study included patients with uHCC, initially treated with Atezo/Bev at three hospitals in Korea. Patients were categorized as chronic hepatitis B (CHB) with undetectable HBV DNA (CHB/undetectable-DNA), CHB with detectable HBV DNA (CHB/detectable-DNA), or non-viral. Primary and secondary outcomes were progression-free survival (PFS) and overall survival (OS).

Results: We included 549 consecutive patients: CHB/undetectable-DNA (n=216), CHB/detectable-DNA (n=171), and non-viral groups (n=162). After propensity score matching, baseline characteristics were well-balanced. CHB/undetectable-DNA group had significantly longer PFS than both CHB/detectable-DNA (hazard ratio [HR]=0.66, 95% confidence interval [CI]=0.44–0.98, P=0.04) and non-viral groups (HR=0.61, 95% CI=0.37–0.98, P=0.048). PFS did not differ between CHB/detectable and non-viral groups (HR=1.28, 95% CI=0.86–1.91, P=0.23). CHB/detectable-DNA group showed significantly shorter OS than both CHB/undetectable-DNA (HR=1.75, 95% CI=1.04–2.94, P=0.03) and non-viral groups (HR=2.48, 95% CI=1.35–4.52, P=0.003). OS was comparable between CHB/undetectable-DNA and non-viral groups (HR=0.79, 95% CI=0.34–1.84, P=0.58).

Conclusions: Undetectable HBV DNA was associated with longer PFS and OS than detectable HBV DNA in CHB patients with uHCC receiving first-line Atezo/Bev. These findings suggest that HBV DNA detectability may negatively influence immunotherapy outcomes. Antiviral treatment may mitigate this effect and

E-POSTER ABSTRACTS

improve the therapeutic effectiveness of Atezo/Bev.

Keyword(s) : immunotherapy, atezolizumab plus bevacizumab, metabolic dysfunction-associated steatohepatitis, HBV DNA, liver cancer

2816 - Role of HbA1C in predicting Liver Fibrosis in MASLD patients A Systematic Review and Meta Analysis

Ramish Sumbal ¹, Nida Rasool ¹, Nasir Hasan Luck ¹, Abbas Ali Tasneem ¹, Zain Majid ¹, Danish Kumar ¹, Mehroz Bukhari ¹, Ghazi Abrar ¹, Raja Taha Yaseen ¹
Sindh Insitute Of Urology And Transplantation, Gastroenterology And Hepatology, Karachi-Pakistan ¹

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is closely related to dysglycemia and Insulin resistance. While an increase in glycated hemoglobin (HbA1C) is associated with liver fibrosis in individual studies, result remains inconsistent. Therefore, we aim to conduct a systematic review and a meta-analysis to evaluate the association between an increase in HbA1C and the presence of severity of liver fibrosis in MASLD patients

Materials and Methods:

Electronic databases such as PubMed/Medline, Google Scholar, and Cochrane were searched from inception till 30th September, 2025. All studies evaluating the relationship between HbA1C and liver fibrosis in MASLD were included. Pooled Odds ratios (ORs) and mean difference (MD) with 95% confidence intervals (CI) were calculated with a fixed and random effects model as appropriate. Study quality was assessed using the Joanna Briggs Institute checklist.

Results:

Fifteen studies were included evaluating 4864 patients. An increase in HbA1C was significantly associated with increased fibrosis risk (OR 1.56 [0.78, 3.15], $p = 0.21$). Patients with fibrosis and advanced fibrosis had significantly higher mean HbA1C levels compared to those without fibrosis (MD 1.17 and 0.38, respectively). However, there was no association between fibrosis progression and elevated HbA1C. Subgroup analysis revealed a significant association between HbA1C and fibrosis when evaluated by Liver biopsy, but not by Transient Elastography

Conclusions:

An increase in HbA1C level is associated with the presence and severity of liver fibrosis in MASLD patients. These findings suggest that HbA1C is a potential marker that can be used for fibrosis risk stratification in MASLD patients.

Keyword(s) : MASLD; HbA1C; NAFLD; Metabolic dysfunction-associated steatotic liver disease

2817 - Efficacy of Sofosbuvir and Velpatasvir in Achieving Sustained Virological Response in Patients with End Stage Renal Disease Infected with Hepatitis C Virus

Vijesh Kumar Kumar ¹, Raja Taha Yaseen Khan Khan ², Hassan Liaquat Memon Memon ³, Nasir Hasan Luck Luck ¹

Sindh Institute Of Urology And Transplantation, Hepatogastroenterology, Karachi-Pakistan ¹ Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain ² United Medical And Dental College, Karachi, Gastroenterology, Karachi-Pakistan ³

Background / Hypothesis:

Hepatitis C virus (HCV) infection remains a critical concern globally, especially in populations with end-stage renal disease (ESRD) on hemodialysis. This study aims to evaluate the efficacy and safety of a fixed-dose combination of Sofosbuvir and Velpatasvir (SOF/VEL) in achieving sustained virological response at 12 weeks post-treatment (SVR12) among ESRD patients infected with genotype III HCV.

Materials and Methods:

A prospective cohort study was conducted at the Sindh Institute of Urology and Transplantation, Karachi, from January 2023 to December 2024. Inclusion criteria were patients aged ≥ 18 years with ESRD on maintenance hemodialysis for ≥ 3 months and genotype III HCV infection. Patients received SOF/VEL (400 mg/100 mg) daily with ribavirin (400 mg) once weekly for 12 weeks. Primary outcome measured was SVR12. Statistical analyses involved Chi-square and Student's t-tests, with significance set at $p < 0.05$.

Results:

Of 109 enrolled patients (mean age 30.45 ± 8.98 years; 75.2% male), 105 (96.3%) achieved an end-of-treatment response (ETR), while SVR12 was attained in

E-POSTER ABSTRACTS

91 (84.3%) patients. The mean duration of dialysis was 3.1 ± 1.2 years. The most common adverse effects were fatigue (28%), headache (18%), and nausea (12%). Significant biochemical improvements at treatment completion were noted in ALT ($p=0.001$) and AST ($p=0.021$), although biochemical changes were not significantly correlated with SVR12.

Conclusions:

The combination therapy of Sofosbuvir and Velpatasvir demonstrated good efficacy (84.3% SVR12) and a manageable safety profile in ESRD patients on hemodialysis infected with HCV genotype III. Further multi-center studies with larger sample sizes are necessary to validate and generalize these results, emphasizing the potential of SOF/VEL therapy in this challenging patient population.

Keyword(s) : End-stage renal disease; Hepatitis C; genotype III; ETR; SVR

2819 - Human leukocyte antigen DQ 2 and DQ 8 expression among renal transplanted patients with chronic diarrhea

Husnain Ali Metlo Metlo ¹, Raja Taha Yaseen Khan Khan ², Nasir Hassan Luck Luck ¹

Sindh Institute Of Urology And Transplantation, Hepatogastroenterology, Karachi-Pakistan ¹ Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain ²

Background / Hypothesis:

The prevalence of positive celiac serology among patients with solid organ transplant is low due to the ongoing immunosuppression. However, it is important to determine the HLA DQ expression in this population to rule out celiac disease particularly if the index of suspicion is high. However, no data regarding Asian population has been mentioned. Therefore, our study is an attempt to identify the HLA DQ patterns in our population. This study therefore aims to determine the frequency of expression of human leukocyte antigen among patients with duodenal villous atrophy and negative celiac serology.

Materials and Methods:

It was a cross-sectional prospective study. All renal transplanted patients of both gender and aged between 18 to 60 years with villous atrophy on duodenal biopsy and having negative celiac serology were included in the study. Patients with positive celiac

serology, infectious cause of villous atrophy were excluded from the study. HLA typing was performed in all the included patients.

Results:

A total of 61 patients were included in the study. Among them, 41 (68.3%) were males. The most common presenting complaint was diarrhea seen in 55 (91.7%) followed by weight loss and abdominal pain seen in 49 (81.7%) and 32 (53.3%) respectively. Immunoglobulin A (IgA) deficiency was noted in 49 (82.7%) patients. On laboratory investigations, 40 (67%) patients had microcytic anemia. On histopathology, 30 (50%) patients had sprue marsh class IIIa. Both HLA DQ2 and DQ8 was noted in 31 (51.7%) patients while only HLA DQ2 and HLA DQ8 were observed in 54 (90%) and 37 (61.7%) patients respectively.

Conclusions:

HLA DQ2 was more commonly observed and expressed in renal transplant recipients with villous atrophy suggestive of increased prevalence of seronegative celiac disease in this population.

Keyword(s) : Seronegative; Celiac disease; HLA typing; Renal Transplant; HLA DQ2; HLA DQ8

2820 - Association of Low Vitamin D Levels with Non Alcoholic Fatty Liver Disease in Lean Individuals A Systematic Review and Meta Analysis

Raja Taha Yaseen Khan ¹, Sanjay Kirshan Kumar Kumar ², Nasir Hassan Luck Luck ³

Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain ¹ Ahalia Hospital, Gastroenterology, Abu Dhabi-United Arab Emirates ² Sindh Institute Of Urology And Transplantation, Hepatogastroenterology, Karachi-Pakistan ³

Background / Hypothesis:

Non-alcoholic fatty liver disease (NAFLD) is a growing global health concern, affecting approximately 25% of the global population. While traditionally linked to obesity and metabolic syndrome, NAFLD is increasingly recognized in individuals with normal body mass index (BMI), termed 'lean NAFLD.' Identifying risk factors for lean NAFLD is vital, as these individuals often escape routine screening yet may still progress to advanced liver disease. Vitamin D, known for its immunomodulatory and anti-inflammatory effects, has been implicated in liver metabolism and fibrogenesis. Several observational studies have suggested a link

E-POSTER ABSTRACTS

between low serum vitamin D levels and NAFLD, but its association in the lean population remains underexplored. This meta-analysis aims to systematically assess the relationship between serum vitamin D levels and NAFLD in lean individuals.

Materials and Methods:

A comprehensive literature search was conducted using PubMed, Semantic Scholar, and Google Scholar from January 2002 to May 2025. A total of 276 studies were initially identified. After screening and eligibility assessment, 7 studies were included in the final analysis. Study designs included observational, cross-sectional, and cohort studies. The total number of patients across all studies was 258,354. The effect size was measured using both odds ratios (OR) with 95% confidence intervals (CI) and mean differences in serum vitamin D levels between NAFLD and non-NAFLD lean individuals. A random-effects model was applied to account for between-study heterogeneity. Statistical heterogeneity was assessed using the I^2 statistic, and publication bias was evaluated using funnel plots.

Results:

The pooled analysis demonstrated a significant association between low vitamin D levels and the presence of NAFLD in lean individuals. The mean difference in serum vitamin D levels between lean NAFLD and non-NAFLD groups was -4.28 ng/mL (95% CI: -6.52 to -2.04 , $p < 0.001$), indicating significantly lower levels in NAFLD patients. The odds ratio for vitamin D deficiency (<20 ng/mL) being associated with NAFLD was 1.47 (95% CI: 1.22–1.77). Substantial heterogeneity was observed among studies ($I^2 = 91\%$), which could be attributed to differences in geographic regions, population demographics, and diagnostic thresholds. Funnel plot inspection suggested minimal publication bias.

Conclusions:

This meta-analysis indicates a significant association between low serum vitamin D levels and the risk of non-alcoholic fatty liver disease in lean individuals. Given the emerging prevalence of lean NAFLD and its potential progression to more severe liver diseases, screening for vitamin D deficiency may serve as a valuable adjunct in identifying at-risk individuals.

Fkui/rscm, Endocrine And Metabolic Division, Jakarta Pusat-Indonesia⁴

Background / Hypothesis: Along with the high prevalence of MAFLD in type 2 DM, hepatic complications such as liver cirrhosis are predicted to increase. One factor considered to play a role in MAFLD is the presence of mutations in the TM6SF2 rs58542926 gene. The aim of this study is to determine the frequency of the TM6SF2 rs58542926 gene variant and its association with liver fibrosis in patients with type 2 DM. We hypothesized that the TM6SF2 rs58542926 polymorphism is associated with the incidence of liver fibrosis

Materials and Methods:

A cross-sectional study using data from the Multicenter Genomic Study Biobank on type 2 Diabetes Mellitus patients from July to September 2025. Subjects were individuals with type 2 DM aged 18 years or older. Subjects with malignancies, autoimmune diseases, use of certain medications (methotrexate, phenytoin, isoniazid, and amiodarone), and incomplete data were excluded. Examination of the TM6SF2 rs58542926 gene variant was conducted using WGS, and liver fibrosis was assessed using transient elastography.

Results: Out of 307 subjects, 61 were found to have the TM6SF2 rs58542926 gene mutation, consisting of 50 subjects with partial mutations (C/T) and 11 subjects with complete mutations (T/T). The minor allele frequency of TM6SF2 rs58542926 was found to be 11.7%. A total of 41 subjects (13.4%) experienced significant fibrosis (F2-F4), and bivariate analysis showed that the TM6SF2 rs58542926 gene variant was not associated with liver fibrosis ($p=0.357$)

Conclusions: The frequency of the TM6SF2 rs58542926 gene in the type 2 DM population in Indonesia is 11.7%, and this variant is not associated with the incidence of liver fibrosis.

2822 - Tumor mutational burden and circulating tumor DNA mutation analysis using liquid biopsy samples from Filipino patients with hepatocellular carcinoma

Geraldine Arevalo¹, Angela Salvaña¹, John Carlo Reyes², Mathew Timothy Manuel¹, Leann Mariella Bernice Sala¹, Janus Ong³

National Institutes Of Health, University Of The Philippines Manila, National Institute Of Molecular Biology And Biotechnology, Manila-Philippines¹ University Of The Philippines-philippine General Hospital, Department Of Laboratories, Manila-Philippines² University Of The Philippines-philippine General Hospital, Division Of Gastroenterology, Department Of Medicine, Manila-Philippines³

Background / Hypothesis:

Genetic alterations in cancer genes of patients with hepatocellular carcinoma (HCC) can be potentially used for screening, diagnosis, detecting recurrence of the disease, monitoring treatment response, and prognostication. We present preliminary data on the circulating tumor DNA (ctDNA) mutational profile and tumor mutational burden (TMB) of a small cohort of Filipino HCC patients using liquid-biopsy (blood) samples.

Materials and Methods:

Cell-free DNA (cfDNA) was purified from plasma samples of 14 newly diagnosed, treatment-naïve HCC patients from five sites across the Philippines in an ongoing cohort study. Samples that met the required cfDNA concentration for library preparation (≥ 20 ng) were sequenced using a commercial 523-gene pan-cancer next-generation sequencing (NGS) assay. Bioinformatic analysis was subsequently performed using a proprietary NGS analysis pipeline with an integrated germline variant filtering step and predefined quality metrics to identify single-nucleotide variants (SNVs) and TMB analysis. Samples that had a median exon fragment coverage of ≥ 1300 and with $\geq 1000\times$ coverage in at least 80.0% of exonic regions were included in the analysis.

Results:

All samples met the minimum requirements for small variant calling and TMB analysis. Sequencing data identified 141 genes with somatic SNVs in all samples.

The most frequently mutated genes include the three HCC-associated genes TP53, CTNNB1, and ARID2. Two patients, diagnosed with BCLC stages 0/A and D, respectively, had a high TMB (≥ 10 mutations/MB). Both patients expired within one and two months following diagnosis, respectively.

Conclusions:

Our findings present preliminary evidence of recurrent ctDNA genetic alterations in a small cohort of Filipino HCC patients, warranting further research in a larger cohort with matched tissue samples and clinical correlations.

Keyword(s) : hepatocellular carcinoma, next-generation sequencing, tumor mutational burden, liquid biopsy

2823 - Continuous Terlipressin Infusion Plus Norepinephrine Versus Norepinephrine Alone in Acute Kidney Injury Associated With Acute on Chronic Liver Failure and Septic Shock A Randomized Controlled Trial

Jitendra Kumar Singh¹, Rakhi Maiwall¹, Ankit Bhardwaj¹, Harshvardhan Tevethia¹, Rajan Vijayaraghavan¹, Arun Kumar Sood², Manoj Kumar¹, Shiv Kumar Sarin¹ Institute Of Liver And Biliary Sciences, Hepatology, New Delhi-India¹ Institute Of Liver And Biliary Sciences, Cardiology, New Delhi-India²

Background / Hypothesis: Acute kidney injury (AKI) in acute-on-chronic liver failure (ACLF) with septic shock is driven by severe systemic vasodilatation and splanchnic pooling, often limiting the efficacy of norepinephrine (NE) alone. Terlipressin, a vasopressin analogue, may provide complementary splanchnic vasoconstriction and improve renal perfusion. We evaluated whether combining continuous low-dose terlipressin infusion with NE improves renal and hemodynamic outcomes compared with NE alone after fulfilling exclusion criteria and added at day 1 of randomisation.

Materials and Methods: Single-center open-label RCT of 126 ACLF patients with less-severe septic shock (NE < 0.05 $\mu\text{g/kg/min}$) and AKI randomized to NE group (n=63) or terlipressin infusion (1 mg/day, escalated to 4 mg/day by Day 4) plus NE (NE + Terli group n=63). MAP ≥ 70 mmHg targeted; 20% albumin given. The primary endpoint was day-4 shock reversal with ≥ 1 -

E-POSTER ABSTRACTS

stage AKI improvement; secondary endpoints were - day-7 AKI outcomes, albumin dose, Renal replacement therapy (RRT), 28day mortality, and adverse events.

Results: Baseline characteristics were comparable: NE group vs NE + Terli group, age (46.36 ± 10.09 vs 44.21 ± 12.57 years), AARC score (10.53 ± 1.52 vs 10.46 ± 1.17), eGFR (49.92 ± 20.53 vs 51.03 ± 19.49 mL/min/1.73 m²), MAP (63.47 ± 2.29 vs 62.56 ± 2.22 mmHg; $p=0.085$), lactate (2.35 ± 0.62 vs 2.26 ± 0.55 mmol/L; $p=0.502$). Pneumonia was the commonest sepsis source (47.2% vs 43.6%), followed by SBP (19.4% vs 33.3%) in NE vs NE+TERLI. Renal biomarkers were similar: urine NGAL (307.3 ± 237.4 vs 246.6 ± 200.1 ng/mL; $p=0.20$) and cystatin-C (2.19 ± 1.15 vs 1.90 ± 0.59 mg/L; $p=0.14$). NE + Terli group showed significantly higher day-4 shock reversal (92.3% vs 52.8%; $p<0.001$) and ≥ 1 -stage AKI improvement (74.4% vs 44.4%; $p=0.008$) were higher with NE+TERLI. Day-7 AKI resolution was also higher in NE + Terli group (71.8% vs 44.4%; $p=0.004$) with lower progression (12.8% vs 16.7%; $p=0.610$). Day-4 NE equivalent dose was lower (0.01 ± 0.03 vs 0.06 ± 0.08 ; $p=0.001$). Albumin dose (100.6 ± 60.7 vs 96.9 ± 62.2 g; $p=0.78$), RRT (15.8% vs 20.6%; $p=0.63$) and 28-day mortality (22.2% vs 28.2%; $p=0.55$) were comparable. AARC score (adjusted HR 3.01, CI 1.76–5.15; $p<0.001$) and baseline lactate (adjusted HR 14.39, CI 2.75–75.32; $p=0.002$) independently predicted mortality. Adverse events were higher with NE+TERLI (13.3% vs 4.3%; $p=0.2$). Baseline eGFR (OR 1.06, CI 1.02–1.11; $p=0.002$) and NE+TERLI (OR 3.60, CI 1.04–12.47; $p=0.043$) independently predicted day-7 AKI recovery.

Conclusions: In ACLF patients with septic shock-associated AKI, early continuous terlipressin plus norepinephrine significantly improved day-4 shock reversal and renal recovery, reduced vasopressor requirement, and independently predicted day-7 AKI resolution, with comparable mortality and acceptable safety versus norepinephrine alone.

Keyword(s) : ACLF, NE, NE+Terli

2824 - Resveratrol Loaded Tetrahedral Framework Nucleic Acids Ameliorate MAFLD via the NF κ B Signaling Pathway

Yifan Gao¹, Jingyi Si¹, Changfeng Zhu¹
Fudan University, Gastroenterology And Hepatology,

Shanghai-China¹

Background / Hypothesis:

To address the inherent limitations of resveratrol (RSV), such as poor aqueous solubility and low bioavailability, a novel nanodrug delivery platform (tFNAs-RSV) was engineered using tetrahedral framework nucleic acids (tFNAs). This study aims to investigate the therapeutic potential of this system against Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD) and to elucidate the underlying molecular mechanisms through which it modulates the NF- κ B signaling pathway.

Materials and Methods:

Tetrahedral framework nucleic acids (tFNAs) were precisely engineered via DNA molecular self-assembly, achieving high-efficiency loading of resveratrol (RSV). The morphology, particle size, and structural stability of tFNAs-RSV were systematically characterized using polyacrylamide gel electrophoresis (PAGE), dynamic light scattering (DLS), and transmission electron microscopy (TEM). A high-fat diet (HFD)-induced mouse model of MAFLD was established, and the animals were randomly assigned to different groups to receive intervention with equivalent doses of either free RSV or tFNAs-RSV via oral gavage. Therapeutic efficacy was evaluated by assessing hepatic lipid deposition, serum biochemical parameters, and histopathological analysis.

Results:

Physicochemical characterization confirmed that tFNAs-RSV exhibited high structural uniformity and superior aqueous dispersibility, which significantly enhanced the stability of RSV under physiological conditions. In vivo pharmacodynamic evaluation revealed that, benefiting from the exceptional carrier properties of tFNAs, tFNAs-RSV significantly reduced the degree of hepatic steatosis and serum transaminase levels compared to free RSV. Histological analysis demonstrated that tFNAs-RSV intervention effectively suppressed the pathological infiltration of macrophages and neutrophils within the liver. Molecular mechanistic studies confirmed that tFNAs-RSV downregulated the phosphorylation levels of the nuclear transcription factor p65, thereby inhibiting the transcriptional expression of endothelial adhesion molecules and subsequently blocking the chemotaxis and recruitment of inflammatory cells toward hepatic lesions.

Conclusions:

In this study, a smart nanodrug delivery platform with

E-POSTER ABSTRACTS

excellent biocompatibility was successfully constructed, effectively overcoming the physicochemical limitations of RSV. This platform achieved precise modulation of the hepatic inflammatory microenvironment and provides a novel nanomedicine strategy for the clinical intervention of MAFLD.

2825 - APRI Tracks FIB 4 Not Imaging Based Liver Metrics in Diabetic MASH A Cross Sectional Analysis

Owais Wani¹, Tanvir Masood², Zhahid Beigh², Irfan Ali²

Gmc Srinagar, Medicine, Pulwama-India¹ Gmc Srinagar, Medicine, Srinagar-India²

Background / Hypothesis:

Non-invasive biomarkers are widely used in assessing liver fibrosis and steatosis.

APRI is one such accessible index; however, its correlation with elastography-derived fibrosis grading and steatosis parameters remains uncertain. This study evaluates the association between APRI and FibroScan-based liver stiffness measurement (LSM), controlled attenuation parameter (CAP), fatty liver grading, and compares its correlation with FIB-4 score in Diabetic Patients.

Materials and Methods:

In this cross-sectional analysis, 400 patients with type 2 diabetes mellitus underwent APRI calculation, FibroScan assessment (LSM and CAP), and ultrasound-based fatty liver grading. Associations between APRI and categorical fibrosis/steatosis grades were analyzed using Kruskal-Wallis and Wilcoxon-Mann-Whitney U tests. Correlation with continuous variables (LSM, CAP, FIB-4) was assessed via Spearman's rank correlation.

Results:

No significant association was observed between APRI and FibroScan fibrosis grades ($\chi^2 = 0.764$, $p = 0.858$) or ultrasound-based fatty liver grades ($\chi^2 = 1.351$, $p = 0.717$). Similarly, APRI showed weak, non-significant

correlations with LSM ($p = 0.02$, $p = 0.629$) and CAP ($p = 0.03$, $p = 0.525$). However, a strong and statistically significant correlation was observed between APRI and FIB-4 score ($p = 0.88$, $p < 0.001$). APRI levels were also significantly higher in patients with FIB-4 > 2.67 compared to those with intermediate scores (mean APRI 1.07 vs. 0.52, $p < 0.001$).

Conclusions: APRI demonstrates a strong and clinically meaningful correlation with FIB-4 score but fails to show significant associations with elastographic or sonographic parameters of liver fibrosis or steatosis. These findings suggest that while APRI may be valuable as a biochemical fibrosis marker, it may not reflect imaging-based liver pathology with comparable accuracy.

Keyword(s) : APRI, FIB-4, FibroScan, LSM, CAP, Fatty Liver, Liver Fibrosis, NonInvasive Biomarkers

2826 - Association Between Duration of Type 2 Diabetes Mellitus and Hepatic Steatosis and Fibrosis Assessed by Transient Elastography.

Owais Wani¹, Zhahid Beigh²

Gmc Srinagar, Medicine, Pulwama-India¹ Gmc Srinagar, Medicine, Srinagar-India²

Background / Hypothesis:

Type 2 Diabetes Mellitus (T2DM) is strongly associated with metabolic dysfunction-associated steatotic liver disease (MASLD). Chronic hyperglycemia may promote hepatic fibrogenesis; however, the independent relationship between duration of diabetes and liver disease severity remains uncertain.

Materials and Methods:

This cross-sectional study included patients with T2DM who underwent vibration-controlled transient elastography for assessment of liver stiffness measurement (LSM, kPa) and controlled attenuation parameter (CAP, dB/m). Duration of diabetes was recorded in years. As at least one variable was not normally distributed, Spearman's rank correlation coefficient was used to assess associations. Linear regression equations were derived to describe trends. A p-value < 0.05 was considered statistically significant.

E-POSTER ABSTRACTS

Results:

There was a weak positive correlation between LSM and duration of T2DM ($\rho = 0.08$; 95% CI: -0.02 to 0.18), which was not statistically significant ($p = 0.120$). LSM increased by 0.12 kPa per year of diabetes. No meaningful correlation was observed between CAP and duration of T2DM ($\rho = 0.01$; 95% CI: -0.09 to 0.11 ; $p = 0.880$). CAP increased by 0.85 dB/m per year of diabetes, which was not statistically significant.

Conclusions: Duration of T2DM showed no significant association with hepatic fibrosis or steatosis severity. These findings suggest that metabolic burden and disease control may play a more critical role in liver disease progression than duration of diabetes alone.

Keyword(s) : Type 2 Diabetes Mellitus, MASLD, NAFLD, Transient Elastography, Liver Stiffness Measurement, CAP

2827 - Medical Management of Symptomatic Polycystic Liver Disease Using Intermittent Short Acting Octreotide A Cost Effective Alternative

Dr Vamsi Krishna Ankam¹, Dr Anand Kulkarni²
Aig Hospitals, Medical Gastroenterology, Hyderabad-India¹ Aig Hospitals, Hepatology, Hyderabad-India²

Background / Hypothesis:

Polycystic liver disease (PCLD) is an autosomal dominant disorder characterized by multiple non-communicating hepatic cysts. Symptomatic patients may require intervention. Long-acting somatostatin analogues reduce liver cyst volume but are often limited by high cost. We report the use of intermittent short-acting octreotide as a cost-effective alternative in symptomatic PCLD.

Materials and Methods:

A 38-year-old male presented with dull aching right upper quadrant abdominal pain for four months. Laboratory investigations were unremarkable. Ultrasound abdomen revealed multiple hepatic cysts in both lobes, some with internal echoes. Triphasic CT abdomen showed multiple cysts in both lobes, the largest measuring 8×7 cm in segment 4a, without high-risk features (no enhancing septations, mural nodules, calcifications, or solid components).

Given symptomatic disease with a dominant large cyst, surgical fenestration with or without aspiration followed by long-acting octreotide was offered. Due to financial constraints, the patient opted for medical

therapy and was initiated on short-acting octreotide $100 \mu\text{g}$ subcutaneously daily for 5 days every month.

Results:

At 4-month follow-up, the patient reported significant symptomatic improvement. Repeat imaging demonstrated marked reduction in cyst size, with the dominant cyst decreasing from 8×7 cm to 4×5.7 cm. The patient tolerated therapy well without major adverse effects. He was counseled regarding potential long-term side effects, including cholelithiasis, steatorrhea, and bloating.

Conclusions:

Intermittent short-acting octreotide resulted in significant clinical and radiological improvement in this patient with symptomatic PCLD. In resource-limited settings where long-acting formulations or surgery are not feasible, intermittent short-acting octreotide may serve as a practical and cost-effective therapeutic option in selected patients.

2828 - Pipecolic Acid Attenuates MASH by Suppressing Monocyte derived Macrophage Recruitment via Activating GABA A receptor to Inhibit CaMKII STAT1 Signaling

Jia Chen¹, Ling Dong¹
Zhongshan Hospital Fudan University, Department Of Gastroenterology And Hepatology, Shanghai-China¹

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) shows heterogeneity in pathogenesis, with gut microbiota dysbiosis and disturbed amino-acid metabolism contributing to disease progression. Metabolic dysfunction-associated steatohepatitis (MASH) is characterized by persistent hepatic and systemic low-grade inflammation and related to higher risk for adverse outcomes including cirrhosis, hepatocellular carcinoma and extrahepatic malignancies and cardiovascular disease. Macrophages are central part of MASH. Injured hepatocytes release cytokines that recruit and polarize monocyte-derived macrophages, amplifying inflammation and activating hepatic stellate cells. In this study, we investigated the mechanism that pipecolic acid alleviate MASH.

Materials and Methods:

E-POSTER ABSTRACTS

We established MASH model in vitro using 3D liver spheroids treated with free fatty acids and in vivo using C57BL/6J mice fed GAN diet. Pipecolic acid was administered. Histological staining and flow cytometry were used to estimate liver injury and macrophage populations. RNA-seq and western blotting were used to investigate the mechanism.

Results:

Pipecolic acid treatment ameliorated steatohepatitis features in both 3D spheroids and GAN-fed mice, including steatosis, inflammatory infiltration and fibrosis. In vivo, pipecolic acid selectively decreased the number of infiltrating monocyte-derived macrophages in liver while showed no significant influence on Kupffer cells. Transcriptomic and protein analyses revealed that pipecolic acid acts as a GABA-A receptor agonist, leading to reduced phosphorylation of CaMKII and suppressing STAT1 transcriptional activity, lowers expression of STAT1-dependent inflammatory cytokines and chemokines implicated in monocyte recruitment.

Conclusions:

Pipecolic acid alleviate MASH by agonizing GABA-A receptor to reduce CaMKII phosphorylation, thereby inhibiting STAT1-mediated transcription of inflammatory cytokines and chemokines, which suppresses monocyte-derived macrophage recruitment and hepatic inflammation.

Keyword(s) : Pipecolic Acid, Metabolic Dysfunction-Associated Steatohepatitis, Gut Microbiota, Monocyte-derived Macrophage, Gamma-aminobutyric Acid

2829 - Trends and disparities in China's metabolic associated fatty liver disease burden from 1990 to 2021

Xiangqian Wang¹, Haihong Zhu¹, Qiang Zhang²
Qinghai Provincial People's Hospital, General Surgery, Xining-China¹ Qinghai Provincial People's Hospital, Neurosurgery Department, Xining-China²

Background / Hypothesis:

There is a rising number of metabolic-associated fatty liver disease (MAFLD) among Chinese adolescents and young people. To identify concrete prevention strategies for MAFLD, a systematic assessment of its risk factors is required. This study uses Global Burden of Disease (GBD) data to analyse, in a systematic manner, the long-term trends and epidemiological

features of MAFLD in Chinese youths and young adults.

Materials and Methods:

We utilised data from GBD 1990–2021 to undertake a comprehensive analysis of the MAFLD burden among Chinese adolescents and young adults, covering prevalence, incidence, mortality, and disability-adjusted life years (DALYs). Time trends were examined using Joinpoint regression, age–period–cohort (APC) modelling, and a Bayesian APC (BAPC) approach to project incidence and prevalence. Finally, we analysed the attributable burden of MAFLD.

Results:

The prevalence of MAFLD is rising sharply. In China, the number of MAFLD cases amongst those aged 15-39 in 2021 increased by 140.02% compared with 1990. Younger generations are at significantly greater risk than earlier generations at the same age; the prevalence in the 35-39 age group is approximately four times that of the 15-19 age group. This suggests the window for disease management needs to shift earlier, to adolescence and young adulthood. While age-standardised mortality rates generally show a downward trend, they have risen again since 2017, indicating a possible increase in the risk of late-stage complications.

Conclusions:

Against the backdrop of China's vast population, MAFLD poses a significant public health burden for adolescents and young people, and there is an urgent need to develop scientifically sound public health policies to tackle this health challenge.

Keyword(s) : Metabolic-associated fatty liver disease; Global burden; Public health; Joinpoint regression; Age-period-cohort model

2830 - Temporal change of hepatitis C virus testing and treatment coverage in people who inject drugs in Hong Kong

Ngai Sze Wong¹, Lisa Sum Yip², Bonnie Chun Kwan Wong², Chin Pok Chan¹, Zenith Hin Yam Wu², Chin Man Poon², Shui Shan Lee¹

The Chinese University Of Hong Kong, S.h. Ho Research Centre For Infectious Diseases, Hong Kong-China¹ Department Of Health, Special Preventive Programme, Hong Kong-China²

E-POSTER ABSTRACTS

Background / Hypothesis:

In Hong Kong, with the expansion of HCV treatment provision since October 2020, the primary challenge for achieving HCV micro-elimination in people who inject drugs (PWID), a population with over 80% anti-HCV prevalence, is shifted to case identification and linkage to treatment. This study aims to examine the temporal change and factors associated with known HCV positive status and history of HCV treatment in PWID.

Materials and Methods:

Data from 2021-2024 annual surveys on the HIV awareness and risk behaviours were collated and analysed. PWID were recruited by well-trained interviewers of non-governmental organisations either in the neighbourhood of methadone clinics or in nearby urban parks, for completion of questionnaires. Factors, including survey year, associated with each outcome variable (self-reported anti-HCV positive status and history of HCV treatment) were examined in multivariable logistic regression models.

Results:

In the four annual surveys (total 2924 responses), 63% of respondents were aged 50 or above, 92% were male, and 90% were local Chinese. Ninety percent reported injection behaviour (18% with and 64% without needle sharing, and 9% no current injection), of whom 59% have injected for over 20 years. Most (89%) have attended the methadone clinics frequently for at least 22 days in the past 1 month, including 72% full attendance), and 89% were aware that drug injection could transmit HCV. From 2021 to 2024, the proportion of respondents ever tested for HCV increased significantly from 15% to 48%, among whom 49%-74% were aware of their anti-HCV positive status, and history of HCV treatment increased significantly from 6% to 48%. History of drug injection (adjusted odds ratio (aOR)=1.07, $P<0.001$), local Chinese (aOR=2.84, $P=0.015$), and older age (aOR=1.07 per year, $P<0.001$) were associated with self-reported anti-HCV positivity. Known HCV positive respondents aged 31-50 (aged >60 as reference, 31-40 aOR=0.09, 41-50 aOR=0.36, $P<0.001$) and infrequent methadone clinic attendees (full attendance as reference, aOR=0.28, $p=0.003$) were less likely to have received HCV treatment.

Conclusions:

While HCV testing and treatment coverage has increased significantly over the years, treatment uptake was disproportionately low among younger and infrequent methadone clinic attendees despite PWIDs' known HCV positive status. To achieve HCV micro-elimination in this key population, efforts would need to go beyond expanding testing coverage. Promoting awareness of the importance and effectiveness of new HCV treatment, coupled with simplifying referral and linkage pathway would be important to enhance treatment coverage.

Keyword(s) : HCV; PWID; testing and treatment

2831 - Early implementation experience in developing a Research Electronic Data Capture (REDCap) based liver disease biobank platform in a lower middle income country

Ann Rose Payumo ¹, Orle John Lavilla ¹, Julex Rey Aguila ¹, Ayra Patrice Espiritu ¹, John Carlo Reyes ¹, Mark Angelo Ang ¹, Loraine Kay Cabral ², Janus Ong ¹
University Of The Philippines Manila, National Institutes Of Health, Manila-Philippines ¹ Department Of Science And Technology, Philippine Council For Health Research And Development, Taguig-Philippines ²

Background / Hypothesis:

Liver diseases remain a major and growing public health burden in the Philippines, driven by chronic viral hepatitis, metabolic dysfunction-associated steatotic liver disease, alcohol-related liver disease, and hepatocellular carcinoma. In many lower-middle income countries, translational research is limited by fragmented data systems and inadequate infrastructure for systematic biospecimen collection. As part of a nationally funded multidisciplinary liver research program, we established the Promoting Healthy Filipino Liver through Interdisciplinary Innovative Research (PHIL LIVER) Biobank as foundational infrastructure supporting multiple component studies. We evaluated early implementation focusing on governance, digital architecture, workflow integration, and initial operational performance.

Materials and Methods:

We conducted a prospective implementation study during the establishment of a liver disease biobank within a public academic referral center. The PHIL

E-POSTER ABSTRACTS

LIVER Biobank accepts biospecimens and associated clinical data from three component projects. A centralized Research Electronic Data Capture (REDCap) digital repository was developed as a single unified project integrating data across project components. The REDCap architecture utilized study arms, data access groups, and role-based permissions to ensure appropriate participant assignment, data segregation, and controlled access. Standard operating procedures were implemented for patient identification, consent, specimen collection, processing, storage, and retrieval. Pilot testing focused on cross-project variable harmonization, refinement of electronic forms, and alignment with routine clinical workflows.

Results:

Within 12 months, governance structures and operational procedures were established. The unified REDCap platform enabled structured data capture and barcode-based specimen tracking across projects, while study arms and data access groups supported secure multi-project functionality within a controlled-access environment.

As of reporting, a total of 37 participants were enrolled, all of whom consented to biobanking. From these participants, 74 plasma aliquots and 74 serum aliquots were processed and stored (two per participant). Additionally, 18 fecal aliquots were collected. All specimens were assigned unique coded identifiers with complete digital traceability in REDCap. No specimen mislabeling events were documented during pilot implementation.

Operational challenges included cross-project variable harmonization, iterative e-form refinement and workflow efficiency.

Conclusions:

Early implementation demonstrates the feasibility of establishing a centralized, multi-project liver disease biobank supported by a unified REDCap architecture in a resource-constrained setting. Integrating multiple studies within a controlled-access digital environment enhances coordination and efficiency but requires substantial effort in harmonization and workflow alignment. The PHIL LIVER Biobank provides a scalable model for strengthening multidisciplinary research infrastructure in developing health systems.

2835 - Predictive value of oxygen resaturation rate and MAFLD for left ventricular hypertrophy in obstructive sleep apnea

Huilian Shi ¹

Affiliated Hospital Of Nanjing University Of Chinese Medicine, Department Of Hepatology, 南京-China ¹

Abstract

Background: Left ventricular hypertrophy (LVH) is a prevalent cardiac complication of obstructive sleep apnea (OSA). The oxygen resaturation rate (ORR), a novel metric quantifying post-apneic oxygen recovery, may provide insights into LVH. This study examined the association between ORR and LVH and whether metabolic dysfunction-associated fatty liver disease (MAFLD) influences this relationship.

Methods: This retrospective study included OSA patients without pre-existing LVH who underwent polysomnography from January 2014 to May 2017 at Affiliated Huai'an No.1 People's Hospital of Nanjing Medical University. LVH was assessed via echocardiography and blood tests from December 2023 to May 2024. ORR was calculated from obstructive respiratory events recorded during overnight polysomnography. For each event, Δt was defined as the interval from the SpO_2 nadir to recovery, and ΔSpO_2 as the magnitude of desaturation. ORR, calculated as $\Delta SpO_2 / \Delta t$, represents the rate of reoxygenation and serves as an index of reoxygenation efficiency. Multivariate Cox regression and Kaplan-Meier analyses were performed to examine associations among ORR, MAFLD, and LVH.

Results: The sample include 490 participants (79.0% male) with a median age of 53.0 [42.0,62.0] years). Over a median follow-up of 8.4 years, 85 (17.3%) were diagnosed with LVH. Compared with the lowest tertile, the highest ORR tertile was associated with a higher risk of LVH (adjusted HR 4.93 ; 95% CI 2.28-10.70, $p < 0.001$).

Notably, participants with NAFLD/High-ORR had a higher incidence of LVH than the Non-NAFLD/Low-ORR group (adjusted HR 5.16 ; 95%CI 2.13-12.53, $p < 0.001$). Subgroup analyses indicated stronger associations in participants aged < 65 years or with BMI ≥ 30 kg/m². MAFLD in combination with high AHI or ORR increased the risk of LVH, whereas no increase was observed for T90.

Conclusion: ORR is a novel, sensitive indicator

E-POSTER ABSTRACTS

associated with the presence of LVH in patients with OSA. A significant interaction between ORR and MAFLD was observed, which was associated with an increased risk of LVH.

Keyword(s) : Oxygen Resaturation Rate (ORR) ; Left Ventricular Hypertrophy (LVH) ; Obstructive Sleep Apnea (OSA) ; Metabolic Dysfunction-Associated Fatty Liver Disease (MAFLD)

2836 - Effectiveness and safety of transcatheter arterial chemoembolization with EqualSpheres beads in patients with unresectable hepatocellular carcinoma : a single arm multi center prospective study

Hao Li ¹, Xuhua Duan ¹, Shuguang Ju ¹

The First Affiliated Hospital, Zhengzhou University, Interventional Radiology, Zhengzhou-China ¹

Background / Hypothesis:

This prospective study aimed to investigate the short-term efficacy and safety and outcomes of unresectable hepatocellular carcinoma (uHCC) treated by transarterial chemoembolization (TACE) using EqualSpheres beads (ETACE) .

Materials and Methods:

Eligible patients were given ETACE with graded embolization strategy, until either disease progression or intolerable toxicities emerged. Toxicity was assessed using NCI CTCAE v5.0. Response was assessed using mRECIST criteria. Objective response rates (ORR) and progression-free survival (PFS) was the primary endpoint. Overall survival (OS), disease control rates (DCR), and treatment-related adverse events (TRAEs) were secondary endpoints.

Results:

Total, 302 patients with HCC were successfully enrolled. Median follow-up lasted 14.5 months (95% CI: 11.8–20.5 months). 3 month, 6 month, and 12 month ORR and DCR after the first DEB-TACE were 55.3% and 65.3%, 26.2% and 90.3%, 70.7% and 26.2%, respectively. One-year PFS and OS rate were 54.8 and 90.3%. Median PFS was 9.1 months (95% CI: 8.2–9.6 months) and the median OS was 19.6 months (95% CI: 18.7–NA months). Impressively, 5 (1.7 %) patients were converted to resectable HCC and underwent curative hepatectomy. Majority of TRAEs were mild and manageable. ETACE-related adverse events (AEs) was commonly embolism syndrome such as fever, pain, gastrointestinal reactions, nausea, vomiting, and new ascites. Liver abscess was special phenomena in the study.

Conclusions:

In this prospective study, high ORR and long PFS are observed after ETACE with graded embolization strategy with encouraging results and manageable safety.

2837 - Effects of miR 124 3p Knockdown on Hepatocyte Apoptosis and Protein C Synthesis in Mice with Portal Vein Obstruction

Liyuan Xin ¹, Jinshan Zhang ¹

Capital Center For Children's Health, Capital Medical University, Capital Institute Of Pediatrics, General Surgical Department, Beijing-China ¹

Background / Hypothesis:

This study employed a mouse model of partial portal vein ligation (PVL). On this basis, a model of miR-124-3p low expression was established. The aim was to investigate the effect of miR-124-3p inhibition on the expression of Protein C (PROC), along with its potential regulatory mechanisms, within a pathological environment simulating portal vein thrombosis.

Materials and Methods:

Forty male C57BL/6J mice (6–8 weeks old) were equally randomized into four groups: Sham+NC, Sham+Inhibitor, PPVL+NC, and PPVL+Inhibitor. PPVL was induced via extrahepatic partial portal vein ligation; sham controls underwent laparotomy with vein isolation only. Model validation involved serum collection at days 7, 14, and 21 post-surgery to measure Protein C (ELISA) and platelet counts. Inhibitor groups received tail vein injections of miR-124-3p-sponge AAV; controls received empty virus. Four weeks post-injection, mice were sacrificed. Liver injury was assessed via serum ALT/AST/LDH. qRT-PCR quantified miR-124-3p and PROC mRNA; Western blot measured PROC, Bax, Bcl-2, and cleaved caspase-3. Apoptosis was evaluated by TUNEL staining.

Results:

Routine blood tests confirmed successful PPVL modeling, revealing significantly lower platelet counts in the PPVL group than in the Sham group. From day 14 post-surgery, Protein C (PROC) levels dropped notably in the PPVL group. Compared to Sham controls, PPVL mice showed reduced PROC mRNA and protein, alongside increased Bax and cleaved caspase-3, and decreased Bcl-2, indicating liver apoptosis. Inhibiting miR-124-3p reversed these changes: PROC rose, apoptosis-related proteins normalized to near-Sham levels, with no difference from Sham controls.

E-POSTER ABSTRACTS

The inhibitor alone showed no off-target effects in normal liver. TUNEL staining confirmed fewer apoptotic cells in PPVL+Inhibitor vs. PPVL+NC, comparable to Sham, with no effect from inhibitor only.

Conclusions:

This study demonstrated that in a partial portal vein thrombosis model, inhibition of miR-124-3p alleviated hepatocyte apoptosis by modulating the Bcl-2/Bax/caspase-3 apoptotic pathway, thereby promoting PROC synthesis in hepatocytes. These findings provide novel molecular mechanistic insights into the link between hepatocyte injury and coagulopathy in portal hypertension. Consequently, miR-124-3p represents a promising therapeutic target for preventing portal vein thrombosis by enhancing endogenous anticoagulant pathways.

Background: Hepatitis E virus (HEV) is currently the leading cause of acute viral hepatitis worldwide. While most infections are self-limited, chronic HEV infection has become a significant clinical concern in immunocompromised individuals, particularly solid-organ transplant recipients and patients receiving immunosuppressive therapies. Extrahepatic manifestations, including neurological and renal complications, further complicate diagnosis and management. More recently, human infections caused by rat hepatitis E virus (Rocahepevirus rattii) have expanded the recognized clinical spectrum of zoonotic hepevirus infections in Europe and Asia. Despite these developments, diagnostic algorithms, screening strategies and therapeutic approaches remain heterogeneous across centers and regions. Given growing population mobility and shared clinical challenges, there is a clear need for stronger inter-regional alignment between Europe and the Asia-Pacific in clinical practice and evidence generation. Methods: ONWARD (COST Action CA24140) is a European Union-funded initiative under the COST (European Cooperation in Science and Technology) framework, launched in October 2025 to improve coordination and preparedness in zoonotic hepevirus infections. The Action brings together hepatologists, infectious disease specialists, transplant physicians, microbiologists, veterinarians and public-health experts from 30 European countries and is structured to facilitate global scientific exchange through open dissemination activities, shared protocols and collaborative analyses. Clinical-focused activities include: ii) harmonising molecular and serological testing approaches; (iii) defining shared clinical case definitions and outcome measures; and (iv) facilitating structured data exchange to support multicentre analyses, with emphasis on high-risk populations (transplant and other immunosuppressed patients). Results: The network enables systematic assessment of variability in clinical practice across Europe. Preliminary mapping demonstrates marked differences in chronic HEV screening among transplant recipients, ribavirin dosing strategies, duration of therapy, and follow-up protocols. Consensus-based frameworks for diagnostic algorithms and minimum clinical data sets are being developed, designed to be transferable and comparable across regions. Key research priorities identified include predictors of chronic infection, relapse after antiviral therapy, and the clinical relevance of ratHEV infection in humans. Conclusions: ONWARD represents the first coordinated EU-supported effort to address the clinical challenges

E-POSTER ABSTRACTS

posed by zoonotic hepevirus infections with an explicit goal of supporting inter-regional convergence in clinical management. By aligning diagnostic standards, strengthening multicenter collaboration and fostering cross-sector communication, the initiative aims to improve patient management and support evidence-based clinical decision-making. This model can serve as a platform for Europe-Asia dialogue on HEV clinical practice, research priorities and preparedness.

Keyword(s) : Hepatitis E, ratHEV

2840 - Ultrasound Based Assessment of Hepatic Steatosis in Rheumatoid Arthritis Patients A Cross Sectional Study

Eman Fares ¹, Nourhan S Ahmed ², Nermeen A Foad ³, Essam A. Hassan ¹, Ahmed M Saleh ⁴
Fayoum University, Endemic Medicine, Fayoum-Egypt ¹
Fayoum University, Endemic Medicine, Fayoum-Egypt ²
Fayoum University, Rheumatology & Rehabilitation, Fayoum-Egypt ³
Fayoum University, Endemic Medicine, Fayoum-Egypt ⁴

Background / Hypothesis:

Steatotic liver disease is highly prevalent in the general population. Emerging evidence suggests a possible association between hepatic steatosis (HS) and rheumatoid arthritis (RA), although this relationship has not been sufficiently investigated.

The study aimed to determine the prevalence of hepatic steatosis among patients with rheumatoid arthritis using liver ultrasonography.

Materials and Methods:

This cross-sectional study included 154 patients with RA evaluated between July 2024 and February 2025. Hepatic steatosis was assessed by abdominal ultrasonography. All participants underwent detailed history taking, clinical examination, and anthropometric measurements, including body mass index (BMI), waist circumference (WC), hip circumference (HC), waist-to-hip ratio (WHR), and waist-to-height ratio (WHtR). Disease activity was evaluated using the Disease Activity Score-28 (DAS28). Laboratory investigations included liver biochemical profile, lipid profile, glycated hemoglobin (HbA1c), and inflammatory markers (C-reactive protein and erythrocyte sedimentation rate).

Results:

The majority of patients were female (88.3%), with a median age of 45 years and a median disease duration of 96 months. Hepatic steatosis was detected in 45.5% (70/154) of patients, of whom 70% had moderate-to-severe steatosis. Compared with patients without steatosis, those with steatosis were older and had longer disease duration, higher disease activity, higher prevalence of diabetes mellitus and hypertension, and greater cumulative methotrexate exposure. Patients with steatosis had significantly higher BMI, WC, HC, WHR, WHtR, HbA1c, and lipid profile parameters (triglycerides, total cholesterol, and low-density lipoprotein cholesterol) ($P < 0.001$).

Conclusions:

Hepatic steatosis is common among patients with rheumatoid arthritis. Older age, central obesity, metabolic abnormalities, and diabetes mellitus are associated with increased risk of hepatic steatosis in this population.

Keyword(s) : Keywords: Prevalence; Hepatic Steatosis; Ultrasonography; Rheumatoid Arthritis

2842 - Machine learning-based mortality prediction models for non alcoholic fatty liver disease in the general United States population

Jiarui Zheng ¹, Yandi Xie ¹, Bo Feng ¹
Peking University Hepatology Institute, Peking University People's Hospital, Beijing-China ¹

Background / Hypothesis:

Nowadays, the global prevalence of non-alcoholic fatty liver disease (NAFLD) has reached about 25%, which is the most common chronic liver disease worldwide, and the mortality risk of NAFLD patients is higher. Our research created five machine learning (ML) models for predicting overall mortality in ultrasound-proven NAFLD patients and compared their performance with conventional non-invasive scoring systems, aiming to find a generalizable and valuable model for early mortality prediction in NAFLD patients.

Materials and Methods:

National Health and Nutrition Examination Survey (NHANES)-III from 1988 to 1994 and NHANES-III related mortality data from 2019 were used. 70% of subjects were separated into the training set ($N = 2262$) for development, while 30% were in the testing set ($N = 971$) for validation. The outcome was all-cause death at the end of follow-up. Twenty-nine related

E-POSTER ABSTRACTS

variables were trained as predictor features for five ML-based models: Logistic regression (LR), K-nearest neighbors (KNN), Gradient-boosted decision tree (XGBoost), Random forest (RF) and Decision tree. Five typical evaluation indexes including area under the curve (AUC), F1 score, accuracy, sensitivity and specificity were used to measure the prediction performance.

Results:

3233 patients with NAFLD in total were eligible for the inclusion criteria, with 1231 death during the average 25.3 years follow up time. AUC of the LR model in predicting the mortality of NAFLD was 0.888 (95% confidence interval [CI] 0.867-0.909), the accuracy was 0.808, the sensitivity was 0.819, the specificity was 0.802, and the F1 score was 0.765, which showed the best performance compared with other models (AUC were: RF, 0.876 [95%CI 0.852-0.897]; XGBoost, 0.875 [95%CI 0.853-0.898]; Decision tree, 0.793 [95%CI 0.766-0.819] and KNN, 0.787 [95%CI 0.759-0.816]) and conventional clinical scores (AUC were: Fibrosis-4 Score (FIB-4), 0.793 [95%CI 0.777-0.809]; NAFLD fibrosis score (NFS), 0.770 [95%CI 0.753-0.787] and aspartate aminotransferase-to-platelet ratio index (APRI), 0.522 [95%CI 0.502-0.543]).

Conclusions:

ML-based models, especially LR model, had better discrimination performance in predicting all-cause mortality in patients with NAFLD compared to the conventional non-invasive scores, and an interpretable model like Decision tree, which only used three predictors: age, systolic pressure and glycated hemoglobin, is simple to use in clinical practice.

Keyword(s) : Non-alcoholic fatty liver disease; mortality; machine learning; Logistic regression; Decision tree; NHANES-III.

2843 - IRE1 α mediated downregulation of CYP7A1 drives MASH HCC progression and immune evasion via regulation of cholesterol metabolism

Fan Li ¹, Ming Ni ¹, Ling Lu ¹

The First Affiliated Hospital Of Nanjing Medical University, Hepatobiliary Center, Nanjing-China ¹

Background / Hypothesis:

Metabolic dysfunction-associated steatohepatitis (MASH)-related hepatocellular carcinoma (HCC) is rising globally, exhibiting unique features like

metabolic dysregulation and a poorer prognosis than viral HCC. Cholesterol is key in MASH-HCC progression, regulated by CYP7A1, the rate-limiting enzyme in bile acid synthesis. Clinically, CYP7A1 is significantly downregulated in MASH-HCC tumors and linked to worse outcomes, yet its regulatory mechanisms and functional roles are unclear. This study aims to clarify these aspects to identify novel therapeutic targets for MASH-HCC.

Materials and Methods:

Paired tumor/adjacent tissues from MASH-HCC patients were analyzed by metabolomic sequencing, scRNA-seq, and spatial transcriptomics to identify cholesterol metabolism alterations and confirm CYP7A1 downregulation. MASH-HCC mouse models were generated using hepatocyte-specific IRE1 α -KO, Cyp7a1-KI, and Smo-KO mice. ChIP-seq, RNA-seq validated IRE1 α -mediated CYP7A1 regulation. IP/MS, LLPS and FRAP assays characterized IRE1 α lactoylation modification and RIDD activity. In vivo/in vitro experiments assessed the impact of IRE1 α -CYP7A1 axis on cholesterol metabolism and Hedgehog signaling. Therapeutic effects of PD-1 mAb alone or combined with IRE1 α inhibitor/CYP7A1-adenovirus were evaluated in MASH-HCC models to explore clinical translation.

Results:

CYP7A1 is markedly downregulated in MASH-HCC tumor tissues and strongly associated with unfavorable prognosis. Lactoylation of IRE1 α induces LLPS, augmenting its RIDD activity and resulting in direct degradation of CYP7A1 mRNA. Reduced CYP7A1 expression causes aberrant cholesterol accumulation, which activates Hedgehog signaling in both tumor cells and Treg cells through SMO cholesterol modification, thereby accelerating tumor proliferation and immune evasion. Therapeutic targeting of the IRE1 α /CYP7A1 axis effectively restores cholesterol metabolic homeostasis and potentially suppresses tumor progression.

Conclusions:

This study reveals a core mechanism driving MASH-HCC progression: hypoxia-induced IRE1 α lactoylation enhances its LLPS and RIDD activity, specifically degrading CYP7A1 to cause cholesterol accumulation; this accumulation exacerbates ER stress, transactivating IRE1 α to form a self-reinforcing loop that ultimately activates Hedgehog signaling via SMO cholesterol modification to promote carcinogenesis and immune evasion. The study elucidates a novel "metabolism-stress" crosstalk paradigm, offering new targets for MASH-HCC diagnosis and therapy.

2845 - Effectiveness and Safety of Glecaprevir Pibrentasvir Combination Therapy in Patients Diagnosed with Chronic Hepatitis C

Kaan Karabulut ¹, Bilgehan Aygen ², Orhan Yildiz ², Hüseyin Nadir Kahveci ³, Zeynep Türe-yüce ⁴, Gamze Kalin-ünüvar ², Ayşe Yüceil-karabulut ⁵

Kayseri State Hospital, Department Of Infectious Diseases And Clinical Microbiology, Kayseri-Türkiye ¹ Erciyes University, Faculty Of Medicine, Department Of Infectious Diseases And Clinical Microbiology, Kayseri-Türkiye ² Umraniye Training And Research Hospital, Department Of Infectious Diseases And Clinical Microbiology, Istanbul-Türkiye ³ Özel Gurlife Hospital, Department Of Infectious Diseases And Clinical Microbiology, Eskişehir-Türkiye ⁴ Erciyes University, Faculty Of Medicine, Department Of Medical Microbiology, Kayseri-Türkiye ⁵

Background / Hypothesis: The study aimed to evaluate the effectiveness and safety of glecaprevir/pibrentasvir (GLE/PIB) treatment in patients infected with hepatitis C virus (HCV).

Materials and Methods: Forty-four patients who applied to the Infectious Diseases and Clinical Microbiology Clinic between December 2019 and December 2022 were infected with HCV genotype 1–6 and came regularly for treatment and follow-up visits were included in the study. The study was conducted retrospectively by accessing patient data through the hospital information management system. In patients receiving GLE/PIB treatment, data regarding the effectiveness and reliability of the treatment were recorded both during the treatment process and after the treatment was terminated.

Results: Of the 44 patients, 47.7% were genotype 1b, 18.2% were genotype 1a, 15.9% were genotype 2, 13.6% were genotype 4, and 4.5% were infected with genotype 3. Early virological response (EVR) was achieved in 81.8% of 44 patients. End-of-treatment response and sustained virological response at the 12th week were achieved in all patients. No treatment failures were observed. There was no significant difference between EVR rates according to genotypes. There was a significant improvement in the liver function tests of the patients from the 4th week of treatment. The most common adverse events were fatigue and itching.

Conclusions: The GLE/PIB combination is an effective and safe treatment option in the treatment of HCV infection. Due to the high EVR rates, more comprehensive studies need to be conducted to keep the duration of GLE/PIB treatment shorter in some patient groups in patients diagnosed with CHC.

Keyword(s) : Effectiveness, glecaprevir, hepatitis c, pibrentasvir, safety

2846 - Prevalence of Sarcopenia in Cirrhotic Patients and Its Association with Prognosis

Sedat Çiçek ¹, Hasan Duyu ², Abdullah Mübin Özeran ¹, Mehmet Yalıniz ¹, Hakan Artaş ³, Ibrahim Halil Bahçecioğlu ¹

Firat University, Gastroenterology, Elazığ-Türkiye ¹ Ergani State Hospital, Internal Medicine, Diyarbakir-Türkiye ² Firat University, Radiology, Elazığ-Türkiye ³

Background / Hypothesis: Sarcopenia is closely associated with quality of life, the development of complications, and mortality in patients with liver cirrhosis, and is considered a systemic reflection of hepatic functional reserve. In this study, we aimed to evaluate the prevalence of radiologically defined sarcopenia in patients with liver cirrhosis and to investigate its associations with cirrhosis stage, sex, body mass index (BMI), presence of ascites, etiology, and metabolic markers (vitamin D, IGF-1). **Materials and Methods:** A total of 90 patients with cirrhosis were included in this retrospective single-center study, comprising 30 patients each with Child-Pugh class A, B, and C disease. Demographic data, body mass index (BMI), presence of ascites, cirrhosis etiology, MELD-Na score, and metabolic markers (vitamin D, IGF-1) were recorded for all patients. Sarcopenia was assessed using the skeletal muscle index (SMI) measured by computed tomography at the level of the third lumbar vertebra (L3) and was coded according to radiological definition as present = 1 and absent = 0. Vitamin D levels were classified as normal (>30 ng/mL), insufficient (20–30 ng/mL), deficient (10–20 ng/mL), and severely deficient (<10 ng/mL). IGF-1 levels were categorized as low or normal.

Statistical analyses were performed using the chi-square test, independent samples t-test, and Pearson correlation analysis, with $p < 0.05$ considered statistically significant.

Results: Sarcopenia was identified in 61.8% of patients (55/90). Its prevalence increased with advancing Child-Pugh stage (46% in Child A, 60% in Child B, and 78% in

E-POSTER ABSTRACTS

Child C; $p = 0.04$). Sarcopenia was significantly more frequent in men (73%; $p = 0.03$). No significant associations were observed between sarcopenia and BMI, MELD-Na score, or presence of ascites ($p > 0.05$).

Vitamin D levels were <30 ng/mL in 92% of patients and were lower in the Child C group; however, the association between vitamin D categories and sarcopenia was borderline significant ($p \approx 0.06$). Although low IGF-1 levels were common, they were not significantly associated with sarcopenia ($p > 0.05$). SMI showed a moderate negative correlation with age ($r = -0.38$; $p = 0.02$), indicating decreased muscle mass with advancing age.

Conclusions: Radiologically assessed sarcopenia demonstrates a high prevalence in patients with cirrhosis and is significantly associated with advanced Child-Pugh stage and male sex. Although vitamin D deficiency and low IGF-1 levels are common, their associations with sarcopenia require confirmation in larger cohorts. These findings suggest that integrating CT-based muscle mass assessment into routine clinical follow-up may facilitate early identification of high-risk patients in the management of

Keyword(s) : Sarcopenia, Liver Cirrhosis, Vitamin D, IGF-1

2847 - influential factors associated with the reduction of peripheral blood neutrophils by PegIFN α and predictive analyses

Jiarui Zheng¹, Bo Feng¹

Peking University Hepatology Institute, Peking University People's Hospital, Beijing-China¹

Background / Hypothesis:

The aim of this study was to understand the effect of PegIFN α on peripheral blood NE, to analyse the relevant influencing factors of moderate to severe NE reduction, and to establish a corresponding prediction model.

Materials and Methods:

Using the data from the Pegabine IIa, IIb and III clinical trials, the clinical data were collected and analysed at baseline and during PegIFN α treatment. All patients were categorised into a moderately severely reduced NE group and a non-moderately severely reduced group according to whether the absolute value of NE decreased to $<0.75 \times 10^9/L$ during treatment.

Results:

A total of 2039 subjects (mean age 34.4 years, 62% male) were included in the clinical trial, 98.4% of patients with The decrease in absolute NE value from baseline appeared in the first 4 weeks of starting treatment, and after the first injection of PegIFN α , 91% showed a decrease in absolute NE value, of which 42.9% showed a decrease of more than 50% from baseline, and then it stabilised at a lower level and gradually returned to the baseline level after discontinuation of the drug.

Throughout the course of treatment, 17.8% of patients experienced moderate-to-severe reductions in absolute NE values ($<0.75 \times 10^9/L$), with a mean time to first moderate-to-severe reduction in NE of 11.0 weeks (standard deviation: 12.2), of which those who experienced moderate-to-severe reductions in NE in the first 12 weeks accounted for 72.9% of all patients with moderate-to-severe reductions in NE.

A prediction model was developed according to the above indicators and age, gender, and patient weight at week 12, with an AUC of 0.89 (cutoff value of 0.283), sensitivity of 0.74, and specificity of 0.88 (Figure 2).

Conclusions:

The vast majority of patients showed an absolute reduction in NE early in PegIFN α treatment, with only a few showing a moderate-to-severe reduction, and the vast majority of the first moderate-to-severe reductions occurred in the first 12 weeks. Baseline low BMI, white blood cell count and absolute NE values, alkaline phosphatase values, the time of occurrence of the lowest NE values, and the decreases in NE at weeks 4 and 12 were associated with the occurrence of moderate-to-severe decreases in NE during the course of treatment, and the prediction model developed on this basis could more accurately identify patients with moderate-to-severe decreases in NE during the course of PegIFN α treatment.

Keyword(s) : PegIFN α , severe NE reduction

2849 - A COMPUTATIONAL INTELLIGENCE APPROACH TO PREOPERATIVE LIVER FUNCTION ASSESSMENT

Mega Dwi Septivani¹

Padang State Polytechnic, Business Administration, Padang-Indonesia¹

E-POSTER ABSTRACTS

Background / Hypothesis:

Assessing liver function is a prerequisite for safe hepatobiliary surgery. This study explores a computational intelligence approach to provide a more precise preoperative evaluation.

Materials and Methods:

In this study, artificial intelligence methods were used to assess liver function. A Random Forest algorithm was applied to a clinical dataset of biochemical markers sourced from a liver patient dataset. The model evaluated the diagnostic significance of various liver enzymes to establish a predictive framework.

Results:

The computational model demonstrated exceptional performance in risk assessment, yielding a predictive accuracy of 98.8% and an AUC-ROC of 0.9975. Beyond global metrics, the Random Forest feature importance analysis revealed that SGPT (Alanine Aminotransferase) and Total Bilirubin were the most statistically significant markers, accounting for the highest computational weight in determining pathological status. The model also showed a high F1-score of 0.99, indicating a balanced precision-recall trade-off that is crucial for minimizing false negatives in preoperative settings

Conclusions:

A computational intelligence approach significantly enhances the reliability of preoperative liver function assessment. This technology offers a data-driven tool for clinicians to optimize surgical risk management.

Keyword(s) :

2850 - Comparative efficacy of ursodeoxycholic acid and s adenosyl methionine in reducing transaminases in patients with non alcoholic steatohepatitis a retrospective prospective cohort study

Candra Carmelli Lavallo¹, Hashamiiya Palma¹, Kristine Joyce Cruz¹

Capitol Medical Center, Gastroenterology, Mandaluyong-Philippines¹

Background / Hypothesis:Non-alcoholic steatohepatitis (NASH) is a progressive form of fatty liver disease associated with hepatic inflammation and fibrosis, for which standardized pharmacologic therapies remain limited. Ursodeoxycholic acid and s-adenosyl methionine have demonstrated hepatoprotective effects in non-alcoholic steatohepatitis. This study

compared the efficacy of these agents in reducing serum transaminases among patients with non-alcoholic steatohepatitis.

Materials and Methods: This retrospective-prospective cohort study included adult patients with clinically suspected non-alcoholic steatohepatitis managed at a tertiary care center. Patients received either ursodeoxycholic acid for three month or s-adenosyl methionine for one month. Serum alanine aminotransferase, aspartate aminotransferase, platelet count, and fibrosis-4 index were measured at baseline and after treatment. Descriptive statistics were used to summarize baseline characteristics. Between-group comparisons were performed using independent t-tests or Mann-Whitney U tests, while within-group changes were assessed using Wilcoxon signed-rank tests. A two-tailed p value <0.05 was considered statistically significant.

Results: A total of 120 patients were included, with 64 receiving ursodeoxycholic acid and 56 receiving s-adenosyl methionine. Baseline demographic characteristics and comorbidities were comparable between groups. Baseline alanine aminotransferase and aspartate aminotransferase levels were higher in the s-adenosyl methionine group. After therapy, both treatment groups demonstrated significant reductions in alanine aminotransferase and aspartate aminotransferase compared with baseline (all p<0.001). Post-treatment alanine aminotransferase levels were significantly lower in the ursodeoxycholic acid group compared with the s-adenosyl methionine group (p=0.019), while post-treatment aspartate aminotransferase levels showed a similar trend without reaching statistical significance. Fibrosis-4 index decreased significantly from baseline in both groups, with no significant difference between treatments.

Conclusions:Both ursodeoxycholic acid and s-adenosyl methionine were associated with significant improvement in serum transaminases and fibrosis surrogate markers in patients with non-alcoholic steatohepatitis. While both agents demonstrated biochemical efficacy, ursodeoxycholic acid was associated with lower post-treatment alanine aminotransferase levels. These findings support the use

E-POSTER ABSTRACTS

of either therapy in clinical practice, with further studies needed to evaluate long-term outcomes.

Keyword(s) : Non-alcoholic steatohepatitis, fatty liver disease, transaminases, ursodeoxycholic acid, s-adenosyl methionine, FIB-4

2852 - Homocysteine is a promising biomarker for predicting acute kidney injury in patients with cirrhosis

Min Zheng¹, Jie Wu¹, Luyan Zheng¹, Baode Chen², Chen Li¹, Shuwen Li¹, Yu Zhang¹

The First Affiliated Hospital, College Of Medicine, Zhejiang University, State Key Laboratory For Diagnosis And Treatment Of Infectious Diseases, Hangzhou-China¹ The First Affiliated Hospital, College Of Medicine, Zhejiang University, Department Of Laboratory Medicine, Hangzhou-China²

Background / Hypothesis:

Acute kidney injury (AKI) occurs very commonly in cirrhotic patients and is associated with poor prognosis. Early identification of AKI is an unmet clinical need. Homocysteine (Hcy) is a classic biomarker for vascular dysfunction, which plays a key role in the pathophysiology of AKI in cirrhosis. Herein, we aimed to assess the predictive value of serum Hcy for AKI in cirrhotic patients.

Materials and Methods:

A prospective series of 463 hospitalized cirrhotic patients was included. Serum samples were collected at admission, and Hcy was measured. The presence of AKI during hospitalization was carefully assessed. Multivariate regression and propensity score matching (PSM) were conducted to examine the association between Hcy and AKI. ROC analysis was then employed to assess the predictive value of Hcy for AKI. Integrated discrimination improvement (IDI) was calculated to assess the impact on published AKI prediction models with the addition of Hcy. Biomarkers of renal dysfunction, such as neutrophil gelatinase-associated lipocalin, kidney injury molecule-1, and liver fatty acid binding protein, were also measured for comparison.

Results:

During hospitalization, 35 cirrhotic patients developed AKI. PSM and multivariate analyses showed that among four biomarkers, only serum Hcy was significantly associated with AKI (OR=1.165, 95% CI: 1.035-1.337). Moreover, serum Hcy could be used to predict the development of AKI in cirrhosis, with an AUC of 0.768 (95% CI: 0.686-0.850). Incorporating Hcy

into existing AKI models substantially enhanced their predictive efficacy in patients with cirrhosis, with the IDI values ranging from 0.072 to 0.106.

Conclusions:

The application of serum Hcy may help to identify cirrhotic patients at risk for developing AKI at an early stage. Exploration of the new role for some old biomarkers may be a cost-effective way for the prediction of AKI.

2853 - Metabolic Dysfunction Associated Fatty Liver Disease Signalling and Organ Dialogue within the Systemic Metabolic Network

Ziwei Yuan¹, Yaqian Mao¹, Yuanbin Zhong¹

The First Affiliated Hospital Of Nanchang University, Infectious Diseases Department, Nanchang-China¹

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) is a multisystem disorder driven primarily by metabolic dysfunction, involving coordinated dysregulation across the liver, adipose tissue, skeletal muscle, gut, and cardiovascular systems. The disease progresses dynamically from steatosis to cirrhosis and hepatocellular carcinoma. The prevailing 'multiple hit' hypothesis fails to explain the stable transmission of cross-organ pathological signals and their cell-specific targeting. Exosomes, as lipid bilayer vesicles measuring 30–150 nm in diameter, possess structural stability, organ-targeting capacity, and information complexity by carrying active molecules such as proteins and nucleic acids. This renders them a pivotal link connecting the multi-organ pathological networks of MAFLD. Research indicates markedly elevated liver-specific miRNAs in circulating exosomes from MAFLD patients, whilst hepatogenic exosomes induce myocardial insulin resistance and renal podocyte apoptosis. Given the multi-organ collaborative nature of MAFLD imposing stringent demands on signal transmission, systematic investigation of exosomal mechanisms is not only theoretically imperative but also provides a critical breakthrough for developing novel therapeutic strategies targeting inter-organ communication.

Materials and Methods:None

2854 - Nanotherapy based on Mesenchymal stem cell derived extracellular vesicles target ADAM17 mediated TREM2 shedding on macrophages to promote efferocytosis for acute liver failure treatment

Shouhan Yao¹, Yelei Cen¹, Guohua Lou¹, Min Zheng¹, Yanning Liu¹

The First Affiliated Hospital, Zhejiang University, Department Of Infectious Diseases, Hangzhou-China¹

Background / Hypothesis :

Acute liver failure (ALF) is a life-threatening condition with high mortality and limited therapeutic options. Impaired macrophage efferocytosis contributes to unresolved inflammation and liver injury during ALF. Mesenchymal stem cell-derived extracellular vesicles (MSC-EVs) represent a promising cell-free therapy, but their mechanisms remain unclear. We hypothesized that adipose-derived MSC-EVs (AMSC-EVs) alleviate ALF by restoring macrophage efferocytosis through regulation of TREM2 signaling.

Materials and Methods:

ALF was induced in mice using lipopolysaccharide/D-galactosamine (LPS/D-GalN). Liver injury, inflammatory responses, and macrophage efferocytosis were evaluated following AMSC-EV treatment. TREM2 knockout macrophages and myeloid-specific TREM2-deficient mice were used to determine TREM2 dependency. Mechanistic studies assessed TREM2 expression, ADAM17 activity, and NF- κ B (p65)-mediated transcriptional regulation.

Results:

AMSC-EVs significantly attenuated liver injury and promoted inflammatory resolution in ALF. Treatment restored macrophage efferocytosis and prevented the loss of full-length TREM2 in liver tissue and on macrophage membranes after inflammatory stimulation. These protective effects were abolished in TREM2-deficient macrophages and mice, demonstrating a TREM2-dependent mechanism. Mechanistically, AMSC-EVs suppressed ADAM17-mediated TREM2 cleavage by inhibiting p65-dependent ADAM17 transcription, leading to enhanced efferocytosis and increased production of anti-inflammatory and pro-resolving cytokines.

Conclusions:

AMSC-EVs ameliorate ALF by restoring macrophage efferocytosis. This study elucidates the mechanism of AMSC-EVs in targeting macrophage dysfunction in ALF through inhibition of p65-dependent ADAM17 transcription and subsequent suppression of ADAM17-mediated TREM2 shedding, highlighting AMSC-EVs as a potential nanotherapeutic strategy for ALF.

2855 - Construction of an Intelligent Early Warning System for Chronic Liver Disease Comorbidities Based on Multimodal Data Fusion and Traditional Chinese Medicine Constitution

Yajie Liu¹, Zhang Xi¹, Yifan Xia¹, Lingru Li¹

Beijing University Of Traditional Chinese Medicine, National Institute Of Traditional Chinese Medicine Body Types And Preventive Medicine, Bei Jing-China¹

Background / Hypothesis: Chronic liver disease (CLD) has a high global prevalence and frequently coexists with metabolic disorders, making early prevention and control challenging. Traditional Chinese Medicine (TCM) constitution theory posits that individual constitutional differences determine disease susceptibility. We hypothesize that integrating TCM constitution identification with modern multimodal data to establish a "liver-gut homeostasis" assessment system may provide a novel strategy for early warning and stratified intervention in CLD comorbidities.

Materials and Methods: Drawing upon TCM theory and contemporary advances in hepatology, microecology, and systems biology, we propose a risk prevention and control framework for chronic liver disease based on multimodal data fusion. This framework incorporates artificial intelligence techniques to integrate heterogeneous data sources and construct a comprehensive risk evaluation model.

Results: We propose an integrative prevention and control paradigm centered on "liver-gut homeostasis," combining Eastern and Western medical perspectives. A multimodal risk stratification model was developed using tongue and pulse characteristics, imaging data, microbiome profiles, and metabolomics signatures. Dynamic network biomarker analysis was applied to identify pathological transition windows, such as the

E-POSTER ABSTRACTS

acceleration phase of liver fibrosis. This approach establishes a closed-loop pathway of “constitution identification – risk prediction – window-based intervention – outcome feedback.”

Conclusions: The integration of TCM constitution theory with multimodal data provides both a conceptual framework and a technical pathway for the “pre-disease prevention” of chronic liver disease comorbidities. Future efforts should focus on developing intelligent early-warning systems and stratified intervention strategies, thereby transforming liver disease management from single-disease treatment toward personalized and precision health management.

Keyword(s) :

2856 - Association of Pre transplant Abstinence Duration

Qun Zhang¹, Jinzhen Cai², Wei Rao¹

The Affiliated Hospital Of Qingdao University, Department Of Hepatology, Qingdao-China¹ The Affiliated Hospital Of Qingdao University, Organ Transplantation Center, Qingdao-China²

Background / Hypothesis:

This study aimed to evaluate the post-transplant patient survival, graft survival, and alcohol relapse rates in recipients with alcohol-related liver disease (ALD) who underwent early liver transplantation (LT) with pre-transplant abstinence <6 months. Furthermore, we sought to investigate the correlation between the duration of pre-transplant alcohol abstinence and post-transplant prognosis.

Materials and Methods:

A single-center retrospective cohort study was performed. A total of 104 consecutive adult patients diagnosed with ALD who underwent primary LT at the Affiliated Hospital of Qingdao University from July 2016 to December 2024 were enrolled. The cohort was stratified into two groups based on pre-transplant abstinence duration: the early liver transplantation (ELT) group (abstinence <6 months, n=41) and the standard liver transplantation (SLT) group (abstinence ≥6 months, n=63). Survival curves were constructed using the Kaplan–Meier method and compared via the log-rank test. A propensity score-based inverse probability of treatment weighting (IPTW) adjusted

Cox proportional hazards regression model was applied to assess the independent impact of short abstinence duration on the risks of post-transplant mortality and graft failure.

Results:

The study cohort comprised 103 males and 1 female, with a median age of 52 years (range: 31–70 years) at transplantation. The median follow-up period was 605 days (interquartile range: 263–1378 days). The 1-, 5-, and 8-year cumulative patient survival rates were 97.6%, 95.1%, and 95.1% in the ELT group, compared with 93.7%, 93.7%, and 93.7% in the SLT group, respectively (log-rank P=0.730). After IPTW adjustment, pre-transplant abstinence <6 months was not associated with an increased risk of mortality (hazard ratio [HR]=0.46, 95% confidence interval [CI]: 0.08–2.62, P=0.380) or graft failure (HR=0.96, 95%CI: 0.20–4.61, P=0.961). Overall, 14.4% (15/104) of patients experienced post-transplant alcohol relapse, predominantly mild relapse. No significant intergroup difference was observed in the incidence of alcohol relapse (P=0.892).

Conclusions:

In adult LT recipients with ALD, a pre-transplant abstinence duration of less than 6 months is not a significant independent predictor of patient mortality or graft failure. Additionally, it does not significantly elevate the risk of post-transplant alcohol relapse.

Keyword(s) : Alcohol-Related Liver Disease ; Liver Transplantation ; Abstinence Duration; Prognosis ; Alcohol Relapse

2857 - Integration of Disease Susceptibility State Theory and Multimodal Artificial Intelligence A Novel Paradigm for Early Warning of Chronic Liver Disease

Yajie Liu¹, Zhang Xi¹, Yifan Xia¹, Lingru Li¹

Beijing University Of Traditional Chinese Medicine, National Institute Of Traditional Chinese Medicine Body Types And Preventive Medicine, Bei Jing-China¹

Background / Hypothesis: The Traditional Chinese Medicine (TCM) theory of “treating disease before its onset” proposes that diseases undergo a latent, preclinical stage known as the “pre-disease” (Wei Bing) state, characterized by increased susceptibility but absence of overt clinical manifestations. Chronic liver diseases (CLDs), including metabolic dysfunction–

E-POSTER ABSTRACTS

associated steatotic liver disease (MASLD), cirrhosis, and hepatocellular carcinoma, typically develop insidiously and are difficult to detect at an early stage. We hypothesize that the TCM-defined “pre-disease” state in liver disorders has a specific biological basis. Elucidating its underlying “disease susceptibility state theory” may provide novel insights for early warning and precision prevention of CLD.

Materials and Methods: An interdisciplinary literature synthesis was conducted across modern hepatology, systems biology, microecology, and artificial intelligence. Based on this integration, we constructed a multidimensional knowledge framework that links the TCM “pre-disease” theory to liver pathophysiology and AI-driven early-warning models.

Results: The TCM “pre-disease” state in liver disorders corresponds to a dynamic and multidimensional phase of heightened disease susceptibility. Its biological underpinnings include redox imbalance and lipid peroxidation, disruption of the gut microbiota, and dysfunction of the gut–liver axis. Dynamic network biomarkers can identify critical pathological transition windows, such as the pre-decompensation stage of cirrhosis. Furthermore, multimodal deep learning models integrating tongue and pulse features, imaging data, and metabolomic profiles enable individualized risk prediction for chronic liver disease.

Conclusions: The disease susceptibility state theory establishes a novel paradigm for precision prevention of chronic liver disease. Future research should focus on developing dynamic monitoring networks that integrate macroscopic TCM phenotypic features with multi-omics molecular data, as well as artificial intelligence–driven early warning and intervention decision systems. Such advances may shift liver disease management from reactive treatment toward proactive prevention at the pre-disease stage.

2858 - Compound Kushen Injection inhibits the formation of malignant ascites by modulating metabolites in malignant hepatocellular carcinoma ascites and influencing immune cells.

Hao Liu¹, Zhuo Yu¹

Shuguang Hospital Affiliated To Shanghai University Of Traditional Chinese Medicine, Hepatology Department, Shanghai-China¹

Background / Hypothesis:

Malignant ascites in advanced hepatocellular carcinoma lacks effective treatments. Compound Kushen Injection, a safe traditional Chinese medicine, may inhibit ascites by regulating phosphatidylcholine metabolism and immune function. This study investigates its mechanism in a mouse model to support clinical application.

Materials and Methods:

This study established a Balb/c mouse model of malignant hepatocellular carcinoma ascites. Mice were divided into model and CKI low- (50μL), medium- (100μL), and high-dose (150μL) groups, treated for 15 days. In vivo imaging on days 3,7,11,15 tracked ascites and tumors. LC-MS analyzed metabolites; H&E staining assessed peritoneal invasion. Immunohistochemistry and flow cytometry evaluated T cells, macrophages, and NK cells.

Results:

Compared with the model group, medium/high-dose CKI reduced ascites (11.6%/19.9%) and prolonged survival (22.5%/37.8%). Metabolomics revealed downregulated CHKa and choline phosphotransferase in COP-choline pathways. H&E staining showed reduced peritoneal hyperplasia, fibrosis, and immune infiltration. VEGF expression decreased. Flow cytometry indicated increased CD8+ T cells and an elevated M1/M2 macrophage ratio.

Conclusions:

Compound Kushen Injection reduces malignant ascites in HCC mice by modulating choline metabolism and enhancing immunity, supporting its therapeutic potential and future clinical application.

Keyword(s) : hepatocellular carcinoma malignant ascites, Compound Kushen Injection, immune cells, phosphatidylcholine

2861 - Diagnosis of acute hepatitis C

Arif Mansur Coşar¹, Sami Fidan², Murat Erkut²

E-POSTER ABSTRACTS

Ktu, Gastroenterology, Trabzon-Türkiye ¹

Gastroenterology, Gastroenterology, Trabzon-Türkiye ²

Background / Hypothesis:

Diagnosing acute hepatitis C is difficult in daily practice because there is no specific serological marker. We present a case of a patient who presented with elevated liver enzymes and jaundice and an acute HCV infection diagnosed.

Materials and Methods:

Case

A 42-year-old male patient, who underwent surgery in 2017 for a cholecystectomy and in 2023 for a meningioma and who has been using levetiracetam, presented with elevated liver enzymes and jaundice. Laboratory tests performed at the time of the admission to determine the etiology of the acute hepatitis showed negative results for viral hepatitis (anti-HAV IgG, HBs, anti-HBs, anti-HBc IgG, anti-HCV). Autoimmune hepatitis markers were weakly positive for ANA and negative for the others (SMA, SLA/LP, LKM-1, LC1, AMA, AMA M2, ASMA, LKM). The ceruloplasmin level was 0.26 g/L. Abdominal imaging was negative for acute hepatitis etiology. Although levetiracetam is generally considered to have a low risk of hepatotoxicity because it undergoes minimal metabolism in the liver compared to many other antiepileptic drugs, cases of drug-induced liver injury (DILI) and even acute liver failure have been documented. Given all these findings, we admitted the patient suspecting DILI, monitored them under supportive care, and initiated pregabalin therapy in consultation with neurology instead of levetiracetam. Although the patient's clinical course remained stable during follow-up, no significant improvement was observed in liver function tests. Therefore, diagnoses other than DILI were reevaluated, and acute viral hepatitis markers were requested again. Surprisingly, the anti-HCV test was reported as positive in this case. The patient, who has been monitored since 2017 and whose anti-HCV results were negative in the system, also had no suspicious contact history in his history. However, the patient who tested positive for HCV RNA was diagnosed with acute hepatitis C, and treatment was initiated with a combination of 100 mg glecaprevir and 40 mg pibrentasvir (Table).

Conclusions:

Anti-HCV antibodies typically become positive 6–12 weeks after infection; therefore, tests performed during the acute phase may be negative. In this case, a preliminary diagnosis of toxic hepatitis was made due to the initial negativity of anti-HCV and other diagnostic tests, but the diagnosis of acute hepatitis C

was confirmed by positivity in repeated serology tests and HCV RNA. As in this case, it would be beneficial to keep in mind that viral markers that are negative in the early stages should be rechecked, especially in cases where another definitive diagnosis cannot be

Keyword(s) : Acute hepatitis C

2862 - Based Prediction of Metabolic Dysfunction Associated Fatty Liver Disease A Meta Analysis of Algorithmic Performance

Yao Yunlong ¹, Zhang Xi ¹, Huang Shuo ¹, Li Lingru ², Zheng Yanfei ²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China ¹ Beijing University Of Chinese Medicine, National Institute Of Traditional Chinese Medicine Constitution And Preventive Medicine, Beijing-China ²

YAO YUNLONG¹, ZHANG Xi¹, HUANG Shuo¹, LI Lingru, ZHENG Yanfei

1School of Traditional Chinese Medicine, Beijing University of Chinese Medicine, Beijing, China

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) is a leading cause of chronic liver disease globally. Increasing availability of large-scale clinical and metabolic datasets has facilitated the development of machine learning models for early detection and risk stratification. However, reported predictive performance varies across studies. This meta-analysis evaluates algorithmic approaches for MAFLD classification and prediction

Materials and Methods:

A systematic search of PubMed, Embase, and Web of Science (2014–2025) identified studies applying ML or deep learning algorithms for MAFLD detection without experimental intervention. Extracted data included model type, dataset characteristics, feature categories, and AUC values. A random-effects meta-analysis was performed to calculate pooled diagnostic performance. Subgroup analyses compared traditional regression, tree-based ensemble models, and deep learning approaches.

Results:

Twenty-eight studies met inclusion criteria. The pooled AUC for ML-based MAFLD prediction was 0.87 (95% CI: 0.84–0.90). Tree-based ensemble models demonstrated

E-POSTER ABSTRACTS

slightly higher pooled performance (AUC 0.89) compared to logistic regression (AUC 0.81). Deep learning approaches showed high accuracy in imaging-based datasets but greater heterogeneity. Feature engineering and dataset size significantly influenced performance stability

Conclusions:

Machine learning algorithms demonstrate robust predictive capability for MAFLD detection, with ensemble and deep learning models outperforming conventional statistical methods. Standardized validation frameworks and transparent reporting are necessary to enhance reproducibility and facilitate broader implementation.

YAO YUNLONG¹, ZHANG Xi¹, HUANG Shuo¹, LI Lingru, ZHENG Yanfei

¹School of Traditional Chinese Medicine, Beijing University of Chinese Medicine, Beijing, China

Background / Hypothesis:

AI-based imaging analytics has become a transformative tool in hepatology. Automated interpretation of ultrasound, CT, and MRI reduces observer variability and improves early detection of liver pathology.

Materials and Methods:

A systematic review of studies (2015–2025) was conducted in PubMed and IEEE Xplore. Included studies evaluated deep learning or machine learning models for liver lesion classification or fibrosis staging. Performance indicators such as AUC, accuracy, and sensitivity were extracted and compared.

Results:

Convolutional neural networks (CNNs) demonstrated

pooled AUC values above 0.90 in differentiating benign and malignant lesions. Ensemble approaches improved robustness across imaging modalities. However, external validation datasets were limited, and model interpretability remained insufficient.

Conclusions:

AI-driven imaging systems show strong diagnostic performance in hepatology. Standardized multicenter datasets and explainable AI frameworks are required to enhance clinical reliability

Keyword(s) : Artificial Intelligence; Deep Learning; Liver Imaging; CNN; Diagnostic Accuracy

2864 - Natural Language Processing for Hepatology Knowledge Mining A Review of Algorithmic Advances

Yao Yunlong¹, Zhang Xi¹, Huang Shuo¹, Li Lingru², Zheng Yanfei²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Beijing University Of Chinese Medicine, National Institute Of Traditional Chinese Medicine Constitution And Preventive Medicine, Beijing-China²

Background / Hypothesis:

The rapid growth of hepatology literature necessitates automated knowledge extraction systems. NLP and transformer-based models offer scalable solutions for text classification and semantic analysis.

Materials and Methods:

Peer-reviewed studies (2016–2025) applying NLP in liver disease research were analyzed. Methods included BERT-based classification, topic modeling, and knowledge graph construction. Evaluation metrics included F1-score and precision

Results:

Transformer architectures consistently outperformed traditional ML models in text classification tasks (F1 >0.88). Knowledge graph approaches improved semantic retrieval and cross-disciplinary mapping. Limitations included domain-specific vocabulary challenges

Conclusions:

NLP technologies significantly enhance knowledge

E-POSTER ABSTRACTS

synthesis in hepatology. Future research should emphasize multilingual corpora and domain-adapted pretrained models.

Keyword(s) : Natural Language Processing; Large Language Models; Text Mining; Hepatology; Knowledge Graph

2865 - Machine Learning Models for Autoimmune Liver Disease Classification A Meta Analysis

Yao Yunlong¹, Zhang Xi¹, Huang Shuo¹, Li Lingru², Zheng Yanfei²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Beijing University Of Chinese Medicine, National Institute Of Traditional Chinese Medicine Constitution And Preventive Medicine, Beijing-China²

Background / Hypothesis:

Immune-mediated chronic liver diseases, including autoimmune hepatitis (AIH) and overlap syndromes, present diagnostic complexity due to heterogeneous serological and biochemical features. Increasingly, machine learning (ML) algorithms have been developed to improve classification accuracy and reduce reliance on subjective scoring systems. However, reported model performance varies substantially across studies. This meta-analysis aims to systematically evaluate algorithmic performance in AIH classification and risk prediction.

Materials and Methods:

A systematic literature search (2013–2025) was conducted in PubMed, Web of Science, and Embase. Studies were included if they developed ML-based classification or prediction models for immune-mediated liver diseases without interventional design. Extracted data included model type, feature categories (autoantibodies, laboratory indices, demographic data), validation methods, and AUC values. A random-effects meta-analysis was applied to calculate pooled diagnostic performance. Subgroup analyses compared logistic regression, support vector machines, and ensemble tree-based methods.

Results:

Twenty-four studies met inclusion criteria. The pooled AUC across ML models was 0.86 (95% CI: 0.83–0.89). Ensemble algorithms demonstrated superior stability (AUC 0.89) compared to traditional regression models (AUC 0.81). Feature selection techniques significantly influenced performance heterogeneity ($P = 0.048$).

Models integrating serological and biochemical features outperformed single-modality datasets.

Conclusions:

Machine learning algorithms provide robust classification performance in immune-mediated chronic liver diseases. Standardized feature engineering and transparent reporting are essential to enhance reproducibility and cross-population applicability.

Keyword(s) :

2866 - Computational Network Modeling in Immune Mediated Liver Diseases A Systematic Review

Yao Yunlong¹, Zhang Xi¹, Huang Shuo¹, Li Lingru², Zheng Yanfei²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China¹ Beijing University Of Chinese Medicine, National Institute Of Traditional Chinese Medicine Constitution And Preventive Medicine, Beijing-China²

Background / Hypothesis:

Immune-mediated liver diseases involve complex inflammatory and signaling cascades that are difficult to interpret using linear analytical methods. Computational network modeling has emerged as a powerful approach to identify key regulatory hubs and pathway interactions. This review summarizes algorithm-driven network analyses in immune-mediated liver disorders.

Materials and Methods:

A structured review of studies (2012–2025) applying protein-protein interaction networks, pathway enrichment analysis, graph theory metrics, and multi-omics integration was performed. Data sources included PubMed and Scopus. Analytical approaches were categorized into topological network analysis, modular clustering, and integrative multi-layer networks. Performance was assessed based on pathway enrichment consistency and hub gene reproducibility.

Results:

Network centrality analyses consistently identified inflammatory hubs such as TNF signaling, IL-6 pathways, and JAK-STAT cascades. Multi-omics

E-POSTER ABSTRACTS

integration improved detection of cross-pathway interactions compared to single-layer transcriptomic models. Graph-based clustering revealed immune-regulatory modules linked to fibrosis progression. However, reproducibility was influenced by dataset heterogeneity.

Conclusions:

Computational network modeling enhances mechanistic interpretation of immune-mediated liver diseases and supports biomarker prioritization. Future research should emphasize standardized data preprocessing and dynamic network modeling approaches.

Keyword(s) : Network Analysis; Systems Biology; Autoimmune Liver Disease; Bioinformatics; Multi-omics Integration

2867 - Superior Survival with Direct Surgery Over TACE Based Strategies in Hemodynamically Stable Patients with Spontaneously Ruptured HCC A Multicenter Propensity Score Matched Cohort Study

Zhengjian Wang¹, Hong Chang¹

Shandong Provincial Hospital Affiliated To Shandong First Medical University, Hepatobiliary Surgery, 济南 - China¹

Background / Hypothesis:

Spontaneously ruptured hepatocellular carcinoma (srHCC) is a life-threatening emergency. For hemodynamically stable patients with early-stage (BCLC A) disease, whether to proceed with direct surgical resection or initial transarterial chemoembolization (TACE) remains a critical, evidence-scarce clinical dilemma.

Materials and Methods:

In this multicenter, retrospective cohort study of 244 patients (189 after propensity score matching), patients treated with direct surgery had significantly better overall and recurrence-free survival than those whose treatment began with TACE (with or without subsequent surgery).

Results:

After 1:1:1 propensity score matching (n=189), the direct surgery group had significantly improved OS and RFS compared to both the TACE-plus-surgery group (OS: $P < 0.001$; RFS: $P = 0.007$) and the TACE-alone group (both $P < 0.001$). Initial treatment strategy was the strongest independent prognostic factor. A clinical prediction model incorporating treatment

modality and postoperative markers showed robust accuracy for recurrence (area under the curve: 0.85 in training, 0.79 in validation). Translational analyses suggested that TACE-associated hypoxia may promote a pro-recurrence tumor microenvironment, potentially through upregulation of the PLAUR gene.

Conclusions: In this study, direct surgical resection was associated with significantly better long-term survival than strategies beginning with TACE for patients with BCLC A srHCC. These findings suggest that upfront TACE should not be routine for this specific patient population and support prioritizing direct surgery when feasible.

Keyword(s) : Spontaneously ruptured hepatocellular carcinoma; Transarterial chemoembolization; HIF-1 α ; PLAUR; M2 macrophage polarization; Tumor recurrence.

2868 - High prevalence of coronary atherosclerosis in HBV related hepatocellular carcinoma and liver cirrhosis a cross sectional study

Rui Wang¹, Feng Liu¹, Ruihang Wang², Yupei Liu¹, Yanhong Ma¹

The Second Affiliated People's Hospital Of Tianjin Medical University, Department Of Hepatology, Tianjin-China¹ The Second Affiliated People's Hospital Of Tianjin Medical University, Department Of Radiology, Tianjin-China²

Background / Hypothesis:

Chronic liver disease (CLD) is increasingly linked to cardiovascular mortality. However, coronary artery disease (CAD) risk stratification across the CLD spectrum—specifically chronic hepatitis B (CHB), liver cirrhosis (LC), and hepatocellular carcinoma (HCC)—remains inadequately defined. Coronary artery calcification (CAC), measured by Agatston score (CACS), is a robust predictor of CAD. This study aimed to compare CAC prevalence and burden across CHB, LC, and HCC cohorts to evaluate CAD risk stratification, with particular emphasis on the HCC population.

Materials and Methods:

1,244 consecutive HBV-related CLD patients were retrospectively enrolled and stratified: CHB (n=575), LC (n=543), and HCC (n=126). Baseline clinical and laboratory data were collected. All participants underwent coronary computed tomography angiography for CAC assessment. Primary outcomes included CAC prevalence, mean CACS, severity grades,

E-POSTER ABSTRACTS

and major vessel involvement. CAD risk was stratified by CACS (0, 1-99, 100-400, >400). Statistical comparisons utilized Kruskal-Wallis and Chi-square tests.

Results:

CAC prevalence increased progressively: 32.9% (CHB), 47.3% (LC), and 61.9% (HCC). Moderate-to-severe risk (CACS>100) was significantly higher in HCC (19.0%) versus LC (10.5%) and CHB (4.7%) ($p<0.001$). HCC patients showed the highest multi-vessel involvement (≥ 2 arteries: 39.7% vs. 20.5% LC vs. 15.1% CHB), particularly in LAD (54.0%) and RCA (39.7%) ($p<0.001$). Additionally, HCC patients exhibited severe liver, hematological, and metabolic derangements, synergistic risk factors for atherosclerosis.

Conclusions: Patients with HCC exhibit substantially elevated CAD risk compared to LC or CHB, evidenced by higher CAC prevalence, burden, and multi-vessel involvement. These findings highlight a critical need to prioritize cardiovascular assessment in HCC management. The confluence of systemic inflammation and metabolic dysfunction in HCC likely accelerates atherosclerosis. We advocate for routine CAC screening in HCC patients and suggest LC and HCC status be considered significant modifiers in CAD risk stratification.

Keyword(s) : hepatocellular carcinoma; coronary atherosclerosis; Coronary artery calcification (CAC); liver cirrhosis; Agatston score (CACS)

2869 - Hepatitis B Reactivation During Leflunomide Therapy The Importance of Pre Immunosuppression Screening

Kübra Yildirim¹

Department Of Infectious Diseases And Clinical Microbiology, Trabzon Kanuni Training And Research Hospital, Türkiye, Department Of Infectious Diseases And Clinical Microbiology, Trabzon-Türkiye¹

Background / Hypothesis: Hepatitis B virus (HBV) reactivation is a well-recognized complication of immunosuppressive therapy and may occur even in patients considered inactive carriers. While high-risk biologic agents are clearly defined, the reactivation risk associated with certain disease-modifying antirheumatic drugs, such as leflunomide, is less clearly established. In clinical practice, inactive HBV carriers are sometimes perceived as low risk, which may lead to insufficient viral assessment before immunosuppressive

therapy. We present a case of significant HBV reactivation following leflunomide therapy, underscoring the importance of appropriate viral screening and multidisciplinary evaluation prior to treatment initiation.

Materials and Methods: A retrospective review of clinical, laboratory, and treatment data of a patient with chronic hepatitis B was performed. Viral markers, HBV DNA levels, liver function tests, and immunosuppressive treatment history were evaluated.

Results: A 50-year-old female with chronic hepatitis B, classified as Phase 3 (HBeAg-negative chronic infection), was under routine follow-up. She was HBsAg positive and anti-HBe positive, with previously low HBV DNA levels ($<2,000$ IU/mL). She presented to rheumatology with persistent joint pain. Autoimmune serologic markers, including RF, ANA, and ENA, were negative. Despite negative serology, leflunomide 20 mg/day was initiated due to clinical arthritis.

After two months of therapy, routine laboratory tests revealed elevated liver enzymes (ALT 170–180 U/L) without accompanying hepatic symptoms. The patient was referred to our clinic for further evaluation. Repeat testing demonstrated a marked increase in HBV DNA to 20,000,000 IU/mL, consistent with HBV reactivation.

Leflunomide was discontinued, and tenofovir disoproxil fumarate was initiated. At one-month follow-up, liver enzymes normalized and viral load decreased, accompanied by significant improvement in joint symptoms.

Conclusions: HBV reactivation may occur in inactive carriers receiving leflunomide. Careful viral screening and multidisciplinary evaluation are essential before immunosuppressive therapy.

Keyword(s) : Hepatitis B; HBV reactivation; leflunomide; immunosuppressive therapy; antiviral prophylaxis

2870 - Risk Stratification of Liver Fibrosis Progression Using Machine Learning A Meta Analytical Evaluation

Yao Yunlong¹, Zhang Xi¹, Huang Shuo¹, Li Lingru²,

E-POSTER ABSTRACTS

Zheng Yanfei ²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China ¹ Beijing University Of Chinese Medicine, National Institute Of Traditional Chinese Medicine Constitution And Preventive Medicine, Beijing-China ²

YAO YUNLONG¹, ZHANG Xi¹, HUANG Shuo¹, LI Lingru, ZHENG Yanfei

¹School of Traditional Chinese Medicine, Beijing University of Chinese Medicine, Beijing, China

Background / Hypothesis:

Progression from fibrosis to cirrhosis remains a major determinant of liver-related morbidity. Machine learning models have been developed to predict fibrosis stages using non-invasive datasets.

Nevertheless, performance heterogeneity across studies limits standardization. This meta-analysis evaluates algorithm-based fibrosis prediction models.

Materials and Methods:

A systematic search (2014–2025) identified studies developing ML models for fibrosis staging or progression prediction without experimental intervention. Extracted metrics included AUC, sensitivity, specificity, dataset size, and model type. A random-effects model calculated pooled AUC values. Subgroup analyses compared gradient boosting, neural networks, and conventional regression.

Results:

Thirty studies were included. The pooled AUC for ML-based fibrosis prediction was 0.88 (95% CI: 0.85–0.91). Gradient boosting methods demonstrated the highest pooled performance (AUC 0.90). Neural networks showed high accuracy but greater heterogeneity. Dataset size and feature diversity significantly influenced model stability.

Conclusions:

Machine learning algorithms provide strong predictive capability for fibrosis progression and may complement traditional non-invasive scoring systems. Future work should prioritize external validation and standardized evaluation protocols.

Keyword(s) : Liver Fibrosis; Cirrhosis; Machine Learning; Risk Stratification; Meta-analysis

2872 - Bibliometric and Topic Modeling Analysis of Global Research Trends in Liver Fibrogenesis

Yao Yunlong ¹, Zhang Xi ¹, Huang Shuo ¹, Li Lingru ², Zheng Yanfei ²

Beijing University Of Chinese Medicine, School Of Traditional Chinese Medicine, Beijing-China ¹ Beijing University Of Chinese Medicine, National Institute Of Traditional Chinese Medicine Constitution And Preventive Medicine, Beijing-China ²

Background / Hypothesis:

The volume of research on liver fibrogenesis has grown substantially, necessitating systematic mapping of thematic evolution. Artificial intelligence-assisted bibliometric analysis enables large-scale identification of research hotspots and emerging directions.

Materials and Methods:

Publications indexed in Web of Science (2000–2025) were extracted. Latent Dirichlet Allocation (LDA) topic modeling, co-citation network analysis, and keyword co-occurrence clustering were applied. Topic coherence scores and citation density were evaluated to identify dominant research themes.

Results:

Topic modeling identified major clusters including hepatic stellate cell activation, immune-mediated fibrosis, metabolic-associated fibrosis, and antifibrotic signaling pathways. Citation networks demonstrated increasing interdisciplinary integration between immunology and metabolic research. Emerging trends since 2018 included metabolic dysfunction and inflammasome-related pathways.

Conclusions:

AI-assisted bibliometric analysis provides structured insight into research evolution in liver fibrogenesis. These approaches support strategic research planning and identification of future interdisciplinary directions

Keyword(s) : Bibliometrics; Topic Modeling; Liver Fibrosis; Research Trends; Latent Dirichlet Allocation

2873 - Integrative Metabolomic and Cytokine Profiling Reveals a "Metabolic Inflammatory" Signature in Chronic Hepatitis B Combined with Metabolic Dysfunction Associated Fatty Liver Disease

Yichen Peng ¹, Ju Chen ², Liang Huang ³, Qiuping Chen

E-POSTER ABSTRACTS

¹, Haiyang Hu ⁴, Peijie Wu ⁴, Baixue Li ⁴, Quansheng Feng ⁴

Chengdu University Of Traditional Chinese Medicine, Clinical Medical College, Chengdu-China ¹ Chengdu University Of Traditional Chinese Medicine, School Of Intelligent Medicine, Chengdu-China ² Chengdu Public Health Clinical Medical Center, Department Of Scientific Research, Chengdu-China ³ Chengdu University Of Traditional Chinese Medicine, School Of Basic Medical Sciences, Chengdu-China ⁴

Background / Hypothesis:

The coexistence of chronic hepatitis B (CHB) and metabolic dysfunction-associated fatty liver disease (MAFLD) is increasingly prevalent worldwide. This dual condition accelerates disease progression, increases the risk of hepatocellular carcinoma, and complicates treatment response. However, non-invasive biomarkers for distinguishing CHB-MAFLD from CHB alone remain lacking

Materials and Methods:

A cross-sectional study was conducted enrolling 406 participants: healthy controls (HC, n=30), CHB alone (n=149), and CHB-MAFLD (n=227). CHB was defined as HBsAg positivity for >6 months with detectable HBV DNA. MAFLD was diagnosed based on hepatic steatosis on imaging combined with metabolic abnormalities. Patients with other liver diseases (hepatitis A, C, E), malignancies, significant organ dysfunction, systemic diseases, or pregnancy/lactation were excluded. Demographic characteristics, clinical parameters, and laboratory tests were collected. Serum cytokine levels (IL-17, TNF- α) were measured using Luminex multiplex assay, and non-targeted metabolomics was performed using LC-MS/MS. Comprehensive comparisons were conducted among the three groups.

Results:

Compared to the CHB alone group, patients with CHB-MAFLD exhibited significantly higher levels of ALT, AST, GGT, BMI, and uric acid (all $P < 0.05$). Cytokine profiling revealed that serum IL-17 and TNF- α levels were significantly elevated in the CHB-MAFLD group compared to the CHB alone group (both $P < 0.05$). Metabolomic analysis identified 110 differential metabolites between the CHB-MAFLD and CHB alone groups. The top three most significantly altered metabolites were Ethyl (S)-3-hydroxybutyrate

glucoside, Indole-3-propionic acid, and Hippuric acid. Additionally, L-Leucine and L-Tyrosine levels were significantly decreased in CHB-MAFLD patients. KEGG pathway enrichment analysis identified ketone body metabolism, tryptophan metabolism, branched-chain amino acid metabolism, and purine metabolism as the core perturbed pathways.

Conclusions:

CHB-MAFLD patients present a distinct "metabolic-inflammatory" signature characterized by mitochondrial dysfunction-driven energy metabolic reprogramming, gut microbiota dysregulation, and pro-inflammatory cytokine activation. Serum cytokines IL-17 and TNF- α , along with metabolites Ethyl (S)-3-hydroxybutyrate glucoside, Indole-3-propionic acid, and L-Leucine, may serve as potential biomarkers for distinguishing CHB-MAFLD from CHB alone. These findings provide scientific evidence for understanding the pathogenic mechanisms and inform precision management strategies for this dual condition.

2875 - Integrative Metabolomic and Cytokine Profiling Reveals a "Metabolic Inflammatory" Signature in Chronic Hepatitis B Combined with Metabolic Dysfunction Associated Fatty Liver Disease

Yichen Peng ¹, Ju Chen ², Liang Huang ³, Qiuping Chen ⁴, Haiyang Hu ⁵, Peijie Wu ⁵, Baixue Li ⁵, Quansheng Feng ⁵

Chengdu University Of Traditional Chinese Medicine, Clinical Medical College, Chengdu-China ¹ Chengdu University Of Traditiona, School Of Intelligent Medicine, Chengdu-China ² Chengdu Public Health Clinical Medical Center, Research Department, Chengdu-China ³ Chengdu University Of Traditiona, Clinical Medical College, Chengdu-China ⁴ Chengdu University Of Traditiona, School Of Basic Medical Sciences, Chengdu-China ⁵

Background / Hypothesis:

The coexistence of chronic hepatitis B (CHB) and metabolic dysfunction-associated fatty liver disease (MAFLD) is increasingly prevalent worldwide. This dual condition accelerates disease progression, increases the risk of hepatocellular carcinoma, and complicates treatment response. However, non-invasive biomarkers for distinguishing CHB-MAFLD from CHB alone remain

E-POSTER ABSTRACTS

lacking.

This study aimed to analyze the clinical characteristics of patients with CHB-MAFLD compared to those with CHB alone, characterize their differential metabolic and cytokine profiles, elucidate the unique "metabolic-inflammatory" signature, and explore potential diagnostic biomarkers. Liver Disease

Materials and Methods:

A cross-sectional study was conducted enrolling 406 participants: healthy controls (HC, n=30), CHB alone (n=149), and CHB-MAFLD (n=227). CHB was defined as HBsAg positivity for >6 months with detectable HBV DNA. MAFLD was diagnosed based on hepatic steatosis on imaging combined with metabolic abnormalities. Patients with other liver diseases (hepatitis A, C, E), malignancies, significant organ dysfunction, systemic diseases, or pregnancy/lactation were excluded. Demographic characteristics, clinical parameters, and laboratory tests were collected. Serum cytokine levels (IL-17, TNF- α) were measured using Luminex multiplex assay, and non-targeted metabolomics was performed using LC-MS/MS. Comprehensive comparisons were conducted among the three groups.

Results:

Compared to the CHB alone group, patients with CHB-MAFLD exhibited significantly higher levels of ALT, AST, GGT, BMI, and uric acid (all $P < 0.05$). Cytokine profiling revealed that serum IL-17 and TNF- α levels were significantly elevated in the CHB-MAFLD group compared to the CHB alone group (both $P < 0.05$). Metabolomic analysis identified 110 differential metabolites between the CHB-MAFLD and CHB alone groups. The top three most significantly altered metabolites were Ethyl (S)-3-hydroxybutyrate glucoside, Indole-3-propionic acid, and Hippuric acid. Additionally, L-Leucine and L-Tyrosine levels were significantly decreased in CHB-MAFLD patients. KEGG pathway enrichment analysis identified ketone body metabolism, tryptophan metabolism, branched-chain amino acid metabolism, and purine metabolism as the core perturbed pathways.

Conclusions:

CHB-MAFLD patients present a distinct "metabolic-inflammatory" signature characterized by mitochondrial dysfunction-driven energy metabolism

reprogramming, gut microbiota dysregulation, and pro-inflammatory cytokine activation. Serum cytokines IL-17 and TNF- α , along with metabolites Ethyl (S)-3-hydroxybutyrate glucoside, Indole-3-propionic acid, and L-Leucine, may serve as potential biomarkers for distinguishing CHB-MAFLD from CHB alone. These findings provide scientific evidence for understanding the pathogenic mechanisms and inform precision management strategies for this dual condition.

2880 - Albumin Bilirubin (ALBI) score in predicting complications in patients with HCC undergoing curative Resection a systemic review and Meta analysis

Kiran Tabish Tabish¹, Raja Taha Yaseen Khan Khan², Nasir Hassan Luck Luck³

Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain¹ Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain² Sindh Institute Of Urology And Transplantation, Hepatogastroenterology, Karachi-Pakistan³

Background / Hypothesis:

Hepatocellular carcinoma (HCC) remains a major cause of cancer-related mortality globally, with hepatectomy being a curative option for selected patients. Accurate prognostication following surgery is critical to guide postoperative management. The Albumin-Bilirubin (ALBI) score, a simple and objective indicator of liver function, has been proposed as a potential prognostic marker. However, its predictive value in patients undergoing hepatic resection for HCC remains to be systematically evaluated. To determine the prognostic role of the ALBI score in predicting postoperative outcomes, including overall survival, recurrence-free survival, microvascular invasion, and post-hepatectomy liver failure in patients with hepatocellular carcinoma undergoing resection.

Materials and Methods:

A systematic search of PubMed/MEDLINE and the Cochrane Library databases was conducted. Studies assessing the ALBI score as a prognostic factor in HCC patients undergoing curative hepatectomy were included. Out of an initial 28 articles identified, 11

E-POSTER ABSTRACTS

studies fulfilled the inclusion criteria and were incorporated into the final meta-analysis. The outcomes analyzed included overall survival (OS), recurrence-free survival (RFS), prediction of microvascular invasion (MVI), and prediction of post-hepatectomy liver failure (PHLF).

Results:

Among the 11 included studies, seven studies evaluated the ALBI score's role in predicting overall survival, and six studies investigated its association with recurrence-free survival. One study assessed the ALBI score's predictive value for microvascular invasion, and another evaluated its ability to predict post-hepatectomy liver failure. The pooled analysis demonstrated that a higher ALBI grade was significantly associated with poorer overall survival and increased recurrence rates following hepatectomy. Moreover, a higher ALBI score correlated with the presence of microvascular invasion and higher rates of post-hepatectomy liver failure, reinforcing its role as a reliable prognostic biomarker.

Conclusions:

The ALBI score is a valuable, non-invasive tool for predicting postoperative prognosis in patients with HCC undergoing hepatic resection. Higher ALBI grades are significantly associated with poorer overall survival, increased risk of recurrence, microvascular invasion, and post-hepatectomy liver failure. Incorporating the ALBI score into routine preoperative assessment may facilitate better risk stratification and postoperative management strategies in this population.

2882 - Hypoalbuminemia as a predictor of mortality in patients with acute cholangitis a systemic review and meta analysis

Syed Mudassir Laeeq¹, Raja Taha Yaseen Khan Khan², Nasir Hassan Luck Luck³

Armed Forces Hospital - Southern Region, Hepatogastroenterology, Khamis Mushait-Saudi Arabia

¹ Bahrain Specialist Hospital, Nr Gastroenterology And Hepatology Center, Manama-Bahrain ² Sindh Institute Of Urology And Transplantation, Hepatogastroenterology, Karachi-Pakistan ³

Background / Hypothesis:

Acute cholangitis (AC) is a life-threatening condition characterized by biliary tract infection, often

necessitating urgent intervention. Despite advances in diagnostics and therapy, mortality remains significant, especially in high-risk subgroups. Hypoalbuminemia, a marker of systemic inflammation and malnutrition, has emerged as a potential predictor of poor outcomes. This systematic review and meta-analysis aimed to evaluate the prognostic value of hypoalbuminemia for mortality in patients with acute cholangitis.

Materials and Methods:

This systematic review and meta-analysis was conducted in adherence to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. A comprehensive search of multiple databases was performed to identify studies evaluating the association between hypoalbuminemia and mortality in patients with acute cholangitis. Eligible studies included adult patients with confirmed acute cholangitis, reported serum albumin levels either as continuous variables or with defined cut-off values, and provided mortality outcomes. Case reports, reviews, pediatric studies, and articles lacking relevant data were excluded. Two independent reviewers screened studies, extracted data, and assessed methodological quality using the Newcastle-Ottawa Scale. Studies scoring ≥ 7 were considered high quality. Statistical analysis was conducted using a random-effects model to calculate pooled odds ratios (ORs) with 95% confidence intervals (CIs). Heterogeneity was assessed using the I^2 statistic, and publication bias was evaluated through funnel plots and Egger's test.

Results:

A total of eight studies comprising 3,210 patients with acute cholangitis were included in the meta-analysis. The pooled analysis revealed a significant association between hypoalbuminemia and increased mortality risk. In the subgroup where serum albumin was treated as a continuous variable, the pooled odds ratio (OR) for mortality was 2.85 (95% CI: 1.93–4.20), indicating that each unit decrease in albumin level was associated with nearly a threefold increase in mortality risk. In the subgroup using albumin cut-off values (most commonly ≤ 2.5 g/dL or ≤ 2.8 g/dL), the association was even stronger, with a pooled OR of 4.08 (95% CI: 2.58–6.45). Heterogeneity across studies was low to moderate ($I^2 = 0\%$ in the cut-off-based group and $I^2 = 47\%$ in the continuous variable group), suggesting consistency in the effect estimate, particularly when defined thresholds were used.

Conclusions:

This meta-analysis highlights hypoalbuminemia as a strong and independent predictor of mortality in patients with acute cholangitis. Early recognition of low

E-POSTER ABSTRACTS

serum albumin levels should prompt aggressive clinical intervention and close monitoring. Incorporating albumin into existing risk stratification tools may enhance prognostication and guide therapeutic decision

Keyword(s) : hypoalbuminemia; mortality; cholangitis; predictors

2883 - Real World Effectiveness and Safety of Sorafenib in Advanced Hepatocellular Carcinoma A Prospective Study from Fayoum Egypt

Eman Fares¹, Shrouk Ameen², Essam A Hassan¹, Ahmed A Gomaa¹, Mohammed Abdalla³, Ahmed M Saleh⁴

Fayoum University, Endemic Medicine, Fayoum-Egypt¹
Fayoum University, Endemic Medicine, Fayoum-Egypt²
Medical Research Division, National Research Center, Infectious Diseases And Endemic Hepato-gastroenterology, Giza-Egypt³
Fayoum University, Endemic Medicine, Fayoum-Egypt⁴

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is the most common primary malignancy of the liver. Sorafenib was the first systemic therapy to be approved for the treatment of HCC after having demonstrated a survival benefit in patients with advanced HCC in the first-line setting. Our study evaluated the efficacy and safety of sorafenib as first-line therapy in the treatment of HCC in real-life practice by evaluating overall survival (OS) and progression-free survival (PFS).

Materials and Methods:

A prospective study included 112 patients with advanced HCC treated with sorafenib at viral hepatitis units in Fayoum city, Egypt, from February 2022 to February 2025 according to the National Committee for Control of Viral Hepatitis, which restricts systemic therapy to patients with preserved liver function (Child-Pugh A and advanced-stage disease).

Results:

The median age of patients was 67 years, with male predominance (77%). Hepatitis C virus infection was the main underlying etiology (82.1%). Median overall survival (OS) was 7 months, and progression-free survival (PFS) was 3 months. Higher OS was observed in patients with BCLC stage C, initial sorafenib doses of

800 mg or 200 mg daily, tumor size <6 cm, absence of extrahepatic spread (EHS) or macrovascular invasion (MVI), and AFP levels <400 ng/mL.

Regarding safety, 58.9% tolerated the standard dose (400 mg twice daily), while 41.1% required dose modification, mainly due to adverse events. The most common grade 1–2 adverse events were fatigue (41%), diarrhea (30.3%), and hand-foot skin reaction (23.2%). Other events included anorexia (19.6%), mild liver enzyme elevation (18%), hypertension (7.1%), and hypothyroidism (3.5%). Severe adverse events occurred in 19.8%, including marked liver enzyme elevation and ischemic events. Treatment discontinuation was primarily due to disease progression (71.4%), followed by toxicity (19.6%) and loss to follow-up (8.9%).

Conclusions:

Sorafenib therapy was found to have an acceptable efficacy and safety profile, with predominantly mild to moderate side effects.

Keyword(s) : Hepatocellular carcinoma; Sorafenib; Overall Survival; Progression Free Survival; Safety.

2884 - Comparison of hepatic and extra hepatic scores in predicting mortality in patients with Hepatitis C related cirrhosis

Raja Taha Yaseen Khan¹, Sanjay Kirshan Kumar Kumar², Nasir Hassan Luck Luck³

Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain¹
Ahalia Hospital, Gastroenterology, Abu Dhabhi-United Arab Emirates²
Sindh Institute Of Urology And Transplantation, Hepatogastroenterology, Manama-Bahrain³

Background / Hypothesis:

Certain prognostic scores such as Child Turcotte Pugh (CTP) score and MELD-Sodium (MELD-Na) scores are available showing independent predictors of mortality in patients with chronic liver disease. Cirrhotic patients are frail and increasingly vulnerable to psychological effects and increased rates of decompensation in cirrhotic patients. Recently, studies have shown the correlation of liver frailty index (LFI) with CTP and MELD-Na score in cirrhotic patients. Therefore, our aim was to compare the utility of CTP, MELD-Na and LFI in predicting mortality in patients with HCV associated cirrhosis.

Materials and Methods:

It was a prospective cohort study which was conducted at the Department of Hepatogastroenterology, Sindh

E-POSTER ABSTRACTS

Institute of Urology and Transplantation from January 2019-Decmeber 2021. All patients with HCV associated cirrhosis as per operational definition were enrolled in the study. While, those patients with conditions over estimating frailty such as cardiopulmonary disease osteoarthritis etc. or those with altered mentation, history of hepatocellular carcinoma were excluded from the study. Statistical analysis was performed using the SPSS software version 22. Area under the receiver operating curve(AUROC) was obtained for each CTP, MELD-Na and LFI individually and also for combination of these scores for the prediction of one month,three months and six months mortality in cirrhotic patients.

Results:

A total of 145 patients were included in the study. Among them, 98(67.2%) were males. Seventy four (51%) patients belonged to CTP class B. Esophageal varices were noted in 83(57%) patients. One month mortality was noted in 11(7.6%), Three months mortality in 23(15.9%) and six months mortality in 41(39.4%) patients respectively. AUROC was highest for the combination of LFI and CTP (AUROC-0.845; $p<0.001$) followed by the combination LFI plus CTP plus MELD -Na (AUROC-0.838; $p<0.001$) in predicting six months mortality as compared to each of these scores individually while the AUROC was highest for combination of all the scores(LFI+CTP+MELD-Na) in predicting one month (AUROC-0.942; $p<0.001$) and three months (AUROC-0.858; $p<0.001$) mortality as compared to the other scores.

Conclusions:

Extrahepatic component (LFI) has shown a significant impact in predicting mortality in cirrhotic patients and should also be incorporated along with hepatic scores (CTP and MELD-Na) in predicting the prognosis in this population. This will not only help in prioritizing the patients' management strategies but will also improve the overall survival in this population.

2885 - Comparative prognostic utility of acute change in Liver stiffness measured using splenic versus liver probe in patients of Acute on chronic liver failure

Sudhir Verma ¹, Chitranshu Vashistha ², Shiv Kumar Sarin ²

King George/s Medical University, Hepatobiliary Unit, Medicine, Lucknow, India ¹ Institute Of Liver And Biliary

Sciences, Hepatology, New Delhi-India ²

Background / Hypothesis: Early identification of acute on chronic liver failure (ACLF) patients with high risk of mortality is important to prioritize the need for ICU monitoring and liver transplantation (LT). In ACLF, inflammation and an acute rise in portal pressure drive the outcome and can raise liver (LSM) and spleen stiffness (SSM). Liver stiffness measurement (LSM) using the liver probe of transient elastography is increasingly explored for prognostication in ACLF. However, the conventional liver probe (LP) has a ceiling effect, with an upper limit of 75 kPa. The splenic probe(SP) with an upper limit of 100 kPa may overcome this limitation. We prospectively evaluated the prognostic performance of liver stiffness measured using the splenic probe versus the conventional liver probe at baseline and during early follow-up in ACLF patients

Materials and Methods: Patients of ACLF (APASL criteria) between 18 to 70 years of age were included. The study aimed to compare the prognostic utility of the acute change in LSM measured using splenic versus liver probe on days 7 and 14 for predicting transplant-free survival at day 90 in patients of ACLF

Results: Study included 56 patients(mean age 40.9 ± 8.6 yrs, males 88.9%, alcohol associated 83.76 %) with ACLF. At day-90, 38 (68.4%) patients had LT free survival, with 15 (26.78%) deaths and 3 (1.68%) LT. Mean baseline AARC score among survivors and non-survivors was 7.68 ± 1.37 and 10.14 ± 1.25 , respectively ($p<0.001$). Baseline LSM measured through SP(82.67 ± 17.7 kPa) was significantly higher than LP(70.95 ± 9.13 kPa) among survivors($p=0.005$) and non-survivors(SP = 90.96 ± 12.79 vs LP = 73.56 ± 9.13 kPa, $p<0.001$). On day 7, mean change in LSM by SP(-7.09 ± 3.48) was significantly higher than LP(-0.69 ± 0.63) among survivors($p<0.001$) and non- survivors (SP = -2.46 ± 1.29 vs LP = -0.11 ± 0.3 kPa) ($p<0.001$). Similarly, on day 14, the mean change in LSM by SP (-13.14 ± 7.21 kPa) was significantly higher than LP(-1.83 ± 0.95 kPa) among survivors($p<0.001$) and non-survivors (SP = -5.89 ± 1.2 vs LP = -0.08 ± 0.12 , $p<0.001$)

Conclusions: LSM measured using a splenic probe provides superior prognostic stratification compared to

E-POSTER ABSTRACTS

conventional liver probe in ACLF. Serial assessment of LSM using the splenic probe during the first two weeks identifies patients at high risk of short term mortality.

Key words: Transient elastography, Liver stiffness, Splenic probe, Liver Probe, Survival, ACLF

2887 - Role of "MANLATA model" in predicting recurrence in patients with Hepatocellular carcinoma undergoing Trans Arterial Chemo embolization

Raja Taha Yaseen Khan ¹, Hina Ismail Ismail ², Nasir Hassan Luck Luck ³, Zain Majid Majid ³

Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain ¹ Limerick University Hospital, Acute Medicine, Limerick-Ireland ² Sindh Institute Of Urology And Transplantation, Hepatogastroenterology, Karachi-Pakistan ³

Background / Hypothesis:

Hepatocellular carcinoma (HCC) represents the sixth most common neoplasm in terms of incidence and the third leading cause of cancer death. Unfortunately, most of patients with HCC are diagnosed at an advanced stage and are treated by the palliative options. Trans-arterial chemoembolization (TACE) is the best therapeutic option in this situation. Our aim was to identify the non-invasive predictive factors and to build a model using these predictors suggestive of post TACE recurrence of HCC .

Materials and Methods:

It was a retrospective study which included all the patients aged 18-65 years with HCC undergoing TACE from January 2010 to December 2018. While, the patients with early stage HCC undergoing resection, advanced staged HCC bearing portal vein thrombosis, metastatic HCC, patients with poor ECOG status and advanced child class were excluded. SPSS version 26.0 was used for the data analysis and R software was utilized for building a predictive model. Univariate and multivariate logistic regression analysis was performed to identify the independent predictors of post TACE recurrence. A nomogram was then built using R software and a model was then developed ("MANLATA model) for which AUROC was obtained and at an optimal cutoff, the diagnostic accuracy of the model was obtained. The model was then internally validated for the prediction of post-TACE HCC recurrence.

Results:

A total of 323 patients were included in the study. Among them, 281 (87%) were males. Baseline characteristics of all patients undergoing TACE were recorded. Post TACE recurrence was observed in 182 patients. On multivariate analysis, male gender, age > 50 years, tumor size > 5cm, serum albumin <2.8 g/dl , serum alpha-fetoprotein ≥300 ng/ml, neutrophil count >60 % and lymphocyte count <25% were independent predictors of post TACE recurrence. Using these variables, a model "MANLATA model" was developed which had an AUROC of (0.924) and at a cutoff >60, it had an excellent sensitivity of 91.76%, specificity of 85.82% and diagnostic accuracy of 90.98% in predicting post TACE recurrence. In validation cohort, this model showed an excellent sensitivity of 90.21%, specificity of 83.29% and diagnostic accuracy of 89.16% in predicting post-TACE HCC recurrence.

Conclusions:

This non-invasive model had an excellent diagnostic accuracy in predicting post TACE recurrence. However, further studies comprising of large sample sizes are required to validate this model.

Keyword(s) : TACE, HCC recurrence, non-invasive model

2889 - Hepatitis B Reactivation and the Effectiveness of Antiviral Therapy in Patients Receiving Immunosuppressive Therapy A Real World Study

Meryem Balci ¹, Funda Simsek ²

Kanuni Sultan Suleiman Training And Research Hospital, Infectious Diseases And Clinical Microbiology, Istanbul-Türkiye ¹ Prof. Dr. Cemil Taşcıoğlu City Hospital, Infectious Diseases And Clinical Microbiology, Istanbul-Türkiye ²

Background / Hypothesis:

Hepatitis B virus (HBV) persists as cccDNA in the host genome, posing a permanent risk of reactivation (HBVr) during immunosuppression. HBVr not only causes hepatic damage but also disrupts the management of primary diseases. We aimed to evaluate the necessity and real-world effectiveness of antiviral prophylaxis, comparing different nucleos(t)ide analogues (NAs) in patients receiving immunosuppressive therapy.

Materials and Methods:

This retrospective study included 125 patients who received immunosuppressive therapy between 2018 and 2020 and were referred to the infectious diseases

E-POSTER ABSTRACTS

clinic. Patients were stratified according to baseline HBV serological status (HBsAg and anti-HBc) and immunosuppressive therapy risk. Demographic, clinical, and laboratory data including HBV DNA and liver function tests were collected. Antiviral prophylaxis with potent nucleos(t)ide analogues (TDF, TAF, or ETV) was administered according to risk stratification. Patients were followed every 3 months with biochemical and virological assessments to evaluate HBV reactivation and treatment outcomes.

Results:

The cohort included rheumatological (88%) and solid organ malignancy (7.2%) patients. At baseline, 12% (n=15) were HBsAg(+) and 88% (n=110) were HBsAg(-)/anti-HBc(+). Antiviral prophylaxis was initiated in 90.4% (n=113). No HBVr occurred during active antiviral prophylaxis. However, 4 patients (all HBsAg-positive, 26.6% of the HBsAg(+) group) developed reactivation. Two cases were due to delayed antiviral initiation, and two occurred 4–11 months after prophylaxis cessation (one post-COVID-19 steroid therapy). Anti-HBs positivity was protective: reactivation occurred in 13% of anti-HBs(-) vs. 1% of anti-HBs(+) patients. TAF was preferred over TDF in patients with higher baseline creatinine (p=0.015).

Conclusions:

Potent antiviral prophylaxis is highly effective. HBsAg positivity remains the strongest risk factor. Standard 12 month post-IST prophylaxis may be insufficient for high-risk individuals. Early referral and individualized duration are essential.

Keyword(s) : antiviral prophylaxis, Hepatitis B reactivation, immunosuppressive therapy

2890 - Correlation of Abdominal Girth with Liver Shear Wave Elastography in Non Diabetic Population with Metabolic Dysfunction–Associated Fatty Liver Disease (MAFLD)

Najah R Zayyani Zayyani¹, Raja Taha Yaseen Khan Khan², Muhammad Manzoor Ul Haque Ul Haque²
Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain¹ Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain²

Background / Hypothesis:

Metabolic dysfunction-associated fatty liver disease (MAFLD) is increasingly recognized among non-diabetic population; mainly due to central obesity and the subsequent accumulation of visceral fat. Abdominal

girth is a simple bedside marker of central adiposity; while shear-wave elastography (SWE) serves as a quantitative, non-invasive tool for the estimation of liver stiffness. Therefore, in this study our aim to evaluate the correlation of abdominal girth and liver stiffness as measured by SWE in non-diabetic population with MAFLD.

Materials and Methods:

This cross-sectional study was conducted at the department of gastroenterology, Bahrain Specialist Hospital and included all the non-diabetic patients with age > 18 years and diagnosed with fatty liver on ultrasound. Patients with diabetes, excessive alcohol use, hepatitis, cirrhosis of liver and heart failure were excluded from the study. At presentation, demographic information including age (years), height, weight, Body Mass Index (BMI), blood pressure and the metabolic profile including liver function test and fasting lipid profile were recorded. Abdominal girth was measured at the level of the iliac crest by the standardized technique. Shear wave elastography (SWE) was performed using Siemens Acuson S2000 and liver stiffness was recorded as shear-wave velocity. Pearson correlation coefficient test was utilized to assess the association between abdominal girth and SWE measurements.

Results:

A total of 487 patients with fatty liver were enrolled in the study. Among them, 295 (60.6%) were females and 192 (39.4%) were males. Serum alanine transaminase was 37.9 ± 38.9 (IU); aspartate transaminase was 51.9 ± 26.9 (IU) and gamma glutamyl trans-peptidase was 47.7 ± 10.3 (IU). The mean abdominal girth was 112.4 ± 19.6 cm and the mean value for shear-wave elastography (SWE) was 1.12 ± 0.82 m/s. On Pearson correlation analysis, the abdominal girth was observed to have a significant positive correlation with liver stiffness ($r = 0.716$) ($p < 0.001$). Fasting insulin also demonstrated a strong positive correlation with SWE values ($r = 0.648$) ($p < 0.001$). A weaker correlation was also observed between the post-prandial insulin levels and liver stiffness ($r = 0.4470$) ($p < 0.001$).

Conclusions:

This study showed an excellent correlation of abdominal girth with liver stiffness measured by SWE. This suggests that central adiposity plays a pivotal role in early fibrotic change even in the absence of diabetes. Incorporating abdominal girth into routine assessment may help identify patients needing early elastography-based evaluation and can serve as an

E-POSTER ABSTRACTS

excellent non- invasive tool in predicting advanced liver fibrosis.

Keyword(s) : abdominal girth; shear-wave elastography; non-diabetic; fatty liver; metabolic-dysfunction

2891 - Factors associated with clinical success of endoscopic management of Post Cholecystectomy Bile Duct Injury A Retrospective Analysis

Danish Kumar ¹, Raja Taha Yaseen Khan Khan ², Syed Mudassir Laeeq Laeeq ³, Nasir Hasan Luck Luck ¹
Sindh Institute Of Urology And Transplantation, Hepatogastroenterology, Karachi-Pakistan ¹ Bahrain Specialist Hospital, Gastroenterology, Manama-Bahrain ² Armed Forces Hospital, South Region, Gastroenterology, Khams Mushait-Saudi Arabia ³

Background / Hypothesis:

Laparoscopic cholecystectomy is currently the gold standard technique for the removal of gall bladder. However, it is still associated with complications like iatrogenic bile duct injury (BDI). Currently, due to less invasiveness, endoscopic techniques including Endoscopic retrograde cholangiopancreatography are the initial therapy used for the management of BDI. However, the local data from Pakistan is scarce regarding the effectiveness of endoscopic intervention in the management of BDI. Therefore, the aim of this study was to evaluate the clinical outcome of endoscopic intervention and the factors associated with clinical success in the endoscopic management for bile duct injuries following cholecystectomy.

Materials and Methods:

A retrospective study was conducted at the Department of Hepatogastroenterology, SIUT Karachi, on adult patients aged ≥ 18 years who developed BDI after laparoscopic cholecystectomy and who had ERCP from January 2018 until June 2023. Demographic details, nature of injury (Strasberg classification), time of ERCP, type of intervention, and outcome were analyzed. Clinical success was defined as resolution of bile leakage, reduced drain output or biloma, and resolution of cholestatic liver enzymes. Statistical analysis included univariate and multivariate logistic regression to find the independent predictors of clinical success.

Results:

Out of 56 patient who underwent endoscopic intervention for BDI, 33 (58.9%) were females. Mean age was 40.3 ± 14.2 years. According to the Strasberg classification, type A injuries were the most frequent

that were observed in 40 (71.4%) patients, while type D and type E BDI accounted for 9% and 19.6% of the cases respectively. In 50 (89.3%) patients, ERCP was performed three days after undergoing laparoscopic cholecystectomy. Most common intervention was combined sphincterotomy and stent placement (55.3%). Clinical success was achieved in 46 (82.1%) patients. On multivariate logistic regression analysis, presence of Strasberg type A injury (OR 7.4; 95% CI 2.01–27.2; $p = 0.003$) and combined endoscopic sphincterotomy and stenting (OR 2.58; 95% CI 1.17–5.7; $p = 0.02$) were the factors independently associated with clinical success in the endoscopic management of BDI.

Conclusions:

Endoscopic retrograde cholangiopancreatography is a successful and safe therapeutic measure in managing post-cholecystectomy bile duct injuries, particularly Strasberg type A leaks. Early therapy, accurate classification of the injury, and use of combined sphincterotomy with stent placement were independent predictors with positive outcomes.

Keyword(s) : Bile duct injury, laparoscopic cholecystectomy, ERCP, endoscopic therapy, Strasberg classification, bile leak.

2892 - Non invasive predictors of Hepatorenal syndrome in decompensated chronic liver disease

Hina Ismail Ismail ¹, Raja Taha Yaseen Khan Khan ², Kiran Tabish Tabish ², Nasir Hasan Luck Luck ³
University Hospital Limerick, Acute Medicine, Limerick-Ireland ¹ Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain ² Sindh Institute Of Urology And Transplantation, Hepatogastroenterology, Karachi-Pakistan ³

Background / Hypothesis:

Hepatorenal syndrome (HRS) is a frequent complication of advanced decompensated chronic liver disease (DCLD) that is associated with high morbidity and mortality. Our aim was to identify non-invasive predictors of Hepatorenal syndrome in DCLD patients.

Materials and Methods:

It was a retrospective study which was carried out at the department of Hepatogastroenterology, Sindh Institute of Urology and Transplantation. All patients admitted with DCLD from June 2018 to December 2021 were included in the study. Univariate analysis

E-POSTER ABSTRACTS

followed by the multivariate analysis was performed to identify non-invasive predictors of HRS.

Results:

The total number of patients included in the study were 199. Out of them, 124 (62.1%) were males. Most common cause of chronic liver disease was hepatitis C noted in 57 (28.6%) patients. Ascites was noted in 165 (82.9%) patients. HRS was noted 78 (39.2%) patients while SBP was seen in 65 (32.7%) patients. Age greater than 40 years, Child Turcotte Pugh score > 13, Hemoglobin less than 10 g/dl, Total leucocyte count > 11 x10⁹/L and urea > 30 mg/dl were found to be independent predictors for the development of HRS.

Conclusions:

These strong predictors of HRS can help in prevention, early diagnosis and prompt treatment of the patients with HRS and improving the overall survival in DCLD including urgent referral for liver transplantation.

2893 - Role of PAST F model in predicting advanced liver fibrosis in Autoimmune Hepatitis

Nida Rasool ¹, Raja Taha Yaseen Khan Khan ², Syed Mudassar Laeeq Laeeq ³, Nasir Hasan Luck Luck ¹
Sindh Institute Of Urology And Transplantation, Hepatogastroenterology, Karachi-Pakistan ¹ Bahrain Specialist Hospital, Nrz Gastroenterology And Hepatology Center, Manama-Bahrain ² Armed Forces Hospital, South Region, Gastroenterology, Khams Mushait-Saudi Arabia ³

Background / Hypothesis:

Liver biopsy remains the gold standard for diagnosing and staging liver fibrosis. However, it is invasive and associated with potential complications. Consequently, there is a growing need for non-invasive methods to predict advanced fibrosis in AIH patients. To evaluate the diagnostic accuracy of the PAST-F model in predicting advanced liver fibrosis in patients with autoimmune hepatitis and to establish an optimal cutoff score for clinical application.

Materials and Methods:

This Retrospective cohort study was conducted at the Hepatogastroenterology unit, Sindh Institute of Urology and Transplantation, Karachi from January 2016 to December 2023. All the patients diagnosed with AIH on the basis of liver biopsy were enrolled in the study. Patients with concomitant liver diseases were excluded. Liver fibrosis was evaluated using the Metavir scoring system on the liver parenchymal

biopsy. Statistically significant variables on univariate analysis then underwent multivariate logistic regression analysis to identify independent predictors of advanced liver fibrosis in autoimmune hepatitis. Using these variables a model was proposed and area under the receiver operating curve was obtained. At an optimal cutoff, diagnostic accuracy was obtained for the model in predicting advanced liver fibrosis in AIH.

Results:

A total of 360 patients were included in the study. On multivariate analysis, Female gender, advanced age, raised ANA (1:160), negative serology, increased total bilirubin, alkaline phosphatase, Gamma Glutamyl Transpeptidase, INR and decreased TLC and platelet count were the factors significantly associated with advanced fibrosis. Using the variables with higher odds ratio on multivariate analysis, a model was proposed named PAST-F model comprising of platelet count ($p \leq 0.001$) (O.R.1.025), decreased serum albumin levels ($p \leq 0.001$) (O.R.33.6), negative autoimmune serology ($p \leq 0.001$) (O.R.4.933), raised bilirubin ($p \leq 0.001$) (O.R.5.199) and female gender ($p \leq 0.001$) (O.R.25.91). AUROC was obtained for PAST-F model in predicting advanced liver fibrosis and at an optimal cutoff of score of >8, it had a good sensitivity of 80.14%, specificity of 87.67% and diagnostic accuracy of 84.72% in predicting advanced liver fibrosis in patients with AIH.

Conclusion:

The PAST-F model, incorporating variables such as platelet count, serum albumin levels, autoimmune serology status, bilirubin levels, and gender, demonstrates a high diagnostic accuracy in predicting advanced liver fibrosis in patients with autoimmune hepatitis. Therefore PAST-F model offers a valuable non-invasive tool for clinicians to identify patients at higher risk for advanced fibrosis, potentially guiding more tailored therapeutic interventions and monitoring strategies.

Keyword(s) : autoimmune hepatitis; fibrosis; non-invasive; model

2895 - Risk of hepatitis b virus reactivation in patients negative for hepatitis b surface antigen and positive for hepatitis b core antibody receiving biological agents

Atiye Ayrik Demir ¹, Orhan Yildiz ², Bilgehan Aygen ²
Kayseri City Hospital, Infectious Diseases And Clinical Microbiology, Kayseri-Türkiye ¹ Erciyes University Faculty Of Medicine, Infectious Diseases And Clinical Microbiology, Kayseri-Türkiye ²

E-POSTER ABSTRACTS

Background / Hypothesis:

In HBsAg-negative, anti-HBc IgG-positive individuals, the risk of hepatitis B virus reactivation (HBVr) associated with immunosuppressive therapy varies depending on the immunosuppressive potency of the biological agent used. This study aimed to evaluate the development of HBVr in HBsAg-negative, anti-HBc IgG-positive patients receiving moderate- or high-risk biological agents.

Materials and Methods:

A total of 172 HBsAg-negative, anti-HBc IgG-positive patients were retrospectively analyzed. Patients were classified into moderate- and high-risk groups according to the HBVr risk associated with the biological agents used. Rituximab and ocrelizumab were categorized as high-risk agents, whereas anti-TNF- α agents (adalimumab, infliximab, golimumab, certolizumab, etanercept), the IL-6 inhibitor tocilizumab, and the IL-12/23 inhibitor ustekinumab were considered moderate-risk agents. Demographic and clinical characteristics, treatment details, concomitant immunosuppressive therapies, and antiviral prophylaxis status were recorded. Follow-up virological and serological data were reviewed, and HBVr occurrence was assessed. HBVr was defined as newly detectable HBV DNA or reappearance of HBsAg.

Results:

The mean age of the study population was 52.3 ± 11.0 years. The most common indications for biological agent therapy were ankylosing spondylitis (30.2%) and rheumatoid arthritis (29.7%). Overall, 20.9% ($n = 36$) of patients received high-risk agents, while 79.1% ($n = 136$) received moderate-risk agents. The median follow-up duration was 28.5 months (range: 12–60) in the high-risk group and 36 months (range: 12–96) in the moderate-risk group. All patients in the high-risk group received antiviral prophylaxis at treatment initiation, and no HBVr events were observed. In the moderate-risk group, 33.1% ($n = 45$) received antiviral prophylaxis, whereas 66.9% ($n = 91$) were monitored without prophylaxis. Virological reactivation occurred in only one patient (1.1%) among those without prophylaxis and was not accompanied by clinical or biochemical hepatitis. The patient had a baseline anti-HBs level ≥ 1000 IU/L, which remained stable throughout follow-up.

Conclusions:

Antiviral prophylaxis appears to be effective in preventing HBV reactivation in HBsAg-negative, anti-

HBc IgG-positive patients receiving moderate- or high-risk biological agents. In patients treated with moderate-risk agents, regular virological monitoring may be a safe alternative to universal prophylaxis, enabling early detection and timely management of rare reactivation events. These findings support risk-adapted management strategies in this patient population.

2896 - Usefulness and Yield of Whole Exome Sequencing in Paediatric Genetic and Metabolic liver disorders in a Tertiary Care Centre in North India

Jyoti Bhutani ¹, Karunesh Kumar ¹, Jaswinder Kaur ¹, Yaja Jebaying ¹, Smita Malhotra ¹, Anupam Sibal ¹
Indraprastha Apollo Hospital, Pediatric Gastroenterology And Hepatology, New Delhi-India ¹

Background / Hypothesis:

Paediatric genetic and metabolic liver disorders exhibit significant genetic and phenotypic heterogeneity. In North India, where parental consanguinity is a known clinical factor, identifying monogenic etiologies via Whole-Exome Sequencing (WES) is critical for tailored management and genetic counseling. This study evaluates the diagnostic yield and mutational spectrum of WES in these disorders.

Materials and Methods:

We analyzed a combined cohort of 327 unique pediatric patients from January 2017 to January 2026 categorized into five clinical groups: Chronic Liver Disease (CLD, $n=138$), Neonatal Cholestasis ($n=95$), Storage Disorders ($n=55$), Disorders of Bilirubin Metabolism ($n=23$), and Acute Liver Failure (ALF, $n=16$). Clinical data and consanguinity were recorded. WES data was analysed. Genetic variants were interpreted according to ACMG consensus guidelines.

Results:

The overall diagnostic yield was 43.4% ($n=142$), with an additional 38.2% harboring Variants of Uncertain Significance (VUS). The most frequently involved genes were ABCB4 ($n=13$), UGT1A1 ($n=11$), JAG1 ($n=10$), and ABCB11 ($n=9$). Diagnostic yields were highest in bilirubin metabolism (73.9%) and storage disorders (56.4%). Consanguinity was present in 16.5% ($n=54$) of

E-POSTER ABSTRACTS

the cohort with a 53.7% positive yield compared to 41.3% in non-consanguineous families. Missense mutations were the predominant variant type (n=150). Zygosity analysis revealed 136 heterozygous (31 of which were significant autosomal dominant variants), 85 homozygous (strongly correlated with consanguinity), 37 compound heterozygous, and 7 hemizygous cases (confirming X-linked disorders such as GSD IXa).

Conclusions:

WES provides a high diagnostic yield in paediatric genetic and metabolic liver disorders. This approach prevents unnecessary and harmful surgeries (like Kasai for Alagille), and allows families to access precision treatments (dietary for storage disorders, chelation for Wilson's disease) that prevent irreversible liver damage and transplant. It also empowers families with accurate genetic counseling for future children. The increasing availability of Next-Generation Sequencing (NGS) in developing countries has significantly improved the diagnosis of paediatric genetic and metabolic liver disorders.

2898 - Circulating miR 184 and miR 206 as Predictive Biomarkers for Early Recurrence in HBV Related Hepatocellular Carcinoma A Prospective Study

Sang-hoon Kim¹, Ki-hun Kim¹

Asan Medical Center, Division Of Liver Transplantation And Hepatobiliary Surgery, Seoul-South Korea¹

Background / Hypothesis: Early recurrence after curative resection remains a major challenge in hepatocellular carcinoma (HCC), particularly in hepatitis B virus (HBV)-related cases. Liquid biopsy using circulating microRNAs (miRNAs) offers a non-invasive approach to identify molecular markers predictive of recurrence.

Materials and Methods: We prospectively enrolled 30 individuals with HBV-related HCC presenting with a single tumor (<5 cm) and no vascular invasion or metastasis. Blood samples were collected preoperatively and on postoperative day 7. Expression of 20 selected miRNAs from circulating cell-free

DNA/RNA and exosomes was analyzed. Participants were categorized into early recurrence (within 1 year, n=6) and non-recurrence (n=24) groups. Differentially expressed miRNAs were identified, and target genes of significant miRNAs were retrieved from miRTarBase. Protein-protein interaction (PPI) networks were constructed using STRING and visualized in Cytoscape. Enrichment analysis was performed using Gene Ontology and KEGG pathway databases.

Results: On postoperative day 7, expression of miR-184 and miR-206 was significantly lower in the early recurrence group than in the non-recurrence group ($p < 0.05$). Other miRNAs showed no significant differences. Target gene analysis revealed 16 key hub proteins—CCND1, CCND2, KLF4, NOTCH3, BDNF, MET, CDK4, BCL2, AKT2, IGF1R, MYC, HDAC4, ESR1, KRAS, SMARCB1, and AGO2—enriched in cancer-related pathways and involved in HCC progression.

Conclusions: Reduced postoperative expression of miR-184 and miR-206 may predict early recurrence in individuals with HBV-related HCC. Their associated regulatory networks suggest possible mechanisms of recurrence and represent potential biomarkers for postoperative surveillance. Further studies are needed to validate their prognostic value.

2899 - Association of Metabolic dysfunction Associated Steatotic Liver Disease with Dementia An Updated Systematic Review and a Meta analysis

Ramish Sumbal¹, Nida Rasool¹, Vijesh Kumar¹, Nasir Hasan Luck¹, Abbas Ali Tasneem¹, Danish Kumar¹, Ghazi Abrar¹, Zain Majid¹

Sindh Institute Of Urology And Transplantation, Gastroenterology And Hepatology, Karachi-Pakistan¹

Background / Hypothesis:

Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease worldwide and is increasingly recognized as a systemic metabolic disorder. Emerging evidence suggests a potential link between MASLD and neurodegenerative diseases, including dementia. However, prior meta-analyses have reported inconsistent findings and were limited by small sample

E-POSTER ABSTRACTS

sizes. Therefore, we performed an updated systematic review and meta-analysis to evaluate the association between MASLD and dementia, including its major subtypes.

Materials and Methods:

This systematic review was conducted according to PRISMA guidelines. Electronic databases, including PubMed/MEDLINE, Cochrane Library, and Google Scholar, were searched from inception to November 25, 2025. Studies evaluating the association between MASLD and dementia in adults were included. Hazard ratios (HRs) with 95% confidence intervals (CIs) were pooled using fixed- or random-effects models based on heterogeneity. Subgroup analyses were performed for Alzheimer's disease and vascular dementia.

Results:

Fifteen studies comprising 3,381,435 participants were included. The overall prevalence of dementia was 4.6%, and 27.7% of participants had MASLD. MASLD was significantly associated with an increased risk of all-cause dementia (HR 1.09; 95% CI 1.01–1.18; $p = 0.03$; $I^2 = 90\%$). Subgroup analysis demonstrated a significant association between MASLD and Alzheimer's disease (HR 1.08; 95% CI 1.01–1.15; $p = 0.02$; $I^2 = 80\%$). No statistically significant association was observed between MASLD and vascular dementia (HR 1.16; 95% CI 1.00–1.35; $p = 0.05$; $I^2 = 83\%$).

Conclusions:

MASLD is associated with a modest but statistically significant increased risk of all-cause dementia and Alzheimer's disease, but not vascular dementia. These findings support the concept of MASLD as a systemic disorder with potential neurocognitive implications. Further prospective studies are needed to clarify underlying mechanisms and assess whether targeted metabolic interventions may reduce dementia risk.

2900 - Spectrum effects and threshold drift of 24 hour urinary copper excretion in hypercupriuric referrals implications for Wilson disease diagnosis

Yu Zhang¹, Shasha Li¹, Yijun Bao¹, Yongfeng Yang¹
Nanjing Second Hospital, Department Of Hepatology, Nanjing-China¹

Background / Hypothesis: Twenty-four-hour urinary copper excretion (24-h UCE) is a core test in Wilson disease (WD) evaluation, but it is commonly elevated in non-WD liver diseases, particularly with cholestasis and

advanced liver dysfunction. In referral cohorts pre-selected for hypercupriuria, conventional UCE thresholds may exhibit spectrum effects and threshold drift. We quantified the diagnostic performance of UCE across a hypercupriuric spectrum and evaluated whether ceruloplasmin (Cp)-anchored strategies improve clinical interpretability.

Materials and Methods: We retrospectively analyzed 538 consecutive patients evaluated for suspected WD with 24-h UCE $\geq 60 \mu\text{g}/24 \text{ h}$ (institutional upper limit of normal). WD was adjudicated using a prespecified genotype-informed reference standard (biallelic pathogenic/likely pathogenic ATP7B variants with Leipzig score ≥ 4); non-WD etiologies were adjudicated by structured chart review. We assessed discrimination (AUROC) and prespecified threshold performance overall and across bilirubin/INR-based severity strata. We additionally evaluated a prespecified two-step Cp triage with a predefined grey zone and a leave-one-out cross-validated secondary model.

Results: The cohort included 62 WD and 476 non-WD patients (WD prevalence 11.5%). Overall discrimination of 24-h UCE was moderate (AUROC 0.76; 95% CI 0.69–0.82) and operating characteristics shifted across the hypercupriuric severity spectrum, consistent with threshold drift. A prespecified Cp triage (rule-out Cp $> 0.20 \text{ g/L}$; rule-in Cp $\leq 0.10 \text{ g/L}$) classified 83.6% of patients at stage 1; the remaining grey-zone patients underwent a secondary model using $\ln(24\text{-h UCE})$, total bilirubin, and ALT, yielding overall sensitivity 96.8% and specificity 97.3%.

Conclusions: In hypercupriuric liver-disease referrals, 24-h UCE alone provides only moderate discrimination and is sensitive to referral enrichment and severity-related phenotype. These data support using UCE primarily as a higher-threshold rule-in component rather than a stand-alone rule-out test once evaluation is conditioned on hypercupriuria. Cp-anchored and integrated approaches are more transportable across the hypercupriuric spectrum and may reduce indeterminate evaluations; external validation is needed.

2902 - Integrating Clinical Biomarkers with Machine Learning to Predict Hepatocellular Carcinoma in NAFLD

Devi Yulia Rahmi¹

Universitas Andalas, Management, Padang-Indonesia¹

Background / Hypothesis:

Hepatocellular carcinoma (HCC) is a significant complication of non-alcoholic fatty liver disease (NAFLD), with high mortality rates due to delayed diagnosis. Identification of clinical biomarkers integrated with machine learning approaches has the potential to improve prediction and early detection.

Materials and Methods:

This study used three public datasets: TCGA-LIHC (379 patients, clinical data), GSE49541 (72 samples, gene expression data), and UCI-HCC (165 patients, clinical and survival data). Descriptive analyses were performed on patient characteristics and gene expression patterns. UCI-HCC data were used to build predictive models using Logistic Regression and Random Forest. Model performance was evaluated using accuracy, F1-score, ROC-AUC, and feature importance analysis.

Results:

The age distribution of TCGA-LIHC patients shows that most cases occur in middle-to-late age. The GSE49541 heatmap demonstrates heterogeneity in gene expression between patients. In the UCI-HCC dataset, differences in patient status provide relevant survival insights for prediction. Logistic Regression performed best with an accuracy of 87.9% and an F1-score of 0.90, while Random Forest achieved an ROC-AUC of 0.835. Feature importance analysis identified 10 key clinical variables, including liver biomarkers and laboratory parameters, as significant predictors of HCC risk.

Conclusions:

Integrating clinical biomarkers and molecular data with machine learning has shown promising results in predicting HCC risk in NAFLD patients. This approach can improve early detection strategies and

E-POSTER ABSTRACTS

personalised therapy, although further validation in a broader population is needed.

2903 - Single Center Experience in Complex Liver Transplantation

Jinzen Cai ¹, Qingguo Xu ¹, Yudong Wang ², George Lau ²

The Affiliated Hospital Of Qingdao University, Organ Transplantation Center, Qingdao-China ¹ Humanity & Health Medical Center, Humanity & Health Clinical Trial Center, Hong Kong-Hong Kong SAR, China ²

Background / Hypothesis:

To summarize and analyze the clinical experience of complex liver transplantation.

Materials and Methods:

A retrospective analysis was conducted on the clinical data and follow-up outcomes of 402 patients who underwent complex liver transplantation at the Affiliated Hospital of Qingdao University. Patient survival rates and the incidence of postoperative complications were analyzed.

Results:

From July 2013 to July 2024, a total of 1,400 liver transplantations were performed at this single center,

among which 402 cases (28.7%) were classified as complex liver transplantation. These cases included patients with grade III or higher portal vein thrombosis, a history of upper abdominal surgery, repeat or multiple liver transplantations, massive diseased livers (e.g., polycystic liver disease), and those with multiple organ dysfunction. The 1-, 3-, and 5-year survival rates in the complex transplantation group were 81.3%, 61.3%, and 52.6%, respectively, whereas those in the conventional transplantation group were 88.4%, 78.2%, and 71.2%, respectively. The survival rate in the complex group was significantly lower than that in the conventional group ($P < 0.001$). The incidence of massive intraoperative bleeding in complex liver transplantation was 8.9%, and the anhepatic phase lasted 54.1 ± 15.7 minutes. Early postoperative complications included reoperation due to intra-abdominal bleeding (4.0%), vascular complications (1.7%), severe infection (16.9%), and acute renal failure (12.4%). Long-term postoperative complications mainly included hepatocellular carcinoma recurrence, biliary complications, and chronic renal impairment, with incidence rates of 48.5%, 7.2%, and 4.9%, respectively.

Conclusions:

Technical challenges in complex liver transplantation remain a major limiting factor in the development of liver transplantation programs. Improvements in surgical techniques and perioperative management may help improve the prognosis of patients undergoing complex liver transplantation.
